**Background:** Impaired sexual satisfaction is a prevalent and distressing issue for female cancer survivors. The aim of this study was to evaluate the impact of vaginal DHEA on vaginal atrophy symptoms and sexual function. **Methods:** A controlled, randomized trial evaluating 3.25 versus 6.5 mg of DHEA vaginally was conducted. Postmenopausal women with previous breast or gynecologic cancer were eligible if they reported $\geq$ moderate vaginal dryness or pain. DHEA was compounded in a bioadhesive vaginal moisturizer. Women inserted the bioadhesive moisturizer with or without DHEA using a pre-filled syringe daily x 12 weeks before going to sleep, after any sexual activity. The most bothersome vaginal symptom (dryness or pain) was evaluated with a single item Likert scale, and sexual function with the Female Sexual Function Index (FSFI). Side effects were graded by providers using the Common Terminology Criteria for Adverse Events (CTCAE) and self-report. Laboratory tests to assess systemic absorption were done. Analysis of change from baseline to 12 weeks (primary endpoint) included independent t-tests, comparing each DHEA treatment arm with plain moisturizer. **Results:** 441 women from 82 institutions were randomized, 147 in each arm. Women in all 3 arms reported significant improvement in their most bothersome symptom. Cohen's d effect size for severity decrease was 1.4, 1.6 for DHEA 3.25, 6.5 mg respectively and 1.3 without DHEA. Compared with no DHEA, women receiving DHEA 6.5 mg reported statistically significant improvements in sexual function at 12 weeks, based on the FSFI full scale score as well as all sexual domain scores except orgasm (p-values $<.0001$ to 0.03.). Effect sizes ranged from 0.3 to 0.6. There were no significant differences in grade 2/3 toxicities. Two self-reported side effects, voice changes and headaches, were worse for DHEA arms compared to no DHEA. Lab data demonstrated no evidence of clinically important systemic estrogenic activity. **Conclusions:** These data support use of a daily vaginal moisturizer to improve vaginal atrophy symptoms. Vaginal DHEA significantly improves sexual desire, arousal, pain and overall sexual function, compared to this bioadhesive moisturizer alone. Clinical trial information: NCT01376349.

**9508 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**NCCTG N10C2 (Alliance): A double-blind, placebo-controlled study of magnesium supplements to reduce menopausal hot flashes.** *Presenting Author: Haeseong Park, Virginia Commonwealth University, Richmond, VA*

**Background:** Hot flashes (HFs) are a common symptom in female breast cancer survivors that can negatively impact quality of life. Preliminary data suggest that magnesium may be an effective, low-cost treatment for HFs causing minimal side effects. **Methods:** A four-arm, double-blinded, placebo-controlled randomized trial was conducted. Postmenopausal women with a history of breast cancer and bothersome HFs were randomized into treatment groups of 800 mg or 1200 mg of magnesium oxide per day, or a corresponding placebo group in 2:2:(1:1) ratios. HF frequency and scores (number times severity) were measured using a validated HF diary. A one-week baseline period preceded initiation of study medication. The primary endpoint was the intra-patient difference in average hot flash score between baseline and at the end of the treatment period, comparing each magnesium arm to the combined placebo arms using a gate-keeping procedure. With a sample size of 80 patients per arm, there was 80% power to detect a difference of 8.6 points in HF score (on 0-100) using a two-sided 5% type I error rate. **Results:** 289 women were enrolled between 12/2011 and 03/2013. The study arms were well balanced. Results were analyzed using a repeated measures model on weekly HF score, based on a modified intent-to-treat principle. Mean HF scores, frequencies, and associated changes at the end of the treatment period for each arm are show in the table. An increased frequency of diarrhea was reported in magnesium arms compared to placebo. No statistically significant difference in other toxicity or quality of life measures occurred. **Conclusions:** The results of this trial do not support the use of magnesium oxide for HFs. Clinical trial information: NCT01439945.

**Decline of cognitive functions among elderly localized breast cancer patients after adjuvant treatment: COG-AGE study.** *Presenting Author: Florence Joly, Unité de Recherche Clinique, Centre François Baclesse, Caen, France*

**Background:** Cognitive deficits (CD) have been reported among patients receiving chemotherapy (CT) for cancer.Despite their increased propensity for age-related CD that may worsen during CT, elderly patients have been poorly studied. We assessed the impact of adjuvant treatment as compared to objective and subjective cognitive functions at baseline among elderly localized breast cancer (LBC). **Methods:** Women >65 years-old with LBC were recruited and compared to a sample of healthy women matched on age and education. Episodic and working memories, executive functions and information processing speed were assessed with neuropsychological tests at baseline and at the end of adjuvant treatment (or at the same interval for healthy women). Questionnaires were used to assess subjective CD, anxiety, depression and fatigue. Geriatric assessment was also performed. Longitudinal neuropsychological scores were analysed with Reliable Change Index of Iverson to control practice effects. **Results:** Concern 119 elderly LBC (71±4 years) (58 received CT and 61 received only radiotherapy (RT)), and 62 healthy women (71±5 years). Patient characteristics are: mastectomy (28%), stage (I-II: 87%), positive hormonal receptor (88%), positive Her2 (17%); and Activities Daily Living (ADL) and Instrumental ADL means were 6(±0.09) and 0.24(±0.79). After adjuvant treatment, 49% of patients had objective cognitive decline compared to the performances of the healthy women. The main objective CD concerned working and verbal episodic memories (25% and 15%, respectively). No significant difference on CD was observed between CT and RT groups. Only patients treated with CT developed more cognitive and quality of life complaints and fatigue than healthy women (p=0.002, p=0.04 and p=0.008). **Conclusions:** This is the first large longitudinal study assessing cognitive function after adjuvant treatment in elderly LBC patients. Patients are more at risk to develop objective cognitive impairments during treatment than healthy women. Cognitive and quality of life complaints and fatigue were mainly reported among patients after CT. However we did not find deleterious impact of CT on objective cognitive functions.

**9510 Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

**Standardized, progressive exercise program (EXCAP) to reduce psychological distress and improve inflammatory cytokines of distress among prostate cancer survivors.** *Presenting Author: Charles Stewart Kamen, University of Rochester Medical Center, Rochester, NY*

**Background:** Psychological distress (a negative emotional, social, or spiritual response to cancer) is among the most common side effects of cancer diagnosis and treatment. Brief and palatable interventions are needed to ameliorate distress in diverse cancer populations, including men with prostate cancer, who may be unwilling to engage in traditional and time-intensive forms of psychotherapy. EXCAP(Exercise for Cancer Patients), a standardized, 6-week, home-based, progressive aerobic and resistance training program, has proven efficacious in improving fatigue among cancer survivors, but its effect on distress and on inflammatory cytokines associated with the pathophysiology of distress are unknown. **Methods:** In this Phase II RCT, 58 older prostate cancer survivors (age M=67) were randomized either to Arm 1) standard care (control) or Arm 2) EXCAP(intervention). Psychological distress (from the Profile of Mood States) and inflammatory cytokines (IFN-γ, IL-6, IL-8, IL-10, sTNFR-1) were measured at baseline and post-intervention (6 wks later). We used ANCOVA to assess the effect of EXCAPon distress and inflammatory cytokines at post-intervention, controlling for baseline values. We used Pearson correlations to evaluate mechanistic associations between change in distress and change in inflammatory cytokines from pre to post. **Results:** Among men with prostate cancer, the EXCAPintervention significantly improved psychological distress relative to standard care, as measured by the POMS Total score (EXCAP M=-5.17, SD=14.02; control M=2.43, SD=8.06; F(4,51)=3.34, p=.02). Decreases in distress among EXCAPparticipants were associated with decreases in IFN-γ ($r$ = .40, p = .03) and IL-10 ($r$ = .39, p = .04). This pattern was not seen in the control arm. **Conclusions:** This study supports the use of EXCAPfor reducing psychological distress and suggests a potential biological mechanism by which this improvement occurs, namely by reducing systemic inflammation. Future, confirmatory research is needed to replicate these findings in larger and diverse samples of cancer survivors. Clinical trial information: NCT00815672.

**9511 Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

**Predictive factors of early death during 100 days after a comprehensive geriatric assessment in older patients with cancer: A prospective cohort study of 576 patients.** *Presenting Author: Rabia Boulahssass, UCOG PACA EST CHU de Nice, Nice, France*

**Background:** The purpose of this study is to analyse predictive factors of early death in older patients with cancer during 100 days after a geriatric comprehensive assessment (CGA) in order to help oncologist in the therapeutic decisions. **Methods:** 576 older patients with cancers are enrolled, 29 cases could not be analyzed because of difficulties of language (aphasia, mutism) finally in the study. This study is a cohort and prospective study approved by an ethics committee. A geriatric comprehensive assessment (CGA) has been done before the treatment decision. Geriatric data (MMSE, MNA, BMI, grip hand grip strength ,ADL, IADL, CIRSg, Gait speed, QLQC30, Charlson, G8 and Balduccci classification) are collected . Characteristics of the cancer, social and demographic data are also collected. During 100 days of follow up, the rate of death, treatments made and geriatric interventions are collected. **Results:** 22% of the patients have died during the follow up of 100 days. Mean age of the patients is 82 years old (70-96). In univariate analyzes, Patients with lower gait speed (HR=4,2 (2,7-6,2)), loss of autonomy in the ADL (HR=2,6(1,7-3,8) and in the IADL (HR=2,8(1,8-4,5), metastatic cancers (HR=2,1 (1,5-3,1)), poor nutritional status with MNA <17 (HR 8,2 (2,6-29)), home confinement (HR=3,3 (2,3-4,8)), Worse quality of life (HR=4(2,3-7,4)), G8<14 (HR=1,6(1,1-2,4)), Charlson pondered >6(HR=2,2(1,1-4,3)) and higher state score on Balducci's classification had significantly more risk to die.In multivariate analyses poor nutritional status with MNA<17 (HR=2,6(1,1-6,8)),metastatic cancers (HR=2,2(1,4-3,5)) and gait speed<0,8m/s (HR=2(1,1-3,7)) had significantly more risk to die. **Conclusions:** This study confirms the importance of the geriatric comprehensive assessment in oncogeriatric patients to predict risk factors of worse outcomes. It's necessary to screen potential deficiencies to introduce geriatric interventions like care plan for nutrition or physiotherapy and could help oncologists in making therapeutic decisions.

**9512 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM**

**The ENABLE III randomized controlled trial of concurrent palliative oncology care.** *Presenting Author: Marie Bakitas, The University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

**Background:** Evidence from randomized controlled trials (RCTs) supports integration of oncology and palliative care; how soon after diagnosis to initiate palliative care has not been defined. **Methods:** We conducted a 'fast track' RCT of patients with advanced cancer in a rural, NCI-designated cancer center, VAMC, and community clinics in NH and VT to determine the effect of immediate vs. delayed (3 months after diagnosis) entry patients into the ENABLE concurrent oncology palliative care intervention on primary outcome measures: QOL (FACIT-pal), symptom impact (Symptom impact subscale of the QUAL-E, mood (CES-D), at 3 and 6 months and survival at 1 year (from enrollment to death or study completion). Other outcomes included: resource use (hospital and ICU days and ER visits-measured by chart review), and quality of EOL care. **Results:** Participants (immediate n=104; delayed=103) were mean age 65; 52% male; 65% married; 96% white; 42% lung; 46% newly diagnosed with advanced disease; 17% with brain metastases. The estimated treatment effects (TE) using a terminal decline model (Cohen's d; immediate minus delayed) for patients from randomization to 3 months were: (mean [SE]: .13 (21.39) for QOL ($P$=.34), -.21 (3.63) for symptom impact ($P$=.09), and .04 (3.91) for depressed mood ($P$=.33). 104 participants died (immediate n=49; delayed n=55) during the study. Compared to delayed entry patients, the risk of death (hazard ratio [HR] (95% CI)) was lower for immediate participants at 1 year 0.72 (95% CI, 0.57-0.89) ($P$=0.003). Median survival for immediate entry patients was 18.3 months (95% CI, 13.2, 28.0) and 11.8 months (95% CI, 9.0, 24.1) for delayed entry patients (P=0.17). Overall median hospital days (3), ICU days (0), and ER visits (1) were identical. 55% (27) of 49 deaths in immediate and 49% (27) of delayed deaths occurred at home. **Conclusions:** Immediate vs delayed entry patients experienced a significant survival advantage at 1 year; however longitudinal TE were not statistically different. Future research is needed to define mechanisms of survival advantage in palliative care trials. Clinical trial information: NCT01245621.

**9515 Poster Highlights Session (Board #1), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Health and functional status of long-term adult medulloblastoma/PNet survivors: A report from the Childhood Cancer Survivor Study.** *Presenting Author: Allison A. King, Siteman Cancer Center, Washington University School of Medicine in St. Louis, St. Louis, MO*

**Background:** Medulloblastoma is the most common malignant childhood CNS tumor. Survival rates increased from 40% to 70% during the past 30 years. The long-term risks of chronic medical conditions, adverse health status, and reduced psychosocial functioning in aging survivors of childhood medulloblastoma/PNET are not known. **Methods:** Using the Childhood Cancer Survivor Study cohort, we analyzed the long-term outcomes of 380 5+ year survivors of medullobastoma/PNET (median age at last follow-up: 30 years, range 7-53), diagnosed between 1970-1986. A sibling cohort (n=4031) served as a comparison population. Neurological outcomes and cataracts were analyzed as time-to-event data with cumulative incidence, with Cox regression models used to calculate hazard ratios (HR) and 95% confidence intervals (CI). Memory complications, educational status, marital status, independent living, employment status, income, and fertility were assessed cross-sectionally using generalized linear models. Comparisons were adjusted for age and sex. **Results:** By 30 years post diagnosis, mortality was 29% (CI 23-36). Cumulative incidence of second malignant neoplasm was 8% (CI 5-12), and recurrence of the original cancer 18% (CI 14-22) at 30 years. Cumulative incidence for hearing loss was 37% (CI 31-44), seizures 34% (CI 29-39), balance problems 72% (CI 67-77), tinnitus 30% (CI 23-37) and cataracts 14% (CI 9-18). Relative to siblings, survivors reported a higher risk of hearing loss (HR=36.0, CI 23.6-54.9), seizures (HR=12.8, CI 9.0-18.1), poor balance (HR=10.4, CI 6.7-15.9), tinnitus (HR=4.8, CI 3.5-6.8), and cataracts (HR=31.8, CI 16.7–60.5). Survivors were less likely to earn a bachelor's degree (RR=0.49, CI 0.39-0.60), to marry (RR=0.35, CI 0.29–0.42), to live independently (RR=0.58, CI 0.52-0.66) and to have a pregnancy or a partner become pregnant (RR=0.23, CI 0.17–0.3). **Conclusions:** Among adult survivors of childhood medulloblastoma/PNET, significant neurologic morbidity and lower levels of educational attainment and social independence exist. Given the high survival rates for these children, interventions to reduce these sequelae and support the survivors should be a high priority.

**9516 Poster Highlights Session (Board #2), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Quality of life and cognitive dysfunction in breast cancer survivors on a feasibility study of donepezil versus placebo.** *Presenting Author: Julia Lawrence, Comprehensive Cancer Center of Wake Forest University, Winston-Salem, NC*

**Background:** Breast cancer survivors report long term cognitive and quality of life effects due to cancer and chemotherapy. Cognitive enhancers (donepezil) could be a treatment option. We conducted a randomized, placebo-controlled phase II study to determine the feasibility of a larger phase III trial to improve cognitive function in breast cancer survivors with self-reported cognitive problems 1 to 5 years following chemotherapy. **Methods:** 62 patients were randomized to receive donepezil (5mg x 6 weeks + 10 mg x 18 weeks) or placebo. Participants completed a comprehensive battery of neurocognitive tests and questionnaires measuring cognitive symptoms, mood, fatigue, sleep disturbance and quality of life at baseline, 24, and 36 weeks post randomization. Women were screened for cognitive impairment with the FACT-Cog Perceived Cognitive Impairment subscale and were eligible if they scored <63. **Results:** The study opened at 16 sites and enrolled 62 women over 6 months (accrual rate of 10.2subjects/month). Ages ranged from 39 to 79 years (median of 56 years). 90% of the women were Caucasian, 87% were overweight or obese, and 65% had completed chemotherapy 1 and 3 years ago. Baseline FACT-PCI scores ranged from 5 to 61; 34 (55%) had scores < 30. Retention was 84% at 12 weeks and 76% at 24 weeks. Adherence to donepezil while on study ranged from 88% to 100%. Scores on the quality of life measures (SF-36, FACIT-Fatigue, PROMIS-7, Epworth Sleepiness Scale, Beck Depression Index and the Beck Anxiety Index) improved over the 24 weeks of treatment in both groups. In addition, scores for most of the neurocognitive tests improved over time in both arms. The study was not powered to detect differences in QOL or neurocognitive performance between arms, but positive trends in favor of Donepezil were noted for total recall and discrimination on the HVLT (Hopkins Verbal Learning Test) (p=0.08 and 0.02, respectively). **Conclusions:** In this cohort of breast cancer survivors reporting cognitive problems 1-5 years following chemotherapy, we had excellent accrual, retention and adherence. QOL and HVLT improved over 24 weeks. These data support a phase III trial of donepezil for the treatment of cognitive dysfunction in this population. Clinical trial information: NCT01466270.

**9517 Poster Highlights Session (Board #3), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Cause-specific mortality among patients with Hodgkin lymphoma (HL) up to 40 years after treatment.** *Presenting Author: Michael Schaapveld, Department of Psychosocial Oncology and Epidemiology,The Netherlands Cancer Institute, Amsterdam, Netherlands*

**Background:** HL treatment is associated with high risk of treatment-related morbidity, including second cancers and cardiovascular diseases. However, only few studies examined excess mortality after prolonged follow-up up to 40 years. **Methods:** We studied cause-specific mortality in a multicenter cohort comprising 3,575 5-year HL-survivors, diagnosed before age 51 and treated between 1965 and 1995. Follow-up was complete until at least January 2010 for 96% of the patients. For 93% of deaths, the cause was known. Mortality after HL was compared with mortality in the general population by calculating standardized mortality ratios (SMRs) and absolute excess mortality (AEM), expressed per 10,000 person-years. Treatment-specific SMRs were compared by Poisson regression. **Results:** After a median follow-up of 21.6 years since HL treatment 1,328 patients had died (19.5% from HL, 32.5% from solid tumors (ST), 15.5% from cardiac diseases (CD), 7.0% from NHL/leukemia). The SMR for causes other than HL was 8.2-fold that of the general population. The cohort experienced 149.2 excess deaths per 10,000 patients per year. The SMR and AEM for causes other than HL increased throughout follow-up: after ≥35 years the SMR was 19.2, translating into 505.9 excess deaths per 10,000 patients per year. ST accounted for the largest part of the excess mortality (overall SMR 5.6, AEM 56.1). While the SMR for ST remained stable, the SMR for CD (overall SMR 9.8, AEM 29.4) increased during follow-up (SMR at ≥35 years 28.8, $p_{trend}<0.001$)). Adjusted for sex, age and follow-up time, risk of death from CD was increased for patients treated with supradiaphragmatic radiotherapy (RT) (Relative Risk (RR) 4.8, p<0.001) or anthracyclines (RR 1.5, p=0.044), independently. The SMR for infectious causes (2.9% of all deaths, including deaths due to influenza/pneumonia) was 6.5-fold increased. Both splenectomy (2.1, p=0.041) and spleen RT (RR 3.2, p=0.001) were associated with increased risk of death due to infectious causes compared to patients not receiving such treatment. **Conclusions:** Even after ≥35 years since treatment, HL patients experienced elevated SMRs and AEMs from ST and CD. Both splenectomy and spleen RT increased mortality due to infections.

**9518 Poster Highlights Session (Board #4), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Comparison of primary and secondary breast cancer in adolescents and young adults (AYA).** *Presenting Author: Melanie Goldfarb, University of Southern California, Keck School of Medicine, Los Angeles, CA*

**Background:** Breast cancer is one of the top malignancies in AYA females (ages 15-39) and may develop de novo or in patients previously treated for cancer. This study compares the tumor characteristics, treatment, and overall survival (OS) of primary and secondary (SMN) breast cancers in the female AYA population. **Methods:** All cases of invasive AYA breast cancer contained in the 1998-2010 American College of Surgeons National Cancer Database were divided into two cohorts according to primary or secondary occurrence. Comparisons using appropriate statistical methods were performed. **Results:** Of 107,373 cases of invasive breast cancer, 6,241 (6.2%) had experienced a prior malignancy. Compared with cases of primary breast cancer, patients with SMNs were more often non-Hispanics (OR:1.21, CI:1.05-1.40), insured (OR:1.58, CI:1.17-2.14), and aged 35-39 (OR:1.34, CI:1.22-1.46). SMNs were more often ER- (OR:1.23, CI:1.09-1.41), PR- (OR: 1.16, CI:1.02-1.32), microcarcinomas <1cm (OR:2.08, CI:1.89-2.30) with lobular histology (OR:1.35, CI:1.15-1.57) that presented without positive lymph nodes (OR:1.38, CI:1.27-1.51) but with distant metastases (OR: 1.60, CI:1.33-1.93). Matched by stage, SMN patients underwent more total mastectomies but received less chemotherapy, radiation, or hormonal therapy. However, SMN patients received definitive surgical treatment almost twice as fast compared to primary cancers (36.12 vs. 67.26 days, p<0.001). Patients with SMNs had a significantly decreased 3-year OS (79% vs 88.5%, p<0.001) with SMN status as an independent risk factor for decreased OS (HR: 1.69, CI: 1.483-1.93). **Conclusions:** AYAs with non-primary breast cancer have smaller, more ER-/PR- tumors but undergo more radical surgery with less adjuvant therapy than AYA's with primary malignancies. SMN status alone is an independent risk factor for decreased OS; AYAs with a breast SMN have almost a 10% lower 3-year OS. Whether the outcome disparity results from previous cancer treatment or differences in biology, environment, or access to care are areas needing further investigation.

**9519 Poster Highlights Session (Board #5), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Long-term survivorship in adult primary glioblastoma: Clinical and neurological outcomes of a large, single-center study.** *Presenting Author: Katherine B. Peters, Duke University Medical Center, Durham, NC*

**Background:** Primary brain tumors represent 1% of all diagnosed cancers, but the survival rates of patients (pts) with the most malignant form of these tumors, glioblastoma (GBM), continues to be poor with <3% of pts surviving at 5 yrs and median OS ranging from 12-14 months. A trend to tailor care to survivorship in oncology has included survivors of other cancers such as breast and prostate, but little has been done to define long-term survivorship in primary GBM and the particular concerns of this population. We sought to identify adult long-term survivors (LTS) in primary GBM and define the clinical and neurological outcomes in this population. **Methods:** In a single-center retrospective study, we evaluated over 9,000 records from January 1, 1998 to February 8, 2010 to identify adult primary GBM pts that survived ≥5 yrs and these were defined as LTS. **Results:** We identified 155 LTS of primary GBM with a median OS of 11.0 yrs (95% CI 9.0, 13.1) and a median follow-up of 9.6 yrs (95% CI 8.7, 10.7). LTS were younger with a mean age of 44.9 yrs (sd=12.1) at diagnosis and had good functional status with KPS≥ 90 for 77.3% (N=120). Most patients had gross total resection (87.7%) and all patients received radiotherapy and chemotherapy (100%). For these LTS, continued oncologic care was required as 52.2% (N=81) had 1-7 recurrences and 52.2% (N=81) had treatment with ≥ 5 chemotherapy regimens. At time of identification of pts for this analysis, there was a reduction in KPS with only 87 pts (56.2%) having a KPS≥ 90. Neurologically, a majority of LTS were on anti-epileptic medications (N=107 (69.1%)) at time of identification. Neurocognitive testing was available for 43 LTS (27.7%) and 39 pts (90.7%) had measurable impairment on testing. Other neurological sequelae included radiation necrosis (N=25), cerebrovascular accident (N=10), hydrocephalus requiring VP shunting (N=6), and dementia (N=3). **Conclusions:** To date, this is the largest single-center retrospective analysis of primary GBM LTS and clinical and neurological outcomes in this population. LTS of primary GBM continue to require specialized oncologic and neurological care and considerations to provide specialized survivorship care for this group are warranted.

**9520 Poster Highlights Session (Board #6), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Treatment summaries and care plans for post-treatment cancer survivors: Association of quality of life with empowerment.** *Presenting Author: Ellen Ingalls Beckjord, University of Pittsburgh, Pittsburgh, PA*

**Background:** We developed a conceptual framework based on Self-Determination Theory that suggests providing treatment summaries (TSs) or care plans (CPs) will positively impact quality of life (QOL) via positive impact on empowerment. We tested this framework with data from the 2012 LIVESTRONG Survey. **Methods:** 5,274 post-treatment cancer survivors (average age = 51; average 7.3 years post-diagnosis) responded to an online survey (fielded June-December 2012) that asked about receipt of a TS, follow-up instructions (FUI), and a CP. QOL was operationalized as a score (1-10) on the Distress Thermometer. Empowerment was measured with three items on confidence in getting support; ability to discuss concerns openly with a doctor; and ability to improve mood. Multivariate logistic and linear regressions modeled the odds of receiving a TS, FUI, or CP and the relationships between TS, FUI, or CP and QOL and empowerment adjusting for sociodemographic and medical characteristics. **Results:** 92% received FUI; 52% received a TS; and 17% received a CP. Women, those further from diagnosis, and those without insurance had lower odds of receiving a TS, FUI, or CP. White survivors were less likely than non-Whites to receive a TS or CP but were more likely to get FUI. Survivors who received more treatment were less likely to get a TS but more likely to get FUI or a CP. TS, FUI, and CP were all positively associated with survivors' empowerment; TS and FUI were associated with better QOL. Sequential regressions showed that the relationships between TS or FUI and QOL were mediated by a positive association between TS or FUI and empowerment. **Conclusions:** These analyses supported our framework linking post-treatment information interventions (TS, FUI) to better QOL via positive associations with empowerment. Some survivors are more likely to report receipt of a TS, FUI, or CP than others; the association between receipt and shorter times since diagnosis may reflect practice changes. As TSs and CPs become more common, research should examine cost- and time-effective methods TS and CP development and delivery and their impact on empowerment, QOL, and health behaviors over time.

**The role of the physician in the prognostic accuracy of advanced cancer patients and their caregivers.** *Presenting Author: Rachel Jimenez, Harvard Radiation Oncology Program, Boston, MA*

**Background:** Accurate understanding of prognosis among terminally ill patients and their informal caregivers is necessary for informed medical decision-making. We report on the relationship between physician prognostic discussions and prognostic accuracy of advanced cancer patients and their caregivers. **Methods:** Coping with Cancer is an NCI/NIMH-funded prospective, longitudinal study of advanced cancer patients and their informal caregivers. Baseline interviews conducted at seven outpatient oncology centers throughout the United States between September 2002 and August 2008, asked patients and caregivers if they had discussed prognosis with a physician and to estimate the patient's life expectancy. **Results:** 240 patient-caregiver dyads were identified. Median survival was 3 months. 39% (94/240) of dyads offered a numeric estimate of prognosis; the remainder answered: "I don't know." 12% of patient and 29% of caregiver estimates were accurate (+/- 3 months of survival); 34% of patients and 31% of caregivers overestimated prognosis (+/- >3-12 months of survival); 52% of patients and 36% of caregivers grossly overestimated prognosis (>12 months from death). Only 2% of patients and 4% of caregivers underestimated prognosis. Caregivers reported more prognostic discussions with the patient's physician (58.3% caregivers; 33.3% patients; $\chi^2 = 7.6$; df=1; p=0.006) and were significantly more accurate in their life-expectancy estimates when reporting a conversation had taken place (OR 5.3, 95% CI 1.7-16.9; p = 0.002), but patients were not. Accurate life expectancy estimates were significantly associated with patient with completion of a DNR Order (OR 11.7; 95% CI 3.6-38.0; p < 0.001). **Conclusions:** Patients and caregivers overestimate life expectancy, but caregivers recall more prognostic discussions with physicians and are more accurate about the patient's prognosis following such discussions than patients. However, patients with greater prognostic accuracy are more likely to complete a DNR order. Therefore, physicians should involve family caregivers in prognostic discussions whenever possible to promote a more accurate understanding of the patient's life-expectancy and advance care planning.

**9522 Poster Highlights Session (Board #8), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Web-based stepped collaborative care intervention in the context of advanced cancer.** *Presenting Author: Jennifer Lynne Steel, University of Pittsburgh, School of Medicine, Pittsburgh, PA*

**Background:** According to the NIH consensus statement, the three most common and debilitating symptoms for cancer patients are depression, pain and fatigue. The aims of this study were to test the efficacy of a web-based collaborative care intervention to reduce cancer-related symptoms and improve quality of life in advanced cancer patients. **Methods**: Patients with advanced cancer were randomized to a web-based stepped collaborative care intervention or usual care arm. The primary outcomes of the intervention included the Center for Epidemiological Studies-Depression (CES-D), Brief Pain Inventory, the Functional Assessment of Cancer Therapy (FACT)-Fatigue, and the FACT-Hepatobiliary. Secondary outcomes included Interleukin (IL)-1b, IL-6 and Natural Killer cells and the Caregiver Quality of Life Index and Caregiver CES-D. An intent to treat analyses was performed and effect sizes were reported using the Cohen's d (Small<0.20; Medium=0.30-0.70; Large>0.80) or Phi (Small=0.10; Medium=0.30; Large=0.50). **Results:** A total of 261 patients and 179 caregivers were enrolled in the study. Patients with clinical levels of symptoms, who were randomized to the intervention arm, reported reductions in depression (Cohen's d=0.32), pain (Cohen's d=0.74), fatigue (Cohen's d=0.48) and improvements in quality of life (Cohen's d =0.38) when compared to patients randomized to the usual care arm at 6-months. Patients randomized to the intervention arm also had reductions in IL-6 (Phi=0.34), IL-1b (Phi=0.38) and increases in NK cell numbers (Phi=0.49). The family caregivers of patients randomized to the intervention arm also had lower levels of stress (Cohen's d=0.75) and depressive symptoms (Cohen's d=0.37) when compared to the usual care arm at 6-months. **Conclusions:** The web-based collaborative care intervention was found to be effective in reducing cancer-related symptoms, immune system dysregulation, and improving quality of life in both the patients and family caregivers. Clinical trial information: NCT01640522.

**9523 Poster Highlights Session (Board #9), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Palliative radiotherapy for bone metastases: Population-based utilization near end of life in a Canadian province.** *Presenting Author: Manpreet Singh Tiwana, BC Cancer Agency, Prince George, BC, Canada*

**Background:** Palliative radiotherapy (RT) plays an important role in the care of patients dying with bone metastases (BM) and is guided by life expectancy . We sought to determine the patterns of RT fractionation in patients with BM towards their end of life in a population-based, publicly funded health care system. **Methods:** Consecutive patients with BM treated with RT between 2007 through 2011 were identified in a provincial Canadian cancer registry database. Associations between choice of RT fractionation, patient and provider characteristics were analyzed. **Results:** A total of 16,898 courses of palliative RT were delivered to 8,601 patients from 2007 through 2011. Of these RT courses 1,734 (10%) and 709 (4%) were prescribed to patients in the last 2-4 weeks and <2 weeks of their life, respectively. Multiple fraction RT was prescribed 52%, 46%, and 36% for patients who died >4, 2-4, and <2 weeks of receiving palliative RT, respectively (p<0.001). Fifteen percent of courses were planned for ≥5 RT fractions in patients who died within 2 weeks of receiving palliative RT. The proportion of patients who died within 4 weeks of RT varied by primary tumour site; lung 25%, gastrointestinal 23%, genitourinary 11%, lymphoma 9%, breast 6%, and other 19.4% (p < 0.001). The proportion of patients who died within 4 weeks of RT varied by treatment site; spine 17%, extremity 14%, pelvis 12%, other 13% (p < 0.001). After controlling for gender, age, tumour type, and treatment site, patients were less likely to receive multiple fraction RT in the last 4 weeks of life (OR 0.54; 95% CI 0.49 – 0.59; p <0.0001). **Conclusions:** This population-based analysis found that 14% of patients with bone metastases received radiotherapy during the last 4 weeks of their life. There was significant variability by primary tumour type, with approximately ¼ of lung and gastrointestinal patients receiving RT with the last 4 weeks of life, suggesting physicians treating these sites should consider benefits of RT versus the short prognosis in these tumour sites. Appropriately, patients who received RT with the last 2 or 2-4 weeks of life were less likely to receive a multiple fraction RT course compared to patients alive >4 weeks since RT.

**9524 Poster Highlights Session (Board #10), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Utilization of antineoplastic chemotherapy near the end of life in patients with solid tumors.** *Presenting Author: Shilpa Paul, Huntsman Cancer Institute, Salt Lake City, UT*

**Background:** The American Society of Clinical Oncology considers cessation of cancer-directed therapy for patients with solid tumors who lack clinical benefit from further treatment as a key opportunity to improve care and reduce costs. This study evaluated the use of chemotherapy (chemo) in solid tumors near the end of life at the Huntsman Cancer Institute (HCI). **Methods:** Patients with breast (BC), non-small cell lung (NSCLC), melanoma (MEL), and ovarian (OC) cancer who received chemo within the last 365 days of life at HCI from 1995-2012 were evaluated. Comparison of chemo use in the last 30 days of life (EOLChemo) was compared across cancer types, stage at diagnosis and change in use over time (2007-2012). Kaplan-Meier analysis was used to assess overall survival (OS) from diagnosis in stage IV patients by EOLChemo utilization. **Results:** The study included a total of 856 patients with BC (n=271, 31.7%), NSCLC (n=237, 27.7%), MEL (n=263, 30.7%), and OC (n=85, 9.9%) who received chemo at HCI within the last year of life. Median age at diagnosis of cancer was 59 years (IQR 29-95) and the average age at death was 63 years (IQR 54-73). The median time from diagnosis of cancer to death was 19.9 months and median time from last chemo to death was 1.9 months (95% CI 57-68, IQR 0.8 – 4.0). Of all patients identified, 253 (29.6%) received EOLChemo. Utilization of EOLChemo was similar (p=0.2452) across cancer types: 72 (27%) BC, 73 (28%) MEL, 78 (33%) NSCLC, and 30 (35%) OC patients. Across all cancer types there was no significant increase in EOLChemo over the past 6 years (p=0.1634). More patients diagnosed with stage IV cancer (n=97, 46.4%) received EOLChemo than those diagnosed with stage I disease (n=21,10%), p=0.0115. Stage IV patients who received EOLChemo had reduced OS compared to those who received chemo greater than 30 days from death (6.8 vs 10.2 months, HR 1.49, CI 1.16-1.90, p=0.0018). **Conclusions:** Of all patients who received chemo in the last year of life, a high percentage (~30%) occurred in the last 30 days of life, irrespective of cancer type. Chemotherapy use in the last 30 days of life was associated with reduced OS. Increased efforts for cessation of chemo near the end of life are warranted.

**9525 Poster Highlights Session (Board #11), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Results from an interdisciplinary palliative rehabiliation program for patients living with advanced cancer.** *Presenting Author: Martin Robert Chasen, Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

**Background:** After treatment, patients with active cancer face a considerable burden from the effects of both the disease and its treatment. Symptom burden has been found to remain consistent until a few weeks before death, when it worsens. The Palliative Rehabilitation Program (PRP) is an interdisciplinary program designed to ameliorate disease effects and to improve the patient's functioning. A particular concern in Palliative Care is depression, which is known to impair functioning and recovery. Depression is also one of the top-two reasons for referral to the PRP, each year. The present study evaluated changes in functioning, symptoms, and well-being after the program. As well, a pilot longitudinal study of symptoms of depression was conducted, three months following PRP completion. **Methods:** There were 171 referred patients with advanced cancer who enrolled in the 8-week PRP; 108 completed the program. Measures of physical, nutritional, social, and psychological functioning were evaluated at entry to the program and at completion. At 3-month follow-up, 20 patients returned self-report measures of depression by mail. **Results:** Participants experienced significant improvements in performance status ($p < 0.000$), nutrition ($p = 0.003$), symptom severity ($p = 0.021$ to 0.000), symptom interference with functioning ($p = 0.001$ to 0.000), fatigue ($p = 0.008$ to 0.000), and physiological measures ($p = 0.002$ to 0.000). Symptoms of depression continued to decrease following PRP completion (linear trend: $p$=0.002). Updated results will be presented. **Conclusions:** Patients living with advanced cancers who underwent the PRP experienced significant improvement in functioning across several domains. Improvements in depression scores continued to improve after completion.

**9526 Poster Highlights Session (Board #12), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Outpatient management of cancer-related pulmonary embolism: Analysis of 562 consecutive patients from the EPIPHANY study.** *Presenting Author: Paula Jiménez-Fonseca, Hospital Universitario Central de Asturias, Oviedo, Spain*

**Background:** Cancer is as a predictor of adverse outcomes in symptomatic pulmonary embolism (PE). Nowadays, the increasing diagnosis of incidental thrombosis in scheduled CT scans implies a change in PE presentation. Clinical guidelines suggest that home treatment is an appropriate alternative for selected low-risk PE-patients although specific data regarding this approach in cancer population remain scarce. The aim of the present report is to describe clinical characteristics, outcomes and feasibility of outpatient management of patients with cancer-related PEs. **Methods:** EPIPHANY is an ongoing multicenter observational study of consecutive cancer-related PEs (acute symptomatic and incidentally-found in scheduled CT scans) recruited from daily clinical practice with a minimum 3-month follow-up after PE. Outpatient management was considered on discharge from hospital less than 24 hours after PE diagnosis. **Results:** From January 2006 to September 2013 we enrolled 562 cancer patients with PE, 385 of whom (68%) were treated in hospital and 177 (32%) were managed as outpatients. Most patients treated at home (93%) had advanced cancer (TNM stages III-IV), most (77%) were being treated with chemotherapy or biological/targeted therapies and 6% underwent major surgery within 1 month. Patients treated at home more likely had an incidentally-detected PE (91% vs. 35%; p<0.001) and were 'truly asymptomatic' cases (86% vs. 30.5%; p<0.001) compared to patients treated with conventional hospitalization. The rate of major complications within 15 days of PE in patients treated at home was 3.4% (95% CI, 1.9-4.9%). Overall mortality rates were lower in outpatients at 30 days (2.3% vs. 21%; p<0.001) and 90 days (9.6% vs. 33%; p<0.001) of follow-up compared to patients treated in hospital. The most frequent cause of death was cancer progression in both groups. The rates of venous thromboembolic recurrences and major bleeding events at 30 and 90 days were comparable in both groups. **Conclusions:** Cancer-related PE can be managed at home in a high proportion of patients, especially those incidentally diagnosed. Further studies addressed to better define low risk patients in this setting should be developed.

**9527 Poster Highlights Session (Board #13), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Cancer worry, anxiety, and behaviors in girls at familial or genetic risk for breast cancer.** *Presenting Author: Angela R. Bradbury, University of Pennsylvania, Philadelphia, PA*

**Background:** Most girls in families at high risk (HR; familial or genetic) for breast cancer learn of that risk at a young age. Additionally, new guidelines support disclosure of incidental findings in cancer predisposition genes regardless of age. The association of this information with psychosocial well-being and health behaviors is unknown. **Methods:** 238 HR and control girls (11-19 YO) and mothers (48 *BRCA1/2*+) completed surveys to evaluate adjustment and behaviors. We used linear and logistic regressions with variable selection. **Results:** Daughter general anxiety (D-Anx), intrusive BC worry (IBCW), and avoidant BC worry (ABCW) were significantly higher in HR girls (Table 1). D-Anx did not differ by mother BC history. In adjusted models, only mother ABCW was associated with D-Anx (Coef 1.4, p<0.01). Mother IBCW (coef 0.3, p<0.01), mother depression (coef -0.2, p=0.01) and higher daughter perceived risk of BC (PRBC, coef 0.7, p=0.01) were associated with D-IBCW. Mother IBCW (coef 0.3, p<0.01) and daughter PRBC (coef 0.5, p=0.02) were associated with D-ABCW. There were no significant differences in risk (e.g. alcohol or tobacco use) or general preventive behaviors (e.g. exercise or diet). HR girls were more likely to perform self-breast exam (SBE) and less likely to have ever had a clinical breast exam (CBE). **Conclusions:** Adolescent girls at familial /genetic BC risk have higher general and BC specific worry, even when mom does not have a history of BC. Daughter BC worry is associated with mother BC worry, regardless of risk group. Interventions to promote adaptive responses to BC risk in mothers and daughters could be beneficial. Also, research evaluating outcomes of disclosure of genetic risk and incidental findings for adult cancer in adolescents is needed.

**9528 Poster Highlights Session (Board #14), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Psychosocial outcomes of siblings of pediatric stem cell transplant survivors.** *Presenting Author: David Kyle Buchbinder, CHOC Children's Hospital, Orange, CA*

**Background:** In addition to associated morbidity and mortality of hematopoietic stem cell transplantation (HSCT) for the recipient, one of the consequences is the impact of the HSCT experience on the family. Our aim was to describe the psychosocial health of siblings of HSCT survivors and to identify factors with adverse psychosocial health. **Methods:** A multi-institutional cross-sectional study design was utilized to assess parent-reported sibling psychosocial health, as measured by the Short Form (SF)-10 Health Survey for Children and the Pediatric Symptom Checklist 17 (PSC-17). Parent physical / emotional health was assessed using the SF-12. Family impact was assessed using the Impact on Family Scale. HSCT and demographic data were collected. Summary statistics were calculated and compared to norms. Associations between sibling psychosocial health and parent physical / emotional health as well as family impact were assessed using correlations and regression. **Results:** Eighty-nine siblings (53% males) with a mean age of 11.2 years (range 4-14) representing HSCT survivors post-HSCT (mean 5.2 years, range 1-14), with malignant (73%) and non-malignant (27%) disorders were assessed. SF-10 psychosocial (mean 49.88, sd 10.90, $p=0.92$) and physical (mean 51.55, sd 8.59, $p=0.10$) health scores were not different from normative data. Behavioral / emotional problems (PSC-17 total score $> 15$) were noted in 24% of siblings. Parents demonstrated greater physical (mean 52.91, sd 8.29, $p=0.002$) and diminished mental (mean 45.89, sd 10.57, $p<0.001$) health compared to norms. Factors associated with adverse sibling psychosocial health included adverse parent physical / emotional health ($p=0.003$ and $p<0.0001$), and greater family impact ($p<0.05$). Factors associated with greater sibling behavioral / emotional problems included adverse parental emotional health ($p=0.006$). **Conclusions:** Siblings of HSCT survivors demonstrate positive outcomes overall; however, behavioral / emotional problems are evident. These concerns are associated with parental emotional health. The impact of HSCT on siblings and parents remains beyond the initial HSCT period. Psychosocial care for HSCT families should be extended for selected siblings and parents.

**9529 Poster Highlights Session (Board #15), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Distress and psychiatric morbidity in cancer patients: Prevalence and association with mortality in a two-year longitudinal study.** *Presenting Author: Caryn Mei-Hsien Chan, University of Malaya, Kuala Lumpur, Malaysia*

**Background:** Distress and psychiatric morbidity in cancer patients are associated with poorer outcomes including mortality. In the present study, we aimed to prospectively examine the prevalence of distress and psychiatric morbidity in a consecutive series of cancer patients in follow-ups of up to 24 months from diagnosis and its association with mortality. **Methods:** Participants were 467 consecutively recruited adult cancer patients attending oncology follow-ups at a single academic medical centre. Assessment consisted of the Hospital Anxiety and Depression Scale (HADS) at baseline (T1) and 4- to 6-weeks (T2), and structured clinical interviews at 6-months (T3) and 12- to 18-months (T4). All patients were followed up to 24-month survival with comparison between co-morbid psychiatric cases and non-cases made. Overall survival was calculated using the Kaplan-Meier method. The research protocol was reviewed and approved by the institutional ethics committee. **Results:** Of 467 patients, 217 patients with elevated total HADS scores ($\geq 16$) at baseline (T1) and 4- to 6-weeks (T2) met criteria for a DSM-IV-TR Axis I disorder (major mental disorders) at 6-months follow-up (T3). At 12- to 18-months follow-up (T4), 115 patients were re-interviewed, with 102 patients assigned a diagnosis. Overall prevalence of psychiatric comorbidity was approximately 46%. Seventy four deaths occurred during the 24-month study period (27 in the non-case group, 47 in the case group). The main cause of death was disease progression. Cancer patients without psychiatric morbidity had a survival benefit of 2.24 months, or 67 days. Mean survival at 24 months was 20.87 months (95% CI 20.06-21.69) for cancer patients with psychiatric morbidity versus 23.11 months (95% CI 22.78-23.43) for those without ($p < 0.001$). **Conclusions:** Findings demonstrated a survival benefit of 2.24 months for cancer patients without psychiatric comorbidity. The high rate of psychiatric morbidity makes it essential for clinicians to identify patients most at risk and offer appropriate intervention, as there is good evidence to support the efficacy of monitoring and active treatment.

**9530 Poster Highlights Session (Board #16), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Efficacy of a video-based psychological intervention for cancer-related insomnia: Results of a randomized controlled trial.** *Presenting Author: Josée Savard, Université Laval, Québec, QC, Canada*

**Background:** Cognitive-behavioral therapy (CBT) is considered the treatment of choice for insomnia but is only rarely offered to cancer patients. It is therefore important to develop treatment formats that would maximize its accessibility in routine care. This study aimed at comparing the short- and long-term efficacy of two different formats of CBT for insomnia, a professionally-administered format (PCBT-I) and a video-based format (VCBT-I), to that of a no-treatment control condition (CTL). **Methods:** A sample of 242 women with breast cancer was randomized to: 1) video-based CBT-I (VCBT-I; $n=80$), composed of a 60-min animated video + 6 booklets; 2) professionally-administered CBT-I (PCBT-I; $n=81$), composed of 6 weekly sessions of 50 min; and 3) no treatment ($n=81$). The main study variables, collected at pre- and post-treatment, as well as at 3-, 6-, and 12-month follow-ups, were the Insomnia Severity Index (ISI) total score and sleep parameters derived from a daily sleep diary: sleep onset latency (SOL), wake after sleep onset (WASO), early morning awakenings (EMA), total wake time (TWT), and sleep efficiency (SE). **Results:** Mixed models analyses revealed that both PCBT-I and VCBT-I were associated with significantly greater sleep improvements, assessed subjectively, as compared to CTL at post-treatment. However, compared to VCBT-I, PCBT-I was associated with significantly greater improvements of ISI scores and EMA, depression, fatigue and dysfunctional beliefs about sleep. The remission rate of insomnia was significantly greater in PCBT-I as compared to VCBT-I (71.3% vs. 44.3%, $p<.005$).Except for WASO, no significant differences were found between the post-treatment and follow-up assessments in PCBT-I and VCBT-I groups (time effects). Between group differences at 3-, 6-, and 12-month follow-ups revealed larger treatment effects in PCBT-I when compared to CTL alone (ISI, WASO, EMA, SE) or both VCBT-I and CTL (SOL, TWT). **Conclusions:** Both short-term and long-term findings show that our video-based CBT-I is a most valuable alternative but that face-to-face sessions remain the optimal format for administering efficaciously CBT for insomnia in cancer patients. Clinical trial information: NCT00674830.

**9531 Poster Highlights Session (Board #17), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Effect of cognitive behavioral therapy for insomnia (CBT-I) and/or armodafinil on insomnia in cancer survivors.** *Presenting Author: Anita Roselyn Peoples, Department of Surgery, University of Rochester Medical Center, Rochester, NY*

**Background:** Insomnia is an underreported distressing side effect of cancer and its treatment, which can persist for months after treatment affecting the course of cancer survival. It exacerbates fatigue and results in reduced quality of life (QOL), allowing for the possibility that treatment of insomnia may improve associated symptoms and QOL. Although CBT-I is considered the nonpharmacologic treatment of choice for insomnia in the general population, it often results in short-term daytime sleepiness. The present study examines whether CBT-I in combination with a wakefulness promoting agent, armodafinil (A), results in greater overall reduction in insomnia in cancer survivors. **Methods:** Primary analyses examine if one or more of the intervention conditions (i.e., CBT-I, A, or both), when compared to placebo (P) group, reduce insomnia in cancer patients following completion of chemotherapy and/or radiotherapy. We report on 88 cancer survivors (mean age 56, 88% female, breast cancer 68%) randomized to one of four 7-week long intervention conditions: 1) CBT-I+A, 2) CBT-I+P, 3) A only, and 4) P only. Insomnia severity was assessed by the validated Insomnia Severity Index (ISI) questionnaire at consent, following the intervention (post), and again three months later (follow-up), with higher scores indicating greater insomnia. **Results:** Mean post ISI scores in groups 1-4 were 4.12, 5.61, 11.32, and 10.28, respectively. ANCOVA with multiple imputation and controlling for scores at time of consent showed that both CBT-I+A ($p=0.001$) and CBT-I+P ($p=0.01$) groups had significantly less insomnia than those in the placebo group, with effect sizes of 1.31 and 1.02, respectively. Armodafinil and placebo groups were not significantly different ($p=0.584$); nor was the CBT-I+A group significantly different from the CBT-I+P group ($p=0.421$). Follow-up ISI scores were essentially the same as post scores. **Conclusions:** These findings show that CBT-I results in clinically significant improvement in insomnia, with effects that persist long term. Armodafinil had no significant effect on insomnia nor on the efficacy of CBT-I. Supported by NCI grant 5 R01 CA126968. Study medication was provided by Teva Pharmaceutical USA. Clinical trial information: NCT01091974.

**9532 Poster Highlights Session (Board #18), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Omega-3 fatty acids for aromatase inhibitor–induced musculoskeletal symptoms in women with early-stage breast cancer (SWOG S0927).** *Presenting Author: Dawn L. Hershman, Columbia University Medical Center, New York, NY*

**Background:** Musculoskeletal symptoms are the most common side effect of aromatase inhibitors (AIs) and can result in decreased quality of life and discontinuation of therapy. Omega-3-fatty acids (O3-FAs) have anti-inflammatory effects and can be effective in decreasing arthralgias from rheumatologic conditions. Omega-3 fatty acids are used by 25% of breast cancer survivors. **Methods:** Women with early-stage breast cancer, taking an AI for ≥90 days and who had a worst pain/stiffness score of ≥5 of 10 using the Brief Pain Inventory (BPI-WP) were randomized to receive either 3.3 grams of O3-FAs or placebo (soybean/corn oil) daily for 12 weeks. Subjects completed quality of life (FACT-ES) and pain assessment (WOMAC, M-SACRAH) at baseline, weeks 6, 12 and 24. Multiple linear regression was used to examine the difference in BPI-WP (primary outcome) between the two groups. Clinically significant change was defined as ≥2-point drop from baseline. **Results:** Among 262 patients registered, 249 were considered evaluable with 122 women in the O3-FA arm and 127 in the placebo arm. No notable imbalances by arm were observed. Baseline BPI-WP was 6.98 and 7.09 in the O3-FA and placebo groups respectively. The mean observed BPI-WP score decreased by 1.74 points at 12 weeks compared to baseline with omega-3, decreased by1.50 points with placebo and decreased further by 24 weeks (2.22 & 1.81 points, respectively) despite discontinuation at 12 weeks. In a linear regression adjusting for the baseline score, osteoarthritis and taxane use, adjusted 12-week BPI-WP scores were similar in both arms (p=0.58). The proportion of patients with a ≥ 2-point drop in 12 week BPI -WP was 61% on Omega-3 and 57% on Placebo, p=.44. O3-FAs resulted in increased grade ≥1 diarrhea (15 vs 6 patients). Serial fasting blood is being analyzed for cholesterol and inflammatory markers. **Conclusions:** We found a substantial (60%) and sustained improvement of AI arthralgias with both the omega-3 and placebo, but found no meaningful difference between the groups. These results suggest either the placebo (soybean/corn oil) had beneficial effects or that a large placebo effect should be expected when conducting trials for AI arthralgias. Clinical trial information: NCT01385137.

**9533 Poster Highlights Session (Board #19), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Effectiveness trial of a community-based supervised exercise program in cancer survivors.** *Presenting Author: Prue Cormie, Edith Cowan University, Perth, Australia*

**Background:** The majority of cancer survivors (50-90%) do not participate in sufficient exercise and there is a paucity of research investigating the effectiveness of 'real life' exercise interventions. The aim of this trial was to determine if a supervised exercise program administered as it would be in a standard survivorship care setting improves patient outcomes. **Methods:** 430 survivors (301 female, 129 male; 61 ± 12 years; BMI: 27 ± 5) within 2 years of a cancer diagnosis participated in this investigation. Participants had been diagnosed with one of 40 different types of cancer, predominately breast – 41%, prostate – 13%, bowel – 10% & lymphomas – 8%. Between 2011-2013 participants self-enrolled in a 3-month community-based exercise program involving aerobic and resistance exercise supervised by accredited exercise physiologists across 12 fitness centres in Western Australia. Assessments were conducted at baseline, post-intervention and 6-months follow-up. **Results:** 306 participants (71%) completed the program attending an average 18 ± 5 out of a possible 24 sessions. No adverse events occurred during the exercise sessions. Significant ($p \leq 0.05$) improvements were observed post-intervention in diastolic blood pressure (3%, -2.1 ± 9.9 mmHg), waist circumference (1%, -0.8 ± 4.6 cm), physical function (400m walk 6%, -15 ± 40 s; repeated chair rise 18%, -2.2 ± 2.5 s; strength 23%, 18 ± 19 kg [n=135]; balance 6%, 4 ± 8 [n=140]), quality of life (all domains of the SF-36 3-10%, 1.4-4.3 ± 5.5-8.7 NBS), fatigue (18%, -2.6 ± 8.1 FACIT-F) and psychological distress (13%, -1.1 ± 5.2 BSI-18). 57% of eligible participants completed the 6-month follow-up (questionnaires only). Significant improvements in all domains of quality of life (4-12%, 1.5-5.1 ± 6.4-10.4 NBS) and fatigue (30%, -4.7 ± 8.9) remained with a borderline improvement in psychological distress (11%, -1.0 ± 6.6 p = 0.053). The estimated monthly medical expenditure (SF-6D utility index) for participants was reduced significantly at post (12%, -$44 ± 114) and follow-up (14%, -$54 ± 139). **Conclusions:** A community-based exercise program of just 3 months in duration resulted in significant and sustained improvements in the physical, mental and social wellbeing of cancer survivors.

**9534 Poster Highlights Session (Board #20), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Effects of resistance training on fatigue and quality of life in breast cancer patients undergoing radiotherapy.** *Presenting Author: Karen Steindorf, German Cancer Research Center (DKFZ) and National Center for Tumor Diseases (NCT), Heidelberg, Germany*

**Background:** Breast cancer patients during and after radiotherapy often suffer from cancer-related fatigue which frequently impairs quality of life (QoL). Exercise may decrease fatigue and improve emotional well-being. However, studies on resistance training for patients during radiotherapy are scarce. Thus, we assessed the effects of a 12-week supervised resistance training intervention on fatigue and QoL in breast cancer patients during adjuvant radiotherapy within a randomized controlled trial. **Methods**: 160 patients (80/arm) with breast cancer stage 0-III undergoing adjuvant radiotherapy were randomly assigned to 12-weeks of progressive resistance training (2x/week) or group-based relaxation training (2x/week). The primary endpoint fatigue was assessed with the 20-item FAQ (0-10 scale), quality of life with the EORTC-QLQ-C30 and BR23 (0-100 scale). Statistical analyses were based on analysis of covariance models for the individual changes from pre- to post-intervention. **Results**: In intention-to-treat analyses, significant between-group mean differences (MD) favoring the intervention group were found for general fatigue (MD=-0.51, 95% confidence interval (CI): -1.01, -0.01, p=.044, effect size (ES)=0.33) and the subscale physical fatigue (MD=-0.83 (-1.48, -0.18), p=.013, ES=0.40), but not for affective (p=.91) or cognitive fatigue (p=.65). For QoL, significantly larger improvements regarding role function (MD=8.5 (0.6, 16.3), p=.035, ES=0.35) and pain (MD=-7.4 (-14.4, -0.3), p=.040, ES=0.34) were seen among exercisers compared to controls. Future perspective improved significantly stronger in the relaxation group than in exercise group (MD=-8.4 (-16.6, -0.1), p=.047, ES=0.34). **Conclusions**: This large randomized exercise intervention trial indicates that a 12-week resistance training program is an effective strategy to improve fatigue and important components of QoL in breast cancer patients during adjuvant radiotherapy. Further, as group-based relaxation training was chosen as control group and not usual care, our results indicate that resistance training provides beneficial effects that may go beyond psychosocial effects induced by group-based programs. Clinical trial information: NCT01468766.

**9535 Poster Highlights Session (Board #21), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Physical activity during cancer treatment (PACT) study: Short- and long-term effects on fatigue of an 18-week exercise intervention during adjuvant chemotherapy in patients with breast or colon cancer.** *Presenting Author: Anne M May, University Medical Center Utrecht, Utrecht, Netherlands*

**Background:** Fatigue is a major problem of cancer patients. Thirty percent of cancer survivors still report serious fatigue three years post- treatment. Physical exercise during cancer treatment might reduce symptoms of fatigue. The primary aim of the present multicenter randomized controlled trial was to compare the short- and long-term effects on fatigue of an 18-week exercise intervention during adjuvant chemotherapy for breast or colon cancer patients. **Methods:** 237 patients (204 breast and 33 colon cancer) were randomly assigned to supervised aerobic and resistance exercise (n=119) or usual care (n=118). In addition to the supervised exercise, the intervention group was asked to be physical active for 30 minutes a day on 3 other days. Fatigue was assessed with the validated Multidimensional Fatigue Inventory at baseline (i.e. within 6 or 10 weeks after diagnosis for breast and colon cancer patients, respectively), after 18 weeks and after 9 months. **Results:** Intention to treat analyses using linear mixed-effects models showed a significant effect over time in favor of the intervention group for general and physical fatigue (p=0.001 and 0.02, respectively). Changes of general and physical fatigue were -0.90 (95% confidence interval: -1.77 to -0.04) and -1.24 (2.17 to -0.32) from baseline to 18 weeks and -1.12 (-2.01 to -0.22) and -0.66 (-1.62 to 0.30) from baseline to 9 months, respectively. Effects for mental fatigue, reduced activity and motivation were not significantly different. **Conclusions:** The 18-week exercise program during adjuvant treatment for breast or colon cancer showed positive results on general and physical fatigue directly after the intervention and also 4 ½ months later. Hence, exercise might be a beneficial addition to routine cancer care during adjuvant cancer treatment. Clinical trial information: ISRCTN43801571.

**9536 Poster Highlights Session (Board #22), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Effect of exercise on weight, body fat, and serum inflammatory biomarkers in breast cancer survivors with aromatase inhibitor arthralgias: The hormones and physical exercise (HOPE) study.** *Presenting Author: Melinda Irwin, Yale University, New Haven, CT*

**Background**: We recently reported that exercise reduced AI-associated arthralgias. This analysis examined potential mechanisms mediating the effect on exercise on arthralgia, specifically weight, body fat and serum C-reactive protein (CRP), IL-6, and TNF-$\alpha$. **Methods**: Women taking an AI for breast cancer and experiencing arthralgia were randomized to exercise (150 min/wk of moderate-intensity aerobic exercise and twice-weekly supervised resistance exercise) or control. Weight, dual energy X-ray absorptiometry scans, and a fasting blood sample were collected at baseline and 12-months. We used analysis of covariance, adjusted for baseline values, to evaluate mean weight, fat and inflammatory changes across groups, and used Baron and Kenny approach for mediation analysis. We evaluated moderation effects by including an interaction in the analysis. **Results**: We randomized 61 to exercise and 60 to control. Exercisers participated in, an average, 70% of resistance training sessions and 119 min/wk of aerobic exercise. Weight, body fat and CRP decreased at 12 months among exercisers (Table 1). Changes in these variables were not correlated with changes in arthralgia, and the interactions were not significant. After adjusting for weight, body fat and CRP, exercise decreased arthralgia by 35% vs. no change among control, p = .0059. **Conclusions**: Exercise decreased weight, body fat and CRP in breast cancer survivors experiencing AI-associated arthralgia. However, these changes did not mediate the effect of exercise on arthralgia. Exercise exerts beneficial effects on arthralgia via mechanisms not related to weight or systemic inflammation.

**Changes in weight, body fat, and inflammatory biomarkers (mean (SE)).**

| | Baseline | | | 12 M change | | |
|---|---|---|---|---|---|---|
| | Exercisers | Control | p-value | Exercisers | Control | p-value |
| **Weight (kg)** | 78.4 (2.1) | 75.9 (2.1) | 0.40 | -2.5 (0.8) | 0.1 (0.7) | 0.018 |
| **Body fat (%)** | 40.8 (0.8) | 40.7 (0.8) | 0.90 | -1.4 (0.6) | 0.3 (0.7) | 0.056 |

**9537 Poster Highlights Session (Board #23), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Genetic associations of fatigue and other symptom domains after breast cancer treatment: Results from a prospective cohort study.** *Presenting Author: Kate Webber, University of New South Wales, Sydney, Australia*

**Background:** We have previously reported on the natural history of cancer related fatigue and other symptoms after adjuvant breast cancer therapy in a prospective cohort study. This paper reports genetic associations with symptom phenotypes in this cohort. **Methods:** Women with early stage breast cancer from six metropolitan teaching hospitals in Sydney were enrolled post-surgery but before adjuvant therapy and followed for up to 5 years, with optional participation in a genetic association substudy. Self-report questionnaires recorded physical and psychological health and disability. Symptom scales for pain, fatigue, depression, anxiety, neurocognitive disturbance and neurotoxicity were derived by prinicipal components analysis from self-report questionnaires at completion of treatment. Genetic associations were sought with functional single nucleotide polymorphisms (SNPs) in cytokine genes tumour necrosis factor (TNF)-$\alpha$, interferon (IFN)-$\gamma$, Interleukin (IL)-10, neuropeptide Y(NPY) and the purinogenic transporter gene P2RX7. **Results:** 151 of the 218 participants provided samples for genetic analyses, of whom 109 were unambiguously Caucasian with corresponding self-report questionnaire data at completion of adjuvant therapy. Depression and anxiety were associated with both the IL-10 -1082 A/A genotype (both p=0.001), as well as the P2RX7 rs208294 A/A genotype (p=0.019 and 0.031). The IL-10 -1082 A/A genotype was also associated with higher levels of fatigue (p=0.032). Associations were found between high levels of neurocognitive dysfunction and homozygosity for the high expression G/G variant of TNF-$\alpha$ -308 (p=0.049). No significant associations between symptoms and NPY or IFN-$\gamma$ were seen in this cohort. **Conclusions:** These findings support for the notion that susceptibility to mood disturbance, fatigue and neurocognitive dysfunction after cancer therapy has a genetic basis. Furthermore, as these associations have also been reported in non-cancer settings, the observed findings may represent inherent susceptibility to these symptoms rather than a response unique to cancer or its treatment.

**9538 Poster Highlights Session (Board #24), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Exercise-induced changes in gene expression, muscular strength, and cancer-related fatigue in older prostate cancer patients.** *Presenting Author: Karen Michelle Mustian, University of Rochester Medical Center, Rochester, NY*

**Background:** Radiation therapy (RT) and androgen deprivation therapy (ADT) impair muscular, mitochondrial and immune function, and result in muscle weakness and cancer-related fatigue (CRF) among prostate cancer patients. We investigated the influence of an exercise intervention (EXCAP), including resistance and aerobic training, on expression of 4825 mitochondrial and nuclear genes, muscular strength and CRF. **Methods:** In this phase II randomized clinical trial, older prostate cancer patients (N=58; mean age=67), receiving RT (47%) or ADT (53%), were randomized to 6 wks of EXCAP (7 days/wk) or standard care (RT or ADT with no exercise). RNA was isolated from muscle biopsies for microarray analyses of 4825 mitochondrial and nuclear genes (N=11). Muscular strength was assessed using multiple repetition maximum testing (chest press and leg extension). CRF was assessed via valid self-report questionnaires (BFI, MFSI). Assessments were pre- and post-intervention. Analyses included robust multi-array average normalization, analyses of covariance (ANCOVA), correlations and partial least squares (PLS) with cross-validation. **Results:** MYH8, MYL5, ACTN3, XIRP1, MTTM, and HLA-DQB1 were significantly correlated with muscular strength and CRF (all p<0.05). Analyses revealed >2-fold down regulation in MYH8 and XIRP1 in the exercise group, no >2-fold changes in expression in the control group, and a >2-fold difference between groups on MTTM where MTTM was down-regulated >1.5-fold in controls with no change in exercisers (all p<0.05). ANCOVAs revealed a trend for group differences in muscular strength (all p<0.10) with significant group differences in CRF on the BFI (p<0.05) and a trend on the MFSI (p<0.10): exercisers improved while controls worsened. PLS suggested down-regulation of MYL5, ACTN3, and HLA-DQB1 may optimally predict increases in CRF. **Conclusions:** Results suggest exercise improves muscular strength and CRF and these improvements may be mediated via exercise-induced expression changes in genes involved in muscle generation and contraction (MYH8, MYL5, ACTN3, XIRP1), mitochondrial function (MT-TM) and immune function (HLA-DQB1). Funding DOD W81XWH-07-1-0341. Clinical trial information: NCT00815672.

**9539 Poster Highlights Session (Board #25), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized trial of Tibetan yoga in breast cancer patients undergoing chemotherapy.** *Presenting Author: Lorenzo Cohen, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Mind-body practices improve quality of life (QOL), yet prior trials have not included *active* control groups. Our prior work found a Tibetan Yoga Program (TYP) resulted in fewer sleep disturbances. This study assessed the effects of TYP versus Stretching Program (STP) and Usual Care (UC) on sleep, fatigue and QOL of breast cancer patients undergoing chemotherapy. **Methods:** Patients with stage I-III breast cancer undergoing chemotherapy were eligible. Participants were randomized to TYP, STP or UC. TYP and STP consisted of four 90-minute sessions. TYP consisted of controlled breathing, visualization, meditation and postures. STP included common stretches for recovery and mirrored TYP postures. Sleep disturbances (PSQI), fatigue (BFI) and breast cancer-specific QOL (FACT-B) were assessed at baseline, 1 week and 1 and 6 months after the last session. **Results:** Participants were 283 women (mean age=48.8 years). We analyzed participants who completed baseline and at least one follow-up with GLM, controlling for corresponding baseline measures and age, menopausal status, stage, time since diagnosis, surgical procedure and chemotherapy regimen. Analyses revealed a significant group main effect at 6-months post-intervention for sleep duration (means: TYP=0.85; STP=1.33; UC=1.21; p=0.02), with TYP reporting greater sleep duration than STP (p=0.008) and UC (p=0.02). Similar results were found for sleep efficiency (means: TYP=1.57; STP=2.17; UC=2.29; p=0.06), with TYP being significantly different from UC (p=002). There were no significant group differences for BFI. For FACT-B, there was a significant group effect at 1-week post-intervention (means: TYP=12.5; STP=14.3; UC=13.9; p=0.05), with TYP reporting fewer symptoms than STP (p=0.02) and UC (marginal at p=0.06). At 3-months post-intervention, there was a significant group effect for FACT-B (means: TYP=7.9; SG=10.5; UC=8.7; p=0.04), with group differences between TYP and STP (p=0.01). **Conclusions:** Participating in a Tibetan yoga program resulted in better long-term sleep quality and QOL than an active control intervention or usual care. Tibetan yoga should be considered to help improve these symptoms for breast cancer patients undergoing chemotherapy. Clinical trial information: NCT00507923.

**9540 General Poster Session (Board #190), Sun, 8:00 AM-11:45 AM**

**Fentanyl exposure after subcutaneous and transdermal administration: Results from a population pharmacokinetic study in cancer patients.** *Presenting Author: Astrid W. Oosten, Department of Medical Oncology, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

**Background:** Transdermal (td) fentanyl is widely used for the treatment of cancer-related pain but is unsuitable for fast titration for severe pain. Titration with subcutaneous (sc) fentanyl is safe and effective. Nonetheless, little is known about the pharmacokinetics (PK) of sc fentanyl compared to the td route and the optimal scheme for rotation from sc to td fentanyl is unknown. Therefore, we performed a population pharmacokinetic study to unravel sc and td fentanyl PK and rotations in cancer patients (pts). **Methods:** Plasma samples for PK analysis were collected from hospitalized pts treated with td or sc fentanyl for moderate-severe cancer-related pain. Pts who were titrated with sc fentanyl were rotated to td fentanyl 1:1 in case of adequate pain control with stable doses. After patch application, sc administration was continued in unchanged dose for 6 hours and in a 50% dose for another 6 hours (Kornick et al, 2001). Baseline and outcome parameters of treatment were registered. PK data were analyzed employing NONMEM, utilizing the model as described for td use (Kokubun et al, 2012) as a starting point. Expected fentanyl levels during and after rotation were calculated using the final model. **Results:** A median of 13 (range 1-86) samples were available for 47 pts, during td administration for 5, sc for 10 and both for 32 pts. The CL/F was estimated to 33.5 L/h following td fentanyl and 54.5 L/h following sc fentanyl. In 7 out of 10 pts with plasma samples available during rotation from sc to td fentanyl, a rise in fentanyl plasma concentrations occurred with clinical signs of fentanyl-related toxicity in 4 pts. Also, calculated fentanyl levels showed a rise during rotation when using the two-step taper in 12 hours. **Conclusions:** This is the first study describing the pharmacokinetics of sc and td fentanyl in a single pt cohort. CL/F was lower for td fentanyl, suggesting that the dose of fentanyl assumed to be delivered using the td route is underestimated. When converting from sc to td fentanyl, the 12 hour method using a 2 step taper can lead to a rise in plasma fentanyl levels and carries a high risk of toxicity. Our new insights champion a shorter time period to rotate fentanyl from sc to td. Clinical trial information: EudraCT Number: 2009-013022-16.

**9541 General Poster Session (Board #191), Sun, 8:00 AM-11:45 AM**

**Intensity of end-of-life care among adolescents and young adults with cancer.** *Presenting Author: Jennifer W. Mack, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Cancer is the leading disease-related cause of death among adolescents and young adults (AYAs), but little is known about the care that AYA patients with cancer receive at the end of life (EOL). Previous work suggests that younger adults may be at risk for receiving aggressive EOL care. However, prior work has focused on the over-65 population in Medicare, with younger adults defined as those closer to 65. Thus much remains unknown about the care that AYA patients receive at the EOL. **Methods:** We evaluated existing measures of EOL care intensity among 381 AYA patients with stage IV/disseminated cancer who received care in Kaiser Permanente Southern California (KSPC), an integrated health care delivery system, and died in the years 2001 to 2010. Patients were eligible for study if they were aged 15-39 at death. Patient characteristics and measures of EOL care intensity were evaluated using KPSC's SEER-affiliated cancer registry and electronic medical records. Intense EOL care measures included chemotherapy use in the last 14 days of life, intensive care unit (ICU) care in the last 30 days of life, more than one emergency room (ER) visit in the last 30 days of life, and hospitalization in the last 30 days of life. We also evaluated a composite measure of medically intensive EOL care comprising any of the aforementioned measures. **Results:** Patients were aged 15-24 (23%), 25-34 (34%), and 35-39 (43%) at death; 50% were male and 48% were white (12% black, 12% Hispanic, 29% Asian, 1% other). Primary cancers included leukemia (25%), lymphoma (12%), colorectal (9%), lung/bronchus (8%), breast (7%), and bone/soft tissue (6%). 11% of patients received chemotherapy within 14 days of death. In the last 30 days of life, 17% of patients were admitted to the ICU; 48% had >1 ER visit; and 66% were hospitalized. Overall, 76% of subjects received at least one aspect of medically intensive EOL care. **Conclusions:** AYA patients frequently receive medically intensive EOL care, with more than three-quarters of patients receiving at least one aspect of aggressive EOL care. These findings suggest the need to better understand EOL needs and access to palliative care in this young population.

**9542 General Poster Session (Board #192), Sun, 8:00 AM-11:45 AM**

**Multimorbidity and racial disparities in use of hospice by older patients dying from cancer.** *Presenting Author: Siran M. Koroukian, Department of Epidemiology & Biostatistics, Case Western Reserve University, Cleveland, OH*

**Background:** While previous studies have documented lower use of hospice by Non-Hispanic Blacks (NHBs) than by Non-Hispanic Whites (NHWs), racial variations have not been examined in the context of multimorbidity (MM), which affects minority patients disproportionately. We sought to determine the impact of MM severity on NHBs' use of hospice in a U.S. representative sample of older adults. **Methods:** We used data from the linked 1991-2008 Health and Retirement Study (HRS), Medicare data, and the National Death Index (NDI). From the NDI, we identified fee-for-service patients ≥65 years of age who died from cancer (n=812), and retrieved their demographic data, presence of comorbidities (COM), functional limitations (FL), and geriatric syndromes (GS) from their last HRS interview. We characterized severity of MM by 3 levels: none or only one of COM, FL, or GS (MM0/1); presence of two of COM, FL, or GS (MM2); or presence of all three of COM, FL, and GS (MM3). Hospice use was identified from Medicare claims data. We developed multivariable logistic regression models to analyze the association between race and hospice use, adjusting for MM and other patient covariates. **Results:** Nearly 12% of the study population was NHB; 61.3% of NHBs and 53.0% of NHWs were identified in MM3 (p=0.057). Overall, 61% of the patients received hospice care (63.7% in NHWs, and 43.0% in NHBs, $p < 0.001$). The distribution NHBs and NHWs by MM was similar across hospice users and non-users. Adjusting for MM and other confounders, NHBs were significantly less likely than NHWs to utilize hospice (Adjusted odds ratio: 0.42, 95% Confidence Interval: 0.27-0.66, $p < 0.001$). **Conclusions:** Despite the greater representation of NHBs in the highest severity of MM category, NHBs remain significantly less likely than NHWs to use hospice, even after adjusting for MM. The findings carry important implications with regard to disparities in providing optimal, and cost effective quality of end-of-life care.

**9543 General Poster Session (Board #193), Sun, 8:00 AM-11:45 AM**

**Cancer care near the end of life (EOL) in the era of molecular-targeted agents: Changes of trend during 10 years at single institution.** *Presenting Author: Younak Choi, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea*

**Background:** In the era of molecular targeted agents, EOL care and use of chemotherapy at the EOL seems to be changed over time. The purpose of this study was to investigate and compare the cancer care near the EOL during 10 years. **Methods:** Advanced solid cancer patients who received palliative chemotherapy and had died at Seoul University Hospital were enrolled. We categorized the consecutive patients into two groups; died in 2002 (n=57), and died in 2012 (n=206). Medical records of the patients were reviewed. Aggressiveness of cancer care near the EOL was evaluated and compared in terms of following aspects; intensive care unit (ICU) care within the last one month, ER visit within the last one month, period between last chemotherapy and death, number of regimens, cycles of chemotherapy, and consultation for hospice. **Results:** The median patient age was 62 years, and 65.4% of patients (n=172) were male (primary tumor: 91 lung cancer, 27 colorectal cancer, 18 breast cancer, and 127 other). ICU care within the last month increased from 2.7 % in 2002 to 19.9% in 2012 ($P < 0.001$), and ER visit within the last month also increased from 33.6 % to 74.8% ($P < 0.001$). Median time between last chemotherapy and death has been significantly shortened from 66.0 days in 2002 to 34.0 days in 2012 ($P < 0.001$). Mean number of regimen and cycles of chemotherapy also significantly increased (1.8 to 2.5, $P < 0.001$, 5.5 cycles to 11.6 cycles, $P < 0.001$, respectively). Of note, 17.0% patients received molecular targeted agents as the last chemotherapy regimen in 2012, while none of patients received molecular targeted agents in 2002 ($P < 0.001$). Although consultation for hospice care increased from 9.1% to 37.4% ($P < 0.001$), timing of consultation was delayed from median 53 days before death to 8 days before death ($P = 0.004$). **Conclusions:** Cancer care near the EOL becomes aggressive in the era of molecular targeted agents. ICU care before death and chemotherapy use near the EOL, including molecular targeted agents, has increased and becomes aggressive during 10 years, while hospice referral has been delayed. Further nation-wide investigations are warranted.

**9544 General Poster Session (Board #194), Sun, 8:00 AM-11:45 AM**

**Patterns of chemotherapy near the end of life for patients receiving palliative bone radiotherapy.** *Presenting Author: Powell Perng, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Appropriate timing of chemotherapy (CT) cessation is important for optimizing quality of life, with consensus guidelines recommending termination of CT within the last 2-4 weeks of life. Yet CT near the end of life is used in 10-30% of patients, often with little realistic chance of benefit (Kelly R, Smith TJ. Lancet Oncology 2014). We review patterns of CT at the end of life among patients receiving palliative bone radiation (RT) at a high-volume academic institution. **Methods:** Electronic medical records were used to identify patients treated with palliative bone RT at 2 centers from 9/1/2007-7/15/2012. Patient demographics and last recorded systemic (hormonal, non-hormonal oral, and non-hormonal IV) therapy characteristics were collected, and rates of CT in the last 2 and 4 weeks of life were calculated. Factors were compared using $\chi^2$and ANOVA analyses. **Results:** Complete records were found for 210 patients, and 92% were deceased at the time of analysis. Among decedents, median age at death was 64 years (22-94), and primary was 36% lung, 15% breast, 13% prostate, 5% hematologic, and 31% other sites. 12% never received CT, and 30% and 13% received CT $<4$ weeks and $<2$ weeks from death. Primary site of disease for patients receiving CT $<4$ weeks from death were 25% lung, 17 % breast, 19% prostate, 8% hematological, and 31% other cancers; there was no significant difference in site between patients receiving CT $<4$ vs. $\geq 4$ weeks or $<2$ or $\geq 2$ weeks from death. Type of CT did not significantly vary relative to time until death; CT $<4$ and $<2$ weeks from death was 53% and 52% IV, 31% and 36% oral, and 17% and 12% hormonal, respectively. 16% and 7% of all patients received IV CT $<4$ weeks and $<2$ weeks from death, respectively. Patients referred to hospice were less likely to receive CT $<4$ and $<2$ weeks from death ($\chi^2$ $p=0.003$ and $p=0.001$, respectively). There was no difference in time-to-death from date of last CT based on cancer primary or CT type. **Conclusions:** Of patients receiving palliative bone RT, rates of CT at the end of life are relatively low, using the Quality Oncology Practice Initiative benchmarks. Chemotherapy use at the end of life is lowest among patients referred to hospice, supporting engagement of hospice in terminally ill patients.

**9545 General Poster Session (Board #195), Sun, 8:00 AM-11:45 AM**

**Evaluation of falls in older adults in a comprehensive cancer center: How are we doing?** *Presenting Author: Emily Jean Guerard, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Falls are a major cause of morbidity and mortality in older adults ($>$ 65 years old) with as many as one in three reporting a fall in the previous year. Twenty percent of falls lead to serious injuries resulting in declines in function and increased likelihood of institutionalized care. Screening for falls is quick and simple and should be included in the clinical evaluation of an older adult by all clinicians since proven interventions to decrease falls can lead to improvements in function, treatment tolerability, and overall quality of life. The aim of this study is to evaluate medical oncologists' ability to recognize and intervene on falls in older cancer patients. **Methods:** As of October 2013, the Carolina Senior Registry had a total of 528 cancer patients greater than 65 years old seen at UNC who were queried about falls as part of a brief geriatric assessment (GA) [Hurria et. al. J. Clin Oncol 2011]. The history and physical and/or clinic notes completed by a medical oncologist within six months after completion of the GA were retrospectively reviewed for the following: documentation of falls, gait assessment, referral to either geriatrics or physical and/or occupational therapy, and measurement of a 25-hydroxy vitamin D level. **Results:** 125 (24%) of the 528 UNC cancer patients in the registry had at least one fall in the previous 6 months. Of these 125 patients, 54% had one fall and 47% had two or more falls. Seventy of these charts were reviewed and the results are shown in the Table. **Conclusions:** In an academic comprehensive cancer center, older adults who fall were not adequately evaluated by medical oncologists. Our estimates indicate that no more than 10% of patients who experience falls have appropriate medical record documentation or referrals. Practical time-sensitive methods for identification and management of falls are needed. We plan to test a point of service tool to improve medical oncologists' awareness of falls and expedite referrals for effective interventions. Supported in part by the Breast Cancer Research Foundation, New York, NY.

| Outcomes | N=70 (100%) | 95% CI |
|---|---|---|
| **Falls documented** | 2 (3%) | 0-10% |
| **Gait assessment** | 13 (19%) | 10-30% |
| **Referrals** | 2 (3%) | 0-10% |
| **Vitamin D level** | 13 (19%) | 10-30% |

**9546 General Poster Session (Board #196), Sun, 8:00 AM-11:45 AM**

**A prospective study to evaluate the Vulnerable Elders Survey-13 (VES-13) as a tool to identify frail older cancer patients (pts).** *Presenting Author: Laura Biganzoli, Sandro Pitigliani Medical Oncology Department, Hospital of Prato, Istituto Toscano Tumori, Prato, Italy*

**Background:** A major challenge in the care of older cancer pts is identification of who might benefit from adjuvant chemotherapy (CT). Frail pts (FP) typically tolerate CT poorly and/or die from causes other than cancer. It is crucial to identify FP to spare them toxicities of potentially non beneficial and non cost-effective therapy. Fried Frailty Criteria (FFC), based on the Cardiovascular Health Study (CHS) tool, and Balducci Frailty Criteria (BFC), based on several components of a comprehensive geriatric assessment (CGA), are the two most commonly used measures to identify FP. Recently a VES-13 score of $\geq 7$ has been suggested as a means to identify FP. **Methods:** Early-stage cancer pts aged $\geq$ 70 years who were candidates for adjuvant therapy were classified as frail/ not frail at baseline based on CHS assessment, CGA and VES-13 score. As FP are at risk of disability and death, pts were seen 6-monthly to assess for functional decline (FD), defined as either a change from no impaired activities of daily living (ADL) or instrumental ADL (IADL) to any IADL or ADL impairment, or a decrease of $\geq 2$ or $\geq 1$ in IADL or ADL score, respectively, confirmed at two consecutive reviews. Date and cause of death were also captured. To avoid cancer itself confounding the ability of the evaluated tools to identify FP, the main analysis included only tumor-independent events; that is, events occurring in pts without cancer recurrence. A baseline blood sample was taken to assess if analysis of serum metabolomic spectra could identify a metabolic "frailty" signature. **Results:** 185 pts, median age 77 years (range 70-91), were enrolled. Most pts had breast (65%) or colorectal cancer (30%). Median follow-up was 36 months. The incidence of tumor-independent events in relation to frailty according to VES-13, BFC and FFC and accuracy of each tool are reported in the table. **Conclusions:** VES-13 score $\geq 7$ may more accurately identify older patients at risk of health deterioration than FFC or BFC. Data comparing metabolomics with other tools to identify FP will be presented.

| Tool | Criteria used to define FP | FP | | Events | | Overall accuracy (95% CI) |
|---|---|---|---|---|---|---|
| | | n | % | n | % | |
| **CHS** | FFC | 31 | 17 | 15 | 48 | 65% (58% - 72%) |
| **CGA** | BFC | 47 | 25 | 18 | 38 | 70% (63% - 77%) |
| **VES-13** | Score $\geq 7$ | 47 | 25 | 27 | 57 | 75% (68% - 81%) |

**9547 General Poster Session (Board #197), Sun, 8:00 AM-11:45 AM**

**Changes in items of a comprehensive geriatric assessment (CGA) during follow-up: Results from the IN-GHO registry.** *Presenting Author: Friedemann Honecker, Tumor and Breast Center ZeTuP, St. Gallen, Switzerland*

**Background:** Elderly cancer patients (pts) are a heterogenous population. A CGA helps to describe the heterogeneity in a structured way, and can help to detect changes occurring during cancer therapy. The internet based IN-GHO registry prospectively collected data of elderly cancer pts from $>$100 centres in Germany and Austria, both at baseline, and during follow-up within 6 months. **Methods:** Demographic data, data on activities of daily living (ADL), instrumental activities of daily living (IADL), Karnofsky-Performance-Statuts (KPS), comorbidity (Charlson score), number of co-medication, mobility (Timed-Up&Go), cognition (Mini-Mental State Examination), and depression (2-question screening SCID) were collected at baseline. ADL, IADL, and KPS were documented again within 8-12 weeks after baseline. Differences of 5 or more points in ADL, 1 or more points in IADL, and 10% or more in KPS were classified as changes. Data from 3,168 pts aged 70+ years were documented, and changes in items of CGA were analyzed by McNemar test to compare the number of pts with increased and decreased scores. **Results:** Mean age was 76 years, 23.9% were $>$ 80 years. 52.7% were female, 77.9% were treated as outpatients, 73.5% had a solid tumor, and 26.5% had a hematological neoplasia. At baseline, ADL was $<$100 in 37.6% (data from 3,113 pts), IADL was $<$8 in 46.6% (data from 3,133 pts), and KPS was $<$80% in 23.5% (data from 2,771 pts). During follow-up, the following changes were observed: ADL score decreased in 23.0% and increased in 13.4% ($p<0.001$; data from 2,261pts), IADL score decreased in 29.8% and increased in 11.8% ($p<0.001$; data from 2,266 pts), and KPS score decreased in 35.5% and increased in 17.7% ($p<0.001$; data from 1,999 pts). Most frequently observed changes affected the items climbing stairs in ADL, and housekeeping in IADL, respectively. **Conclusions:** In ADL, IADL, and KPS, significant changes were observed in elderly cancer pts during follow-up. Highest frequency of changes was observed in KPS. While the majority of changes signified deterioration, a minority of pts showed improvement, indicating a beneficial effect of therapy.

**9548 General Poster Session (Board #198), Sun, 8:00 AM-11:45 AM**

**The underutilization of occupational and physical therapy for older adults with cancer.** *Presenting Author: Mackenzi Pergolotti, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Older adults are at risk of suffering adverse consequences of cancer and its associated treatments. Occupational and physical therapy (OT/PT) services seek to reduce morbidity, mortality and improve the quality of life of individuals, however little is known about the needs and use of OT/PT for this population. **Methods:** This study analyzed data from an institution-based registry of older adults 65 + with cancer and linked billing-claims data. Patients completed a geriatric assessment for registry and their clinicians were blind to results. Variables include cancer type and status, functional status (defined by Activities of Daily Living (ADL), Instrumental Activities of Daily Living (IADL), cognition, falls, timed up and go (TUG), and social limitations), social support, demographics linked to billing claims for inpatient and outpatient OT/PT. Logistic regression was used to model predictors of need. **Results:** 524 patients with cancer, median age of 71, 87% Caucasian, 57 % married, 53% post-secondary education, 81% retired, 63% with breast cancer were included. 65% have at least one functional deficit and 42% have at least two functional deficits potentially requiring OT/PT. Deficits included 40% ADL, 35% IADL and 25% falls. In a multivariable model, less education and older age were significantly associated with the number of deficits (p = 0.05, 0.0001). Odds of having any deficits were higher for patients with no post-secondary education compared to adults with advanced degrees [OR= 1.8] and increased with age [5 year OR= 1.4]. Of patients with functional deficits, 6% (20/339) received OT/PT within the last year and 1.6% (5/319) received OT/PT within 3 months of noted deficit. **Conclusions:** There is severe underutilization of OT/PT for older adults with cancer. This project is significant because it is the first to outline and define predictors of functional needs and usage of OT/PT in an older population with cancer. These results outline the great need for intervention and referrals to OT/PT in this population. Future policy should be directed towards identifying and breaking down barriers to receipt of rehabilitation services by older cancer patients to decrease morbidity, and improve quality of life.

**9549 General Poster Session (Board #199), Sun, 8:00 AM-11:45 AM**

**Geriatric oncology: Comprehensive geriatric assessment tools (CGA) implementation and interdisciplinary clinical approach for elderly patients (pts) in AC Camargo Cancer Center (ACCCC), Sao Paulo, Brazil.** *Presenting Author: Aldo A. Dettino, A. C. Camargo Cancer Center, Clinica David Erlich, Sao Paulo, Brazil*

**Background:** Ageing is a global phenomenon, also in Brazil. That shift in demographics has huge impact in healthcare. Although still emerging in developing nations, there is no major national innitiative focusing on oncologic geriatric pts. The study describes a program to improve care in >70y cancer pts in A C Camargo Cancer Center, Sao Paulo. We hypothesized that incorporating CGA into daily practice can improve individualized care. **Methods:** aims of the study were to evaluate if: 1) CGA could be feasible in daily practice, 2) it could be useful as a tool in treatment/tx decision making, 3) analyse the impact of CGA in the selection of tx, with its ability to predict complications (such as dose reduction, hospitalization, or tx discontinuation) in a recently implemented Oncogeriatric Unit. Pts >70y, candidates to receive systemic tx, underwent CGA assessments, which included scales of: ADL (Katz, Lawton), mini-nutritional assessment, depression (GDS), comorbidities and polypharmacy. Patients were classified as fit (around 50%), borderline or frail. Fit pts received mainly full treatment; frail/borderline pts, mainly modified tx and/or specific supportive care. **Results:** From Mar/12-Jan/13, 620 pts were evaluated by CGA - female 56%; cancers (%): breast 30, prostate 14, colorectal 13, hematologic 12. Katz A=75%, Lawton 27=50%; polipharmacy (>=5): 49%; depression 10%, undernutrition: 28%. There was association between the choice of oncologic treatment (original vs modified: 89 vs 11%; with additional dose reduction 11%) with Katz (p=0.011, likelihood ratio[lr]=6), Lawton (p<0.001, lr=26), depression (p=0.035, lr=9) and nutrition scales (p=0.004, lr=14). The ability to complete the individualized proposed treatment (96%) was correlated with Lawton (p=0.04, lr=9) scale. Hospitalization during chemotherapy was associated with comorbidities (p=0.038), altered Katz (p=0.004, lr=4.5), Lawton (p=0.012, lr=6.5) and depression scales (p=0.032, lr=10). **Conclusions:** In this cohort, the incorporation of CGA in daily practice was feasible and useful to predict complications of systemic cancer tx.

**9550 General Poster Session (Board #200), Sun, 8:00 AM-11:45 AM**

**Age as an independent predictor of chemotherapy treatment decisions in 20 common cancers.** *Presenting Author: Peter Hall, Leeds Institute of Health Sciences, Leeds, United Kingdom*

**Background:** There have been recent concerns regarding ageism in oncological management. A debate is on-going as to what extent age alone influences the decision to offer a patient adjuvant or palliative chemotherapy, or whether apparent ageism is simply a reflection of correlation between age and other prognostic or predictive factors. This study aims to measure the independent effect of age on the decision to use chemotherapy in 20 common cancers. **Methods:** Patients with an ICD-10 coded diagnosis of cancer were identified within a regional cancer registry between 2000 and 2011. The data was linked to UK national diagnostic data (Hospital Episode Statistics) to provide information on comorbidity. The odds ratio for receiving chemotherapy dependent on age was estimated using logistic regression to adjust for stage, morphology, grade, socioeconomic status, surgery, radiotherapy, other treatments and 15 different comorbidities. Cox regression analysis on 10 year overall survival was used test for a predictive effect of age on benefit from chemotherapy, adjusted for these factors. **Results:** 96,165 patients were included in the study. The odds ratio for older patients receiving chemotherapy (age 70 or greater) was 0.03 (95% CI 0.03 - 0.04, p=<0.001) for early breast cancer; 0.10 (95% CI 0.05 – 0.20, p = <0.001) for metastatic breast cancer; 0.43 (95% CI 0.25-0.74, p=0.003) for ovarian cancer; 0.18 (95% CI 0.15 – 0.22, p=<0.001) for Dukes B and C colorectal cancer; 0.21 (95% CI 0.17 – 0.27, p<0.001) for metastatic colorectal cancer and significant for all other cancer types. For overall survival, the interaction between age and chemotherapy was significant (p<0.01) for many tumour types including early breast cancer, colorectal cancer, bladder cancer and pancreatic cancer. **Conclusions:** Age exerts an independent effect on the decision to treat with chemotherapy in all types of cancer studied. There is evidence that the size of this effect and the age cut-off for a likely decision to treat varies between cancer types. Age may be predictive of benefit from chemotherapy in many cancer types. Further research is needed to clarify to contribution of subjective attributes such as performance status, frailty and patient or clinician attitudes on treatment decisions.

**9551 General Poster Session (Board #201), Sun, 8:00 AM-11:45 AM**

**Multidisciplinary risk assessment to reveal cancer treatments in unfit cancer patients.** *Presenting Author: Pascaline Boudou-Rouquette, Cochin Hospital, AP-HP, Paris Descartes University, Sorbonne Paris Cité, Paris, France*

**Background:** Older age is a cause of disparity in cancer treatment decision. Treatment guidelines for patients with comorbidities, polypharmacy, denutrition or psycho-social frailty are needed. A pre-therapeutic multidimensional assessment might improve the unfit patient management. We developed an experimental program of integrated medicine called ARIANE. We report 18 months activity of this outpatient setting evaluation, its feasibility and impact on treatment decision-making. **Methods:** Unfit patients with predefined cancer treatment strategy entered into the program. A one-day evaluation combined consultations of cardiologist, geriatrician, diabetologist, anesthetist, pharmacist, pain specialist, dietician, psychologist and social worker. Evaluation of performance status, ECG, ejection fraction, ASA score, diabetes, social vulnerability and malnutrition was performed including a geriatric assessment, which focused on items like comorbidity (CIRS-G), dependence (ADL, IADL), fails (Up and Go Test), cognitive impairment (MMSE, Clock Drawing Test) and depression (GDS scale). A pharmacist assessed the risk of drug-drug interactions. **Results:** Eighty-seven pts, median age 81 years (range 25-94), 76% male, 51% PS 0-1, 77% grade 3 or 4 comorbidity were included. Genito-urinary, lung cancers and sarcoma represented 77% of pts. Eighty-two percent of pts were assessed by at least ≥ 7 participants. Identified factors of vulnerability were polypharmacy (n=65; 75%; >3 drugs), social distress or severe malnutrition (both n=21; 24%), depression (n=17; 19.5%) and cognitive impairment (n=13; 15%). We identified drug interactions in 18 pts (27%). The risk assessment resulted in anticancer treatment changes in 47/87 patients (54%): protocol adaptation (n=19/87; 22%), less aggressive treatment (n=15/87; 17.2%), or more intensive therapy (n=13/87; 15%). **Conclusions:** A one-day multidisciplinary risk assessment is an answer to the complexity of unfit cancer patients and improves the safety of anticancer treatments.

**9552 General Poster Session (Board #202), Sun, 8:00 AM-11:45 AM**

**Association of frailty markers with treatment decision in patients seen in oncogeriatric clinic: Results from the ASRO pilot study.** *Presenting Author: Anais Farcet, Centre Gerontologique Departemental, Marseille, France*

**Background:** Comprehensive geriatric assessment (CGA) is the gold standard to help oncologist in choosing the best cancer treatment in their older patients. Some authors recently suggest that the concept of frailty, developed by L Fried, could be a more useful approach in this population. We investigated if frailty markers (FM) are associated with treatment recommendations in an oncogeriatric clinic. **Methods:** This prospective multicenter study included patients 65 years and older, with solid tumors, referred to the oncogeriatric consultation after a cancer treatment plan. A CGA includes 9 domains (autonomy, comorbidities, medication, cognition, nutrition, mood, neurosensory deficits, falls and social status) was performed. Five FM were assessed (nutrition, physical activity, energy, mobility, strength). Patients were classified as Frail (3 or more FM), pre frail (1 or 2 FM) or not frail (0 FM). Treatment recommendations were classified in 3 categories: Standard treatment, Standard treatment with adaptation, supportive/palliative care. A polytomus logistic regression models were used to analyze factors associated with treatment recommendations. **Results:** 217 patients, mean age 83 years (± SD 5,3) were included. The most prevalent of the FM were mobility (77%), physical activity (65%), and nutrition (61 %). 42% had at least 3 markers. In univariate analysis, grip strength, physical activity, mobility, nutrition, ADL, IADL, social status, depression, ECOG-PS and sexe were significantly associated with treatment recommendations. In the multivariate analysis, only the number of FM and ADL were significantly associated with treatment recommendations (respectively p=0.001 and p=0.015). Treatment recommendations were significantly different into the 3 FM groups (p=0,001). In the non frail group, standard treatment or standard treatment with adaptation was maintained for more than 90% of patients. In the frail group, a support/palliative care was proposed for 60% of patient. **Conclusions:** Frailty markers are associated with treatment recommendations in older cancer patients. Longitudinal studies are warranted to better precise their use in geriatric oncology setting.

**9553 General Poster Session (Board #203), Sun, 8:00 AM-11:45 AM**

**Frailty markers for prediction of mortality in first-line chemotherapy for colon cancer patients: Results of MOST/ASRO 101 study.** *Presenting Author: Frederique Retornaz, Centre Gerontologique Departemental, Marseille, France*

**Background:** The concept of frailty may help in to detect vulnerability in patients with digestive cancer in surgery setting. We investigated whether frailty markers predict grade 3-4 toxicity or 6 months death in older colon cancer patients receiving a first line chemotherapy. **Methods:** This prospective multicenter study included patients aged ≥75 years, with colon cancer, receiving first line of chemotherapy for adjuvant or metastatic situation. Five frailty markers were examined (nutrition, physical activity, energy, mobility, strength). Logistic regression was used to examine the association between frailty markers and grade 3-4 toxicity at 3 and 6 months, and cox regression to examine deaths at 6 months. **Results:** 99 participated, and 98 were eligible for analysis. Median age was 79 years. At baseline, 26 patients (26.5%) had 3 or more frailty markers. Twenty six (26.5%) had grade 3-4 toxicity after 3 months, and 18 (18.4%) after 6 months. Twelve patients died during the 6 months follow-up. In multivariate analysis, at 3 months and 6 months, none of the studied frailty marker predicted grade 3-4 toxicity. At six months, significant predictive factors for death were the frailty marker "energy" (Hazard Ratio [HR]; 13.92 (95% CI [3.22-60.15] p=0.0004) and presence of 3 or more frailty markers at baseline (HR, 4.50 (95% CI [1.30-15.64] p=0.02). **Conclusions:** Frailty markers are predictive of death at 6 months but are not predictive of severe toxicity. These results suggest that frailty markers, in particular "energy" should be taken into account when treating an elderly cancer population. Further researcher investigating the usefulness of frailty markers is needed.

**9554 General Poster Session (Board #204), Sun, 8:00 AM-11:45 AM**

**Outcomes of invasive mechanical ventilation in elderly patients with metastatic cancer.** *Presenting Author: Achuta Kumar Guddati, Massachusetts General Hospital, Boston, MA*

**Background:** Aggressive management of elderly patients with metastatic cancer has helped prolong their survival. Respiratory failure in elderly patients with metastatic disease may significantly contribute to a decline in their functional status. However, the outcomes of the use of invasive mechanical ventilation (IMV) in patients with rapidly declining functional status have not been studied in detail. **Methods:** Using the Healthcare Cost and Utilization Project – Nationwide Inpatient Sample database 2000-2009, patients aged 65 and above undergoing IMV were identified using appropriate ICD-9-CM codes. The rates of prolonged IMV (≥96 hours) and use of tracheostomy were examined. Chi square test and Wilcoxon rank test were used to compare discrete and continuous variables respectively. Significance was defined as p value set at <0.05. Bonferroni's correction as applied for multiple comparisons. **Results:** 4,256,372 patients aged 65 and above underwent IMV during the years 2000 to 2009. Of these, 192,852 (4.5%) had metastatic cancer. After adjusting for age, the odds of mortality were 1.86 times higher (95% CI 1.8-1.9) when compared to those without any cancer. The outcomes of patients undergoing IMV are shown below (see Table). **Conclusions:** The hospital LOS and hospital charges in patients undergoing IMV were higher in patients with cancer and in those with metastatic disease. The mortality was however significantly higher in patients with metastasis. Of the survivors, almost twice the number of patients are discharged to hospice facilities when compared to cancer patients with no metastatic disease. The use of prolonged IMV portends a higher mortality and worser outcomes in elderly patients with metastatic disease.

**9555 General Poster Session (Board #205), Sun, 8:00 AM-11:45 AM**

**Phase angle for prognostication of survival in patients with advanced cancer.** *Presenting Author: David Hui, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Accurate survival prediction is essential for decision making in cancer therapies and care planning. Objective physiologic measures may improve the accuracy of prognostication. In this prospective study, we determined the association of phase angle, hand grip strength, and maximal inspiratory pressure with overall survival in patients with advanced cancer. **Methods:** We enrolled hospitalized patients with advanced cancer who were seen by palliative care for consultation. We assessed the phase angle, hand grip strength, maximal inspiratory pressure and known prognostic factors including Palliative Prognostic Score (PaP), Palliative Prognostic Index (PPI), serum albumin and body composition. We conducted univariate and multivariate survival analysis, and examined the correlation between phase angle and other prognostic variables. **Results:** 222 patients were enrolled: average age 55 (range 22-79), female 59%, gastrointestinal cancers 33%, mean Karnofsky performance status (KPS) 55%, and median overall survival 106 days (95% confidence interval [CI] 71-128 days). The median survival for patients with phase angle 2-2.9°, 3-3.9°, 4-4.9°, 5-5.9° and ≥6° was 35, 54, 112, 134 and 220 days, respectively (P=0.001). We found that PaP (P<0.001), PPI (P=0.003), KPS (P<0.001), fat free mass (P=0.02) and hypoalbuminemia (P<0.001) were significantly associated with survival, but not cancer diagnosis (P=0.10), hand grip strength (P=0.08) and maximal inspiratory pressure (P=0.08). In multivariate Cox regression analysis, phase angle, PaP, albumin, and fat free mass were independently significant (Table). Phase angle was only weakly ($\gamma$<0.4) associated with other prognostic variables. **Conclusions:** Phase angle was a novel predictor of poor survival, independent of established prognostic factors in the advanced cancer setting. This objective and noninvasive tool may be useful for bedside prognostication.

**Multivariate survival analysis.**

| Variables | Hazard ratio (95% CI) | P value |
|---|---|---|
| **Phase angle (per degree increase)** | 0.86 (0.74-0.99) | 0.04 |
| **Palliative Prognostic Score (per point increase)** | 1.07 (1.02-1.13) | 0.008 |
| **Albumin (per g/dL increase)** | 0.67 (0.50-0.91) | 0.009 |
| **Fat free mass (per kg increase)** | 0.98 (0.96-0.99) | 0.02 |

**9556 General Poster Session (Board #206), Sun, 8:00 AM-11:45 AM**

**Availability of single-fraction palliative radiotherapy for cancer patients receiving end-of-life care within the Veterans Healthcare Administration.** *Presenting Author: Drew Moghanaki, Hunter Holmes McGuire Veterans Affairs Medical Center, Richmond, VA*

**Background**: Multiple randomized phase III trials have established a single fraction of palliative radiotherapy is equally effective at relieving pain when compared to longer treatment courses. However, recent surveys demonstrate <20% of radiation oncologists in the US offer this shorter treatment option. As 500,000 Veterans currently receive cancer care within the Veterans Healthcare Administration (VHA), a study was conducted to determine whether this finding held true in this healthcare system. **Methods**: A web-based survey was emailed to all radiation oncologists currently practicing at VHA medical centers. Associations of responses were evaluated by Fisher's exact test. **Results**: The response rate was 90% (70/78). Half of respondents were full-time employees of the VHA, and the majority (70%) had thoroughly read guidelines on palliative radiotherapy for bone metastases recently published by either the American College of Radiology (ACR, 2009) or American Society of Radiation Oncology (ASTRO, 2011). Single-fraction palliative radiotherapy for bone metastases had been prescribed by 76% of respondents, and 93% had prescribed a short course of ≤6 fractions. Respondents were less likely to have prescribed a single fraction for patients who had survival estimates of either >6 months or >12 months, (66% vs 37%, $p < 0.0001$).Those not offering single-fraction palliative radiotherapy (24%) were more likely to be >10 years out of training (37% vs 10%, $p = 0.01$), and more likely to have worked in private practice at some point in their career (36% vs 12%, $p = 0.03$). There were no associations with employment status, history of an academic appointment, or having previously read the recently published ACR or ASTRO guidelines. **Conclusions**: Single fraction palliative radiotherapy is widely available in the VHA. Its use is preferred by radiation oncologists for patients with a limited life expectancy of less than 6 months. These data demonstrate rapid adoption of recently published guidelines that are designed to ensure access to care is not limited by a preference for prolonged treatment courses that may discourage patients and clinicians from seeking this care.

**9557 General Poster Session (Board #207), Sun, 8:00 AM-11:45 AM**

**Phase II clinical trial of *uncaria tomentosa* (cat´s claw) in patients with advanced solid tumors.** *Presenting Author: Larissa Carvalho Lopes De Paula, ABC Foundation School of Medicine, Santo André, Brazil*

**Background:** Cat's claw (*Uncaria tomentosa*) is a native amazonic plant that exhibits anti-inflammatory and antitumor properties. **Methods:** This prospective phase II study assessed the effects of a 100-mg dose of a dry extract of *U. tomentosa*three times per day on individuals with advanced solid tumors, with no further therapeutic options and with at least 2 months life expectancy. We used the EORTC QLQ C30 and FACIT-F questionnaires to assess the participants´ quality of life, the HADS questionnaire to assess their anxiety and depression and the Pittsburgh index (PSQI) to assess their sleep quality. In addition, several biochemical and inflammatory parameters were analyzed. **Results:** We recruited 51 volunteers; their median age was 64 (33-85) years old, and 47% were females. Their scores on the Karnofsky scale were equal to or less than 80% for more than 65% of the volunteers. Treatment caused an improvement in the patients' overall quality of life ($p= 0.0411$) and social functioning ($p= 0.0341$), as assessed by EORTC QLQ C-30, and a reduction of fatigue ($p= 0.0496$) by the Chalder Fatigue Questionnaire. None of the biochemical or inflammatory parameters assessed (interleukins 1 and 6, C-reactive protein, tumor necrosis factor alpha, erythrocyte sedimentation rate and alpha-1-acid glycoprotein) exhibited significant changes. No tumor response was detected according to the RECIST criteria; however, the disease stabilized for more than eight months in four participants. The medication was well tolerated by most patients. **Conclusions:** We conclude that use of cat´s claw might be beneficial for patients with advanced cancer because it could improve their quality of life and reduce fatigue. The mechanism of this action does not seem to be related to the anti-inflammatory properties of this plant. Clinical trial information: NCT02045719.

**9558 General Poster Session (Board #208), Sun, 8:00 AM-11:45 AM**

**Assessing 2-month clinical prognosis in patients with solid tumors: Final results of PRONOPALL study.** *Presenting Author: Hugues Pierre Bourgeois, Clinique Victor Hugo, Le Mans, France*

**Background:** In 2008, results about a prognostic score defined by 4 factors (Karnofsky index PS, number of metastatic sites, serum albumin and LDH levels) in a population of 177 hospitalized patients in two hospitals were published (Barbot et al, 2008). Albumin threshold is 33 g/L and LDH one is 600 IU/L. The scoring allowed to define 3 different patient populations: A : low score (0 to 3), B: intermediate score (4 to 7) and C : high score (8 to 10). The survival rates at 2 months were 92.2% ± 3.8 (population A), 42.7% ± 5.2 (population B) and 8.3% ± 4.6 (population C). **Methods:** in order to validate this score, we decided to start a multicentric trial with a high proportion of out-patients. **Results:** between October 2009 and October 2010, 302 patients were included from 16 institutions. Inclusion criteria: adult patients with a solid tumor in a palliative setting with one or more of the three following criteria: life expectancy of less than 6 months, PS ≥ 2, evidence of disease progression during palliative chemotherapy. All patients signed an informed consent form. 265 (88%) patients were evaluable for the first analysis. 37 patients were not eligible. Median age: 66 years [37-88], women 59%, men 41%. PS 0-1 (45%), PS 2 (37%), PS 3-4 (18%). The most frequent primary sites: breast (29%), colon/rectum (28%), lung (13%), ovary (11%), pancreas (11%), other (8%). One metastatic site (32%), two (35%), more than two (31%). Median LDH level was 397 IU/L [118-4314]. Median level of serum albumin was 35 g/L [13-54]. According to the prognostic score, the 2-month survival rate was 92% and the median survival rate was 301 days [209-348] (population A, 131 patients), 64% and 78 days respectively [71-113] (population B, 113 patients) and 24% and 35 days respectively [14-56] (population C, 21 patients). These three populations are statistically different ($p<0.0001$). Among the 4 factors, only PS, LDH and serum albumin were statistically connected to survival rate ($p<0.0001$). 63 patients, aged 75 years and older, allowed to validate the prognostic score for oncogeriartric patients too ($p=0.0002$). **Conclusions:** PRONOPALL confirms the three prognostic profiles defined by the combination of these four factors and is useful in daily practice. Clinical trial information: 2009-A00936-51.

**9559 General Poster Session (Board #209), Sun, 8:00 AM-11:45 AM**

**Spirituality and quality of life among caregivers of advanced cancer patients.** *Presenting Author: Tai Chung Lam, Dana-Farber Cancer Institute/ Brigham and Women's Cancer Center, Boston, MA*

**Background:** Religion and/or spirituality (R/S) is important to most advanced cancer patients, and often upholds patient quality of life (QoL) within illness. However, the role of R/S within the caregiving experience has not been adequately studied. **Methods:** Data from 570 caregiver-patient dyads participating in the Coping with Cancer study were included. Caregivers completed R/S measures on R/S importance, positive and negative religious coping, and degree of spiritual support from medical teams and religious communities. The correlations of caregiver R/S variables to patient R/S were assessed. Multivariable models (MVA) were employed to assess relationships of caregiver R/S measures with their QoL (SF-36 questionnaire) and perceptions of care-giving experience, controlling for confounding factors (e.g., sociodemographic factors, self efficacy). **Results:** Caregivers (median age 53 years, 51% spouses) largely reported religion to be important (85%). Most (85%) endorsed at least some positive religious coping, and 31% endorsed at least some negative religious coping. Thirty-nine percent and 17% of caregivers reported being highly supported by R/S communities and medical system, respectively. Caregivers' R/S variables were correlated with patient R/S, including religiosity ($r=.24$, $p<.001$), positive religious coping ($r=.41$, $p<.001$) and negative religious coping ($r=.21$, $p<.001$). In MVA assessing relationship of R/S variables to caregiver QOL, negative religious coping was significantly related to lower caregiver QoL (SF-36 mental component summary, $\beta=-2.2$, $p<.001$). In MVAs of the relationship of R/S to perceptions of care-giving experience, greater positive religious coping (OR 1.95, $p=.04$) and greater medical team spiritual support (OR 2.02, $p=.01$), were related to more positive perceptions of the caregiving experience. **Conclusions:** R/S is important to most caregivers and is correlated with patient R/S. Caregiver negative religious coping is associated with poorer QoL. Caregiver positive religious coping and spiritual support from medical teams are related to caregivers' positive perceptions of caregiving experience. Results suggest approaches to improve caregiver QoL should involve intervention on R/S.

**9560 General Poster Session (Board #210), Sun, 8:00 AM-11:45 AM**

**Differences between patient and caregiver ratings of advanced cancer patients' quality of life and correlates of their disagreement.** *Presenting Author: Tai Chung Lam, Dana-Farber Cancer Institute/Brigham and Women's Cancer Center, Boston, MA*

**Background:** Assessment of patient quality of life (QoL) by surrogates, particularly informal caregivers (e.g. spouse), is important to the care of advanced cancer patients. However, accuracy of such surrogate QoL assessments has been questioned. This study sought to assess differences between patients' QoL self-assessments compared to assessments by their informal caregivers, and to determine characteristics associated with the disagreement. **Methods:** Data from 570 advanced cancer patient-caregiver dyads participating in the multi-site, Coping with Cancer study were included. Patients assessed their QoL with the McGill QoL questionnaire. Caregivers estimated patients' QoL using the same questionnaire. Paired t-tests were used to compare the dyadic estimates of QoL scores. Multiple linear regression (MVA) was performed to examine factors potentially associated with the difference in dyadic QoL estimates. **Results:** Caregivers' mean age was 53 years, 71% were female, and 51% were spouses. The overall mean patient QoL score, as assessed by caregivers, was lower than the overall mean QoL by patient assessment [6.4 (SD=1.8) vs. 7.1 (SD=1.6), p<.0001]. In MVA assessing factors contributing to patient-caregiver differences in QOL assessment, sociodemographic factors, overall coping, positive religious coping, and interpersonal support were not associated with any significant disagreement. Higher level of caregiver negative religious coping ($\beta$=.31, p=.0002) and burden ($\beta$=.77, p<.001), lower caregiver self-efficacy ($\beta$=-.54, p=.005), higher stressful caregiving adult reactions to experiences of dying scale (SCARED) ($\beta$=1.28, p<.0001) and higher patient self-estimated QoL ($\beta$=2.92, p<.0001) were significantly associated with greater disagreement between patient and caregiver estimates of patient QoL. **Conclusions:** Caregiver assessments of patient QoL are underestimated as compared to patient self-assessment. Caregiver factors, including negative religious coping, self-efficacy, burden and SCARED, are associated with patient-caregiver disagreement in estimates of patient QoL, suggesting ways to improve accuracy of caregivers' evaluation of patient QoL.

**9561 General Poster Session (Board #211), Sun, 8:00 AM-11:45 AM**

**Change in palliative performance scale score as prediction of survival in patients with advanced cancer.** *Presenting Author: Yong Joo Lee, Department of Palliative Medicine, Seoul St. Mary Hospital, The Catholic University of Korea, Seoul, South Korea*

**Background:** The Palliative Performance Scale (PPS) is a widely-used prognostic tool in patients with advanced cancer. While single PPS measures are predictive of survival, the utility of serial PPS measurements warrants further study. We hypothesized that changes in PPS are associated with survival, and thus may be useful in forecasting health services utilization in Korea, where late referral to palliative care services is common. This study examines associations between change in PPS score and survival in patients with advanced cancer. **Methods:** We identified a cohort of 606 inpatients who died at a Korean university hospital's hospice/palliative care center, and abstracted relevant chart data. PPS scores were measured twice as part of standard care: (1) on admission, and (2) after three days in the hospital (D3). 'Change at D3' was defined as the difference between initial PPS and PPS at D3, divided by initial PPS. We used a Cox regression modeling approach to explore the association between this change score and survival, adjusting for the influence of age, sex and primary cancer type. **Results:** Patients' median survival was nine days (range 1-65). Change scores were statistically significantly associated with survival. A change score of >30% yielded a hazard ratio for death of 2.66 (95% CI 2.19-3.22), compared to a change score of ≤ 30%. PPS of ≤ 30 on D3 also independently predicted survival, with a hazard ratio of 1.67 (95% CI 1.38-2.02) compared to PPS of >30. PPS at admission was not independently associated with survival. **Conclusions:** A change of over 30% in PPS appears to predict survival in patients with advanced cancer at our center, even after adjustment for confounders. PPS at admission did not predict survival. Change in PPS may be a more sensitive indicator of impending death than a single PPS measurement at admission in cancer patients near the end of life. Further prospective study is needed to test this important finding in other populations.

**9562 General Poster Session (Board #212), Sun, 8:00 AM-11:45 AM**

**Intensive care unit admissions and in-hospital mortality in patients admitted through the emergency department of a comprehensive cancer center.** *Presenting Author: Ahmed F. Elsayem, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The National Cancer Policy Forum advocated for improving quality of end life care, and reducing cost for cancer patients. Identifying those at high risk for Intensive Care Unit (ICU) admission, and hospital death may allow earlier palliative care and avoid futile interventions. The purpose of this study is to examine risk factors for ICU admission, and hospital death among cancer patients admitted through the Emergency Department (ED). **Methods:** We queried MD Anderson Cancer Center databases for all patients who visited our ED in 2010. ICU admission and hospital deaths of these patients were reviewed, and individual patients' data were analyzed. **Results:** In 2010, 16,038 ED visits were made by 9,246 unique cancer patients. Of these patients, 5,362 (58%) were admitted to the hospital at least once (range 1-13 admits). Of all patients admitted through the ED, 697 (13%) were admitted at least once to ICU. Of all patients admitted, 11% died during hospitalization; of those, 29% died in ICU. Among patients who died in ICU, 73/233 (31.3%) had hematologic malignancies and 96/354(27.1%) had solid tumors (P<.001). Patients admitted to ICU had median lengths of hospital stay (MLOS) of 13 days for hematologic and 8 days for solid tumors (P<.001; using means); patients without ICU admission had MLOS of 6 and 5 days, respectively (P<.001). In a multivariate logistic regression model for predicting in-hospital mortality, we found that ED presenting symptoms of respiratory distress or altered mental status (fever and pain non-significant); primary tumor of lung cancer, leukemia, unknown primary, or lymphoma; and non-white race were independent predictors of death, while controlling for age, gender and residence. **Conclusions:** Cancer patients admitted through the ED experience high ICU admission rates, and hospital mortality. Lung and certain other cancers; race; and symptoms of respiratory distress and altered mental status were associated with increased risk of in-hospital death. Patients with these risk factors may benefit from efforts to improve palliative care and prevent unnecessary interventions.

**9563 General Poster Session (Board #213), Sun, 8:00 AM-11:45 AM**

**Pre and postradiation lymphopenia predicts survival in management of bone metastases.** *Presenting Author: Sara R. Alcorn, Department of Radiation Oncology and Molecular Radiation Sciences, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Radiation-induced lymphopenia (RIL) has recently been identified as an adverse prognostic factor in select solid tumors, yet its prognostic value is unknown in the management of metastatic lesions. We examine the relationship between RIL and survival in patients receiving palliative radiation (RT) for bone metastases. **Methods:** Palliative bone RT plans were identified through medical records at a high-volume institution from 9/1/2007-7/15/2012. Patient and treatment characteristics were recorded, including lymphocyte count (LC) ≤6 weeks before RT and within 1-3 months after RT. Comparative statistics were performed using t-tests, ANOVA, and Kaplan-Meier analyses. **Results:** Of 573 palliative bone RT plans, 405 plans from 251 patients with complete baseline data were analyzed; 227 plans had complete post-RT data. At a median follow-up of 4.3 months, 9% of patients were living. Median age and KPS were 64 years (range 22-94) and 70 (range 30-100), respectively. RT sites were 51% spine, 20% pelvis, 19% extremity, and 10% other. Median RT dose was 30 Gy (range 2-48 Gy). Prior to RT, 13% and 46% of patients had LC<500 and LC<1000, respectively; on survival analyses, baseline LC <500 was associated with lower median survival as compared to LC≥500 (1.4 vs 5.6 mo.; p<0.001), as was baseline LC<1000 vs LC≥1000 (3.1 vs 6.7 mo.; p<0.001). Mean LC was significantly higher before RT (1270, SD=1247) than after RT (903, SD=867; paired samples t-test p<0.001.) Excluding baseline LC<500, median survival was lower for patients with LC<500 vs LC≥500 after RT (4 vs 11.1 mo.; p<0.001); post-RT LC<1000 did not predict survival. Whereas daily pre-RT steroid use was associated with higher percent change in LC after RT (t-test p=0.001), steroids at the time of post-RT labs and peri-RT chemotherapy did not significantly affect LC. Histology, RT site, RT to >4 vertebral bodies, and RT dose >30 Gy were also not associated with post-RT LC. **Conclusions:** Lymphopenia prior to and after RT appears to be a prognostic factor in the treatment of bone metastases, and significant RIL can occur irrespective of RT characteristics such as field and dose. These data suggest for careful consideration of hematologic status during patient selection for palliative RT.

**9564 General Poster Session (Board #214), Sun, 8:00 AM-11:45 AM**

**Previous cancer of spouse as a predictor for mortality after personal diagnosis of cancer.** *Presenting Author: Tamar Peretz, Sharett Institute of Oncology, Hadassah Hebrew University Medical Center, Jerusalem, Israel*

**Background:** Previous experience may affect further coping with illness. The aim of the current study was to evaluate the association between prior cancer of spouse with mortality following a personal diagnosis of cancer. **Methods:** A historical prospective study, with cohort inception and baseline measurement of people participating in the Central Bureau of Statistics 1995 census, was designed. Cancer incidence was ascertained through the Israel Cancer Registry and followed up until 2011. Multivariate Cox proportional hazards models were used to assess hazard ratios for mortality among study subjects following cancer of their spouse, while controlling for age, sex, marital status and ethnicity. In order to exclude lead time bias and smoking effect, further analyses which restricted to stage IV cancers and models which excluded smoking associated cancers (lung, head and neck, renal, and bladder cancers) were carried. **Results:** A total of 133,550 cases of cancer and 61,048 deaths were reported during the study period. The effect on mortality was mediated by spouse's survival at the time of self-diagnosis; mortality of spouse, at the time of personal diagnosis of cancer was associated with increased risk for death (HR=1.07, 95%CI: 1.02-1.12) compared with reduced risk of personal mortality following a diagnosis of cancer in spouse whose was alive at time of diagnosis (HR=0.90, 95%CI: 0.87-0.94). The gender effect was more prominent in stage IV patients; only males were susceptible to the negative effect after spouse mortality (HR=1.20, 95%CI: 1.06-1.36) while the protective effect of a spouse who was alive at time of self-diagnosis was significant only among females (HR=0.79, 95%CI: 0.71-0.89). These results were similar in the models which included only non-smoking associated cancers. **Conclusions:** Mortality followed cancer diagnosis is affected by prior diagnosis of cancer among the spouse. This effect is influenced by the survival of the spouse at the time of cancer diagnosis and gender.

**9565 General Poster Session (Board #215), Sun, 8:00 AM-11:45 AM**

**Biopsychosocial predictors of pain among women recovering from surgery for gynecologic cancer.** *Presenting Author: Kelsey R. Honerlaw, University of Wisconsin, School of Medicine and Public Health, Madison, WI*

**Background:** Pain is a common and sometimes debilitating symptom for women recovering from surgery for gynecologic cancer, but little is known about psychological and biological risk factors that account for individual differences in pain. We investigated the extent to which psychological distress and inflammation were associated with pain post-surgery. **Methods:** Women (N=90) who underwent surgery for ovarian or endometrial cancer participated in this prospective, longitudinal study. They completed well-validated self-report measures of pain (intensity and interference with daily activities) and distress (depression and anxiety) at 1 week, 1 month, and 4 months post-surgery. Inflammatory cytokines were measured in peripheral blood at the same time points using an electrochemiluminescence platform. Mixed-effects and subject-level fixed-effects linear regression models were used to examine the extent to which distress measures and cytokines predicted pain intensity and interference. **Results:** Pain intensity and interference improved greatly over the four months post-surgery (p values$<$0.001).Participants who reported greater depression and anxiety experienced greater pain intensity ($z=8.00$, $p<0.001$; $z=3.32$, $p=0.001$). The same pattern was seen for pain interference. Those with higher IL-6 and IL-10 also experienced greater pain intensity ($z=2.44$, $p=0.015$; $z=2.03$, $p=0.042$), but not interference. All models controlled for time since surgery, surgical method (laparoscopy or laparotomy), disease stage, age, and BMI. Within-subjects analyses revealed that among individual patients, changes in distress and cytokine levels across the assessments were associated with corresponding changes in pain, with patients reporting greater pain intensity when depression ($t=4.92$, $p<0.001$), IL-6 ($t=2.72$, $p=0.008$), and IL-10 ($t=2.40$, $p=0.019$) were most elevated. Pain interference was greatest when depression ($t=6.61$, $p<0.001$) and anxiety ($t= 2.58$, $p=0.011$) were highest. **Conclusions:** Results suggest that depression, anxiety, and inflammation may exacerbate pain following surgery for gynecologic cancer. These risk factors can be targeted to improve post-surgical recovery and enhance quality of life.

**9566 General Poster Session (Board #216), Sun, 8:00 AM-11:45 AM**

**Effect of contralateral prophylactic mastectomy on quality of life in women undergoing surgery for breast cancer: A prospective study.** *Presenting Author: Chang Xia, Hematology, Oncology, and Blood & Marrow Transplantation, UIHC, Iowa City, IA*

**Background:** There has been a marked increase in the use of contralateral prophylactic mastectomy (CPM) for women with unilateral breast cancer. Previous studies on quality of life (QoL) measures for women who have undergone CPM are mixed. Most surveys were conducted only post-operatively. This analysis reports QoL changes within the same patient before and after surgery, using a validated tool. **Methods:** This study includes women who were prospectively enrolled in the University of Iowa Breast Molecular Epidemiologic Resource. We included all women who had mastectomy on the affected side. Patients completed a validated QoL survey (FACT-B) which covered: overall QoL and additional cancer-specific concerns. Responses followed a five-point scale. Surveys must have been completed any time before surgery and 6-18 months after surgery. A Fixed Effects linear regression model was used to discern within-person changes in QoL measures before and after surgery. Analysis was stratified by unilateral mastectomy (UM) or CPM. **Results:** The study cohort included 34 women, 17 received CPM and 17 received UM. Mean age was 61.5 for women who chose UM and 50.6 for women who chose CPM ($p<0.001$). There were no differences in baseline QoL measures between the two groups. After surgery, both groups felt less nervous, though the change in the CPM group was greater ($p<0.001$). There were no other differences for the UM group in pre-post QoL measures. Women undergoing CPM did have QoL decrements (Table). **Conclusions:** Women who chose CPM feel less nervous after surgery. However, these women lose some sense of femininity and are more likely to experience physical post-operative sequelae. This adds to knowledge that can be used to counsel women about physical and emotional costs associated with CPM that manifest 6-18 months after surgery.

| | UM | | CPM | |
|---|---|---|---|---|
| QoL: Pre to postoperative change | Pre-post change | p | Pre-post Change | p |
| I feel nervous | -1.18 | <0.001 | -1.46 | <0.001 |
| I am able to feel like a woman | 0 | 1.0 | -1.18 | 0.01 |
| I have certain parts of my body where I experience pain | 0.73 | 0.21 | 1.18 | 0.03 |
| Movement of my arm is painful | 0.57 | 0.14 | 0.88 | 0.03 |
| I have stiffness of my arm | 0.43 | 0.27 | 0.63 | 0.04 |
| My arm feels numb | 0.43 | 0.60 | 1.13 | 0.07 |

**9567 General Poster Session (Board #217), Sun, 8:00 AM-11:45 AM**

**Default of cancer treatment association with psychological distress and desire for psychological support.** *Presenting Author: Caryn Mei-Hsien Chan, University of Malaya, Kuala Lumpur, Malaysia*

**Background:** Default of treatment is highly prevalent among cancer patients, with delayed or incomplete treatment shown to result in worse clinical outcomes such as treatment resistance, disease progression as well as poorer survival. Our objective was to identify psychosocial variables and characteristics associated with cancer default. We hypothesized that cancer patients who are psychologically distressed are more likely to: (a) refuse, delay or discontinue cancer treatment and routine patient follow up, and (b) decline offers for psychological support. **Methods:** This study is part of a larger prospective study assessing the psychosocial needs of patients with cancer. A total of 467 consecutive adult cancer patients attending scheduled oncology follow-ups at a single academic medical centre completed the Hospital Anxiety and Depression Scale and reported their preference for psychological support at baseline, 4-6 weeks and 12-18 months follow-up. Default was defined as refusal, delay or discontinuation of treatment or visit, despite the ability to do so. **Results:** A total of 159 of 467 (34.0%) cancer patients were defaulters. Of these 159 defaulters, 89 (55.9%) desired psychological support, compared to only 13 (4.22%) of 308 non-defaulters. Although not associated with each other, desire for psychological support and psychological distress were the only variables found to be significantly associated with default of appointment or cancer treatment using a chi-square and a repeated-measures ANCOVA at $p = 0.001$ and $p = 0.015$ respectively. No other remarkable differences between defaulters and non-defaulters were discerned. **Conclusions:** To date there are few published studies on rates of default among adult oncology patients. Our results show that defaulters had higher psychological distress but greater desire for support compared to non-defaulters. Patients who refuse cancer treatment initially should be offered psychological support, with their desire for treatment re-evaluated later on. Patients may be more willing to accept cancer treatment if desirous of and given psychological support. This in turn could potentially increase treatment acceptance rates and improve survival.

**9568 General Poster Session (Board #218), Sun, 8:00 AM-11:45 AM**

**Mental mood of gynecologic cancer patients assessed by distress and impact thermometer (DIT; a two-item, self-report questionnaire) and hospital anxiety and depression scale (HADS; a 14-item, self-report questionnaire) during the initial treatment in the first 6 months: KCOG-G1103 study.** *Presenting Author: Yoshio Itani, Nara Prefectural Nara Hospital, Nara, Japan*

**Background:** Thirty percent of cancer patients are reported to suffer from psychological distress which detracts from treatment adherence, but that is often underestimated in clinical settings. HADS is one of the validated scales for screening emotional distress in cancer patients. However, it is not used widely because it is cumbersome to score. DIT is a 2-item (the Distress and the Impact) self-report questionnaire, but is not well verified. **Methods:** One hundred and seventeen patients were enrolled between 2011.5.1 and 2012.3.31 and 95 were eligible. Median age was 54 years (range 31–77). The numbers of completed questionnaires (HADS & DIT) at (a) pretreatment, (b) 3 months, and (c) 6 months were 95, 80, and 70, respectively. No patients relapsed during the investigated period. **Results:** 1) Areas under the curve of receiver operating characteristic curves for Distress and Impact with respect to HADS positivity were 0.855 and 0.875 respectively. At Distress $\geq$4 and Impact $\geq$2, sensitivity, specificity, positive predictive value, and negative predictive value were 0.818 (95% confidence interval (CI): 0.707–0.898), 0.875 (95%CI: 0.739–0.945), 0.9 (95%CI: 0.786–0.957), and 0.778 (95%CI: 0.637–0.875), respectively. 2) In each patient, the mean scales of (b) were significantly reduced in HADS (mean 3.2; $p<0.0002$) and in Distress (mean 1.7; $p<0.0001$), but not in Impact (mean 0.66; $p=0.072$) compared with (a). Those of (c) were significantly reduced in HADS (mean 4.5; $p<0.0001$), in Distress (mean 2.3; $p<0.0001$), and in Impact (mean 1.09; $p=0.031$) compared with (a) (Student's paired t-test). **Conclusions:** 1) DIT is a reliable tool for ruling out clinical psychiatric distress. 2) For the first 6 months of treatment, mental mood would have a tendency to be improved, but not completely. Therefore, gynecologic oncologists should screen psychiatrically distressed patients by DIT and introduce them to psychiatric treatment early in the initial treatment. Clinical trial information: 000005727.

**9569 General Poster Session (Board #219), Sun, 8:00 AM-11:45 AM**

**The subjective quality of life of young patients with breast cancer and their partners.** *Presenting Author: Laurence Vanlemmens, Centre Oscar Lambret, Lille, France*

**Background:** The subjective experience of young breast cancer (BC) women has some specifics related to the impact of illness and treatments on the issues specific to their age. The partner is most often the primary caregiver and is himself affected by the disease. A better understanding of couples facing cancer at every stage of treatment program appears crucial to improve the overall care. This study aims to better understand the quality of life of these young couples (women <45 at diagnosis), by comparing the subjective experience of patients and partners from chemotherapy (CT) to the end of treatments period. **Methods:** 491 couples in which the woman has non-metastatic BC (28.7% under CT, 10.2% under Trastuzumab, 33% under hormone therapy, 28.1% under supervision) completed a self-administered questionnaire assessing their subjective experience. **Results:** Patients report more difficulties than partners in terms of management of children and of everyday life, body image and sexuality, career management and financial difficulties. The 2 groups were comparable with regard to the feeling of couple cohesion and the deterioration of relations with relatives. In addition, patients reported more support from relatives than partners, but this support decreases along the treatment program. While overall, patients undergoing CT and Trastuzumab and their partners reported more difficulties than those under hormone therapy or under surveillance, the negative affectivity / apprehension for the futureremains stable and relatively high from CT to the end of treatment, for the patient as well as for her partner. **Conclusions:** The difficulties of patients appear to be particularly strong in the early course of care and decrease over time, indicating a gradual adjustment to the disease. It is the same for partners, who also have concerns. However, there are differences between the experience of patients and partners. A longitudinal follow-up assessing the couple experience in a dyadic design would allow us to support these findings, and ultimately to better assess the couples' needs in order to better respond to it by an optimal care management, including the establishment of follow-up consultations for couples.

**9570 General Poster Session (Board #220), Sun, 8:00 AM-11:45 AM**

**Has health-related quality-of-life assessment in EORTC clinical trials helped to obtain regulatory approvals and change clinical practice? A review of the EORTC experience in cancer clinical trials.** *Presenting Author: Efstathios Zikos, European Organisation for Research and Treatment of Cancer Headquarters, Brussels, Belgium*

**Background:** Health-related quality of life (HRQOL) has been an important part of the randomised controlled trials (RCTs) conducted by EORTC since 1980. This review aims to provide an update on a previous descriptive evaluation of EORTC RCTs from 2002 and select those whose HRQOL results changed clinical practice and helped to obtain regulatory approvals. **Methods:** The EORTC database was reviewed, restricting the search to the period 2002–2013. The published review from 1980–2001, involving over 65,000 patients, was also taken into consideration. We investigated the number of EORTC RCTs including HRQOL and identified those that altered clinical practice and influenced label claims. **Results:** 52 RCTs with HRQOL assessment were identified, involving 37,417 patients. The majority of phase II and III RCTs (n=45) have HRQOL as secondary endpoint. EORTC also conducted supportive care and translational research trials with an HRQOL component. The EORTC clinical groups with the most RCTs containing HRQOL were Radiation Oncology (17%, n=9) and Brain Tumour (13%, n=7). As examples of practice-changing RCTs, EORTC 22952-26001 found whole-brain radiotherapy not to improve OS while affecting HRQOL adversely (global health status (GHS), physical/cognitive functioning, and fatigue). EORTC 62072 in patients with advanced soft-tissue sarcoma, following chemotherapy treatment, found that pazopanib toxicity did not translate into significantly worse HRQOL (GHS: P=0.291; average difference=2.6 points) and nearly tripled PFS (HR 0.31; $p<0.0001$). RCTs whose HRQOL component helped to obtain regulatory approvals were EORTC 18991, 26981, and 62072. **Conclusions:** Our review shows how patient perspective in palliative and curative trials has been considered of major importance in oncology and demonstrates how recent findings in EORTC RCTs have altered clinical practice, providing recommendations for future improvements and helping label claims. The inclusion of patient perspective in drug development shows that a more comprehensive HRQOL assessment has taken place over time as better instruments have become available.

**9571 General Poster Session (Board #221), Sun, 8:00 AM-11:45 AM**

**Mobile cognitive assessment battery (MCAB) for assessment of cancer-related cognitive changes.** *Presenting Author: Shelli Kesler, Stanford University, Stanford, CA*

**Background:** A majority of patients with cancer report cognitive decline associated with cancer treatments. Traditional cognitive measures may lack adequate sensitivity to these cognitive difficulties, are weakly associated with patient self-report and have limited feasibility. We aimed to evaluate cognitive change in patients with breast cancer (BC) using our novel Mobile Cognitive Assessment Battery (MCAB) and compare MCAB with traditional neuropsychological measures. **Methods:** We have enrolled 39 women newly diagnosed with primary BC (mean age = 50 +/- 9 years) and 35 matched healthy women. Patients were assessed prior to any surgery requiring general anesthesia (T1) and again within one month of completing chemotherapy but prior to any radiation or hormonal therapy (T2). Controls were assessed at yoked intervals. We administered the Comprehensive Trail Making, Controlled Oral Word Association and Rey Auditory Verbal Learning tests, the Behavioral Rating Inventory of Executive Function (BRIEF) and our in-house MCAB. MCAB is administered via mobile tablet with tests including n-back, multi-tasking, and task switching. We compared cognitive function between the groups at baseline using analysis of variance, change in cognitive function over time using linear mixed modeling and correspondence between subjective and objective measures using Pearson correlations. **Results:** There were no differences between groups in cognitive function at T1. Compared to controls, the BC group showed no change in cognitive function from T1 to T2 as measured by traditional tests. Patients' self-rated cognitive problems (BRIEF) increased significantly over time ($p = 0.031$). MCAB (requiring 15 minutes to administer), detected significantly lower cognitive function over time in the BC group compared with controls in task switching ($p < 0.001$) and multi-tasking ($p = 0.019$). Traditional tests (40 minutes) were not significantly correlated with patients' self-ratings although MCAB tests were ($p < 0.039$). **Conclusions:** Our MCAB may be more convenient, more sensitive to changes in cognitive function and subjective patient report associated with BC treatment compared to traditional measures.

**9572 General Poster Session (Board #222), Sun, 8:00 AM-11:45 AM**

**Feasibility of neurocognitove and psychological assessments in allogeneic stem cell transplantation: A pilot study.** *Presenting Author: Tara K. Gregory, Colorado Blood Cancer Institute, Denver, CO*

**Background:** Neurocognitive and psychological measures may provide insightful and even prognostic information, yet are not routinely incorporated into pre-allogeneic hematopoietic stem cell transplant (HSCT) assessments. We conducted a longitudinal pilot study to assess the feasibility of using neurocognitive and psychological tools in the HSCT setting. **Methods:** Patients age 27-72 with diagnoses of hematologic malignancies underwent neurocognitive/psychological assessments within 4 weeks prior to HSCT, at day +100 and day +180. The Montreal Cognitive Assessment (MOCA) Version 7 assessed neurocognitive impairment. Center for Epidemiological Studies Depression Scale (CES-D), State-Trait Anxiety Inventory (STAI), and Neuropsychiatric Inventory(NPI), evaluated depression, anxiety, and caregiver interpretation of patient distress, respectively. Evaluations were performed by a clinical psychologist. **Results:** 21 successive patients scheduled for HSCT were evaluated for feasibility of conducting the above evaluations. One patient declined to participate in the full initial evaluation. The evaluation was scheduled during a pre-existing psychosocial intake and required an additional 30 minutes of clinician and patient time. The MOCA required 10 minutes. The CES-D, STAI, and EORTC QLQ–C30 required 5 minutes each. Scoring required 10 minutes. Neurocognitive impairment was frequent at baseline and worsened post-HCST. Pre-HSCT anxiety/depression was very severe (expected incidence <10%), and persisted in 6-month survivers. Most patients had sub-clinical levels of anxiety/depression which may impact function. **Conclusions:** Longitudinal neurocognitive/psychological inventories in the HSCT setting are feasible and informative. An expanded, prospective study will be performed to correlate the measures with post transplant outcomes and QoL.

| Measure | Pre-HSCT n=20 | Day 100 n=12 | 6 month n=8 |
|---|---|---|---|
| **MOCA** | 30% | 16% | 0 |
| **Normal** | 50% | 25% | 38% |

**9573 General Poster Session (Board #223), Sun, 8:00 AM-11:45 AM**

**Evaluation of an online, skill-building, group intervention for cancer patients and caregivers: Pillars4Life.** *Presenting Author: Jonathan David O'Donnell, Duke University School of Medicine, Durham, NC*

**Background:** Psychosocial distress is common for those with cancer; new interventions are needed. Pillars4Life is an online educational program that teaches coping skills in a group format. What is the relationship between participation in the LiveStrong-funded Pillars4Life program and personal psychosocial outcomes? **Methods:** This was a longitudinal observational cohort study. Cancer patients and caregivers participating in the Pillars4Life program were recruited from the 20 hospitals that received the LiveStrong Community Impact Award. Consenting participants participated in 10 weekly sessions and completed electronic surveys at baseline and 3 months. Patient reported measures included: distress [Distress Thermometer (DT), Patient Care Monitor (PCM)], depression [Patient Health Questionnaire 9 (PHQ9)], anxiety [Generalized Anxiety Disorder 7 (GAD7)], posttraumatic stress [PTSD Checklist-Civilian (PCLC)], quality of life and despair (PCM), fatigue [Functional Assessment of Chronic Illness Therapy (FACIT)], and cancer-related wellbeing [Functional Assessment of Cancer Therapy-General (FACTG)] outcomes. **Results:** Participants (n=80) were: mean age 55.5±11.1 years; 90% female; 87% white; 58% married; 46% employed; and 91% cancer patients, of which 54% had breast cancer and 72% were receiving treatment. Mean scores significantly improved from baseline to month 3 on all patient-reported outcome measures: DT (-0.8, $p$=.01); PCM Distress (-2.9, $p$=.01); PHQ9 (-2.7, $p$<.001); GAD7 (-2.2, $p$<.001); PCLC (-4.9, $p$<.001); PCM Quality of Life (3.8, $p$<.001) and Despair (-3.6, $p$<.001); FACIT-Fatigue (3.7, $p$=.004); and FACT-G (5.7, $p$=.002). Patient participants who reported distress at baseline (DT≥4; n=43) had clinically significant improvements (moderate to strong effect sizes ranged from 0.5 to 1.0 standard deviation units) in DT; PCM Distress, Quality of Life, and Despair; PHQ9; GAD7; PCLC; FACTG, among others. **Conclusions:** Participation in Pillars4Life was associated with statistically and clinically significant improvements on key psychosocial and quality of life patient-reported outcomes measures. Importantly, distressed patients experienced meaningful improvement.

**9574 General Poster Session (Board #224), Sun, 8:00 AM-11:45 AM**

**Quality of life of young mothers with breast cancer in Germany.** *Presenting Author: Dorothea Fischer, University of Schleswig-Holstein, Campus Luebeck, Luebeck, Germany*

**Background:** Aim of the study is to analyze the health-related quality of life (QoL) in young breast cancer patients and to compare it to that of an age-heterogeneous breast cancer cohort and of an age-adjusted general population sample. Further, predictors for a reduced QoL should be identified. **Methods:** A retrospective study analyzed quality of life of 517 young mothers (at least 1 child <12 years) first diagnosed between 2006 and 2011 with primary breast cancer. The patients participated in a resident mother-child program. The standardized questionnaire focused on medical, clinical and social data and especially on QoL (EORTC QLQ-C30, -BR23). The data were compared with those of an age-heterogeneous cohort with breast cancer and an age-adjusted general population sample from the state of Schleswig-Holstein, Germany. **Results**: The median age of the young cohort was 39 years. Inability to work, being unemployed and a higher body mass index were predictors for a reduced global QoL /health status. Unanticipated treatment and clinical issues did not affect quality of life. Young breast cancer patients – as compared to the older breast cancer cohort – showed a reduced social, emotional and cognitive functioning. In contrast, physical and sexual functions were significantly higher and stress by hair loss was significant better tolerated by the younger patients. Compared to the general population the patients showed a seriously reduced QoL. **Conclusions:** Because of their high risk of reduced QoL, young breast cancer patients with children under the age of 12 should be carefully observed with a focus on emotional and social functions and their ability to work. Our results imply the need to develop interventional procedures to enhance QoL in the vulnerable group of young breast cancer patients.

**9575 General Poster Session (Board #225), Sun, 8:00 AM-11:45 AM**

**Social and perceptual influences on alcohol consumption in cancer survivors.** *Presenting Author: Lawson Eng, Princess Margaret Hospital, Ontario Cancer Institute, Toronto, ON, Canada*

**Background:** We previously demonstrated that second-hand smoke (SHS) is inversely associated with smoking cessation in lung and other cancers (PMID: 24419133, 23765604, Eng *et al*, ASCO 2013; abst 9536) with adjusted odds ratio of 6-9. We now evaluated the effects of social alcohol exposure (i.e., having spouse, friends, or peers drink alcohol) on alcohol consumption. **Methods:** 707 cancer survivors across multiple disease sites at a single cancer centre were surveyed on their smoking and alcohol consumption prior to and after diagnosis. Home, spousal and peer exposure to smoking and alcohol and the perceived impact of these behaviours on prognosis, fatigue and quality of life were documented. Multivariate logistic regression models evaluated their association with change in each habit after diagnosis adjusted for significant socio-demographic and clinico-pathological covariates. **Results:** 116 patients smoked at diagnosis; 60% quit afterwards, none of the 218 ex-smokers or 367 never smokers started smoking after diagnosis. Among 354 current drinkers, 192 reduced consumption while 20 of the 129 ex-drinkers restarted. Negative perceptions of alcohol consumption were associated with cessation of alcohol use ($aOR_{quality\ of\ life}$ = 1.8, 95% CI [1.1-2.9]; $aOR_{prognosis}$ = 2.8 [1.6-4.8]; $aOR_{fatigue}$ = 2.2 [1.4-3.6]), and with negative perceptions on smoking (r = 0.31 to 0.35, p = 5.0E-17 to 5.6E-13). Neither smoking nor alcohol perceptions were associated with smoking cessation (p > 0.05). Exposure to SHS was associated with exposure to social alcohol use (ORs = 1.9 to 4.1, p = 5.0E-3 to 0.05). Social exposure to others drinking alcohol was associated with cancer survivors restarting to drink alcohol after diagnosis ($aOR_{home\ exposure}$ = 2.7 [0.9-8.2]; $aOR_{peer\ exposure}$ = 2.9 [1.1-7.9]; $aOR_{spousal\ exposure}$= 6.0 [1.2-29.1]). **Conclusions:** Spouse, peer, and home exposure to alcohol use by others was associated with cancer survivors restarting alcohol use, and with SHS exposure. The social environment can have an important impact on the health habits of cancer survivors.

**9576 General Poster Session (Board #226), Sun, 8:00 AM-11:45 AM**

**Factors influencing advanced cancer patients' preferences for quality or length of life.** *Presenting Author: Eva C. Winkler, National Center for Tumor Diseases, Heidelberg, Germany*

**Background:** The integration of individual patients' preferences is paramount for patient-oriented care in oncology at the End of Life (EOL). The aim of this study was to explore patients' preferences for Quality (QL) or Length of Life (LL) and the factors influencing them. In addition, communication preferences of patients about limiting treatment were explored. **Methods:** We surveyed 194 cancer patients at the National Center for Tumour diseases and the Thorax Clinic at Heidelberg University using a set of questionnaires. Socio-demographic, clinical data, preferences regarding QL and LL, communication preferences cancer-related distress and family role in the decision-making were assessed. **Results:** Patients' attitudes toward treatment could be categorized into striving for QL, striving for LL, and no clear preference. Patients' preferences were slightly higher for QL (mean=3.5; SD=0.7) than for LL (mean=3.15; SD=0.9). Patients who indicated that their next of kin play an important role in therapeutic decisions were more likely to strive for LL (p=.01). Patients who preferred LL tended to avoid communications with their physicians about limiting treatment (p=.03) whereas patients who strived for QL preferred their physicians initiating this discussion early on (p=.00). Patients were predominantly men (68%); mean age was 63 years (SD=10.3). Age, gender, prognosis and cancer-related distress had no impact on preferences for QL or LL. **Conclusions:** Family involvement in treatment decisions had considerable impact on patients' preferences and was associated with patients striving for LL. Those patients did not want their oncologists to discuss treatment limitation with them. Hence, in orchestrating decision making about cancer specific treatment near the EOL it is important for oncologists to involve the family and enable the communication about realistic treatment goals early on.

**9577 General Poster Session (Board #227), Sun, 8:00 AM-11:45 AM**

**Traumatic stress symptoms in patients with acute leukemia (AL).** *Presenting Author: Gary Rodin, Princess Margaret Hospital, University Health Network, Toronto, ON, Canada*

**Background:** AL is associated with an immediate threat to life, an intensive treatment regimen, and substantial suffering relating to the disease and its prognostic uncertainty. This longitudinal study was undertaken to assess psychological and physical distress in the first 3 months following diagnosis or relapse of AL. We report here the findings at 3 months. **Methods:** Patients with newly diagnosed or recently relapsed acute myeloid, lymphoblastic and promyelocytic leukemia were recruited at Princess Margaret Cancer Centre within one month of diagnosis or relapse. Patients completed a baseline assessment and monthly follow-ups for 3 months. The frequency of traumatic stress symptoms that met criteria for acute stress disorder (ASD; symptoms above threshold <1 month) was determined. Multivariate regression analysis was used to identify predictors of traumatic stress symptoms. Self-report measures included: Stanford Acute Stress Reaction Questionnaire (SASRQ), Memorial Symptom Assessment Scale, CARES Medical Interaction Subscale, Experiences in Close Relationships-SF and FACIT SP-12. **Results:** 178 participants completed >3 time-points; mean age was 49+16 years, 58% male, 91.6% newly diagnosed, and 96.6% receiving chemotherapy with curative intent. Mean SASRQ score at baseline was 27.2+21.8 (range 0-97) and 27% reported symptoms >threshold for ASD at baseline. Of those who provided at least 3 assessments, 10% scored above cut-off 3 or more times; 12.4% twice; 20.8% only once; and 56.7% at no time. Regression analyses indicated that female gender, psychological symptoms, worse communication with health care providers, lower spiritual well-being and attachment anxiety were significant predictors of traumatic stress. **Conclusions:** Significant traumatic stress symptoms occurred in more than 40% of patients with AL within 3 months of diagnosis, which persisted in almost 25% of the sample across 3 or more time-points. Traumatic stress symptoms in this population are linked to a number of potentially treatable factors. Further research is needed to demonstrate the benefit of early psychological and palliative interventions.

**9578 General Poster Session (Board #228), Sun, 8:00 AM-11:45 AM**

**Marital distress (MD), quality of life, and psychological morbidity among advanced cancer patients (ACP) in phase I trials and their spousal caregivers (SC).** *Presenting Author: Fay J. Hlubocky, The University of Chicago Medicine, Chicago, IL*

**Background:** Prior research identifies marriage as a protective resource for couples during the cancer trajectory. However, the prevalence of potential MD and its effect on the quality of life (QOL) and psychological morbidity of ACP in Phase I trials has not been described. **Methods:** A prospective cohort of ACP enrolling in phase I trials was assessed at baseline (T1) and one month (T2) using the following measures: depression (CES-D), state-trait anxiety (STAI-S/T), quality of life/qol (FACIT-Pal), global health (SF-36), and marital satisfaction (DAS). Semi-structured interviews evaluated ACP-SC experiences re MD including: fulfillment, contentment, intimacy, conflict. **Results:** To date, a total of 54 married phase I ACP-SC couple dyads (n=108 subjects) were separately interviewed at T1 and T2. For the total population: median age 60y (28-78y); 50% male; 88% Ca; 68%> HS educ; 57% GI dx; 52% income <$65,000 yr. Couples were married on average for 37y (15-50y) and 18% ACPs reported this was a second marriage. At T1, 45% of ACP reported marital fulfillment; 37% reported marital contentment; 67% reported intimacy concerns; 65% reported marital conflict. For SC at T1, 31% reported marital fulfillment; 50% reported marital contentment; 74% SC reported intimacy concerns; and 79% reported marital conflict. Rates remained stable for both ACP and SC with the exception of increased self-reported marital conflict at 68% and 83% respectively at T2. At T2, ACP who reported marital conflict had higher STAI-S (33 ± 10 v 28 ±12, p=0.01) and CES-D (13 ± 12 v 11 ± 9, p=0.03). SC with self-reported marital conflict had higher STAI-S anxiety (39 ± 17 v 35 ± 13, p=0.03) at T2. In regression analyses, ACP with intimacy concerns had poorer FACIT-Pal QOL over time. Also, SC with intimacy concerns at T2 was negatively associated with SF-36 and DAS scores over time. ACP and SC qualitative inquiry re MD exposed various themes: conflicts re EOL tx/advanced directives/estate planning; lack of physical/emotional intimacy; non-existent sex life; lack of communication. **Conclusions:** MD is negatively associated with QOL among clinical trial subjects and SC in phase I trials.

**9579 General Poster Session (Board #229), Sun, 8:00 AM-11:45 AM**

**Persistent pain following breast cancer surgery: A case-control study.** *Presenting Author: Sara N. Edmond, Duke University Medical Center, Durham, NC*

**Background:** Persistent pain following surgery for breast cancer is increasingly recognized as an important clinical problem. The mechanisms responsible remain to be determined, but psychological factors have been implicated in studies of breast cancer survivors. However, case control studies that provide direct comparisons to matched samples of healthy women are rare in this literature. **Methods:** We recruited breast cancer survivors (n=200) at the time of their first postsurgical mammogram (approx 1 yr) and compared their responses on validated self-report measures of pain, and select psychological factors (symptoms of anxiety and depression) to a matched sample (n=150) of healthy women receiving mammograms on the same day. The majority of women were white, married, and well educated. Only racial representation differed between the groups, so all analyses controlled for that factor. **Results:** Women with a history of cancer were more likely to meet criteria for persistent pain and reported greater levels of pain intensity, pain unpleasantness, pain interference, and pain frequency (all p<0.01). They also reported using medication for pain more frequently (p<0.01). There were no statistical differences in BMI, caffeine consumption, or smoking status. Symptoms of depression, but not anxiety were significantly (p=0.01) higher in women with histories of breast cancer. Persistent pain was related to the severity of the women's depressive symptoms (p=0.002). When persistent pain and symptoms of depression were included in multivariate analyses of case-control differences, there was no longer a significant difference between the groups in persistent pain (p=0.25). **Conclusions:** Women who have undergone breast cancer surgery have higher levels of persistent and current pain, as well as higher levels of depressive symptoms compared to women without histories of breast cancer. Analyses suggest that higher levels of depressive symptoms may make a substantial contribution to the higher levels of persistent pain in these women. Future research should test this causal assumption with randomized trials of behavioral interventions known to reduce the contribution of psychological factors to pain (e.g., targeted pain coping skills training).

**9580 General Poster Session (Board #230), Sun, 8:00 AM-11:45 AM**

**Survival differences by race/ethnicity in adolescents and young adults diagnosed with non-Hodgkin lymphoma.** *Presenting Author: Chun Chao, Kaiser Permanente Southern California, Pasadena, CA*

**Background:** Adolescents and young adults (AYAs) with cancer have not experienced the same degree of survival improvements as in younger children and older adults. Several barriers have been identified in delivering optimal oncology care in AYAs, including lack of knowledge on the biology and factors affecting survival in AYA cancer. Here we evaluated if survival differs by race/ethnicity in AYAs diagnosed with non-Hodgkin lymphoma (NHL). **Methods:** AYAs (ages 15-39) diagnosed with incident NHL in 1990-2010 were identified at Kaiser Permanente Southern California (KPSC), a large managed care organization. KPSC members have relatively equal health care access, which minimizes confounding due to access variations. Information on demographic and cancer characteristics was obtained from KPSC's Surveillance, Epidemiology and End Results-affiliated cancer registry. Mortality data were obtained from California and national death registries. Patients were followed from NHL diagnosis to 5 year after or 12/31/2012, whichever came first. Multivariable Cox model was used to evaluate the association between race/ethnicity and mortality, adjusting for age, sex, cancer stage and year of diagnosis. **Results:** A total of 724 AYAs with NHL were included (mean age at diagnosis: 31), of whom 60% were male, 45% were non-Hispanic white, 10% were African American, 36% were Hispanic, and 8% were Asians. The distribution of stages at diagnosis was 18% stage I, 17% stage II, 16% stage III, and 40% stage IV. Overall 5-year survival was 70% (number of deaths =218). Compared to non-Hispanic whites, all minorities were associated with increased 5-year mortality: hazard ratio for African American = 1.74, 95% confidence interval (1.10-2.74), for Hispanic =1.31 (0.95-1.82), and for Asians =1.84 (1.03-3.28). Male sex, increasing age and advanced cancer stage were all significantly associated with elevated mortality. A significant survival improvement was observed over calendar years. **Conclusions:** A survival disparity for race/ethnicity was observed in AYAs with NHL despite relatively equal access to care. These results call for studies to further understand mechanisms underlying the inferior survival among minority subgroups.

**9581 General Poster Session (Board #231), Sun, 8:00 AM-11:45 AM**

**The potential role of pNF-H, a biomarker of white matter damage in central nervous system, as a predictive marker of chemotherapy-induced cognitive impairments.** *Presenting Author: Akina Natori, Division of Medical Oncology, Department of Internal Medicine, St. Luke's International Hospital, Tokyo, Japan*

**Background:** Chemotherapy-induced cognitive impairments (CICI) have been recognized as a clinically-significant issue for cancer survivors, it is urgently required to elucidate the mechanism of CICI and develop diagnostic and therapeutic measures. Previous studies using magnetic resonance imaging showed more decreased white matter integrity in CICI patients than healthy controls. Increased level of the circulating phosphorylated form of the high-molecular-weight neurofilament subunit NF-H (pNF-H), which is one of the major structural proteins in axon, has been reported to be elevated in central nervous system (CNS) disorders. We hypothesize CICI is caused by demyelination in CNS. We examined neuropsychological tests and serum pNF-H level in breast cancer patients receiving adjuvant chemotherapy in a cross-sectional manner. **Methods:** Early breast cancer patients in various phase of treatment (5 were naïve to chemotherapy, 20 were after 1 cycle of chemotherapy, 20 were after 3 cycles of chemotherapy, 20 were after 7 cycles of chemotherapy, 12 were past chemotherapy patients) were assessed by neuropsycological tests (EuroQOL-5 Dimension, Hospital Anxiety and Depression Scale, State Trait Anxiety Inventory, PainDetect, Epworth Sleepiness Scale, Colored Progressive Matrices, and Cognition Fail Question) and pNF-H at one point. Patients with pNF-H >70.5 $\mu$g/ml were considered pNF-H positive. The Chi-square test and the Mann-Whitney test were used to compare data. **Results:** Increased level of pNF-H was observed in 28.8% of patients who underwent chemotherapy. The rate of pNF-H positive patients of each group significantly increased in proportion to the number of chemotherapy (1 cycle:9.1%, 3 cycle:27.8%, 7 cycle: 61.1%; p<0.05), but none of past chemotherapy patients and chemotherapy-naive patients were pNF-H positive. No differences were observed in neuropsycological tests between each group. **Conclusions:** Serum pNF-H level in breast cancer patients on chemotherapy was increased in cumulative dose-dependent manner, suggesting its potential application as a biomarker to survey neural damage after chemotherapy.

**9582 General Poster Session (Board #232), Sun, 8:00 AM-11:45 AM**

**Follow-up of 1,001 adults and children after fertility preservation for oncologic conditions within a publicly financed health care program.** *Presenting Author: Kenny A Rodriguez-Wallberg, Karolinska Institutet and Karolinska University Hospital, Reproductive Medicine, Stockholm, Sweden*

**Background:** Options for fertility preservation (FP) among adults and children are currently available for female and male individuals of all ages. In Sweden, publicly financed health care covers assisted reproduction and freezing of gametes and tissues for medical reasons. **Methods:** We reviewed clinical data of 1001 cancer patients enrolled in the FP programme at Karolinska University Hospital, Sweden, between 1998 and 2013. **Results:** This cohort included 945 adults and 56 children. By the time of this report, 95% of women, 90% of men and 77% of children are in the survival cohort. Most common cancer diagnoses were breast cancer, testicular cancer and lymphoma in adults, and leukemia in children.Women and children were counseled by gynecologists and pediatricians. Adult males were counseled by oncologists. All patients had access to FP options within a few days. Female patients (N=478) were offered cryopreservation of embryos, non-fertilized oocytes or pieces of ovarian cortical tissue. Males (N=523) were offered sperm freezing and cryopreservation of adult or pre-pubertal testicular tissue. Nearly one-third of survivors have returned for fertility counseling and treatment. Transfer of frozen-thawed embryos and use of frozen sperm in fertility treatments had resulted in births in over 50% of cases; in vitro fertilization of frozen-thawed oocytes resulted in transfer of embryos, but not in pregnancies. Ovarian function resumed in three women after transplantation of thawed ovarian tissue, with one pregnancy achieved. No signs of cancer recurrence related to the transplantation of ovarian tissue were observed. Five girls, prepubertal at the time of cancer treatment, underwent additionally ovarian stimulation after puberty, and mature eggs were frozen for the future. **Conclusions:** The utilization rates of cryo-stored gametes and embryos in this cohort are higher than those reported earlier. Although our results are encouraging, the efficacy of FP procedures can only be estimated in the group of cancer survivors who came back for fertility treatment. We have offered counseling and FP within the publicly financed health care. This may not be possible in all countries.

**9583 General Poster Session (Board #233), Sun, 8:00 AM-11:45 AM**

**Effect of exercise on cancer-associated cognitive dysfunction: A proof-of-concept randomized controlled trial.** *Presenting Author: Kristin Campbell, University of British Columbia, Vancouver, BC, Canada*

**Background:** Changes in cognitive function are reported in 15-75% of individuals during or following cancer treatment. Currently, there is little available evidence of effective intervention strategies to address this issue. However, exercise presents a potentially effective intervention, as improvements in cognitive function with exercise have been demonstrated in other populations. However, to date there have been no published randomized controlled trials examining the effect of exercise on cognitive function in cancer survivors. **Methods:** A proof-of-concept randomized controlled trial (RCT) in women, treated for breast cancer within the past 3 years, who self-report persistent cognitive dysfunction following chemotherapy treatment (n=20). Participants were randomized to a 24-week aerobic exercise intervention or delayed exercise control. The primary outcome was self-reported cognitive function and impact on quality of life (QoL), using the FACT-CoG. The secondary outcome was performance on a standard neuropsychological test battery. **Results:** Compared to the control group, the exercise group had improvements in the Impact on QoL subscale (+2.9, 95% CI -0.3 to 6.0, p=0.07) and Comments of Others subscale (+1.4, 95% CI -0.9 to 3.6, p=.20) of the FACT-Cog. The exercise group also had improvements in verbal fluency, using the animal naming (5.7, 95% CI 1.8 to 9.6, p=<0.01) and motor processing speed, using Trail Making A (-12.2 seconds, 95% CI -51.1 to 26.7, p<0.01), while a reduction in time to complete Trail Making B did not reach statistical significance (-12.2 seconds, 95% CI -51.1 to 26.7, p=0.51). **Conclusions:** The results from this proof of concept RCT demonstrate the potential of exercise to improve self-reported symptoms cancer associated cognitive dysfunction and neuropsychological test performance in areas of verbal fluency and motor processing speed. The point estimates and variance provided by this proof-of-concept trial will serve to inform the development of a future, definitive, multi-site RCT.

**9584 General Poster Session (Board #234), Sun, 8:00 AM-11:45 AM**

**Patients' expectations of oncologists and primary care providers (PCPs) in addressing reproductive and sexual health.** *Presenting Author: Ying Wang, University of British Columbia, Vancouver, BC, Canada*

**Background**: The risk of infertility and sexual dysfunction from cancer therapy is inadequately discussed at the time of cancer diagnosis (Wang et al, ASCO 2013) even though these issues can cause significant distress. Our aims were to survey young cancer patients to 1) ascertain their expectations of physicians in addressing these concerns and 2) characterize how patients' expectations modify the likelihood of having discussions about reproductive and sexual health. **Methods**: Patients aged 20 to 39 diagnosed with solid tumors from 2006 - 2008, evaluated at any 1 of 5 regional cancer centers in British Columbia and alive at >/= 2 years after diagnosis were surveyed to determine their views about oncologists' and PCPs' responsibilities for reproductive and sexual health. Survey responses were paired with tumor and treatment characteristics from patients' medical records. Using logistic regression, we explored for associations between expectations and whether or not patient-physician conversations had occurred. **Results**: A total of 453 patients (response rate 57%) were included: median age was 35 years, 29% were men, 88% had ECOG 0, and 78% reported being in a relationship. Tumor sites included breast (50%), testicular (27%), gynecological (17%) and colorectal (6%). Patients expected their PCPs to be more involved than their oncologists in addressing fertility and sexual function (82% vs. 76% and 73% vs. 49%, respectively). However, only 55% and 7% of individuals actually engaged in conversations about these issues with their physicians. In multivariate models, higher patient expectations of oncologists' involvement in reproductive and sexual health did not correlate with greater likelihood of having a discussion (OR 1.22 p=0.49 and OR 0.99 p=0.98, respectively). Conversely, increased patient expectations of their PCPs correlated with receipt of a discussion about fertility (OR 2.44 p=0.01) but not about sexual function (OR 0.62 p=0.15). **Conclusions**: Patients prefer to address their reproductive and sexual health concerns with their PCPs. Whereas most discussions appear to be driven by physician factors, fertility conversations with PCPs can be facilitated by increased patient engagement.

**9585 General Poster Session (Board #235), Sun, 8:00 AM-11:45 AM**

**Feasibility of using home-based mobile sensors for remote patient monitoring in cancer care and prevention.** *Presenting Author: Susan K. Peterson, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Remote monitoring of patients outside of the clinic setting during critical periods of care is an emerging paradigm in oncology. CYCORE (CYberinfrastructure for COmparative effectiveness REsearch) is a software-based prototype for a user-friendly cyberinfrastructure that supports collection and analyses of data from multiple domains using home-based mobile sensors. We evaluated CYCORE's feasibility in three studies that represented diverse oncology settings and that assessed: (1) physical functioning in colorectal cancer (CRC) patients; (2) adherence to swallowing exercises in head and neck cancer (HNC) patients during radiation therapy; and (3) tobacco use in cancer survivors who completed an in-house tobacco treatment program (TTP). **Methods:** Eligible participants were ≥ age 18 years, English proficient, and had a history of cancer. Participants used home-based sensors for two non-consecutive 5-day periods. CRC patient sensors provided blood pressure, heart rate, accelerometry and global positioning system (GPS) data; HNC patient sensors captured video of swallowing exercises; and TTP patient sensors captured expired carbon monoxide and adherence videos. Patient-reported outcome measures were completed daily using smartphones. Feasibility outcomes included study completion rate, and perceived ease of use, self-efficacy and overall satisfaction with sensors. **Results:** For the CRC, HNC and TTP studies, respectively, we enrolled 50, 37, and 50 participants over 18, 8.5, and 20 month time periods, with 96%, 84%, 96% completion rates. Participant characteristics for the respective studies included: 50%, 27%, 72% female; 70%, 92%, 70% White; 68%, 97%, 46% married; and 80%, 68%, 58% with at least some college education. Between 91-100% of all participants rated their ease and self-efficacy for each sensor as highly favorable, 72-100% gave equivalent ratings for overall satisfaction, and 72-93% had low or no concerns about data privacy. **Conclusions:** Using home-based mobile sensors for remote monitoring was feasible and highly acceptable for patients. CYCORE serves as a new model for sensor- and home-based monitoring that can inform both research and clinical care.

**9586 General Poster Session (Board #236), Sun, 8:00 AM-11:45 AM**

**Sexual problems of female cancer survivors compared to women without cancer.** *Presenting Author: Ah Reum An, Department of Family Medicine, Seoul National University Hospital, Seoul, South Korea*

**Background:** Sexual dysfunction is one of the distressing problems experienced by female cancer survivors. In this study, we aimed to investigate female sexual dysfunction of cancer survivors compared to women without cancer in South Korea across various cancer types. **Methods:** We performed a case-control study of 5,350 women visited the center for health promotion and optimal aging at Seoul National University Hospital between January 2010 to December 2011. Cases were defined as women who were diagnosed cancer before the health check-up and completed the female sexual function index (FSFI) questionnaires (n = 233), and controls were women without cancer before and after the health check-up and completed the FSFI questionnaires (n = 3,024). The control group was matched on age to survivors at a 1:1 ratio individually. **Results:** The proportion who are sexually active female cancer survivors were not different from that of controls (37.8% vs. 36.9%, P = 0.848). Among sexually active women, the mean total FSFI score were 22.3 ± 5.4 in cancer survivor group and 24.2 ± 4.4 in control group (P = 0.012). Cancer survivors scored lower than controls in domains of desire, lubrication and orgasm. Thyroid cancer survivors tended to have more difficulties having desire and reaching orgasm than their matched controls with marginal significance. Breast cancer survivors reported significantly more troubles in lubrication and more pain. Cancer survivors of other cancer types tended to have more dyspareunia compared to the controls. No difference in any aspects of sexual function was observed between gynecologic cancer survivors and the controls. **Conclusions:** Female cancer survivors have poorer sexual function compared to women without cancer. Sexual problems vulnerable in cancer survivors seemed different according to cancer types.

**9587 General Poster Session (Board #237), Sun, 8:00 AM-11:45 AM**

**Acute changes in endothelial function with cisplatin among germ cell tumor (GCT) patients (Pts).** *Presenting Author: Darren Richard Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** We hypothesized that the increased risk of cardiovascular disease (CVD) in GCT pts following cisplatin-based chemotherapy (CBCT) may be due to endothelial damage. **Methods:** In this pilot study, men age ≥18 with GCT, no prior chemotherapy (CT) or radiation, and no history of CVD were enrolled to the CT group (CG) if CBCT was planned and to the surgery group (SG) if only surgical management (orchiectomy +/- RPLND) was planned. Endo-PAT2000, a noninvasive method of quantifying endothelial function, was used to measure the peripheral arterial tonometry reactive hyperemia index (PAT-RHI). Lower values correlate with endothelial dysfunction. Circulating endothelial cells (CECs) were quantified by immunomagnetic capture as a secondary endpoint. Covariates included hypertension, smoking status, dyslipidemia, diabetes, and fasting lipids, glucose, HbA1C, and testosterone. Measurements were obtained at time points $T_1$-$T_5$ for CG pts and $T_1$, $T_2$ and $T_5$ for SG pts (Table). Nonparametric tests were used to compare PAT-RHI values at $T_1$ (baseline) vs later time points in each group and at $T_1$, $T_2$, and $T_5$ across the two groups. **Results:** Among 22 CG pts (median age 29, range 21-49), PAT-RHI was non-significantly lower at $T_2$ (after the 1st dose of CT) and $T_5$ (14-34 weeks post $T_1$) vs $T_1$. For SG pts (n=20, median age 35, range 25-45), PAT-RHI was non-significantly higher at $T_2$ and $T_5$ vs $T_1$. However, PAT-RHI was significantly lower in CG men vs SG men at $T_2$ and $T_5$ (Table). There was also a trend toward greater decreases in PAT-RHI values at $T_2$ vs $T_1$ (p=0.08), $T_5$ vs $T_1$ (p=0.07), and $T_5$ vs $T_3$ (p=0.07) for CG pts with ≥1 (n=12) vs. no CVD risk factors (n=8). For CG men, median number of CECs/7.5mL was lower at $T_2$ (18) vs T1 (35; p<0.01) and borderline higher at $T_5$ (33) vs $T_2$ (p=0.05). There were no differences in CECs over time for SG men. **Conclusions:** CBCT may acutely cause endothelial dysfunction. Further study with a larger sample size and longer follow-up is warranted. Clinical trial information: 01453660.

**Median PAT-RHI.**

**9588 General Poster Session (Board #238), Sun, 8:00 AM-11:45 AM**

**Characterizing self-reported memory problems in adult-onset cancer survivors in the United States: Importance of sleep duration and insomnia.** *Presenting Author: Pascal Jean-Pierre, University of Notre Dame, South Bend, IN*

**Background:** Memory dysfunction is a debilitating adverse effect of cancer and its treatments. We examined the relationships between self-reported memory problems (SRMP) and sleep disorders in adult-onset cancer survivors. **Methods:** We used data from 151 adults, 41-64 years old, cancer survivors who completed the 2007-2008 National Health and Nutrition Examination Survey. Population-weighted binary logistic regression analyses examined SRMP as outcome and included age, sex, education, race-ethnicity, income, and overall health as covariates. Sleep duration was categorized as very short (<=4hrs), short (5-6hrs), normal (7-8hrs) or long (>=9hrs). Initial insomnia was assessed as difficulty falling asleep. Middle insomnia was assessed as difficulty maintaining sleep. Late insomnia was assessed as waking too early. These insomnia subgroup were categorized as none, mild (<15 days/month) and severe (>=15 days/month). A combined insomnia variable categorized individuals as insomnia if they had severe insomnia of any type (early, middle, late). **Results:** Overall, presence of insomnia was associated with SRMP ($p<0.0001$). Severe initial insomnia was associated SRMP ($p=0.006$). Mild and severe middle insomnia were associated with SRMP ($p=0.007$ and $p<0.0001$, respectively). Late severe insomnia was associated with SRMP ($p=0.037$). Additionally, long sleep was negatively associated with SRMP ($p=0.019$). Among participants without a history of cancer ($N=2,001$), none of the sleep variables were associated with increased likelihood of memory problems ($p>0.05$). **Conclusions:** The findings seem to indicate that sleep may be a mechanistic pathway through which cancer impact memory.

**9589 General Poster Session (Board #239), Sun, 8:00 AM-11:45 AM**

**Genetic testing referral patterns and clinical outcomes among high-risk breast cancer survivors.** *Presenting Author: Rashmi Krishna Murthy, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Referral patterns for genetic testing in breast cancer survivors are not well understood. We sought to identify a cohort of high-risk breast cancer survivors who had not been referred to understand patterns of referral and assess clinical outcomes. **Methods:** We identified breast cancer survivors (> 5 years) at MD Anderson who met at least one high-risk criteria and identified those who had not been referred for genetic counseling at our institution. Descriptive statistics were used to assess their characteristics and clinical outcomes. **Results:** We identified 5,941 high-risk breast cancer survivors, of whom 74% (N= 4,406) had not been referred for genetic counseling at our institution. The majority were female with a mean age at diagnosis of 43 years, and a median follow-up time of 116 months. Among those who had not been referred, 44% were initially diagnosed and treated at MD Anderson, whereas the rest were initially diagnosed and treated elsewhere. 52% were diagnosed prior to year 2000 and the majority (70%) had stage I or II disease at diagnosis. Of the patients where receptor status was known (N = 2,406), the majority had hormone receptor positive breast cancer (54%), followed by HER2/neu positive (21%), and triple negative (25%). A total of 606 patients experienced local recurrences (median time 436 months) and 838 patients experienced distant recurrences (median time 316 months). Among 59 patients with death events, 50 died with evidence of breast cancer. A total of 126 patients were diagnosed with secondary malignancies, such as bilateral breast cancer (N = 2), ovarian cancer (N = 7), endometrial cancer (N = 18), pancreatic cancer (N = 1), and thyroid cancer (N = 12). **Conclusions:** A significant number of breast cancer survivors who meet current standards for genetic testing referral may not have undergone BRCA mutation testing. Reasons for lack of referral for genetic testing may include unrecognized risk, lack of complete risk assessment, or not meeting established criteria at the time of diagnosis. The identification of untested high-risk breast cancer survivors allows for further studies that may reveal potential barriers to referrals and creates awareness.

**9590 General Poster Session (Board #240), Sun, 8:00 AM-11:45 AM**

**Long-term survivors in phase I clinical trials: Who are they and what predicts their survival?** *Presenting Author: Begona Jimenez Rodriguez, Drug Development Unit at The institute of Cancer Research and The Royal Marsden NHS Fundation Trust, London, United Kingdom*

**Background:** Phase I trials (PhIT) participants are those who have exhausted standard treatment (tx) or for whom no standard tx exists; most patients (pts) are unlikely to benefit from new drugs. Response rate and median overall survival (OS) are ~ 5-10% and 10 months (m), respectively; however, we observe pts with improved outcomes. This study aims to characterize who these long-term survivors are and define factors predicting for this prolonged OS. **Methods:** Retrospective analysis of patients treated at the Drug Development Unit, RMH-ICR, UK, between 01/05-12/12 and who survived ≥12m within ≥1consecutive PhIT. Kaplan-Meier method was used to estimate OS. Cox-regression-model was applied for HR estimation and for MVA of prognostic (px) factors for OS. **Results:** Of 1424 pts, 86 pts (6%, 44M/42F) survived ≥12m. Median (range): age 56 (23-85), PS 0 (0-1) and no. of prior Tx 2 (0-7). Most common tumor types: 34% gynaecological (79% ovarian) & 24% genitourinary (GU) (86% prostate). RMHscore (0-1/2-3) 76/10. Visceral disease (Y/N %) 46/54 (14% only bone metastases). 20% pts $BRCA^{mut}$. 37 pts (43%) were treated in >1PhIT. % pts and drugs administered: 39.5% DNA repair-chromatin remodeling; 16.3% hormone synthesis; 46.5% growth-factor-receptor-pathways; 28.8% cytotoxic+new drug and 34.9% others. 42% pts had CR+PR v SD in 58% pts. Median OS was 46.5 m, with improved median OS for those who achieved CR+PR v SD (59.7m v 41.8m, p=0.02). Survival rate at 18,24 &36m was 95,90 & 68%. Cox-regression univariate analysis showed px significance of: GU-tumors [HR 0.43 (0.22-0.85),p=0.016), no-visceral –disease [HR 0.42 (0.25-0.72),p=0.002], only-bone-metastases [HR 0.28 (0.1-0.78),p=0.015], RMH<2 [HR 0.45 (0.21-0.96); p=0.034] clinical benefit with last anticancer tx[HR 0.56 (0.32-0.96), p=0.034] and response to PhIT [HR 0.55 (0.32-0.94), P=0.028]. MVA showed only the presence of visceral disease to be an independent px factor for OS. **Conclusions:** Despite an overall poor prognosis, a proportion of pts treated on PhIT demonstrate a clinically meaningful OS; moreover, in those who respond this outcome is significantly better. This is primarily dictated by low burden of disease, and may support the earlier referral of appropriate pts.

**9591 General Poster Session (Board #241), Sun, 8:00 AM-11:45 AM**

**Ventricular arterial coupling in early breast cancer patients following treatment with anthracycline-containing adjuvant chemotherapy.** *Presenting Author: Graeme J Koelwyn, University of British Columbia, Kelowna, BC, Canada*

**Background**: Use of anthracyclines is limited by dose-dependent cardiotoxicity. Research has focused on cardiac specific damage, although injury may extend beyond the heart to the vascular network. We sought to explore the utility of ventricular-arterial coupling (VAC), an integrative measure of heart and arterial function, at rest and during exercise, to evaluate cardiovascular function post therapy. **Methods:** Thirty ER+/HER2- breast cancer survivors (6.1 ± 2.4 yrs post anthracyclines) with normal left ventricular ejection fraction (LVEF) (59 ± 6) and 30 age-activity matched healthy controls were studied. Echocardiographic measurements were performed at rest and during exercise at 25%, 50%, and 75% of a predetermined maximal workload ($W_{max}$) to determine arterial elastance (Ea), end systolic elastance (Ees) and VAC (Ea/Ees). Endothelial flow-mediated dilation (FMD), carotid intima-media thickness (CIMT), arterial stiffness and peak oxygen consumption ($VO_{2peak}$) were also measured. **Results:** At rest, Ea, Ees, Ea/Ees and LVEF were not different between survivors and controls. The expected increase in Ees during exercise was attenuated in survivors compared to controls at 25% $W_{max}$ (5.28 ± 2.39 vs. 7.0 ± 2.11 mmHg/mL, $p<0.001$), 50% $W_{max}$ (5.94 ± 1.62 vs. 8.26 ± 2.76 mmHg/mL, $p<0.001$), and 75% $W_{max}$ (6.75 ± 2.29 vs. 10.26 ± 4.22 mmHg/mL, $p<0.001$). Accordingly, the Ea/Ees ratio was significantly higher at all exercise-related workloads in survivors compared to controls (p's<0.05). Ea, diastolic relaxation and filling, endothelial independent and dependent FMD, CIMT, arterial stiffness and $VO_{2peak}$were not different between groups (p's >0.05). **Conclusions:** While not detectable at rest, significant reductions in contractile performance (Ees) of the left ventricle were observed in survivors when the cardiovascular system was challenged by exercise. This subclinical cardiovascular dysfunction appears to be isolated to the heart as no differences in vascular function were observed at rest or during exercise. VAC assessment during exercise is a viable tool to evaluate late-occurring cardiovascular dysfunction in early breast cancer patients.

**9592 General Poster Session (Board #242), Sun, 8:00 AM-11:45 AM**

**Chemotherapy-induced amenorrhea (CIA) risk associated with taxane/platinum-based chemotherapy in young (≤45 years) breast cancer patients.** *Presenting Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS*

**Background:** Twenty-five percent of women with breast cancer (BC) are premenopausal and 15% are diagnosed in reproductive age group (≤45 years), thus at risk of CIA. Although CIA rates with alkylating agents/topoisomerase inhibitors (Alk/Topo) are well documented, there is inadequate data addressing the impact of newer Docetaxel/Carboplatin(TP) regimen on menstrual function. The objective of this study was to determine the incidence of long-term (>12 months) CIA related to different chemotherapy regimens in BC patients < 45 years. **Methods:** We identified 283 premenopausal women with BC ≤ 45 years treated with at least 4 cycles of Neo/adjuvant chemotherapy at University of Kansas from 2005 to 2012. Menstrual status information was extracted from medical records. Standard statistical methods were used to assess the association of CIA with variables of interest. **Results:** 165 patients met eligibility criteria and had sufficient follow up. Median age: 39 years(24–45 yrs), 62%:<41 years and 38%:41-45 years. 41%:HR+, 20%:HER2+/HR+, 12%:HER2+/HR-, 27%: TNBC. 79%(130/165) received Alk/Topo regimens (AC+/-T=113, TAC=8, TC=9) and 21%(35/165) received TP regimen. Median ages of patients receiving Alk/Topo and TP regimens was similar. The overall rate of CIA was 34%. BMI, smoking, parity & Tamoxifen use did not impact CIA. Rates of CIA were lower in younger patients and in patients receiving TP chemotherapy. When examined by age at diagnosis CIA rates were 17% (<41yrs) and 63% (>41yrs), respectively (P<0.001). When examined by chemotherapy type the rates of CIA were 42% (Alk/Topo group) and 6% (TP group), respectively (p<0.001) in all patients and 22% (Alk/Topo group) and 0% (TP group) in patients <41 years (p=0.010). **Conclusions:** Risk of long term CIA with TP regimen is much lower (6%) compared with Alk/Topo regimens (42%) in premenopausal women ≤ 45 years. Premature menopause is associated with considerable side effects like menopausal symptoms, loss of fertility, risk of osteoporosis and cardiovascular disease. Information regarding CIA rates of different chemotherapy regimens is of value to young patients and physicians to aid in adjuvant chemotherapy regimen decision making.

**9593 General Poster Session (Board #243), Sun, 8:00 AM-11:45 AM**

**Cardiovascular mortality (CVM) among testicular nonseminoma (TN) survivors after chemotherapy (CHEM) or surgery (SURG).** *Presenting Author: Chunkit Fung, James P. Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY*

**Background:** Increased long-term risks of cardiovascular (CV) disease after CHEM for testicular cancer are well established whereas few studies have quantified the association of cisplatin-based chemotherapy with arterial thromboembolic events (ATE). We examined CVM in a large population-based cohort of TN survivors managed with modern combination CHEM, which usually includes cisplatin. **Methods:** Standardized mortality ratio (SMR) of CVM stratified by time since TN diagnosis were calculated for 15,006 TN survivors reported to the SEER program (1980-2010) initially managed with CHEM (n=6,909) or SURG (n=8,097) alone without RT, with each cohort accruing 60,065 (median 6.5) and 81,227 (median 7.9) person-years (PY) of follow up, respectively. **Results:** After CHEM, significant excesses of CVM occurred (n=54; SMR 1.4; 95% CI 1.03-1.8; absolute excess risk (AER) 2.4 per 10,000 PY) including deaths from heart disease (n=42; SMR 1.3; 95% CI 0.9-1.7), cerebrovascular disease (CVA) (n=10; SMR 2.4; 95% CI 1.2-4.4) and other arterial diseases (n=2; SMR 6.5; 95% CI 0.8-23.5). Excess CVM was concentrated within 1 yr after diagnosis, with SMRs during the <1, 1-4, 5-9, 10-14, 15-19 and 20+ yr periods 5.3 (95% CI 2.7-9.5), 1.7 (95% CI 0.9-2.9), 1.2 (95% CI 0.6-2.2), 0.9 (95% CI 0.4-1.9), 1.2 (95% CI 0.5-2.3), and 0.8 (95% CI 0.3-1.7), respectively. In particular, significantly elevated 4- to 22-fold risks of mortality due to either heart disease (n=6; SMR 3.5; 95% CI 1.3-7.5) or CVA (n=5; SMR 21.7; 95% CI 7.1-50.7) occurred in the <1 yr period. In contrast, among those managed with SURG only, no excess deaths were observed, either for all CVM taken together (n=50; SMR 0.8; 95% CI 0.6-1.1), heart disease (n=43; SMR 0.8; P>0.05) or CVA (n=7; SMR 1.07; P>0.05). Univariate Cox regression analysis showed excesses of CVM after CHEM vs. SURG (hazard ratio 1.5; 95% CI 1.01-2.2). **Conclusions:** Early ATE associated with modern CHEM may in part explain the excess deaths due to heart disease and CVA during the <1 yr period. Future analytic studies should not only quantify temporal trends of CV disease incidence and CVM in TN survivors, but include mechanistic investigations to facilitate the development of preventive efforts.

**9594 General Poster Session (Board #244), Sun, 8:00 AM-11:45 AM**

**Long-term quality of life among localized prostate cancer survivors: Qalipro population-based study.** *Presenting Author: Anne-Valérie Guizard, Centre François Baclesse, Caen, France*

**Background:** If treatments can cure localized prostate cancers (LPC) they often induce acute toxicities and definitive sequelae with impact on quality of life (QoL). However, very few studies focused on the long-term QoL of survivors of LPC. The goal of this population based case-control-study was to evaluate QoL 10 years after treatments for LPC in comparison with aged-matched healthy controls. **Methods:** LPC patients diagnosed in 2001 were issued from 11 French Cancer Registries. Controls were recruited among the general population and were matched to patients on age and geographic area. EORTC QLQ-C30, EPIC, HADS and MFI self-reported questionnaires were used to measure QoL, anxiety and fatigue. Patients were identified into 3 groups according to previews treatments: radical prostatectomy (RP), radiotherapy (RT) and radical prostatectomy plus radiotherapy (RP+RT). Patients could receive hormonotherapy (HT). Student's paired t and McNemar $\chi^2$ tests were used for the analysis between patients and controls. Analysis between treatments groups were performed with ANOVA. Only clinically relevant QoL score differences (≥ 5 points) were reported. **Results:** There were 287 patients and 287 controls. The participation rate of patients was of 46. Among LPC patients 143 (50%) were treated with RP, 78 (27%) with RT and 33 (11%) with RP+RT. 60 (21%) and 47 patients (16%) received HT at baseline and at the time of the study respectively. There was no socio-demographic difference between patients and controls. Patients didn't report more anxiety, depression and fatigue than controls, but lower EORTC-QLQ social functioning score (p=0.003). LPC long-term survivors reported more urinary troubles (urinary function and incontinence) (p<0.0001) and more sexual dysfunctions (p<0.0001) than controls, whatever the treatment group. RP and RP+RT groups had worse urinary function and incontinence than RT (p<0.01). LPC survivors treated with HT at the time of study reported more sexual dysfunction (p<0.0001) and hormonal troubles (dysfunction and bother) (p=0.002) than the other survivors. **Conclusions:** 10 years after treatments, long term survivors of LPC reported important urinary and sexual dysfunctions with poor social QoL.

**9595 General Poster Session (Board #245), Sun, 8:00 AM-11:45 AM**

**Chemotherapy-induced ovarian failure in young breast cancer patients: The role of vascular toxicity.** *Presenting Author: Irit Ben-Aharon, Davidoff Cancer Center, Rabin Medical Center, Petach-Tikva, Israel*

**Background:** Chemotherapy-related amenorrhea is a frequent side effect observed in young breast cancer patients (pts). We had formerly described a mechanism of ovarian toxicity manifested by decreased ovarian blood flow and diminished post-treatment AMH levels. We report herein the continuous prospective evaluation of ovarian function in this cohort. **Methods:** Young breast cancer pts (<40 years) undergoing adjuvant/neoadjuvant chemotherapy were evaluated by transvaginal ultrasound prior to initiation of chemotherapy, immediately upon completion of chemotherapy, at 6 and 12 months after cessation of chemotherapy . Doppler-flow velocity indices of the ovarian vasculature and size measurements were visualized. Hormonal profile, AMH and menopausal symptoms were assessed at the same time points. **Results:** Twenty breast cancer pts were enrolled into the study. Median age was 34+5.24 years. Ovarian blood flow was significantly reduced immediately following chemotherapy (p=0.01) after treatment. These parameters were partially recovered at later points of assessment (6 months and 12 months post treatment); patients <35 years exhibited a significant regaining of ovarian blood flow compared with patients >35 years (p<0.05). AMH dropped dramatically in all patients following treatment (P<0.001), and was recovered in only 6 patients (all <35 years). Hormonal profile shortly after chemotherapy depicted a post-menopausal profile for most patients, accompanied by related symptoms. FSH levels were recovered in 14/20 of the patients, and significantly returned to premenopausal range in patients <35 years (p-0.04). The pattern of vascular impairment (reflected by flow velocity) was lessened in patients treated with a trastuzumab-based protocol, though results did not reached statistical significance (p-0.07). **Conclusions:** Continuous prospective evaluation of ovarian vasculature and function in a cohort of young patients with breast cancer following chemotherapy indicate that ovarian toxicity may derive from acute vascular insult. Regaining ovarian function may be affected by age, whereas recovery of blood flow and premenopausal FSH levels at later assessment were notable in patients <35 years.

**9596 General Poster Session (Board #246), Sun, 8:00 AM-11:45 AM**

**Assessing the prevalence of compromised bone health among overweight and obese African-American breast cancer survivors.** *Presenting Author: Patricia M. Sheean, Loyola University Chicago, Maywood, IL*

**Background:** Osteoporosis is considered a late effect of breast cancer treatment. Previous studies included predominantly European-American women and analyzed African-American (AA) survivors in aggregate, despite their known differences in bone mineral density. Our purpose was to examine the prevalence of osteoporosis in a sample of exclusively AA women. **Methods:** This cross-sectional study included 111 overweight or obese AA women, aged 31-80 years, previously diagnosed and treated for stage I-IIIa breast cancer. Women completed questionnaires and underwent dual energy x-ray absorptiometry and phlebotomy prior to their enrollment in a weight loss intervention. Participants were categorized as having normal bone density, low bone mass or osteoporosis using the WHO definition for femoral neck T-scores. **Results:** Despite the frequent use of adjuvant hormone therapies (45%), a decreased ability to absorb ultraviolet light (54% reported dark/very dark skin), suboptimal intake (diet + supplements) of calcium and vitamin D [949 (± 569) mgs and 325 (± 231 IUs), respectively], the infrequent use of bisphosphonates (7%), and a high occurrence of vitamin D insufficiency/deficiency (49% had serum 25(OH)D levels <20 ng/ml), the prevalence of osteoporosis and low bone mass was <1% (n=1) and 16% (n=17), respectively. The 10-year probability of a major osteoporotic fracture was 2.4%. Age (p=0.004) was the only significant predictor of compromised bone health. **Conclusions:** These findings challenge the clinical assumption that osteoporosis is highly prevalent among all breast cancer survivors, providing foundational evidence to support differences by race/ethnicity and reiterating the necessity of regular dialogue concerning nonpharmacologic preventative options (e.g., diet and physical activity).

**9597 General Poster Session (Board #247), Sun, 8:00 AM-11:45 AM**

**Impact of current treatment status on QOL in cancer survivors.** *Presenting Author: Eon Sook Lee, Department of Family Medicine, Inje University Ilsan Paik Hospital, Goyang-si, Gyeonggi-do, South Korea*

**Background:** Many cancer survivors have been reported to have poor health related quality of life (HRQoL). This could be caused by various symptoms of cancer itself and treatment. For better understanding of cancer treatment and HRQoL, we investigated HRQoL and associating factors according to current treatment status and compared them with general population. **Methods:** Using national survey data in South Korea (KNHANES IV-V) from 2007 to 2010, we analyzed 14,396 subjects aged over 50years. Cancer survivors were defined as person diagnosed cancer by physician and divided into two groups, with current treatment and no treatment. Euro QOL was measured as HRQoL. Socioeconomic status (age, sex, education, having SSI), number of non-cancer disease, depressive mood, time since diagnosis and health behaviors (smoking, alcohol, physical activity) were collected as risk factors. EQ5D index and EQ_VAS of survivors receiving treatment were compared with no treatment group and general population, respectively. **Results:** Cancer survivors with treatment (N=191) showed lower EQ_VAS ($\beta$=-3.57, P=0.047) when compared to the general population, while group with no treatment (N=464) did not show the difference in multivariate analysis. Depressive mood was a consistent risk factor of poor HRQoL regardless current cancer treatment status (OR=3.73, 95% CI=1.18-11.78 in cancer treatment, 2.64 95% CI=1.37-5.09 in non-treatment), and same even in non-cancer group (OR=2.37, 95%=2.11-2.65). Except depressive mood, other risk factors influencing poor HRQoL could be attenuated among survivors with treatment. Survivors with no treatment still had a number of non-cancer morbidity and lower income as risk factors for low score of EQ5D index, similar to the non-cancer group. **Conclusions:** Current cancer treatment is a strong indicator for poor HRQoL in survivors. Cancer survivors had different risk factors for poor HRQoL according to current treatment status. Depressive mood was an important factor for poor HRQoL in both treatment and non-treatment groups. For evaluating HRQoL of cancer survivors even in long term group, the influence of current treatment status should be considered. Attention and management of depressive mood should be part of the care of cancer survivors.

**9598 General Poster Session (Board #248), Sun, 8:00 AM-11:45 AM**

**Association of physical activity with cardiorespiratory fitness and cardiac function in cancer survivors with chemotherapy-related heart failure.** *Presenting Author: Karen Basen-Engquist, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Studies have shown that physical activity can have a positive effect on cancer survivors, but there is scant research that addresses whether physical activity is beneficial to survivors who have chemotherapy related heart failure (CRHF). **Methods:** The purpose of this study was to evaluate the association between physical activity and cardiac function in cancer survivors with CRHF. There were 24 survivors, 20 were female, with a mean age of 54, 42% where white and the most common cancer site was breast (62.5%). The mean BMI was 30.5 and mean peak VO2 was 13.1. B-type natriuretic peptide (BNP), troponin, ejection fraction and peak VO2 were measured at a baseline assessment. Patients also filled out the CHAMPS physical activity questionnaire. Correlations and regression models were used to determine if physical activity measured by the CHAMPS was associated with the CRHF measures and peak VO2. All regression models included gender, age, race and BMI. Separate models were run for CHAMPS total hours and CHAMPS hours of moderate or greater intensity activity. **Results:** Both total hours and hours of moderate or greater activity from the CHAMPS were significantly correlated with peak VO2 (Total: R = .473, P = .026; Moderate or greater: R = .538, P = .010). There was no significant relationship between the CHAMPS activity variables and ejection fraction, BNP or Troponin. The regression models showed that BMI was a significant predictor of peak VO2 (B = -.253, P = .014) and CHAMPS moderate or greater intensity hours approached significance (B = .458, P = .062), but CHAMPS total hours was not a significant predictor. Age was the only variable to significantly predict BNP (B = 6.54, P = .017) and race (P = .05) was a significant predictor of ejection fraction with white subjects having higher values. There were no significant predictors of troponin. **Conclusions:** In this study, patients' current physical activity levels were not related to measures of cardiac function. Current exercise and BMI were related to peak VO2 suggesting that despite the CRHF, cardiorespiratory fitness may improve with exercise. Future randomized trials should test the effects of exercise in survivors with CRHF.

**9599 General Poster Session (Board #249), Sun, 8:00 AM-11:45 AM**

**Leukocyte telomere length and risk of secondary primary tumors in long-term breast cancer survivors.** *Presenting Author: Maria Alma Rodriguez, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Leukocytetelomere length (LTL) has been associated with cancer risk including breast cancer. Telomere shortening is observed in response to chemotherapy and/or ionizing radiation exposure. More recently, a report has shown a significant association between short LTL and increased risk of treatment-related thyroid cancer, whereas a suggestive, non-significant association was found between LTL and treatment-related breast cancer (Gramatges MA, et al. Clin Cancer Res, Nov. 2013). We hypothesize that LTL at diagnosis may be associated with breast cancer survival and risk of developing secondary primary tumors (SPT) in long-term breast cancer survivors. We used a case-control study to test this hypothesis. **Methods:** We used a quantitative real-time PCR method to measure LTL in 168 long term breast cancer survivors (including 68 with SPT, and 100 without SPT), 96 newly diagnosed breast cancer cases, and 97 controls. Cases and controls were matched by years since diagnosis, age at time of sample collection and race. Wilcoxon-rank sum test was used to compare LTL among these three groups and between those long-term survivors with and without SPT. **Results:** We found that LTL was significantly longer in long-term breast cancer survivors than newly-diagnosed breast cancer patients (Mean (SD), 1.31 ±0.26 vs 1.22 ±0.31; p=0.005), and healthy controls (1.31±0.26 vs 1.10±0.30, p<0.001). Overall, there were no significant differences in LTL between long term survivors with SPT and without SPT. However, in stratified analyses, we observed that breast cancer survivors with SPT had significantly or borderline significantly shorter LTL than those without SPT in individuals with low BMI (<=25) (1.23±0.19 vs 1.44±0.25; p<0.006) and in ever smokers (1.21±0.31 vs 1.36 ±0.32, p =0.071). **Conclusions:** Longer telomeres were observed in long term breast cancer survivors when compared to new diagnosed cases and healthy controls. A relation between short LTL and increased risk of SPT in long term breast cancer survivors was observed in individuals with low BMI and ever smokers. These results suggest a role of telomere dysfunction in long term breast cancer survivorship.

**9600 General Poster Session (Board #250), Sun, 8:00 AM-11:45 AM**

**Factors associated with bone fractures following hematopoietic stem cell transplantation.** *Presenting Author: Xerxes Pundole, Department of General Internal Medicine, Section of Rheumatology, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The number of long-term survivors of hematopoieticstem cell transplantation (HSCT) is growing. These survivors have increased bone fragility and susceptibility to fracture, leading to death and long-term disability; however, risk factors associated with fractures in these survivors are unclear. **Methods:** We conducted a retrospective study of patients who received HSCT from January 1, 1997, to December 31, 2011, at The University of Texas MD Anderson Cancer Center. Kaplan-Meier survival function plots and Cox proportional hazard models were used. **Results:** A total of 7,650 patients underwent HSCT during the 15-year period. Among them, 631 (8%) developed at least 1 fracture after HSCT; approximately 11% (n = 440) of those who underwent autologous HSCT and 5% (n = 191) of those who underwent allogeneic HSCT developed a fracture. Univariate Cox proportional hazard analyses showed that age >50 years at the time of HSCT, multiple myeloma or solid organ tumors, and autologous HSCT were associated with a higher hazard of developing a fracture. In a multivariable model including all predictors of interest (age at HSCT, sex, and race) except type of HSCT, age >50 years at the time of HSCT (hazard ratio [HR], 1.31; 95% confidence interval [CI], 1.09-1.56), multiple myeloma (HR, 4.96; 95% CI, 4.13-5.95), and solid tumors (HR, 1.61; 95% CI, 1.18-2.21) were associated with an increased risk of developing a fracture. In another multivariable model with type of HSCT included, and indication not included showed that age >50 years at the time of HSCT (HR, 1.94; 95% CI, 1.64-2.30) and autologous HSCT (HR, 1.58; 95% CI, 1.33-1.88) were associated with an increased risk of developing a fracture. **Conclusions:** HSCT and its associated treatment particularly increase the risk of fractures in those who undergo autologous HSCT and are older than 50 years. Regular screening to prevent bone loss should be initiated early, and establishment of a new fracture risk assessment tool is warranted in this patient population.

**9601 General Poster Session (Board #251), Sun, 8:00 AM-11:45 AM**

**Risk factors and prevalence of cognitive deficits in women with gynecologic malignancies.** *Presenting Author: Anne Van Arsdale, Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY*

**Background:** Cognitive impairment has implications in counseling, treatment, and survivorship for women with gynecologic malignancies. The purpose of our study was to evaluate prevalence and risk factors associated with cognitive impairment. **Methods:** After IRB approval, 165 women at an urban ambulatory facility were queried using a Montreal Cognitive Assessment (MOCA), Depression Scale, Wong-Baker pain scale, and neuropathy scale. The association of cognitive deficit with age, education, race/ethnicity, disease site, stage, treatment, pain, neuropathy, anxiety and depression was evaluated. **Results:** Mean MOCA score was 24.1 (range 13-30.) 24% of patients had MOCA scores less than 22. Low scores (<22) were associated with older age, non-white race/ethnicity, lower education level, uterine cancer, and pain > 5 ($p<0.05$). There was a trend toward lower scores for with chemotherapy and radiation treatment ($p=0.10$). Low cognition scores were not associated with pain medication use. **Conclusions:** There was a high prevalence of cognitive deficits in women with gynecologic malignancies. Further research is needed to evaluate the impact of deficits on treatment adherence and outcomes.

| Variable | Normal cognition (≥22) | Low cognition (<22) | p-value |

**9602 General Poster Session (Board #252), Sun, 8:00 AM-11:45 AM**

**Breast imaging two years post-breast conserving therapy (BCT): Do more frequent mammograms (MMG) yield benefits?** *Presenting Author: Jingjing Hu, Hematology/Oncology, Baystate Medical Center/Tufts University School of Medicine, Springfield, MA*

**Background**: High level evidence defining the optimal timing and frequency of MMG surveillance (6-monthly vs. annually) after breast-conserving therapy (BCT) is lacking. The purpose of this retrospective study was to determine the value of 6-monthly MMG in detecting cancer events after BCT. **Methods**: AJCC stage 0 to IIIC breast cancer and ductal carcinoma in-situ (DCIS) patients (n=492) treated with BCT from 2005-2009 who had two years of surveillance MMG were selected. MMG-associated events, additional imaging and biopsies (Bx) triggered by abnormal mammograms, and tumor recurrences were analyzed by time intervals. A 6-monthly MMG group (n=400) was compared with annual MMG group (n=92). MMG yield was defined as MMG detected events divided by total MMG. We analyzed results using simple frequencies and Fisher's exact test. **Results:** Of 1591 total MMG, 144 were pre-radiation; 69 additional imaging tests (38 ultrasounds, 22 magnification MMG and 9 MRIs) were performed. 1407 and 182 MMGs were performed in 6-monthly MMG group and annual MMG group respectively. 44 biopsies were triggered by abnormal MMGs (table). At 24 months after BCT, MMG detected 3 ipsilateral invasive cancers and 2 contralateral DCIS; 1 ipsilateral regional and 5 distant cancer events were found clinically. Two-year MMG yield was 0.31% (95%CI: 0.04-0.59%); First-year MMG yield was 0.10% (95%CI: 0-0.4%) and second- year MMG yield was 0.66% (95%CI: 0.02%-1.3%). MMG yields were 0.21% (95%CI: 0-0.45%) for the 6-monthly group and 1.0% (95%CI: 0-4.0%) for the annual group with no significant difference (p=0.11). **Conclusions:** The addition of 6-monthly MMG over annual screening did not significantly increase cancer detection, but was associated with unnecessary images and biopsies.

| Interval after BCT(mos.) | Positive ipsilateral MMG-triggered Bx (n) | Ipsilateral MMG-triggered Bx (n) | Positive contralateral MMG-triggered Bx (n) | Contralateral MMG-triggered Bx (n) | Total positive MMG-triggered Bx n,(%) | Positive non-MMG triggered Bx |
|---|---|---|---|---|---|---|

**9603 General Poster Session (Board #253), Sun, 8:00 AM-11:45 AM**

**Trends in health-related quality of life (HRQoL) and income over time in older adults with and without cancer: Evidence from the Surveillance, Epidemiology, and End Results–Medicare Health Outcomes Survey (SEER–MHOS) linked database.** *Presenting Author: Veena Shankaran, Seattle Cancer Care Alliance/Fred Hutchinson Cancer Research Center, Seattle, WA*

**Background:** The impact of cancer diagnosis (dx) on the financial health and HRQoL of older adults is not well understood. The goal of this study was to explore longitudinal changes in HRQoL and self-reported income in a population-based sample of older Medicare enrollees with and without cancer. **Methods:** SEER-MHOS links data on cancer patients (pts) dx in 1998–2007 with a longitudinal HRQoL survey of Medicare Advantage Organization enrollees. We identified pts age ≥ 65 with primary breast, colorectal, prostate, lung, or head and neck cancers who had completed at least 2 MHOS surveys (1 pre and 1 post dx). 2,514 cancer cases were matched 1:4 with 8,616 non-cancer controls by age, gender, race, and time between surveys (mean age 75.3); controls were assigned a pseudo-dx date when their age was the same as the dx age of the matched cancer case. Mean physical component score (PCS) and mental component score (MCS) were determined at various time intervals before and after dx. The proportions of individuals experiencing a decline in household income were also reported. **Results:** A similar proportion of cases and controls reported declines in at least 1 income category after dx (24.4% vs. 24.1%). More cancer pts than controls reported a transition from owning a home to rented housing after dx (2.9% vs. 1.9%, $p < 0.05$). Mean PCS and MCS scores were similar in the 2 years leading up to dx but dropped significantly in the 6 months after dx in cancer pts relative to controls. By 2 years post dx, mean PCS and MCS were again similar between groups (Table). **Conclusions:** Cancer dx has a significant and time-sensitive impact on HRQoL in older Medicare enrollees. While there is some evidence of instability in household income and home ownership in this population, further investigation into the factors associated with these changes is warranted.

**9604 General Poster Session (Board #254), Sun, 8:00 AM-11:45 AM**

**Arterial elasticity in testicular cancer survivors.** *Presenting Author: Anne Hudson Blaes, University of Minnesota, Minneapolis, MN*

**Background:** Testicular cancer survivors are known to have an increased risk of cardiovascular (CV) disease. We aimed to explore the impact of platinum based chemotherapy on endothelial function. **Methods:** Survivors < 30 years at diagnosis who received platinum chemotherapy 2002-2012 and 17 similarly-aged healthy male controls were identified. A history of CV disease was excluded. Subjects underwent pulse wave analysis using the HDI/PulseWave CR-2000 Cardiovascular Profiling System and Pulse contour analysis using the Endo-PAT2000 system. Biomarkers were obtained to evaluate lipids and inflammatory markers. Comparisons were made using T-tests and Wilcoxon Rank-Sum tests. **Results:** 13 survivors (median age 30.2 years, body mass index [BMI] 27.3) and 17 health controls (median age 27.1 years, BMI 24.8) enrolled. Median time from chemotherapy was 4.7 (range 0.8-14) years. Four cases (30.8%) and no controls smoked. There was no difference in lipid profiles between cases and controls.* Median systolic blood pressure (SBP) was elevated (124.5 mmHg cases, 113.4 mmHg controls, p=0.010). Despite the young age of participants, cases had reduced small artery elasticity (9.0 vs 10.4 ml/mmHg x 10, p=0.086). Smoking appears to exacerbate SBP, lipids and artery elasticity. **Conclusions:** In this pilot study, testicular cancer survivors early after the completion of cancer therapy have elevations in SBP and reduced small artery elasticity, suggesting premature CV risk. Further follow up is warranted.

| Measure | Normals | All cases | Smoker cases | Non-smoker cases | Controls | p-value* |
|---|---|---|---|---|---|---|
| SBP (mmHg) | <140 | 124.5 (10.9) | 128.0 (13.7) | 122.1 (9.8) | 113.4 (10.9) | 0.010 |
| Diastolic blood pressure (mmHg) | <90 | 77.7 (9.9) | 83.8 (9.3) | 74.7 (9.1) | 73.4 (5.8) | 0.182 |

**9605 General Poster Session (Board #255), Sun, 8:00 AM-11:45 AM**

**Patient-reported outcomes from adolescent/young adult (AYA) cancer survivors.** *Presenting Author: James M. Metz, Hospital of the University of Pennsylvania, Philadelphia, PA*

**Background:** AYA survivors may experience unique toxicites compared to older survivors, and these may be difficult to measure. This Internet based study evaluates patient-reported outcomes during cancer survivorship. **Methods:** Data were gathered via a convenience sample frame from cancer survivors voluntarily utilizing a publically available, free, Internet-based tool for creation of survivorship care plans. Available at www.livestrongcareplan.com and through the OncoLinkwebsite, it provides customized guidelines for survivor care. During use of the tool, survivors are queried regarding late effects for which they are at risk. All data have been maintained with IRB approval. **Results:** The tool has been used by over 35,000 persons, with PRO available for 11,301; 32% of these were AYA. Median age of AYA survivors was 30 (Range 18 – 35; median diagnosis age 27). Median age of older survivors was 54 (Range 36 – 93, median diagnosis age 50). AYA survivors were 70% female and older were 76% female. In the AYA cohort, most common cancer diagnoses were hematologic (30%), breast (25%), and genitourinary (GU) (18%), compared to breast (44%), gastrointestinal (11%), and GU (10%) in the older cohort. AYA survivors reported cognitive changes (54%), and sexual side effects most frequently. Among males, erectile dysfunction (ED) was reported by 7% of AYA survivors, all of whom denied ED prior to treatment; of these, 14% reported that they had not maintained an erection until completion of intercourse since cancer treatment, and 23% reported that they could do so about 50% of the time. Retrograde/dry ejaculation was reported by 53%. Among females, sexual concerns such as vaginal dryness and shrinkage were reported by 47%. Time since cancer diagnosis ranged from <1yr to 15 years for the AYA cohort (median 2.1 years). **Conclusions:** AYA survivors are prominent users of this tool, although their diagnosis profile differs from that of older users. They report significant late effects, including perceived cognitive changes and prominent sexual side effects, and these may warrant specific counseling and support.

**9606 General Poster Session (Board #256), Sun, 8:00 AM-11:45 AM**

**Dose delays, dose reductions, and relative dose intensity in patients with cancer who received (neo)adjuvant chemotherapy in community oncology practices.** *Presenting Author: Menaka Bhor, McKesson Specialty Health and the US Oncology Network, The Woodlands, TX*

**Background**: Neutropenic complications, such as febrile neutropenia (FN), often necessitate delays or reductions in doses of myelosuppressive chemotherapy. The resulting reduced relative dose intensity (RDI) may lead to poorer disease-free survival and overall survival. **Methods**: Using the McKesson Specialty Health/US Oncology iKnowMed electronic health record database, we retrospectively identified the first course of (neo)adjuvant chemotherapy received by patients without metastases who initiated treatment between 1/1/2007 and 3/31/2011. For each regimen, we estimated mean RDI and the incidences of reduced RDI (< 85% over the course), dose delays (≥ 7 days in any cycle of the course), and dose reductions (≥ 15% in any cycle of the course) relative to the corresponding standard regimens described in the National Comprehensive Cancer Network (NCCN) guidelines or in published phase 3 trials. We also estimated the proportion of patients who received colony-stimulating factor (CSF) prophylaxis in the first 5 days of cycle 1. **Results**: See Table. **Conclusions**: The incidences of chemotherapy dose delays, dose reductions, and reduced RDI varied greatly across tumor types and regimens. CSF prophylaxis also varied, but was most frequently associated with regimens with a high risk (> 20%) of FN according to the NCCN guidelines. Further research should evaluate the impact of reduced RDI on long-term survival.

| Tumor type and regimen | Sample size | Mean RDI, % (SD) | RDI < 85%, % | Dose delay ≥ 7 days, % | Dose reduction ≥ 15%, % | CSF prophylaxis in cycle 1, % |

* High risk of FN according to the NCCN.

**9607 General Poster Session (Board #257), Sun, 8:00 AM-11:45 AM**

**A multicenter observational study comparing physician-assessed febrile neutropenia (FN) risk and prediction-model severe neutropenia (SN) or FN risk in patients (pts) with nonmyeloid malignancies.** *Presenting Author: Gary H. Lyman, Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle, WA*

**Background**: A prediction model was previously developed that estimates the risk of SN or FN during the first cycle of chemotherapy (ctx) based on pt characteristics, disease characteristics, and the myelotoxicity of the ctx regimen (Lyman, 2011). **Methods**: This prospective, multicenter, observational study (124 community-based oncologists; 944 pts) was directed at investigating the relationship between physician-assessed FN risk and prediction-model SN or FN risk. The subjects of this study were the physicians, not the pts. Pts were included if they were ≥ 18 years old, newly diagnosed, and candidates for initiating an NCCN intermediate (10%–20%) FN risk ctx regimen. Physicians entered clinical data about the pts into a database and made a clinical prediction of FN risk. Physician-assessed FN risk was then compared to prediction-model SN or FN risk. Physicians were blinded to the data elements collected by the model and the risk predicted by the model. No outcome data were collected. **Results**: Physicians were hematologists/oncologists (79.8%), oncologists (18.5%), and gynecologists/oncologists (1.6%). Median (Q1, Q3) years of clinical experience was 12.0 (6.5, 20.0). Pts were 65.5% women, median (Q1, Q3) age was 62.0 (53.0, 70.0) years, and the most common tumor types were breast (38.6%), colorectal (27.4%), and NSCLC (12.2%). Correlation estimates (approximate 95% CI) for physician-assessed FN risk and prediction-model SN or FN risk were 0.194 (0.000, 0.373) for NHL, 0.166 (0.027, 0.298) for breast, 0.130 (–0.068, 0.318) for colorectal, 0.121 (–0.134, 0.362) for NSCLC, 0.008 (–0.309, 0.323) for SCLC, and –0.050 (–0.483, 0.403) for ovarian. Correlation between risk estimates was highest for physicians with 8–17 years of clinical experience, oncologists, and those working in clinical settings with > 4 physicians. **Conclusions**: The lack of correlation between physician-assessed FN risk and prediction-model SN or FN risk suggests that community oncologists would benefit from use of a standardized and systematic approach to assess FN risk among pts receiving intermediate-risk ctx regimens.

**9608 General Poster Session (Board #258), Sun, 8:00 AM-11:45 AM**

**Palonosetron (PAL) in combination with 1-day versus 3-days dexamethasone (DEX) to prevent nausea and vomiting in patients receiving paclitaxel and carboplatin (TC).** *Presenting Author: Naoto Furukawa, Department of Obstetrics and Gynecology, Nara Medical University, Nara, Japan*

**Background:** According to current guidelines the combination of PAL and 3-days DEX is the standard antiemetic treatment in pts receiving TC. However, PAL has prolonged efficacy in preventing delayed nausea and vomiting, and pts receiving DEX reported moderate to severe problems in the week following chemotherapy. The aim of present study was to evaluate the efficacy and toxicity of PAL and DEX on day 1 only in pts with gynecological cancer receiving TC. **Methods:** This study is a prospective, randomized phase II study. Pts were stratified according to age (over 50 years or under 50 years) and habitual alcohol intake (yes or no). Chemotherapy-naïve pts >20 years old were randomly assigned to receive PAL (0.75mg iv) plus DEX (20mg iv) on day1 before receiving TC (D-1 group), or PAL (0.75mg iv) plus DEX (20mg iv) on day1 before receiving TC and DEX (8mg po) on days 2 and 3 (Std group). Primary endpoint was complete response (CR; defined as no vomiting episodes and no rescue medication) for 24-120 h after the first chemotherapy cycle initiation. Nausea and vomiting were evaluated with the MASCC Antiemesis Tool (MAT). Toxicity assessments were conducted using the NCI-CTC investigator guide (version 4.0). **Results:** Between April 2012 and December 2013, a total of 88 pts were randomized: 82 pts (D-1 group=43, Std group=39; median age D-1 group=59 years, Std group=62 years; habitual alcohol intake D-1 group=4, Std group=3) were available for the efficacy and toxicity analysis. 69.8% (30/43) and 76.9% (30/39) of pts reported delayed CR in D-1 and Std, respectively (P = 0.465). Acute and overall CR in D-1 and Std were similar (95.4% vs. 94.9%, P =0.920; 67.4% vs. 76.9%, P=0.340). The most common adverse event was grade 1 constipation (18.6% vs. 20.5%, P=0.828) and grade 1 insomina (16.3% vs. 12.8%, P=0.658). In logistic analysis, age under 50 years was associated with a lower incidence of delayed CR (odd ratio 3.79). **Conclusions:** The antiemetic treatment with DEX on day 1 only seemed as effective as the standard treatment for prevention of nausea and vomiting in pts receiving TC. In addition, in pts < 50 years old other antiemetic drugs may be necessary in addition to DEX and PAL. Clinical trial information: 000007491.

**9609 General Poster Session (Board #259), Sun, 8:00 AM-11:45 AM**

**Perceptions regarding the value of the physical examination in patients with advanced cancer: A survey study.** *Presenting Author: Kunal C. Kadakia, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Despite its clinical utility, progressive reliance on technology can lead to devaluing the physical examination in patients with advanced cancer. The primary objective was to determine whether these patients have a positive or negative perception of the physical examination. Secondarily, to determine if these perceptions are related to interpersonal/relational values (symbolic) or diagnostic/objective values (pragmatic). **Methods:** One-hundred and fifty patients with cancer receiving concurrent oncology and palliative care were administered a 26-item survey regarding their overall perception of the physical examination. The primary outcome, patient responses to "I believe my experience while undergoing physical examinations has been overall: very negative (-5) to very positive (+5)", was analyzed using the Sign test. Other items were predefined as symbolic or pragmatic statements and responses from strongly disagree (1) to strongly agree (5) were further analyzed. Multivariable logistic regression was utilized to test for associations between baseline characteristics and the primary outcome. **Results:** Most patients (83%) found the overall experience of being examined to be highly positive (median=4, interquartile range [IQR]=2-5, p=<0.0001). Patients valued both the pragmatic (median=5, IQR=4-5) and symbolic (median=4, IQR=4-5) aspects of the physical examination. Increasing age was independently associated with a more positive perception of the physical examination (odds ratio=1.07 per year, 95% confidence interval 1.02-1.12, p=0.01). **Conclusions:** Patients with advanced cancer find the physical examination to be a highly positive aspect of their care. These benefits are perceived as having both symbolic and pragmatic value. The physical examination should remain a cornerstone of clinical encounters.

**9610 General Poster Session (Board #260), Sun, 8:00 AM-11:45 AM**

**A randomized phase II study evaluating the use of prydoxine to prevent hand-foot syndrome associated with capecitabine therapy for advanced or metastatic breast cancer.** *Presenting Author: Akiyo Yoshimura, Department of Breast Oncology, Aichi Cancer Center, Nagoya, Japan*

**Background:** Pyridoxine (Pyr) is a drug of activated vitamin B6 and usually used for allergic dermatitis. Pyr is frequently used to prevent the HFS, although the evidence of benefit is lacking in Japan. The aim of this is to determine whether Pyr could reduce capecitabine (Cap)-induced HFS in advanced or metastatic breast cancer patients. This study is an open label, multicenter, randomized phase II study conducted by Tokai Breast Cancer Research Group (TBCRG) in Japan. **Methods:** All patients were received either concomitant pyridoxine (60mg P.O per day) or none with Cap containing regimens (Cap monotherapy, Cap plus cyclophosphamide, Cap plus weekly paclitaxel). Patients were stratified by chemotherapy regimens, line of therapy after metastases, and institutes. The study treatment was given until grade 2 HFS or incidence of other severe adverse events or progression disease. Primary endpoint is the period until the incidence of grade 2 or worse HFS from start of protocol treatment. The key secondary endpoints were incidence and period until all grade HFS and safety. **Results:** A total of 135 advanced and metastatic breast cancer patients were randomized the concomitant Pyr arm (n=67) and Cap alone arm (n=68). The baseline characteristics were well balanced in both arms. Grade 2 or worse HFS developed in 19 of 66 patients (28.8%) versus 21 of 67 patients (31.3%) in concomitant Pyr arm and Cap alone arm, respectively. The median HFS-free period (grade 2 or worse) was 13.6 and 10.6 months in concomitant Pyr arm and Cap alone arm, respectively (Hazard ratio=0.75 [95%CI: 0.40-1.40], P=0.364). Grade 1 HFS-free period were not significant difference in both arms (Hazard ratio=0.92 [95%CI: 0.61-1.38], P=0.659). HFS-free period in each regimens were not evaluated because of small events in combination regimens. Interestingly, leucocytopenia and neutropenia were significantly increased in concomitant Pyr arm (p=0.020 and 0.006, respectively). The ratio of other adverse events were similar with both arms. **Conclusions:** Prophylactic pyridoxine use may delay the period until the incidence of severe Cap-induced HFS in advanced and metastatic breast cancer patients. Clinical trial information: UMIN000002932.

**9611 General Poster Session (Board #261), Sun, 8:00 AM-11:45 AM**

**Prevention of irinotecan-induced diarrhea by probiotics: Randomized double-blind, placebo-controlled phase III study.** *Presenting Author: Michal Mego, Faculty of Medicine, Comenius University and National Cancer Institute, Bratislava, Slovakia*

**Background:** Diarrhea is one of the dose limiting toxicity of irinotecan. SN-38 is main irinotecan metabolite responsible for diarrhea development. SN-38 is excreted in glucuronidated form into the intestine. Due to the bacterial enzyme beta-D-glucuronidase in intestinal lumen it is deconjugated and in this form causes direct damage to the intestinal mucosa associated with the development of diarrhea. This study aimed to determine the effectiveness of the probiotics in the prevention of irinotecan induced diarrhea due to reduction of intestinal beta-D-glucuronidase activity. **Methods:** Between January 2011 and December 2013, 46 patients with colorectal cancer starting a new line of irinotecan based therapy were included. 5-flurouracil/capecitabine along with irinotecan was administered to 26 (56.5%) patients and 22 (47.8%) patients received biological therapy as well. Patients were randomized 1:1 to probiotics (PRO) or placebo (PLA). Probiotic formula Colon Dophilus, was administered at a dose of 10x $10^9$CFU of bacteria tid, orally for 12 weeks of chemotherapy. Primary endpoint was incidence of grade 3/4 diarrhea. The study was prematurely terminated due to slow accrual, when 46 of 220 planned patients were accrued. Herein, we report final analysis of the study. **Results:** 23 patients were randomized to PRO and 23 patients to PLA. Administration of probiotics compared to placebo led to a reduction in the incidence of severe diarrhea of grade 3 or 4 (0% for PRO vs. 17.4% for PLA, p = 0.11), as well as reduction of the overall incidence of diarrhea (39.1% for PRO vs. 60.9% for PLA, p = 0.24) and incidence of enterocolitis (0% for PRO vs. 8.7% for PLA). Patients on PRO used less loperamid compared to PLA (mean duration of loperamid use: 4.5 days for PRO vs. 10.4 days for PLA, p = 0.45; mean number of loperamid tablets: 5.9 for PRO vs. 37.7 for PLA, p = 0.49). There was no infection caused by probiotic strains recorded. **Conclusions:** Administration of probiotics in patients with colorectal cancer treated with irinotecan-based chemotherapy is safe and could lead to a reduction in the incidence and severity of gastrointestinal toxicity. Phase III clinical trials with adequate sample size are warranted. Clinical trial information: NCT01410955.

**9612 General Poster Session (Board #262), Sun, 8:00 AM-11:45 AM**

**A genome-wide association study (GWAS) of docetaxel-induced neutropenia in CALGB 90401/60404 (Alliance).** *Presenting Author: Daniel Louis Hertz, University of Michigan, Ann Arbor, MI*

**Background**: The objective of this analysis was to perform unbiased discovery of genetic variants that modulate neutropenia risk early in docetaxel treatment. **Methods**: Chemotherapy-naive metastatic castration-resistant prostate cancer (mCRPC) patients treated with docetaxel and prednisone ± bevacizumab on the CALGB 90401 trial who experienced grade 3+ neutropenia (ANC < 1,000 cells/mm$^3$) within the first two treatment cycles (cases) were compared with controls who completed two cycles without grade 3+ neutropenia. All single nucleotide polymorphisms (SNPs) genotyped on the Illumina HumanHap610-Quad platform that passed quality control were included in a genome-wide association study (GWAS) in genetically-defined European subjects. SNPs selected for future replication, based on p-value and biological relevance to neutropenia, were adjusted for treatment arm, age, baseline ANC, smoking status and palliative radiation. **Results**: The incidence of grade 3+ neutropenia within the first two cycles was 22.6% (172/761). 590 European subjects fulfilling the case or control criteria were evaluated in a discovery GWAS of 498,022 SNPs. The top hit was an intronic SNP (rs12431732) in *ACTN1*, which bundles actin in the neutrophil cytoskeleton. Actin specific antibodies have been detected in auto-immune neutropenia, providing a plausible biological mechanism. Ten SNPs, many in genes involved in leukocyte homeostasis such as *SERPINA3* and *BAALC*, were prioritized for future replication (Table). **Conclusions**: GWAS in a prospectively enrolled mCRPC patient cohort identified SNPs that may influence risk of docetaxel-induced neutropenia, adjusted for bevacizumab treatment. Replication in independent cohorts of docetaxel treated patients is necessary to verify the influence of these SNPs on neutropenia risk.

| GWAS rank | rsID | Gene | Minor allele frequency | Adjusted hazard ratio | Adjusted p value |

**9613 General Poster Session (Board #263), Sun, 8:00 AM-11:45 AM**

**Use of aprepitant in uncontrolled delayed nausea and vomiting associated with preparative regimens in stem cell transplantation: A retrospective analysis.** *Presenting Author: Linh Tran, Stanford Hospital/Clinics, Stanford, CA*

**Background:** Aprepitant, a well tolerated antiemetic, is indicated for the prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of highly emetogenic chemotherapy in combination with other antiemetic agents. Aprepitant has not been studied for the treatment of established or refractory nausea and vomiting. We report the experience of an academic medical center in the treatment of uncontrolled delayed nausea and vomiting in the stem cell transplant (SCT) population. **Methods:** Between 2008-2013, 110 patients were identified retrospectively to have been treated with a 3-day course of oral aprepitant for uncontrolled delayed nausea and/or vomiting after receiving preparative regimen for SCT. Primary outcome was to determine the rate of complete response ($CR_{NV}$, defined as no vomiting with grade 0-1 nausea, using CTCAE 4.02 at 5 days) and partial response ($PR_{NV}$, defined as a reduction in grade of nausea and vomiting without achieving CR at 5 days). Further analysis to assess CR, PR and time to control (reduction in the grade) for nausea ($CR_N$, defined as grade 0-1 nausea at day 5; $PR_N$, defined as a reduction in grade of nausea without achieving CR at day 5) and vomiting ($CR_V$, defined as no vomiting at day 5; $PR_V$, defined as a reduction in grade of vomiting without achieving CR at day 5) was also performed. **Results:** Of 110 patients, 37% were female, average age was 46.9 years (range, 21-75 years), 46.4% received alloSCT (25.5% FTBI), 52.7% autoSCT, and 0.9% syngeneic SCT. After receiving aprepitant, $CR_{NV}$ was achieved by 23.6%, with 50% $CR_N$ and 51.8% $CR_V$. 14.5% achieved a $PR_{NV}$ with 24.5% $PR_N$ and 1.8% $PR_V$. Median time to control nausea was 2 days (range, 1-5 days) and vomiting was 1 day (range, 1-2 days). All but 2 patients received ondansetron and dexamethasone prior to aprepitant administration. Of 21 patients who received at least one agent from a new class of antiemetic after administration of aprepitant, 6 (29%) of those patients achieved $CR_{NV}$ and 2 (10%) achieved $PR_{NV}$. **Conclusions:** The use of aprepitant shows efficacy in the treatment of uncontrolled delayed nausea and vomiting associated with preparative regimens in SCT.

**9614^ General Poster Session (Board #264), Sun, 8:00 AM-11:45 AM**

**Multicenter randomized double-blind controlled phase III study of hhpg-19K as prophylactic therapy in patients with advanced non-small cell lung cancer (NSCLC) receiving myelosuppressive chemotherapy.** *Presenting Author: Caicun Zhou, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China*

**Background:** HHPG-19K (19K) is a long-acting pegylated recombinant G-CSF that can be dosed only once-per-chemo cycle. The aim of this phase III study was to investigate the efficacy/safety of HHPG-19K as prophylactic therapy in patients with advanced NSCLC treated with myelosuppressive chemotherapy. **Methods:** Patients were randomized (1:1:1) blindly to three treatment arms to receive 19K 100mg/kg, 6mg fixed dose or CONTROL (saline) in cycle 1. In cycles 2 to 4 following unblinding at the end of cycle 1, patients in CONTROL received short-acting G-CSF at dose of 5$\mu$g/kg once daily subcutaneously 48h after chemotherapy while patients randomized in 2 19K arms to receive the same doses as in cycle 1. All patients received 4 cycles of docetaxel (75mg/m$^2$) plus cisplatin (75mg/m$^2$) or carboplatin (AUC=5) per 21 days. The primary endpoint was the incidence of grade 3/4 neutropenia evaluated in cycle 1. **Results:** 151 chemo-naive patients with histopathology stage III/IV NSCLC enrolled into this study. The distribution of patients' baseline characteristics was well balanced among 3 arms. The incidence of grade 3/4 neutropenia was significantly decreased in patients received 19K 100$\mu$g/kg and 6mg-fixed compared to CONTROL in cycle 1 and showed no statistical difference in cycle 2 to 4. Mean duration of grade 3/4 neutropenia and median recovery time from neutropenia for two 19K arms were significantly shorter than that of CONTROL in cycle 1 and were similar in three arms in cycles 2 to 4. Four (8.00%) febrile neutropenia were observed in CONTROL in cycle 1 only. Nausea, fatigue and anorexia were the most common observed adverse events and no statistical difference among three arms in all cycles. **Conclusions:** This study demonstrated that the efficacy of HHPG-19K (either 100 $\mu$g/kg or 6 mg-fixed dose) was superior to placebo treatment and was comparable to short-acting G-CSF as prophylactic use in patients with NSCLC receiving chemotherapy. HHPG-19K was well tolerated and no unexpected adverse events were observed. The 6 mg-fixed dose is more convenient for administration and is recommended in further clinical practice. Clinical trial information: NCT01560195.

**9615 General Poster Session (Board #265), Sun, 8:00 AM-11:45 AM**

**A phase II study evaluating efficacy of zoledronic acid in prevention of aromatase inhibitor (AI)-associated musculoskeletal symptoms: The ZAP trial.** *Presenting Author: Cesar Augusto Santa-Maria, The Johns Hopkins University School of Medicine and The Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

**Background:** Aromatase inhibitor-associated musculoskeletal symptoms (AIMSS) contribute to significant morbidity and therapy discontinuation. Retrospective data suggest that bisphosphonates may reduce the prevalence of AIMSS. **Methods:** We conducted a single-arm prospective clinical trial in postmenopausal women with stage 0-III breast cancer scheduled to initiate adjuvant AI, designated ZAP. Eligible women received intravenous zoledronic acid 4 mg (ZA) at baseline and 6 months, and started letrozole 2.5 mg daily 1-2 weeks afterwards. We compared the percentage of women who developed AIMSS over 12 months to historical controls not taking bisphosphonates from the Exemestane and Letrozole Pharmacogenetics (ELPh) trial (NCT00263913). AIMSS were defined as an increase of 0.22 from a scale of 0-3 in the Health Assessment Questionnaire Disability Index (HAQ-DI) and/or 2.0 cm in the Visual Analog Scale (VAS). AIMSS were assessed at 1, 3, 6, and 12 months and compared between studies with a logistic regression model adjusting for patient age, body mass index, race, prior chemotherapy, and prior tamoxifen use. We also evaluated the probability of AI discontinuation or change to another endocrine therapy by 1 year using a Kaplan Meier approach. **Results:** From 2011 to 2013, 59 women enrolled in ZAP. All (100%) and 52 (88%) women received baseline and 6 month ZA, respectively. 435 of 502 women from ELPh were eligible as historical controls. Both cohorts had similar characteristics, except more women in ELPh received prior tamoxifen. Twenty-two (37%) and 267 (61%) women on ZAP and ELPh, respectively, reported AIMSS during the first year ($p<0.001$). Five (8%) and 67 (15%) women on ZAP and ELPh discontinued AI or changed endocrine therapy ($p=0.24$). The cumulative probability of discontinuing AI or changing endocrine therapy was 9% for ZAP and 21% for ELPh (log rank $p=0.05$). **Conclusions:** Compared to historical controls, ZA prophylaxis in the adjuvant setting is associated with reduced AIMSS and decreased probability of AI discontinuation or change. A prospective randomized control trial is required to confirm these findings. Clinical trial information: NCT01194440.

**9616 General Poster Session (Board #266), Sun, 8:00 AM-11:45 AM**

**Effects of fosaprepitant (Fosa) administered as single dose versus two doses, on nausea/vomiting (N/V) in patients receiving multiday chemotherapy (CT) with a highly emetogenic regimen of doxorubicin and ifosfamide (AI): Randomized cross-over study.** *Presenting Author: Saroj Vadhan-Raj, Section of Cytokines and Supportive Oncology, Department of Sarcoma Medical Oncology. The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background**: AI is multi-day regimen of highly emetogenic chemotherapy, with high incidence of delayed N/V. Fosa, NK1 receptor antagonist (RA), administered IV as single dose (FDA-approved), with 5HT3RA and dexamethasone has improved the control of emesis. However, delayed N/V still remains problematic. Purpose of the study was to examine the effects of fosa administered IV on day 1 vs days 1 and 4 on N/V and the effect on ifosfamide (Ifex) and its active metabolites, due to potential drug interactions via CYP450. **Methods**: Sarcoma pts, planned to receive AI, were randomized 1:1 to Arm A (single- dose Fosa on day 1) or Arm B (2-doses, on days 1 and 4). Within each arm, patients were randomized to Group-1: Fosa in cycle-1 (C-1) and no Fosa in cycle-2 (C-2), and group-2: no Fosa in C-1 and Fosa in C-2. Blood samples were drawn for levels of Ifex/metabolites to be analyzed at the end of study. All pts could receive 2 doses of Fosa during cycles 3-6. Pts were monitored for N/V with daily symptom diary and FLIE (functional living index -- emesis) score (days 1, 5 and 10). **Results:** Of 47 pts, 40 eligible pts were randomized. There were 13 men and 27 women, with median age of 45 years (range, 19-65) and KPS of 90 (80-100). At present, 34 pts have completed 2 CT cycles. As shown below, Fosa administered as 2 doses resulted in significantly better control of delayed N/V as compared to single-dose or the control cycle. Furthermore, in cycle-3 the higher CR rate for N/V was maintained with 2 doses. Treatment with Fosa (one or two doses) was well tolerated with no enhanced neurological toxicity. **Conclusions**: The results of this study showed for the first time that Fosa administered as 2 doses is well tolerated and more effective in the control of delayed N/V than single dose or no Fosa with 5HT3RA + Dexa in pts receiving multi-day CT. Clinical trial information: NCT01490060.

**Complete response (CR*) in C-1 and C-2.**

| Study groups | No. of pts | Day 1 N (%) | Days 2-5 N (%) | Days 1-10 N (%) |
|---|---|---|---|---|

**Noninvasive liver fibrosis index changes during chemotherapy: Marker for oxaliplatin-induced hepatic sinusoidal obstruction syndrome.** *Presenting Author: Sehhoon Park, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea*

**Background:** Even though oxaliplatin (OXA) could induce hepatic sinusoidal obstruction syndrome (SOS), OXA-based regimes are still standard treatment for patients with colorectal (CRC) and advanced gastric cancer (AGC). The aim of the study was to evaluate the utility of non-invasive liver fibrosis index (NIFI) for monitoring OXA-induced hepatic SOS. **Methods:** From February 2004 to December 2013 patients with CRC or AGC who received OXA-based chemotherapy (CTx) were identified in the institutional electronic patient database. Liver fibrosis were evaluated before and after the OXA exposure with splenic volume index (SVI) and 4 different NIFIs: age-platelet index (API), AST to platelet ratio index (APRI), platelet to spleen ratio (PSR), Fibrosis-4 score (FIB-4). Adjusted odd ratio (aOR) with 95% confidence intervals (CI) were analyzed to evaluate risk after matching age, body mass index, cancer type, stage, previous chemotherapy cycle. **Results:** A total of 288 patients (pts) were eligible for evaluation: 211 pts were male and median age was 65; 206pts had CRC; 82pts had AGC; median OXA cumulative dose was 798.80mg/m$^2$and median duration of OXA based chemotherapy was 4.87 months. Increase in SVI were directly correlated with the cumulative OXA dose (p=0.005). Using a cutoff of SVI $\geq$ 0.3, 120 pts (41.67%) were positive for hepatic SOS. All of the 4 NIFIs were significantly correlated with SVI. aOR for each NIFI were show in the Table. **Conclusions:** Changes of NIFIs showed good correlation with SVI changes during OXA-based chemotherapy. NIFIs could be useful for non-invasive monitoring of OXA induced hepatic SOS.

| | N=288 (mean ± standard deviation) | SVI ≥ 0.3 N=120, (41.67%) | SVI<0.3 N=168, (58.33%) |

**Enobosarm and lean body mass in patients with non-small cell lung cancer.** *Presenting Author: Jeffrey Crawford, George Barth Geller Professor for Research in Cancer, Duke University Division of Medical Oncology, Durham, NC*

**Background:** Cancer induced muscle wasting is a selective and progressive cancer related symptom that begins early in the course of malignancy. Greater than 50% of NSCLC patients have muscle wasting at diagnosis, increasing to >80% prior to death. Historically, interventions targeting muscle wasting and cachexia focused on weight, ignoring the importance of lean body mass (LBM).Enobosarm is a first-in-class, non-steroidal, oral, selective androgen receptor modulator (SARM). We report results for 2 Phase 3 clinical trials of enobosarm, POWER 1 (P1) and POWER 2 (P2), for the prevention and treatment of muscle wasting in patients with advanced NSCLC. **Methods:** Patients (pts) with Stage III or IV NSCLC were randomized at initiation of first-line chemotherapy based upon the planned chemotherapy regimen; platinum + taxane (P1, n=321) or platinum + non-taxane (P2, n=320). Pts (males and postmenopausal females ≥30y with ECOG ≤1) received either enobosarm 3mg or placebo (pbo) for 5 months. LBM was measured by Dexa and body weight (BW) by scale weight, w/hospital gown & w/o shoes, at baseline day (d)84 and 147. **Results:** In P1 and P2, decreases in BW were observed from baseline in both enobosarm and pbo groups. In P1, enobosarm treated pts had a lower rate of decline in BW as compared to pbo through d84 (p=0.053) and 147 (p=0.038). Despite declining BW, increases in LBM were still observed in enobosarm pts (+0.41 kg) compared to pbo (-0.92 kg) by continuous variable analysis at d84 (p=0.0002) and 147 (p<0.0001). In P2, there was no difference in loss of BW between groups; however, enobosarm pts demonstrated significant increases in LBM (+0.47 kg) compared to pbo (-0.37 kg) at d84 (p=0.0111) and 147 (p=0.0028). Additionally, a larger proportion of pts receiving enobosarm maintained or increased LBM at d84 and 147 in both trials (P1: p=0.036 and 0.026; P2: p=0.113 and 0.013; by responder analysis) as compared to pbo. The incidence of adverse events was similar between enobosarm and pbo in both trials. **Conclusions:** Overall, enobosarm was safe and well tolerated. Enobosarm had a clinically significant effect on muscle, despite decreases in BW, which may translate into improvement in physical function. Impact on survival will be evaluated. Clinical trial information: NCT01355497, NCT01355484.

**9619 General Poster Session (Board #269), Sun, 8:00 AM-11:45 AM**

**Effect of body mass index and menopausal disorders during menopause on vasomotor symptoms of postmenopausal Japanese breast cancer patients treated with anastrozole: A prospective multicenter cohort study of patient-reported outcomes.** *Presenting Author: Kaori Tane, Hyogo Cancer Center, Akashi, Japan*

**Background:** Although vasomotor symptoms induced by aromatase inhibitors are frequently recognized, risk factors are ill-defined. To identify risk factors for vasomotor symptoms of Japanese breast cancer patients treated with adjuvant anastrozole, we conducted a prospective cohort study based on patient-reported outcomes (PROs). Patients and **Methods:** For this prospective cohort study (SAVS-JP, UMIN000002455), 391 postmenopausal Japanese estrogen receptor-positive breast cancer patients who were treated with adjuvant anastrozole were recruited from 28 centers. The PRO assessment was obtained from a self-reported questionnaire at baseline, 3, 6, 9 and 12 months between August 2009 and April 2012. Vasomotor symptoms, comprising hot flashes, night sweats, and cold sweats, were categorized into four grades (none, Grade 1: mild, Grade 2: moderate, Grade 3: severe). Pre-existing symptoms were only included if they worsened post-baseline. **Results:** Hot flashes, night sweats, and cold sweats at baseline were reported by 80 (20.5%), 59 (15.1%), and 32 (8.2%) patients respectively. New or worsening symptoms were experienced by 139 (38.4%), 106 (29.3%), and 104 (28.7%) patients. About 80% of newly occurring symptoms were grade 1, and less than 5% were grade 3. Overall vasomotor symptoms were reported by 201 (55.5%) out of 362 patients. Patients with vasomotor symptoms were significantly younger, had higher body mass index (BMI), shorter time period aftermenopause, and more menopausal disorders during menopause. Multivariate analysis showed that BMI (odds ratio: 1.09, 95% confidence interval: 1.02-1.16, P=0.009) and experience of menopausal disorders (2.11, 1.35-3.30, P=0.001) were significantly associated with vasomotor symptoms. **Conclusions:** We found that high BMI and experience of menopausal disorders at menopause were significantly associated with occurrence of vasomotor symptoms. These data are expected to prove useful for management of postmenopausal Japanese women treated with aromatase inhibitors. Clinical trial information: UMIN000002455.

**9620 General Poster Session (Board #270), Sun, 8:00 AM-11:45 AM**

**Prediction of major complications in patients with solid tumors and apparently stable febrile neutropenia: Validation of the CISNE risk score.** *Presenting Author: Javier Espinosa, Hospital General Universitario de Ciudad Real, Ciudad Real, Spain*

**Background:** In order to improve the risk stratification of patients with febrile neutropenia (FN), we previously developed a prognostic score predicting major complications in patients with solid tumors and apparently stable episodes (Br J Cancer. 2011;105[5]:612-7). **Methods:** On the basis of our previous multivariate analysis, 6 predictors were associated to serious complications [ECOG PS≥2 (2points), chronic obstructive pulmonary disease (1point), cardiovascular disease (1point), mucositis NCI grade≥2 (1point), monocytes <200 (1point) and stress-induced hyperglycemia (2points)]. We have integrated these factors into a score ranging from 0 to 8, which allows the classification of patients into 3 prognostic classes: low (0points), medium (1-2points) and high risk (≥ 3points). We present here a validation of this score (CISNE) and a comparison with MASCC and Talcott models. **Results:** From Oct/12 to Dec/13, we prospectively recruited 780 patients with apparently stable FN from 21 hospitals. The rate of infection-related complications and death was 15.6% (95%CI, 12.9%-18.6%) and 1.7% (95%CI, 0.9%-3%), respectively. CISNE classified 26%, 41% and 33% of the patients as low, medium and high risk, respectively. The rate of complications and death within each of these groups was 1.5%, 7.5% and 37.1% (p<0.001), and 0, 0.9% and 4.3%, respectively (p<0.001). The Table summarizes the comparison of the 3 scales to predict serious complications. The AUCs were 0.84 (95%CI, 0.81-0.86) for CISNE; 0.72 (95%CI, 0.68-0.75) for MASCC and 0.57 (95%CI, 0.54-0.61) for Talcott. **Conclusions:** CISNE is a valid score that classifies apparently stable FN episodes more accurately than MASCC and Talcott.

| Parameter | CISNE (<3 vs ≥3) | MASCC (<21 vs ≥21) | Talcott (I-III vs IV) |
|---|---|---|---|
| **Sensitivity % (CI-95%)** | 77.8% (69.4- 84.8) | 35.2% (26.8 - 44.4) | 27.8% (20.1-36.7) |

**9621 General Poster Session (Board #271), Sun, 8:00 AM-11:45 AM**

**The impact of docetaxel-related toxicities on health-related quality of life in patients with metastatic cancer (The QoLiTax-Trial of the Arbeitsgemeinschaft Internistische Onkologie, AIO).** *Presenting Author: Claudia Pauligk, Krankenhaus Nordwest, University Cancer Center, Frankfurt, Germany*

**Background:** Docetaxel is a widely used cytotoxic agent. It causes a number of side effects, most frequently leukopenia and neutropenia, alopecia, nausea, diarrhea, and fatigue. This study evaluates the impact of docetaxel toxicities on patient's health-related Quality of life (QoL). **Methods:** We conducted a multicenter, prospective, non-interventional trial, in which the QoL was assessed using the EORTC QLQ-C30 questionnaire at baseline and every 4 weeks up to 40 weeks in patients receiving a docetaxel-based chemotherapy for metastatic disease. The primary endpoint was the 4-months ≥5% deterioration rate of the global health status/QoL scale in patients with vs. those without grade 3/4 leukopenia or neutropenia. Secondary endpoints were the effect of other treatment-related adverse events on QoL. Uni- and multivariate analyses were applied. **Results:** From January 2008 to June 2011 a total of 2,659 patients were included. The majority of patients (48.1%) had prostate cancer, followed by breast (17.1%) and non-small-cell-lung cancer (15.8%). Patients received a median of 5 docetaxel cycles with median dose of 75 mg/m$^2$. The 4 months ≥5% deterioration rate of the global health status/QoL was similar between patients with and without grade 3 or 4 leukopenia/neutropenia (adjusted odds ratio 1.024, p=.4). Among other treatment-related toxicities, the presence of grade 3/4 diarrhea showed the strongest effect on global health status/QoL average scores (50.91 vs. 33.06), followed by vomiting (50.91 vs. 35.17), dyspnea (50.94 vs. 35.81), stomatitis (50.88 vs. 36.41), nausea (50.91 vs. 36.68), infection (50.90 vs. 37.14), fatigue (50.90 vs. 43.82) and anemia (50.91 vs. 41.03), p<0.05 for all comparisons. Grade 3/4 leukopenia/neutropenia, alopecia, constipation, neuro- and nail toxicity had no significant impact on the global health status/QoL or other items. **Conclusions:** Docetaxel associated non-hematological toxicity, but not isolated leukopenia strongly impact patient's QoL. This has to be considered by clinicians while making therapeutic decisions.

**9622 General Poster Session (Board #272), Sun, 8:00 AM-11:45 AM**

**Scrambler therapy for treatment of chemotherapy-induced peripheral neuropathy.** *Presenting Author: Breanna L Weisbrod, Mayo Clinic, Rochester, MN*

**Background:** More effective treatment is needed for chemotherapy-induced peripheral neuropathy (CIPN). Preliminary data support the use of Scrambler therapy, a device which treats pain via non-invasive cutaneous electrostimulation, for the treatment of CIPN (Smith TJ et al. J Pain Symptom Manage 2010). The current abstract reports data from a pilot trial, performed to investigate the effect of Scrambler therapy for the treatment of established CIPN. **Methods:** Eligible patients: age ≥ 18 years, ECOG PS ≤2, life expectancy ≥3 months, CIPN symptoms of ≥1 month duration with tingling and/or pain ≥4/10 during the prior week. Patients were treated with Scrambler therapy to the affected area(s) for up to 10 daily 30 minute sessions. Symptoms were monitored using a neuropathy questionnaire consisting of numerical analogue scales ranging from 0-10, daily before therapy as well as weekly for 10 weeks after therapy. Descriptive summary statistics formed the basis of data analysis. During the daily therapy, last values carried forward were used. **Results:** We report on 37 patients enrolled between 7/18/2011 and 5/6/2013, 12 men and 25 women; the mean age was 58. While the study technically remains open to obtain more experience with this procedure, the first 37 accrued CIPN patients are the basis of our final CIPN-related manuscript from this project (in development). Patients had a history of exposure to various neurotoxic chemotherapeutic agents and the majority (78%) had symptoms ≥1 year. 25 patients were treated primarily on their lower extremities while 12 were treated primarily on their upper extremities. The table portrays data (average symptoms during the previous 24 hours) at baseline, on the last of the 10 planned days of therapy, and at the end of 10 weeks of follow up, regarding patient reported pain, tingling, and numbness. There were no substantial adverse events. **Conclusions:** Scrambler therapy appears to be effective for the treatment of CIPN: a prospective placebo-controlled clinical trial should be performed. Clinical trial information: NCT01347723.

| | Mean baseline score | Mean final Rx score (day 10) | Average percent drop in score (day 10) | Mean final Rx score (week 10) | Average percent drop in score (week 10) |
|---|---|---|---|---|---|
| **Pain** | 5.8 | 2.6 | 53% | 3.1 | 47% |
| **Tingling** | 6.0 | 3.3 | 44% | 2.9 | 26% |

**9623 General Poster Session (Board #273), Sun, 8:00 AM-11:45 AM**

**Bone health in prostate patients: An opportunity for screening and intervention.** *Presenting Author: George A. Dawson, VA New Jersey Healthcare System, East Orange, NJ*

**Background:** Despite known risk factors, men are not routinely screened for bone health. Men with prostate cancer are at an increased risk of bone disease because of treatment with androgen deprivation therapy (ADT). Risk factors include family history, calcium and vitamin D deficiency, certain medications, being thin or small-boned, tobacco use, alcohol abuse. and lack of physical activity. We started a screening and management program to mitigate the effects of ADT on bone health in veterans beginning treatment for prostate cancer. This study evaluates the pre-existing risk factors in pts who had baseline dexa scans before ADT. **Methods:** We completed a retrospective chart review of 182 veterans diagnosed with prostate cancer and referred to Radiation Oncology for radical treatment from 2009 to 2013. This reports on the 160 pts who had baseline dexa scans. Clinical variables analyzed were demographics, tobacco and alcohol use, vitamin D levels, incidence of AODM (adult onset diabetes mellitus), and calcium or vitamin D use. Descriptive statistics as well as bivariate analysis including Chi Square tests and odds ratios were calculated. **Results:** The mean age of the study participants was 66.6 yrs (47-82.8 yrs); 52% were African American, 45% White, 3% Hispanic. Baseline dexa scans were abnormal in 63% of pts, showing osteoporosis and /or osteopenia. Vitamin D levels were abnormal in 61%. Abnormal vitamin D levels were found in 26% of pts with normal DEXA scans. Almost 99% pts received calcium and Vitamin D supplements. Twenty percent had a history of alcohol abuse, 56% used tobacco, and 33% had AODM. Ethnicity may be a factor ( p<0.05) but the sample sizes per group were not equivalent. Smokers with an abnormal Vitamin D level were at increased risk of bone disease as comparedto non smokers (p<0.01) . **Conclusions:** Pre-ADT screening confirms the risk of underlying bone disease in this previously unscreened veteran population. Guidelines for treatment and prevention of bone disease should be implemented in all patients over age of 50. An opportunity exists to identify and treat men at risk when seen for prostate cancer treatment whether they receive ADT or not.

**9624 General Poster Session (Board #274), Sun, 8:00 AM-11:45 AM**

**Clinical risk prediction in anthracycline cardiotoxicity.** *Presenting Author: Bonnie Ky, University of Pennsylvania, Philadelphia, PA*

**Background:** Anthracyclines are highly effective as anticancer therapies and have led to important survival gains. There are, however, significant concerns over cardiotoxicity. The overall objective of this study was to define the incidence and clinical predictors of anthracycline-induced cardiotoxicity in a prospective, community-based cohort. **Methods:** The PREDICT study included 586 patients undergoing an anthracycline-based chemotherapy across 24 community oncology programs. Participants underwent detailed cardiovascular (CV) evaluation including B-type natriuretic peptide (BNP) biomarker assessment and serial echocardiograms at baseline and multiple standardized intervals over a maximum followup of 12 months. A cardiac event was defined as asymptomatic left ventricular dysfunction (LVD), symptomatic heart failure (HF), symptomatic arrhythmia, acute coronary syndrome, or cardiac death. Multivariable logistic regression analyses, and specifically a backwards stepwise elimination procedure, were used to determine the relationships between baseline clinical risk factors and subsequent cardiac events. **Results:** The median age was 53 years (range 18-86), and 77% were non-Hispanic white and 81% female. At baseline, there was a high prevalence of CV risk factors including hypertension (21%), diabetes (13%), hyperlipidemia (25%), and tobacco use (39%). During follow-up, 11% of the participants experienced at least 1 cardiac event, primarily being LVD or HF. In multivariable analyses, the strongest predictors of subsequent cardiotoxicity were: number of CV risk factors at baseline (Odds Ratio [OR] 1.3, 95% CI 1.1-1.5, p=0.01); cancer type (OR 1.7, 95% CI 0.9-3.1, p = 0.10 for lymphoma compared to breast; OR 2.8, 95% CI 1.2-6.3, p=0.02 for other compared to breast); and a baseline BNP>100 pg/ml (OR 2.6, 95% CI 0.99-6.8, p=0.05). **Conclusions:** In a large, prospective community-based cohort, the number of CV risk factors, cancer type, and a baseline BNP>100 pg/ml were associated with cardiotoxicity. The significance of these predictors according to anthracycline dose and the potential differences according to sex remain to be further elucidated.

**9625 General Poster Session (Board #275), Sun, 8:00 AM-11:45 AM**

**Outcomes of early palliative care referrals for patients with advanced lung cancer.** *Presenting Author: Sriram Yennurajalingam, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background**: Despite previous studies showing benefits of early referral to palliative care in improving quality cancer care, late referral and underutilization are major concerns. The aim of this study was to determine the impact of early palliative medicine specialist referral (EPC) on quality cancer care outcomes in advanced lung cancer pts at a comprehensive cancer center. **Methods**: In this prospective non-randomized controlled study, pts with advanced non-small cell lung cancer with oncologist estimated survival of ≤ 6 months were referred to EPC, N=51. A control group of similar characteristics were recruited from pts with regular follow-up at the thoracic oncology clinic [standard oncology care,UC], N=52. Descriptive statistics and Wilcoxon rank sum tests were used to describe change in FACT-lung, Edmonton Symptom Assessment Scale(ESAS)-symptom distress scores and Hospital Anxiety and Depression Scale(HADS) at follow-up visit. **Results**: The median age was 61yrs; 52% were female. There was no difference in age, gender, race (p>0.1) at baseline between the two groups, but the EPC pts had a higher symptom burden (EPC 30.5 vs. UC 11.0 p=.001). At follow-up EPC pts had significant improvement in symptoms scores. EPC pts also were more likely to have improved QOL and EOL discussions (Table). **Conclusions**: EPC was associated with improved symptom distress scores and improved health utilization outcomes, although baseline symptom distress scores were worse in EPC at time of referral.

**Change in the symptom scores at follow-up and quality-care outcomes in UC and EPC.**

**Mortality from malignant bowel obstruction in hospitalized U.S. cancer patients.** *Presenting Author: Olatunji Boladale Alese, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Malignant bowel obstruction (MBO) affects an estimated 3 - 15% of cancer patients globally, with a mean survival rate no longer than 4 weeks in inoperable MBO. We assessed predictors of survival and the influence of treatment modality in hospitalized MBO patients in the US. **Methods:** Data were obtained from all US states that contributed to the Nationwide Inpatient Sample (NIS) by Agency for Health Care Research and Quality in 2006 and 2010. MBO diagnoses and treatment variables were identified using Clinical Classification Software code based on ICD9 and CPT codes. Univariate and multivariate analyses were performed with a logistic model, weighted chi-square test, and a generalized linear model with the use of generalized estimated equation. Initial analysis in the 2006 NIS data was validated in the 2010 NIS data. **Results:** 942,014 and 1,103,528 eligible MBO patients were identified in 2006 and 2010 respectively. The in-hospital mortality was 24.5% in 2006, decreasing to 21.4% by 2010. The commonest concurrent condition was chronic lung disease (20.4%). Medical management (vs. surgical management), health insurance coverage, and obesity were significantly associated with better hospital survival in MBO patients. Adjusted analysis showed significantly increased odds of death with male gender, older age, stage IV disease, multiple co-morbid conditions (except obesity and AIDS) and weight loss. **Conclusions:** Lack of insurance coverage, weight loss and surgical management are associated with higher mortality in hospitalized MBO patients.

**Multivariable analysis of in-hospital mortality in 2010 (with covariates found significant in 2006).**

**Predicting the risk of gastrointestinal (GI) toxicity in early colon cancer (CC) patients treated with adjuvant chemotherapy: Developing a GI toxicity scoring system.** *Presenting Author: Gillian Gresham, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** Baseline demographics and clinical factors may contribute to a patient's overall risk for developing chemotherapy-related GI toxicity, such as nausea, vomiting, and diarrhea. We aimed to develop a simple GI toxicity scoring system to better stratify early CC patients who may be at higher risk of developing GI toxicity from adjuvant FOLFOX chemotherapy. **Methods:** Patients diagnosed with early CC from 2005 to 2008 and treated with FOLFOX at any 1 of 5 regional cancer centers in British Columbia were reviewed. GI toxicities of interest included: (1) nausea/vomiting, (2) diarrhea, and (3) any GI side effects. Baseline variables that were analyzed consisted of age, sex, ECOG, time to adjuvant chemotherapy (TTAC) and laboratory parameters. Stepwise regression was used to develop a multivariate model for each toxicity and a weighted risk scoring system was subsequently devised based on the magnitude of the parameter estimates in the multivariate model. **Results:** In total, 475 pts were included: median age was 62 years (range 26-89), 16% were aged >70 years, and 55% were men. The majority (90%) was ECOG 0/1. Independent predictors for nausea/vomiting included age >70 years (OR 2.46, 95%CI 1.3-4.8, p=0.01), GFR <50 (OR 1.68, 95% CI 1.1-2.7, p=0.02), and TTAC >8 weeks (OR 1.33, 95% CI 0.9-2.1, p=0.14) whereas independent predictors for diarrhea included age >70 years (OR 1.44, 95% CI 0.79-2.62, p=0.12) and GFR <50 (OR 1.67, 95% CI 1.1-2.6, p=0.02). The multivariate model for the risk of any GI toxicity included age >70 years (OR: 2.61, 95% CI 1.1-6.1, p=0.04), GFR <50 (OR 1.69, 95% CI 1.1-2.6, p=0.004), and TTAC >8 weeks (OR 1.79, 95% CI 1.2-2.7, p=0.006). Points were assigned: 2 points for long TTAC and poor GFR and 1 point for advanced age. The study cohort was classified into their risk groups based on their score (Table). **Conclusions:** We developed a simple 5-point scoring system to stratify early CC pts receiving adjuvant FOLFOX into low and high risk groups for GI toxicity based on baseline clinical factors. Validation of this scoring system is currently underway.

| **Risk group** | **Risk (%) of any GI toxicity** | **P value** |
|---|---|---|
| **Low risk (0-2 points)** | 44.7 | 0.0075 |
| **High risk (3-5 points)** | 59.4 | |

**9628 General Poster Session (Board #278), Sun, 8:00 AM-11:45 AM**

**Randomized phase II pilot study of loratadine for the prevention of bone pain caused by pegfilgrastim.** *Presenting Author: Julia Moukharskaya, College of Medicine, Fletcher Allen Health Care, University of Vermont, Burlington, VT*

**Background:** Bone pain is a common side-effect of pegfilgrastim and can interfere with a patient's quality of life and treatment adherence. Antihistamine therapy may have analgesic activity in such patients. This study was designed to investigate the impact of antihistamine loratadine prophylaxis on pegfilgrastim-induced bone pain (PIP). **Methods:** This is a two stage trial design with the first stage identifying eligible patients who developed significant clinical PIP after receiving an initial dose of pegfilgrastim (6 mg SC) in the chemotherapy setting, and the second stage representing a randomized trial of a 7-day course of loratadine 10 mg daily or placebo starting on day 1 of pegfilgrastim administration. Significant PIP, assessed by Worst Pain Scale (0-10) of the Brief Pain Inventory, was defined as worst pain score >5 and a 2 point increase during the 7 days after pegfilgrastim. The primary end-point of the study was reduction of significant PIP with loratadine, defined as 2 point decrease in worst PIP between treatment and observation stages. Rescue use of other analgesics was allowed. Target sample size was based on the following assumptions: 30% incidence of significant pain, 10% benefit with placebo, 50 % benefit with loratadine, 89% power (chi-square test, 2-sided alpha=0.05) , and stratification by taxane use. **Results:** A total of 227 patients were enrolled in the observation stage, of whom 213 were included in the final analysis. Incidence of significant PIP was 30.5%. 45 patients with breast, lung and GI malignancy entered the randomization stage, male/female 11 /34, median age 56 (range 31-89). Gender, age, malignancy type, taxane use, and additional use of rescue NSAIDS and non-NSAIDS were all comparably distributed in loratadine vs. placebo groups (p=0.58). The rate of improvement in the significant PIP was 59.1% for loratadine arm and 54.5% for placebo arm (p=1.0). Results were unchanged after adjustment for rescue analgesic use or taxane therapy. **Conclusions:** Administration of prophylactic loratadine does not decrease the incidence of significant PIP. Clinical trial information: NCT01311336.

**9629 General Poster Session (Board #279), Sun, 8:00 AM-11:45 AM**

**The effects of oncologists' physical activity recommendations and information packages on level of physical activity and the quality of life in cancer survivors.** *Presenting Author: Ji-Hye Park, Yonsei University, Seoul, South Korea*

**Background:** Physical activity participation has been associated with reduced cancer-specific and all-cause mortality in breast and colorectal cancer survivors. The purpose of this study was to examine the effects of oncologists' recommendations of physical activity with and without information packages on physical activity on the amount of physical activity and quality of life in cancer survivors. **Methods:** A total of 161 stage I~III breast and colorectal cancer survivors, who were 52.08±8.21 years old were recruited for this study. They were assigned to one of three groups: 1) control group, 2) oncologists' recommendations for physical activity group, and 3) oncologists' recommendations for physical activity combined with information packages group. At baseline and after 4 weeks, the level of physical activity was measured using the Godin Leisure-Time Exercise Questionnaire. Quality of life, including self-reported physical function, was measured with the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30. **Results:** Out of 161 participants, 130 participants completed the trial (78.8%). Our study found that participants who received oncologists' physical activity recommendations with information packages significantly increased their levels of physical activity compared with the control group (pre: 9.91±7.75 vs. post: 14.21±11.89 Metabolic Equivalent of Task (MET) hours per week, p<0.01).Participants who only received oncologists' physical activity recommendations did not increase their physical activity levels. Furthermore, the pain levels of participants who received physical activity recommendations with information packages were significantly reduced after 4 weeks compared with those of the control group. **Conclusions:** It is important to provide physical activity information packages in addition to oncologists' recommendations in order to increase levels of physical activity among breast and colorectal cancer survivors. This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education(2013R1A1A2005986).

**9630 General Poster Session (Board #280), Sun, 8:00 AM-11:45 AM**

**Effects of a 12-week home-based exercise program on quality of life, psychological health, and the level of physical activity in colorectal cancer survivors.** *Presenting Author: Ji Young Kim, Yonsei University, Seoul, South Korea*

**Background:** Although the importance of physical activity (PA) and exercise has been recognized, there are few randomized controlled trials which investigated the effects of exercise on psychological health of colorectal cancer survivors. Therefore, the purpose of this study is to examine the effects of home-based exercise program on quality of life (QOL), psychological health, and the level of PA in colorectal cancer survivors. **Methods:** One hundred twenty three colorectal cancer survivors were randomized into either home-based exercise (Intervention) group or control group. The home-based exercise program included unsupervised walking, stationary bike, or swimming for aerobic exercise and providence of resistance exercise DVD, pedometer, and exercise logs. QOL was measured by the Functional Assessment of Cancer Therapy - Colorectal (FACT-C) scale. The 7 Day physical activity recall (PAR) was used to assess the level of physical activity. In addition, the Functional Assessment of Chronic Illness Therapy (FACIT) Fatigue scale and Patient Health Questionnaire (PHQ) were administered. All assessments were conducted at baseline and 12 week. **Results:** Ninety nine participants completed the trial (80.5%). Both QOL and fatigue improved in the intervention group (QOL *p*-value =.020; fatigue *p*-value =.022), while they did not change in the control group (QOL *p*-value =.395; fatigue *p*-value =.265). The change in QOL and fatigue between intervention and control group was not statistically. The level of PA was significantly increased at 12-week in the intervention group, and the change was significantly different from the control group (*p*-value=.004). **Conclusions:** The 12-week home-based exercise program improves the QOL and psychological health in colorectal cancer survivors. In addition, we have demonstrated that home-based exercise program was effective to increase level of physical activity in stage II–III colorectal cancer survivors. This study was supported by the National Research Foundation of Korea (2013K2A1A2054437) and the National R&D Program for Cancer Control, Ministry of Health and Welfare, Republic of Korea (1120230).

**9631 General Poster Session (Board #281), Sun, 8:00 AM-11:45 AM**

**PROCAPP: A randomized, open-label phase III trial comparing mapisal and urea hand-foot cream as prophylaxis for capecitabine-induced hand-foot skin reaction (HFSR) in patients (pts) with gastrointestinal (GI) tumors or breast cancer—A study of the AIO Quality of Life Working Group.** *Presenting Author: Deniz Gencer, University Hospital Mannheim, Mannheim, Germany*

**Background:** HFSR is a frequently occurring dermatologic reaction associated with capecitabine (CAPE). Thus far, no effective prophylaxis has been established, but urea-containing skin ointments are frequently used. Mapisal (medac, Wedel, Germany) is a topically applied ointment with high radical protection factor currently investigated as a prevention strategy against HFSR. It has shown preliminary activity as prophylaxis against HFSR in patients treated with pegylated liposomal doxorubicin. **Methods:** This randomized phase-III study compared treatment with Mapisal and an urea (10%) containing cream as prophylaxis for HFSR in pts with GI tumors or breast cancer treated with CAPE. The primary endpoint was prevention of HFSR of any grade within 6 weeks based on a standardized patient diary. Pts were randomized in a 1:1 ratio and stratified according to sex and CAPE dose. The study had 80% power to show an absolute 20% reduction of the incidence of overall grade HFSR with Mapisal (30% -> 10%) with a type I error of 5%. Herein, we report on the first preliminary data. Secondary endpoints were time to develope HFSR >grade 1, CAPE dose intensity, and QoI analyses (EORTC QIQ C30 & DLQI). **Results:** Between 05/12 and 09/13, 160 pts were enrolled. 152 pts are evaluable for the current analysis. Median age was 65 years, 96 pts were female (60.0%). 63 pts had breast cancer (41.4%), 89 pts had GI tumors. In total, 47 / 152 pts experienced HFSR (30.9%). 30 out of 77 pts (39.0%) receiving Mapisal experienced HFSR (grades 1/2/3 [%]: 66.7 / 26.7 / 6.7 of total events). In the urea arm, 17 out of 75 pts (22.7%) reported HFSR (grades 1/2/3 [%]: 52.9 / 41.2 / 5.9). Using Mantel-Haenszel chi-squared test the stratified common odds ratio was 2.365 (95%-CI 1.154 – 4.848; p=0.027). **Conclusions:** Mapisal failed to show superiority over an urea-containing cream as prophylaxis for CAPE-associated HFSR. The final analysis will be presented at the meeting. Studies on the use of Mapisal as prophylaxis of HFSR in patients receiving pegylated liposomal doxorubicin are ongoing. Clinical trial information: NCT01626781.

**9632 General Poster Session (Board #282), Sun, 8:00 AM-11:45 AM**

**Pegfilgrastim (P) administration after 24, 72, or 96 hours (h) to allow dose-dense (DD) anthracycline- and taxane-based chemotherapy (CT) in breast cancer (BC) patients (pts): A single-center experience within the GIM2 randomized phase III study.** *Presenting Author: Matteo Lambertini, Department of Medical Oncology, U.O. Oncologia Medica 2, IRCCS AOU San Martino-IST, Genova, Italy*

**Background:** The GIM2 study (ClinicalTrials.gov number, NCT00433420) compared two different schedules of CT (DD versus standard duration) as adjuvant treatment of 2,091 node positive BC pts. DD arms were supported by P scheduled 24 h after CT. P can induce early leukocytosis after its administration with the potential risk of capillary leak syndrome and spleen rupture. To evaluate the best timing of P administration, 3 different cohorts of pts enrolled in the GIM2 study and treated at the coordinating center received P 24 or 72 or 96 h after CT. **Methods:** 5 pts were planned to be enrolled in each cohort; pts in cohort A received P after 24 h, pts in cohort B after 72 h and pts in cohort C after 96 h. After the preliminary results, cohort A and B were expanded up to 9 and 21 pts. A complete blood count was obtained 24 h after P and every 2 days for each cycle thereafter. **Results:** Median values of white blood cell (WBC) counts for all anthracycline and taxane cycles are reported in the table. Pts in cohort A showed WBC and neutrophil (N) counts 24 h after P higher than pts in the other cohorts; pts treated with P after 96 h showed a high WBC and N counts at day 13 (i.e. the day before the following CT cycle). No differences in CT delays were observed between pts treated with P after 24 h or 72 h. On the basis of these findings, the protocol was amended and pts in the DD arms received P after 72 h. **Conclusions:** The best timing of P administration in DD regimens is 72 h after CT. Clinical trial information: NCT00433420.

**Phase 3 trial results for rolapitant, a novel NK-1 receptor antagonist, in the prevention of chemotherapy-induced nausea and vomiting (CINV) in subjects receiving moderately emetogenic chemotherapy (MEC).** *Presenting Author: Ian D. Schnadig, Compass Oncology and The US Oncology Network, Portland, OR*

**Background:** Rolapitant is a highly selective competitive long acting NK-1 receptor antagonist that demonstrated efficacy in a large randomized phase 2 dose-finding study. This study evaluated the 200 mg dose for efficacy and safety in the prevention of CINV in subjects receiving MEC. **Methods:** Randomized phase 3 double-blind active-control study. 1,369 chemonaïve patients treated with MEC (cyclophosphamide, doxorubicin, epirubicin, carboplatin, irinotecan, daunorubicin or cytarabine) were randomized 1:1 to either (1) rolapitant + granisetron + dexamethasone or (2) placebo + granisetron + dexamethasone. The primary endpoint was complete response (CR=no emesis and no rescue medication) in delayed phase (>24-120 hrs) post-chemo. Secondary endpoints included CR in acute (0-24 hrs) and overall (0-120 hrs) phases. Treatment comparisons were performed using Mantel-Haenszel chi-square test; to control for type 1 error testing for key secondary endpoints was conducted in a stepwise fashion. Subjects recorded episodes of emesis, nausea and rescue medication using a diary during 0-120 hrs post-chemo. **Results:** There were 1,344 evaluable patients (>50% received anthracycline-cyclophosphamide therapy). Subjects in rolapitant group had a significantly higher CR rate for the primary study endpoint during delayed phase compared to control (71.3% vs 61.6%, p<0.001, respectively). CR rates were also higher in rolapitant group for acute and overall phases (83.5% vs 80.3%, p=0.143; 68.6% vs 57.8%, p<0.001, respectively). The rolapitant group achieved higher rates of complete protection (no emesis, no rescue medication and maximum nausea VAS <25mm) in both delayed and overall phases compared to control (64.3% vs 56.9%, p=0.006; 62.0% vs 53.2%, p=0.001, respectively). AE rates were similar across both groups. **Conclusions:** Rolapitant in combination with a 5-HT3 receptor antagonist and dexamethasone was well-tolerated and demonstrated superior efficacy over control in the primary endpoint of the prevention of delayed CINV in subjects receiving MEC in a global phase 3 study. Clinical trial information: NCT01500226.

**9634 General Poster Session (Board #284), Sun, 8:00 AM-11:45 AM**

**Risk of severe diarrhea associated with ipilimumab in cancer patients.** *Presenting Author: Robert Charles Hendler, Stony Brook University Hospital, Stony Brook, NY*

**Background:** Ipilimumab is a human cytotoxic T-lymphocyte antigen 4 (CTLA-4)-blocking antibody, which augments T-cell activation and proliferation and is thought to indirectly affect the T-cell mediated anti-tumor immune response. It has been approved by the FDA for treatment of unresectable or metastatic melanoma, and several trials have also shown promising results regarding ipilimumab's role in the treatment of other types of cancer. Ipilimumab has been associated in some individual studies with an increased rate of diarrhea, a serious adverse event associated with morbidity and treatment discontinuation. However the overall incidence and risk of diarrhea to ipilimumab is unknown. **Objective:** To conduct a systematic review of relevant clinical trials, and perform a meta-analysis to determine risk of diarrhea with ipilimumab. **Methods:** Articles from PubMed from January 1998 to November 2013 and abstracts presented at the American Society of Clinical Oncology up to 2013 were searched to identify relevant studies. The incidence and relative risk (RR) of diarrhea and its 95% Confidence Intervals were calculated using random effects or fixed effects models depending on the heterogeneity of included studies. **Results:** There were a total of 1571 patients across 10 clinical trials included in this meta-analysis. The overall incidence of all-grade diarrhea was 41.6% (95% CI: 33.6-50.0%). The overall incidence of high-grade diarrhea was 8.4% (95% CI: 5.5-12.7%). In comparison with controls, ipilimumab significantly increased the risk of all-grade diarrhea with an RR of 1.63 (95% CI: 1.37-1.97, P<0.001) and high-grade diarrhea with an RR of 2.19 (95% CI: 1.11-4.34, P=0.025). **Conclusions:** There was a significant risk of severe diarrhea in cancer patients treated with ipilimumab.

**9635 General Poster Session (Board #285), Sun, 8:00 AM-11:45 AM**

**Frequency, intensity, and correlates of financial distress (FD) among advanced cancer patients (AdCa).** *Presenting Author: Marvin Omar Delgado-Guay, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Financial problems are frequent and severe for AdCa. There is limited data on the effects of FD on suffering and quality of life(QOL) of AdCa. In this prospective cross sectional study, we examined the frequency of FD and its correlates in AdCa. **Methods:** We interviewed 149 AdCa, 77 at a Comprehensive Cancer Center(CCC) and 72 at a General Public Hospital-(GPH). AdCa completed self-rated FD(subjective experience of distress attributed to financial problems) numeric rating scale(0=best, 10=worst) and also validated questionnaires assessing symptoms(ESAS), psychosocial distress(HADS), and QOL(FACT-G). **Results:** Median age (Interquartile range:IQR): 60 years(55-65). 74/149(50%) were female. 78/149(52%) were married. 48/77 (62%) at CCC vs. 13/72(18%) at GPH were white (p<0.0001); 21/77(27%) vs. 32/72(38%) were African American(p<0.0001), and 7/77(9%) vs. 27/72(38%) were Hispanics(p<0.0001). 44/77(58%) at CCC vs. 14/72(19%) at GPH had college education and an advanced degree(p<0.0001). The median(IQR) current income was $3,000($1,400-$7,000) for CCC vs. $940($350-$1,300) at GPH, p=0.0017. 72(51%) AdCa self-reported as middle class before cancer diagnosis vs. 52(39%) at the time of the evaluation(p<0.0001). FD was present in 65/75[86% (95%CI=76-93%)] at CCC vs. 65/72[90% (81-96%)] p=0.45. However the median intensity of FD(IQR) at CCC was 4(1-7) vs. 8(3-10), p=0.0003. AdCa reported that FD was affecting their general well-being(0=not at all, 10=very much) with a median(IQR) of 5(1-8). FD was reported as more severe than physical distress, distress about physical functioning, social/family distress and emotional distress by 45(31%), 46(32%), 64(43%), and 55(37%) AdCa respectively (all significantly worse for GPH). Spearman Correlation of FD with financial burden r=0.53, p<0.0001; FACT-G r=-0.23, p=0.005; HADS-Anxiety r=0.27, p=0.001; ESAS-Anxiety r=0.2, p=0.01; and ESAS-depression r=0.18 p=0.03. **Conclusions:** FD was very frequent in both groups but intensity was double among GPH patients. FD was associated with worse anxiety, depression and poor QOL. More research is warranted to confirm these associations and establish interventions to improve this aspect of the care of AdCa.

**9636 General Poster Session (Board #286), Sun, 8:00 AM-11:45 AM**

**Safety of rolapitant, a novel NK-1 receptor antagonist, for the prevention of chemotherapy-induced nausea and vomiting (CINV) in patients receiving moderately or highly emetogenic chemotherapy (MEC or HEC).** *Presenting Author: Laszlo Urban, Matrahaza Healthcare Center and University Teaching Hospital, Matrahaza, Hungary*

**Background:** Rolapitant is a highly selective competitive long acting NK-1 receptor antagonist that successfully achieved the primary endpoint of complete response (no emesis and no rescue medication) in the delayed phase of CINV in two phase 3 studies in subjects receiving MEC or HEC. In addition, these studies evaluated the safety and tolerability of rolapitant in these subjects. **Methods:** Two separate phase 3 double-blind active control studies were conducted. 1369 subjects scheduled to receive MEC (cyclophosphamide, doxorubicin, epirubicin, carboplatin, ifosfamide, irinotecan, daunorubicin or cytarabine), and 555 subjects scheduled to receive HEC ($\geq$60 mg/m$^2$ cisplatin) were randomized 1:1 to either (1) rolapitant 200 mg + granisetron + dexamethasone or (2) placebo + granisetron + dexamethasone. Adverse events (AE) and serious adverse events (SAE) were collected for all subjects. **Results:** AE rates in cycle 1 were similar across rolapitant and control groups for both the MEC and HEC studies (63.9% vs 66.0%; 64.7% vs 60.2%, respectively). The most frequent AEs observed across both the rolapitant and control groups, respectively, for the MEC study were fatigue (16.3% vs 15.4%), constipation (10.3% vs 14.1%) and alopecia (11.3% vs 12.3%); and for the HEC study were constipation (7.4% vs 10.9%), asthenia (6.6% vs 11.3%) and neutropenia (9.9% vs 6.9%). SAEs rates in cycle 1 were also similar across rolapitant and control groups for both the MEC and HEC studies (6.6% vs 7.1%; 12.5% vs 14.2%, respectively). The most frequent SAEs across both the rolapitant and control groups, respectively, for the MEC study were febrile neutropenia (1.2% vs 2.1%), neutropenia (0.3% vs 0.9%) and neutrophil count decrease (0.3% vs 0.6%); and for the HEC study febrile neutropenia (0.7% vs 1.1%), neutropenia (0.7% vs 1.1%) and thrombocytopenia (1.1% vs 0.7%). No serious, related and unexpected AEs were reported for either study. **Conclusions:** Rolapitant 200 mg in combination with a 5-HT3 receptor antagonist and dexamethasone was demonstrated to be safe and well tolerated in two global phase 3 studies in subjects receiving HEC or MEC. Clinical trial information: NCT01500226.

**9637 General Poster Session (Board #287), Sun, 8:00 AM-11:45 AM**

**Symptoms in gastrointestinal stromal tumors.** *Presenting Author: Loretta A. Williams, Department of Sarcoma Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** A major barrier to effective symptom management in gastrointestinal stromal tumors (GIST) is lack of recognition of the symptom burden of the disease and treatment. Symptom burden is the combined impact of disease- and treatment-related symptoms on daily functioning. Our aim was to describe the symptom burden of patients with GIST. **Methods:** After giving IRB-approved informed consent, 150 patients with GIST completed the 20 symptom severity and 6 interference items of the MD Anderson Symptom Inventory for GIST (MDASI-GIST) at least every 2 weeks for 1 year. Symptoms and interference were rated on 0-10 scales (0 = none or no interference, 10 = worst imaginable or complete interference). Patients also answered a single overall quality-of-life (QOL) question every 3 months. Demographic and disease information was collected on all patients. Trajectory analysis determined higher and lower symptom groups. Mixed modeling identified factors predictive of symptom burden. **Results:** Mean subject age was 59.2 years (standard deviation [sd] = 11.7). 51% (77) of the subjects were female, 83% (124) were white, 47% (70) were employed. Subjects had been diagnosed for an average of 48.3 months (sd = 63.2) and 52% (78) were receiving imatinib. Mean overall QOL rating was 7.7 (best = 10, sd = 2.4). Symptoms reported as most severe over the course of the year were fatigue (mean [M] = 2.95, sd = 2.60), drowsiness (M = 2.30, sd = 2.38), general weakness (M = 2.18, sd = 2.40), disturbed sleep (M = 2.16, sd = 2.46), and muscle soreness/cramping (M = 2.06, sd = 2.41). The mean severity of the 5 most severe symptoms, the interference items, and QOL were all significantly correlated (all $P < 0.001$). 36.5% of patients were in the higher symptom trajectory group. Younger age, having a primary diagnosis of gastric GIST, and not currently receiving imatinib were predictive of higher symptom burden. **Conclusions:** Approximately 1/3 of patients with GIST experience higher symptom burden primarily related to fatigue, sleep difficulty, weakness, and muscle discomfort. Higher symptom burden significantly impacts QOL. Additional research is needed to identify effective methods of symptom management. Clinical trial information: NCT01178307.

**9638 General Poster Session (Board #288), Sun, 8:00 AM-11:45 AM**

**Phase 3 trial results for rolapitant, a novel NK-1 receptor antagonist, in the prevention of chemotherapy-induced nausea and vomiting (CINV) in subjects receiving highly emetogenic chemotherapy (HEC).** *Presenting Author: Bernardo Leon Rapoport, The Medical Oncology Center of Rosebank, Johannesburg, South Africa*

**Background:** Rolapitant is a highly selective competitive long acting NK-1 receptor antagonist that demonstrated efficacy and safety in a large randomized phase 2 dose-finding study. This study evaluated the 200 mg dose for efficacy and safety in the prevention of CINV in subjects receiving HEC. **Methods:** Randomized phase 3 double-blind active-control study. 555 cisplatin-naïve subjects treated with HEC ($\geq$60 mg/m$^2$ cisplatin) were randomized 1:1 to receive either (1) rolapitant + granisetron + dexamethasone or (2) placebo + granisetron + dexamethasone. The primary endpoint was complete response (CR=no emesis and no rescue medication) in the delayed phase (>24-120 hrs) post-chemotherapy. Secondary endpoints included CR during the acute (0-24 hrs) and overall (0-120 hrs) phases. Treatment comparisons were performed using a Mantel-Haenszel chi-square test; to control for the type1 error, testing for the key secondary endpoints was conducted in a stepwise fashion. Subjects recorded episodes of emesis, nausea and rescue medication using a subject diary during 0-120 hours post-chemotherapy. **Results:** There were 544 evaluable subjects. Subjects in the rolapitant group had a significantly higher CR rate for the primary study endpoint during the delayed phase (70.1% vs 61.9%, p=0.043) compared to control. CR rates were also higher in rolapitant group for acute and overall phases (83.4% vs 79.5%, p=0.233; 67.5% vs 60.4%, p=0.084, respectively). The rolapitant group achieved higher rates of no nausea (maximum Visual Analog scale <5mm, 0-100mm) in both the delayed and overall phases compared to control (58.3% vs 46.9%, p=0.007; 55.0% vs 44.0%, p=0.009, respectively). AE rates were similar across both groups. **Conclusions:** Rolapitant in combination with a 5-HT3 receptor antagonist and dexamethasone was well-tolerated and demonstrated superior efficacy over control in the primary endpoint of the prevention of delayed CINV in subjects receiving HEC in a global phase 3 study. Clinical trial information: NCT01500213.

**9639 General Poster Session (Board #289), Sun, 8:00 AM-11:45 AM**

**Effect of baseline characteristics, including antihypertensive therapy, on survival and hypertension during treatment with vascular endothelial growth factor (VEGF) signaling pathway inhibitors (VSP-Is).** *Presenting Author: Ole-Petter Riksfjord Hamnvik, Brigham and Women's Hospital, Boston, MA*

**Background**: Oral VSP-Is are associated with a significant risk of hypertension (HTN), yet little is known regarding clinical predictors. We describe the association between baseline clinical characteristics, including antihypertensive (antiHTN) therapy, and increased blood pressure (BP) and survival in patients prescribed VSP-Is. **Methods:** Clinical data was obtained from1120 adults prescribed VSP-Is, identified from electronic medical records (Partners HealthCare, Boston, MA). The primary outcome was worsening HTN (BP$\geq$160/100 mmHg on $\geq$1 occasion or requiring intensification of antiHTN therapy) in patients with pre-existing HTN, or the development of new HTN in patients with no prior history. **Results:** The most common cancers wererenal cell (32.2%), hepatocellular (11.6%), GIST (12.5%), and other sarcomas (15.3%). Most patients received sunitinib (52%), sorafenib (25.9%) or pazopanib (18%). Pre-existing HTN was present in 65.4%. The primary BP outcome was identified in 49.9% (median follow-up 4.3 months). In a fully adjusted Cox model, risk factors for the BP outcome were increasing age (hazard ratio (HR) 1.01, 95% confidence interval (CI) 1.006-1.021), BMI (HR 1.02, 95%CI 1.01-1.03) and pre-existing HTN (HR 1.70, 95%CI 1.32-2.20), whereas tumor type, VSP-I prescribed, race and gender were not. The absolute BP increase was similar in patients with and without pre-existing HTN (21/15 mmHg). Improved survival was seen in patients who developed the BP outcome (11.1 months) vs. those who did not (4.2 months; HR 0.51, 95%CI 0.43-0.60). Patients taking angiotensin system inhibitors (ASIs) at baseline had improved survival vs. other antiHTN agents (HR 0.81, 95%CI 0.65-0.998, median survival 7.5 vs. 5.8 months). **Conclusions:** Pre-existing HTN is a risk factor for worsening HTN during therapy with VSP-Is, likely due to a higher baseline BP. Adequate BP control prior to VSP-I initiation may mitigate the risk. While the class of baseline antiHTN agents did not change the risk of worsened BP control, our finding that ASIs are associated with improved survival in patients starting VSP-Is warrants further study.

**9640 General Poster Session (Board #290), Sun, 8:00 AM-11:45 AM**

**Survival benefit with low-molecular-weight heparin in patients with advanced solid tumors: A post hoc analysis of PROTECHT trial.** *Presenting Author: Sandro Barni, Department of Medical Oncology, Treviglio and Caravaggio Hospital, Treviglio, Italy*

**Background:** Use of low molecular weight heparin (LMWH) are approved to reduce the thromboembolic events in patients with solid tumors. The effect of LMWH on overall survival (OS) has been debated but not demonstrated, and current guidelines recommend against its use to increase OS. We have conducted a post hoc analysis of PROTECHT (PROphylaxis of ThromboEmbolism during CHemoTherapy) randomized study that compared nadroparin to placebo in patients with metastatic or locally advanced solid tumors. **Methods:** In our post-hoc analysis, individual patient data (n=1,150) was reviewed and analyzed to assess response to chemotherapy and overall survival. Tumor response to chemotherapy was assessed using Response Evaluation Criteria in Solid Tumors. Survival analysis was performed through a Cox regression model with treatment, response to chemotherapy and their interaction term (treatment-by- response to chemotherapy) as covariates. A statistically significant interaction indicates that an overall comparison between the two treatments is inappropriate, and therefore hazard ratios (HRs) with associated 95% CI and p-values must be evaluated separately in each group (disease control / no disease control). **Results:** A statistically significant interaction between treatment and response to chemotherapy (P=0.0435) was found, suggesting the hypothesis that OS treatment difference depends on the response to chemotherapy. A statistically significant difference in OS in favour of nadroparin treatment was found in the subgroup of patients with disease control (HR=0.665 [95%CI 0.442 - 1.00], P=0.05), but not in the subgroup of patients without disease control (HR=1.077 [95%CI 0.857 - 1.35], P=0.525). In patients with disease control, 1-year survival rate was 83% [95%CI 79% - 87%] in nadroparin and 76% [95%CI 70% - 83%] in placebo respectively; conversely in patients without disease control 1-year OS was 49% [95%CI 44% - 53%] in nadroparin and 51% [95%CI 45% - 58%] in placebo. **Conclusions:** this post hoc analysis support the hypothesis that LMWH could increase survival albeit limited to patients responding to chemotherapy. Clinical trial information: NCT 00951574.

**9641^ General Poster Session (Board #291), Sun, 8:00 AM-11:45 AM**

**A randomized double-blind phase III pivotal study of febuxostat (FEB) versus allopurinol (ALL) in the prevention of tumor lysis syndrome (TLS): Florence study.** *Presenting Author: Michele Spina, National Cancer Institute, Aviano, Italy*

**Background:** Tumor lysis syndrome (TLS) is an oncologic emergency characterized especially by elevated serum uric acid (sUA). FEB is an orally administerd selective xanthine oxidase inhibitor to reduce sUA. **Methods:** This was a randomized, double blind phase III trial of FEB vs ALL in terms of control of sUA level and preservation of renal function in patients undergoing chemotherapy (CT) for hematologic malignancies at intermediate to high risk of TLS. Patients werestratified according to TLS risk and sUA level to FEB or ALL starting from 2 days prior CT and continued for 7-9 days. Assigned treatment was blinded, while daily dose level (low/standard/high containing ALL 200/300/600 mg or fixed FEB 120) was upon investigator's choice. Primary endpoints were sUA area under the curve (AUC $sUA_{1\text{-}8}$) and change in serum creatinine (sC) level both from baseline to Day 8, analyzed through ANCOVA including treatment and stratification factors as covariates. Secondary endpoints were response rate (sUA $\leq$ 7.5 mg/dL from CT start to Day 8), incidence of laboratory and clinical TLS and safety. The study was run in 79 sites in Europe and Brazil (NCT01724528). **Results:** 346 patients were included with similar baseline demographics in both groups. 82.1% of patients were at intermediate risk of TLS, 87.6% had a baseline sUA $\leq$ 7.5 mg/dl and 82.7% received standard dose level. Intention to treat (ITT) analysis: mean AUC $sUA_{1\text{-}8}$ (mgxh/dl) was significantly lower in FEB arm (514.0 $\pm$ 225.71 vs 708.0 $\pm$ 234.42; p $<$ .0001). No significant difference in mean sC change(%) occurred between FEB and ALL arms (-0.83 $\pm$ 26.98 vs -4.92 $\pm$ 16.70 respectively, p=0.0903). No significant difference was detected among secondary efficacy endpoints. Incidence of all adverse events (AEs) and related AEs was 67.6% vs 64.7% and 6.4% vs 6.4% in FEB and ALL arm, respectively. **Conclusions:** In this largest TLS prevention trial FEB proved to be significantly superior over ALL with a 28% lower exposure to sUA during CT. As no dose adjustment of FEB in patients with preexisting mild or moderate renal impairment is necessary makes FEB a preferable preventive measure of TLS. Clinical trial information: NCT01724528.

**9642 General Poster Session (Board #292), Sun, 8:00 AM-11:45 AM**

**Quality of life (QOL), mood, and prognostic awareness during hospitalization for hematopoietic stem cell transplantation (HSCT).** *Presenting Author: Areej El-Jawahri, Massachusetts General Hospital, Boston, MA*

**Background:** During HSCT, patients endure significant side effects in the hopes of curing their disease. While many studies have focused on the long-term outcomes of HSCT recipients, the acute impact of hospitalization for HSCT on patients' QOL and mood is unknown. Furthermore, data on patients' perception of their prognosis are lacking. **Methods:** We conducted a prospective longitudinal study of patients hospitalized at Massachusetts General Hospital for HSCT. At baseline and weeks 1, 2, and 3 of hospitalization, we assessed QOL (Functional Assessment of Cancer Therapy- Bone Marrow Transplantation [FACT-BMT]; higher scores indicate better QOL), fatigue (FACT-Fatigue; high scores indicate less fatigue), and mood (Hospital Anxiety and Depression Scale score $>$ 7 on anxiety or depression subscale considered clinically significant). Using a 10-item questionnaire, we measured patients' information preferences, and perception of their prognosis. **Results:** We enrolled 60 consecutive patients undergoing autologous (n=30), or myeloablative allogeneic (n=30) HSCT. Patients' QOL declined and fatigued increased throughout hospitalization [Table 1]. The proportion of patients with depression symptoms increased from baseline to week 3 (18.3% to 33.3%, p=0.002) whereas the proportion of patients with anxiety did not change significantly from baseline (22.6%, p=0.7). Although 90.0% of patients stated that it is 'extremely' or 'very' important to know about their prognosis, 86.2% reported inaccurate and overly optimistic perception of their prognosis compared to their physicians (p $<$ 0.0001). **Conclusions:** Patients undergoing HSCT report an overly optimistic perception of their prognosis and experience significant decline in QOL with increasing rates of depression throughout their hospitalization. Interventions to improve QOL, psychological outcomes, and prognostic awareness of patients hospitalized for HSCT are warranted.

| Outcome | Type HSCT | Week-1 | Week-2 | Week-3 | P-Value |
|---|---|---|---|---|---|

**9643 General Poster Session (Board #293), Sun, 8:00 AM-11:45 AM**

**Treating diabetic patients with chemotherapy: Single-center experience of toxicity and outcomes.** *Presenting Author: Jenny F. Seligmann, St. James's Institute of Oncology, Leeds, United Kingdom*

**Background:** Epidemiological evidence suggests diabetics are at increased risk of several cancers, with inferior cancer outcomes. There is little data to describe the experience of diabetic patients during chemotherapy. We have compared outcomes of diabetic patient(pts) with non-diabetics receiving palliative chemotherapy for advanced colorectal cancer (aCRC) in a single centre. **Methods:** We performed a retrospective case note analysis between 2004 and 2011. Diabetic pts starting first line chemotherapy for aCRC were identified using an electronic patient record database (Patient Pathway Manager) and chemotherapy prescription software (ChemoCare). Data for chemotherapy regimen, acute admissions, subsequent therapy and survival were compared, corrected for age, performance status (PS), comorbidity and initial regimen (single vs combination agent). **Results:** 146 diabetic pts and 730 controls were included. Median age was 66 years; 94% of diabetic pts had type 2 diabetes, 17% were receiving insulin. Performance status was similar (PS 0-1in 76% in diabetics vs 77% controls); more diabetic pts had comorbidity (61% vs 25%). Diabetics received less upfront combination chemotherapy (OR = 0.41, 95% CI=0.29-0.65, p$<$0.001). Only 5% of diabetic pts had upfront steroid reduction. Diabetes was associated with an increased risk of acute admission (OR=2.35, 95%CI 1.6-3.45, p$<$0.0001). A higher incidence of infective episodes requiring hospitalisation were observed in diabetics (OR = 3.79, 95% CI 2.25-6.38, p$<$0.001). No other factors predicted for increased risk of admission. Poor glycaemic control led to admission in 6.9% of diabetics. Subsequent treatment with second line chemotherapy (p=0.87) and overall survival (p=0.21) was similar in both groups. Increased age and poor PS were independently prognostic for survival. **Conclusions:** Diabetic pts with aCRC achieved the same survival with palliative chemotherapy as non-diabetic patients. However diabetic pts receiving chemotherapy have over double the risk of an acute admission during treatment, despite reduced use of combination chemotherapy. Awareness of this risk and consideration of potential contributing factors may enable these episodes to be avoided.

**9644 General Poster Session (Board #294), Sun, 8:00 AM-11:45 AM**

**Prediction and early detection of anthracycline-related cardiotoxicity using cardiac biomarkers.** *Presenting Author: Patrick Lawson Stevens, Vanderbilt University Medical Center, Nashville, TN*

**Background:** Anthracyclines (ANTH) are widely used as cancer therapies but carry a significant risk of heart failure (HF) and left ventricular dysfunction (LVD). Improved cardiovascular (CV) risk stratification is necessary to decrease the growing incidence of CV and oncologic morbidity during ANTH chemotherapy. The overall objective of this study was to define the utility of cardiac biomarkers, B-type natriuretic peptide (BNP) and Troponin I (TnI) in the identification of subsequent ANTH cardiotoxicity. **Methods:** The PREDICT study was a multicenter, prospective cohort of 586 patients initiating ANTH chemotherapy. Patients underwent serial biomarker evaluation at baseline, before each chemotherapy cycle, and at 6 and 12 months. Echocardiography was performed at baseline, 6 months, and 12 months, or for suspected CV events. CV events were defined as symptomatic HF, asymptomatic LVD, acute coronary syndrome, symptomatic arrhythmia, or cardiac death. **Results:** At baseline, the median BNP was 17pg/ml (range 0.5-188pg/ml) and 95% of participants had a TnI <0.05ng/ml. At baseline or during chemotherapy or follow-up, 17% had a BNP >100pg/ml and 41% had a TnI>0.05ng/ml. Overall, 63 patients (11%) suffered a CV event. In univariate analysis, a baseline BNP >100 pg/ml was associated with cardiotoxicity (OR 3.6, 95% CI 1.4-9.0, p=0.007) as was an elevated BNP >100 pg/ml at any time during or after therapy (OR 3.2, 95% CI 1.8-5.6, p<0.0001). Elevations in TnI at baseline or during therapy or follow-up were not associated with cardiotoxicity (p=0.52; 0.98, respectively). BNP demonstrated a high specificity and negative predictive value (Table), whereas TnI had less discriminative ability. **Conclusions:** Elevations in BNP were significantly associated with cardiotoxicity in patients undergoing ANTH chemotherapy and appeared superior to TnI. Cardiac biomarker assessment in addition to other clinical factors may assist in the identification of ANTH cardiotoxicity. Clinical trial information: NCT01311843.

**Diagnostic performance of BNP and TnI in predicting cardiac events.**

| Marker | Sensitivity (95% CI) | | Specificity (95% CI) | | PPV (95% CI) | | NPV (95% CI) | |
|---|---|---|---|---|---|---|---|---|
| BNP > 100 pg/ml | 35 | (23, 48) | 85 | (81, 88) | 22 | (14, 31) | 92 | (89, 94) |
| TnI > 0.05 ng/ml | 41 | (29, 54) | 59 | (54, 63) | 11 | (7, 15) | 89 | (85, 92) |

**9645 General Poster Session (Board #295), Sun, 8:00 AM-11:45 AM**

**Phase 3 trial of APF530 versus palonosetron (PALO) in preventing chemotherapy-induced nausea and vomiting (CINV): Efficacy in breast cancer patients (pts) receiving moderately (MEC) or highly (HEC) emetogenic chemotherapy.** *Presenting Author: Ralph V. Boccia, Center for Cancer and Blood Disorders, Bethesda, MD*

**Background:** APF530 provides controlled, sustained release of granisetron for preventing acute (0-24 h) and delayed (24-120 h) CINV. In a phase 3 trial measuring complete response (CR; no emesis or rescue medication), APF530 was noninferior to PALO in preventing acute and delayed CINV in MEC pts and acute CINV in HEC pts (defined by Hesketh, J Clin Oncol. 1997). We report data from 608 breast cancer pts in this trial. **Methods:** Pts receiving single-dose MEC or HEC were randomized to APF530 250 or 500 mg SC (granisetron 5 or 10 mg) or PALO 0.25 mg IV prior to cycle 1 (C1). In C2-4, PALO pts were randomized to APF530 250 or 500 mg; APF530 pts continued their C1 APF530 dose. Between-group comparisons used Fisher's exact test. **Results:** In C1, 78% of 423 MEC pts and 75% of 185 HEC pts received cyclophosphamide + doxorubicin or epirubicin. CRs with APF530 250 or 500 mg in C1 were not significantly different from those with PALO in preventing acute and delayed CINV with MEC or HEC (Table). There were no significant differences in within-cycle CRs between APF530 doses for acute and delayed CINV in MEC or HEC in C2-4. Both APF530 doses combined elicited high CRs during acute CINV in C2 (72%, 78%), C3 (75%, 84%), and C4 (82%, 85%) for MEC and HEC, respectively, trending toward higher CRs in later cycles. High CRs occurred in C2-4 during the delayed phase and overall risk period. **Conclusions:** APF530 has substantial activity in preventing CINV in first and subsequent cycles of chemotherapy in breast cancer pts receiving MEC or HEC. Clinical trial information: NCT00343460.

**Management approaches and outcomes of lung cancer patients hospitalized for malignant pleural effusions.** *Presenting Author: Madhusmita Behera, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background**: Malignant pleural effusion (MPE) in lung cancer is associated with significant morbidity and poor prognosis. There has been a significant lack of progress regarding the current and recommended management of MPE. We studied MPE management in a large cohort of hospitalized lung cancer patients (pts). **Methods**: We utilized nationwide inpatient data from 2008-2010 from the Agency for Healthcare Research and Quality- Healthcare Cost and Utilization Project. All lung cancer pts with MPE among top 3 discharge diagnoses were selected. Therapeutic procedures used were identified using ICD 9-CM procedure codes. All analyses were performed using SPSS 20.0. **Results**: A total of 8570 pts, accounting for 2.5% of all lung cancer-related hospitalizations, had MPE (median age- 71 years, whites-66%, females- 48%, teaching hospitals-46%, urban locations-88%, elective admissions- 16%, median costs- $29,967). Median length of stay (LOS) was 5 days; mortality rate was 10.5% and 70% had major or extreme loss of function at discharge. Rural hospitals had a higher mortality compared to urban (14% vs. 10%, p=0.002). Thoracentesis(T), thoracostomy tubes(TT) and pleurodesis(P) were the top three procedures, with 48% having a T. Overall pneumothorax rate was 7.4%. There were significant differences in LOS and severity measures in pts sub-groups based on type of intervention (p<0.001). The TT group had higher mortality (Table). Univariate analyses showed significant difference in outcomes between elective and non-elective admissions in P group (p<0.001). **Conclusions**: Elective admissions for the management of MPE are associated with lower mortality and reduced loss of functional capacity over emergency hospitalizations. Pleurodesis is associated with longer length of stay, but lower mortality and better functional status at discharge.

**A phase II randomized, double-blind placebo-controlled trial of an antiemetic, 6-gingerol in solid tumor patients receiving moderately to highly emetogenic adjuvant chemotherapy.** *Presenting Author: Jitprapa Konmun, Ramathibodi Hospital, Bangkok, Thailand*

**Background:** Several studies showed that ginger powder could reduce chemotherapy-induced nausea and vomiting (CINV). 6-gingerol is a natural compound extracted from ginger. It has an antagonistic activity to NK1, serotonin, and dopamine receptors. **Methods:** Patients who received moderately to highly-emetogenic chemotherapy were randomized to 6-gingerol 10 mg or placebo PO BID continuously, started 3 days prior to chemotherapy and continued for 4 cycles. 5-HT3 receptor antagonist and dexamethasone were given to all patients. The Likert scale was used to evaluate severity of nausea and loss of appetite. Vomiting was graded according to the CTCAE v.4. Quality of life (QoL) was measured by the FACT-G score. All parameters were evaluated at baseline and before each cycle. Primary endpoints were severity of acute (≤24 hours after chemotherapy) and delay (>24 hours) CINV between 2 groups. **Results:** 87 patients (median age of 53) were enrolled. Patient characteristics were equally distributed between 2 groups. Most patients received anthracyclines (64%) and platinum-doublets (20%). 6-gingerol group had significantly less CINV, improved QoL and appetite, correlated with cytokine changes (see Table). **Conclusions:** 6-gingerol significantly reduces CINV, improves appetite and QoL. A larger clinical trial is warranted to confirm these results.

**9648 General Poster Session (Board #298), Sun, 8:00 AM-11:45 AM**

**A prospective, randomized, double-blind phase 3 trial of extended-release granisetron (APF530) versus palonosetron (PALO) for preventing chemotherapy-induced nausea and vomiting (CINV) associated with moderately (MEC) or highly (HEC) emetogenic chemotherapy: Does a reanalysis using newer ASCO emetogenicity criteria affect study conclusions?** *Presenting Author: Harry Raftopoulos, Hofstra North Shore-LIJ School of Medicine, Lake Success, NY*

**Background:** APF530 provides controlled sustained release of granisetron to prevent acute (0-24 h) and delayed (24-120 h) CINV. In a phase 3 trial in 1395 patients, single doses of subcutaneous (SC) APF530 250 and 500 mg were noninferior to intravenous (IV) PALO 0.25 mg in preventing acute CINV after MEC or HEC; APF530 500 mg was noninferior to PALO in preventing delayed CINV after MEC, but not superior in preventing delayed CINV after HEC (Grous et al. *J Clin Oncol* 2009, abs 9627). The primary efficacy endpoint was complete response (CR, no emesis or rescue medication). Chemotherapy emetogenicity was assigned by Hesketh criteria (Hesketh et al. *J Clin Oncol* 1997). However, ASCO reclassified some chemotherapy regimens in its 2011 antiemesis guidelines (Basch et al. *J Clin Oncol* 2011). **Methods:** Study data were reanalyzed with chemotherapy regimens reclassified as MEC or HEC using ASCO criteria. Noninferiority was shown if the CI difference in CR for APF530 – PALO had a lower confidence bound greater than −15%. **Results:** Using ASCO emetogenicity criteria (MEC = 609; HEC = 690), APF530 maintained noninferiority to PALO for all endpoints previously reported. The table shows CR rates by group, using ASCO criteria. **Conclusions:** Single-dose APF530 SC is an alternative to PALO for preventing acute and delayed CINV after MEC or HEC, with generally mild and manageable adverse events. In this post hoc analysis, reclassifying chemotherapy emetogenicity by ASCO criteria did not alter the initial study conclusions. Clinical trial information: NCT00343460.

**9649 General Poster Session (Board #299), Sun, 8:00 AM-11:45 AM**

**Sleep problems and increased risk of mortality in the context of advanced cancer.** *Presenting Author: Kevin P Collins, University of Pittsburgh, Pittsburgh, PA*

**Background:** Sleep problems have been linked to increased mortality in the general population. The prevalence of sleep problems in those diagnosed with cancer is even higher than the general population. The aims of the proposed study were to examine the type and prevalence sleep problems, and to determine whether sleep problems are associated with survival, in advanced cancer patients. **Methods**: The study was prospective in design. A total of 355 patients with advanced cancers (stage III and IV) affecting the hepatobiliary and pancreatic systems were administered a battery of questionnaires including the Pittsburgh Sleep Quality Index (PSQI) and the Center for Epidemiological Studies-Depression (CES-D) scale. Descriptive statistics, Mann Whitney U test, and Cox regression analyses were performed to test the aims. **Results:** The majority of patients were male (64%) and the mean age 62 years (SD=11). Fifty-nine percent of patients reported poor sleep quality (PSQI $>$ 5); 43% reported sleeping $<$6 hours and 2% $>$ 10 hours; 27% reported sleep latency greater than 30 minutes for 3 or more nights per week; 80% reported poor sleep efficiency (less than 85% time in bed spent sleeping); and 19% reported taking a sleep aid 3 or more times per week. Fifty-eight percent of patients reported clinically significant levels of depression (CES-D $>$16) and those with clinically significant depressive symptoms reported shorter sleep duration (median=6) than those without clinical levels of depression (median=7; p=$<$0.001). Median survival for the entire sample was 7.6 months. After adjusting for factors known to contribute to survival (i.e., age, gender, vascular invasion, depression, and snoring), a curvilinear relationship was observed between sleep duration and mortality (Chi-square=27.8, p=$<$0.001). **Conclusions:** Consistent with findings in the general population, a curvilinear relationship between sleep duration and mortality was observed in advanced cancer patients.

**9650 General Poster Session (Board #300), Sun, 8:00 AM-11:45 AM**

**Cancer patients and their information needs for prediction of symptom burden during and after treatment: Implications for symptom management.** *Presenting Author: Luke Joseph Peppone, Department of Surgery, University of Rochester Medical Center, Rochester, NY*

**Background:** Throughout and after treatment, cancer patients often face a high symptom burden (e.g. fatigue, pain, cognitive difficulties, etc.). A high symptom burden can reduce QOL and treatment adherence, potentially reducing survival. However, predicting the symptom burden in cancer patients remains challenging. **Methods:** Cancer patients scheduled to receive chemotherapy and/or radiation therapy were prospectively surveyed at pre-treatment (n=972), during treatment (n=748), and 6-month follow-up (n=652). At pre-treatment, patients indicated symptom concern (Low, Moderate, or High) and the desire for additional information (Yes, No) on relieving symptoms. During treatment and at 6-month follow-up, patients reported on the severity (an 11-point scale: 0 "None" to 10 = "Worst") of 12 symptoms (fatigue, hair loss, memory, nausea, depression, sleep, pain, concentration, hot flashes, weight loss, skin problems, and dyspnea). Total Symptom Score (TSS) is the sum of all 12 symptoms. Mean symptom severity by symptom concern and additional information desire were determined by ANCOVA analysis. **Results:** Symptom concern at pre-treatment predicted symptom severity during treatment (Table). Patients who wanted more information on symptoms management before also had a significantly greater TSS (Yes = 46.7 vs No = 39.4; p=0.02) during treatment. Patients with high concern at pre-treatment also had a significantly higher TSS 6 months after treatment (High = 24.5 vs Low = 21.1; p$<$0.05). **Conclusions:** Pre-treatment patient symptom concern and wanting more symptom management information predicted symptom burden during treatment and 6 months after treatment. Clinicians should consider using these questions as indicator to which patients may require additional symptom management care.

| | Low | Moderate | High | P |
|---|---|---|---|---|
| **Total symptom score (TSS)** | 37.9 | 39.7 | 44.9 | $<$0.001 |
| **Fatigue** | 5.5 | 5.8 | 6.1 | 0.044 |
| **Pain** | 3.4 | 3.2 | 3.9 | 0.030 |
| **Concentration** | 2.8 | 3.0 | 3.6 | 0.014 |
| **Memory** | 2.7 | 2.9 | 3.4 | 0.021 |

| **Nausea** | 2.3 | 3.2 | 3.7 | $<$0.001 |

*Adjusted for severity of the respective symptom at pre-treatment.

**9651 General Poster Session (Board #301), Sun, 8:00 AM-11:45 AM**

**Understanding of early-phase clinical trials among a cohort of advanced cancer patients with limited standard treatment options.** *Presenting Author: Daniel Paul Dohan, University of California, San Francisco, San Francisco, CA*

**Background:** Early phase (EP) trials are typically offered to ACP once they exhaust standard treatment options. Limited knowledge exists about what patients understand regarding EP trials as they approach the end of standard treatments. **Methods:** ACP were recruited from five clinics at an academic medical center with an EP trials program. Patients were eligible if treating oncologists deemed them likely to exhaust standard treatment in 6-12 months. Eligible patients completed a 60 minute qualitative interview. Clinical research was only discussed if patients raised it during the interview. Interviews were audio recorded and transcribed; Atlas.ti was used for thematic coding. **Results:** 82 patients were recruited; 60 mentioned clinical research. Thematic analysis showed that understanding of clinical research differed along two dimensions: Accuracy and Specificity. Some ACP accurately described research; others had inaccurate understandings. Patients described the research process with different degrees of specificity (see Table). **Conclusions:** ACP with limited standard treatment options had mixed understandings of clinical research. Improving ACP understanding before EP trials are discussed may be appropriate.

| | Accurate | Inaccurate |
|---|---|---|
| **Specific** | It is randomized in the fact that there are three different levels to it. So you have somebody that's going to get the highest dosage of both drugs, you're going to have a group that's going to get the lowest dosage and then you're going to have a third group that's going to take the [study drug]. | The [study drug] appears to have put a second roadblock to cell division and I think it was January that they started this phase. So it may be just a carry-on from the first one or it may be a new phase [I] of a new study . . . to determine the efficacy of the drug and how it affects the patients. |
| **General** | One of them's about ready to be whatever the last phase is. I think that's the one we're going with. It's about ready to be approved, FDA approved, so it must be on the later phases. | I am still in a double-blind study so nobody knows if I'm getting the drug, which is a bummer. If I was in a Phase III, I would know I'm getting it. |

**9652 General Poster Session (Board #302), Sun, 8:00 AM-11:45 AM**

**Nervous system sequelae of chemotherapy treatment: Associations and proposed mechanisms.** *Presenting Author: Kelly N. H. Nudelman, IUPUI, Indianapolis, IN*

**Background:** Breast cancer treatment with chemotherapy often results in neurotoxic sequelae including chemotherapy-induced peripheral neuropathy (CIPN) and cognitive dysfunction. Although CIPN and cognitive dysfunction are often viewed as separate phenomena, we hypothesized that these effects may be related. **Methods:** Breast cancer patients treated with (Ctx+, n=27) and without (Ctx-, n=26) chemotherapy and healthy controls (HC, n=26) were assayed post-surgery, pre-treatment and one month post-treatment. All but one Ctx+ treatment included paclitaxel or docetaxel. Peripheral neuropathy symptom severity (PNS) was evaluated with the sum of the self-reported FACT/GOG-Ntx 11-item scale, cerebral gray matter density (GMD) and perfusion were assessed using MRI, and cognitive complaints, depression, and fatigue were assessed with the Multiple Ability Self-Report Questionnaire (MASQ), the Center for Epidemiologic Studies Depression scale, and the Fatigue Symptom Inventory. **Results:** Chemotherapy treatment was associated with increased PNS and cognitive complaints ($p<0.01$), which remained significant after adjusting for fatigue and depression. PNS was associated with increased cerebral perfusion in the left anterior cingulate (LAC) gyrus, a region associated with pain processing. Interestingly, a previously published Ctx+ frontal GMD decrease in this cohort was correlated with the LAC perfusion change ($p<0.01$) and PNS change ($p<0.01$). Individuals with GMD decrease showed lower LAC perfusion and fewer PNS, while increased PNS were correlated with increased cognitive complaints ($p<0.05$) and depression and fatigue (both $p<0.01$). **Conclusions:** This is the first study to identify cerebral perfusion change associated with peripheral neuropathy symptoms in a breast cancer cohort. Our findings suggest that chemotherapy-associated gray matter decrease may also reduce LAC perfusion and associated pain perception. This finding and the observed relationships between CIPN symptoms, depression, fatigue, and cognitive complaints highlight the importance of further research on the causal pathways underlying these effects, and of developing therapies targeting this symptom cluster.

**9653 General Poster Session (Board #303), Sun, 8:00 AM-11:45 AM**

**Prechemotherapy cognitive function in 362 breast cancer (BC) patients and 362 age-paired controls without cancer: A nationwide longitudinal trial conducted through the University of Rochester Cancer Center (URCC) Community Clinical Oncology Program (CCOP) Research Base (RB).** *Presenting Author: Michelle Christine Janelsins, University of Rochester Medical Center, Rochester, NY*

**Background:** Cancer-related cognitive impairment (CRCI) impairs quality of life. 15% of patients experience CRCI prior to chemotherapy (CT), 75% during CT and 35% after CT. Large studies are needed to confirm these results. **Methods:** We are conducting a large, nationwide, longitudinal observational study through the URCC CCOP RB and 23 CCOPs to elucidate the natural history of CRCI among BC patients receiving CT compared to similarly aged women without cancer. BC participant eligibility: 1) stage I-IIIc , 2) CT naïve, 3) ≥21 years, 4) no central nervous system disease, 5) scheduled to receive anthracycline or non-anthracycline-based CT with no concurrent radiation. Controls meet eligibility #2-4. CRCI is assessed within one week (wk) prior to CT, within 4 wks after CT and 6 months post-CT. Controls are assessed at the same time intervals. CRCI domains (i.e., memory, attention, processing speed, executive function) are assessed via patient report (Functional Assessment of Cancer Therapy-Cognitive (FACT-Cog) and Behavior Rating Inventory of Executive Function (BRIEF)), and objective measures (computerized neuropsychological battery (CANTAB) and paper-based Trail Making Test (TMT-A)). **Results:** 362 BC patients were recruited (85% white, mean age=53) and paired with 362 controls.Adjusting for age, education, and WRAT-4 reading score (cognitive reserve), at pre-chemotherapy, BC patients performed less well than controls on FACT-Cog (Effect Size (ES)=0.4), BRIEF (ES=0.2;all $p<0.05$), CANTAB processing speed/attention and motor task tests (ES=0.2;all $p<0.05$), and the TMT-A (ES=0.2;$p<0.07$). There was no difference in these measures in BC patients scheduled to receive anthracycline-based CT vs. non-anthracycline-based CT. **Conclusions:** BC patients demonstrate poorer processing speed, attention, motor control, and perceived cognitive function prior to CT compared to women without cancer, suggesting it is clinically important to assess for CRCI before CT. NCI Grants: K07CA168886, U10CA037420. Clinical trial information: NCT01382082.

**9654 General Poster Session (Board #304), Sun, 8:00 AM-11:45 AM**

**Use, misuse, and overuse of white cell growth factors (GF) in community oncology practices in southeastern United States.** *Presenting Author: William J. Hrushesky, Oncology Analytics, Inc., Plantation, FL*

**Background:** Level 1 data, multiple national guidelines, and ASCO Choosing Wisely policy recommend that GFs be employed if the risk of febrile neutropenia (FN) exceeds 20%. Virtually every common chemotherapy regimen has been documented to put cancer patients at low (<10%) or intermediate (10-20%) or high risk (>20%) for FN. Oncology analytics (OA) screens all requests for GFs. If low risk regimens are employed, their use is challenged serially by: 1. electronically in initial request interaction, 2. informational fax bearing all relevant data, and 3. oncologist-to-oncologist peer review. We hypothesize that these agents are being overused in the community oncology setting among 2,800 practices we advise in the southeastern united states. **Methods:** During the 10 months between April 2013 and Jan 2014, we reviewed 1,700 requests for GFs: 894 for pegfilgrastim, 725 for filgrastim, and 62 for other GFs. **Results:** 355 of the 890 pegfilgrastim requests (40%) were made for patients receiving low-risk chemotherapy regimens; 455 (50%) intermediate risk, and 91 (10%) high risk regimens. Record reviews, educational faxes, and peer-to-peer reviews were serially instituted for all GF requests for low risk regimens. 113 (12%) of these were withdrawn or rescinded resulting in diminished cost of 2.1 million dollars in those 10 months. **Conclusions:** This ongoing pre-approval process results in more guidelines-compliant cancer care and diminishes waste.

**TPS9655 General Poster Session (Board #305A), Sun, 8:00 AM-11:45 AM**

**Single-center, prospective pilot study to evaluate advance care planning implementing the 3 Questions and 3 Elements to identify an informed health care proxy in an outpatient oncology palliative care clinic.** *Presenting Author: Eric Roeland, University of California, San Diego, Moores Cancer Center, La Jolla, CA*

**Background**: Despite the growing cancer therapeutics arsenal, the vast majority of advanced cancer patients will die. Consequently, understanding and communicating their end-of-life (EoL) care wishes is critical. Advance care planning (ACP) should occur in the non-emergent outpatient setting. However, given social and pragmatic challenges, these discussions are delayed until moments of crisis. In order to increase the probability that patients receive care consistent with their EoL wishes, health care providers require simple, effective, and efficient tools to initiate and complete meaningful ACP discussions. **Methods**: This is a single center, prospective, pilot study sponsored by the American Cancer Society to evaluate the average identification rate of an informed health care proxy by advanced cancer patients implementing a novel ACP tool in an academic oncology palliative care clinic over one year. Eligible subjects must have a known cancer diagnosis and a prognosis of less than 1 year. Consented subjects engage in a 1-hour ACP discussion initiated by the *3 Questions* which include: 1) the identification of potential health care proxy; 2) proxy's awareness about being designated as a health care proxy; 3) proxy's understanding of patient's wishes. The *3 Elements* define a meaningful ACP discussion and include: 1) the patient's personal definition of quality of life (QoL) 2) a specific plan if that personal QoL definition is not achieved 3) the patient's preferred location of death. Details of this ACP conversation are documented in the electronic medical record. The primary aim is to determine the proportion of advanced cancer patients who identify a health care proxy implementing the *3 Questions* and *3 Elements* versus a historical standard. Secondary aims include: 1) to determine the location of death of the subject 2) to determine if the subject's desired code status was honored. 3) to evaluate the health care proxy's satisfaction in understanding subject's wishes for EoL care after the subject's death.

**TPS9656 General Poster Session (Board #305B), Sun, 8:00 AM-11:45 AM**

**Quality of life (QOL) measurement in patients receiving neoadjuvant therapy in the I-SPY 2 trial.** *Presenting Author: Michael Hwang, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

**Background:** The I-SPY 2 TRIAL is a phase 2 trial investigating novel, targeted therapies in combination with standard chemotherapy in the neoadjuvant setting for stage 2 and 3 breast cancer. While the toxicities of chemotherapy alone are well characterized, introduction of experimental agents may significantly alter the toxicity profiles of these regimens, and could lead to short-term and long-term changes in QOL for patients. During the screening process, the trial informs patients of having either a tumor with a "low risk" (not eligible for the I-SPY 2 treatment phase) vs. "high risk" (eligible) profile, allowing the opportunity to study the impact on QOL of providing prognostic information prior to and throughout treatment. **Methods:** Patients who consent to the screening phase of I-SPY 2 are asked to participate in the QOL sub study. Patients complete a QOL questionnaire at baseline prior to treatment. For those patients who consent to the treatment phase of I-SPY 2, additional questionnaires are completed on the first day of treatment, after 12 weeks, prior to surgery, and then 1, 6, 12 and 24 months post-surgery. Questionnaires include established QOL measurements: the European Organization for the Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) and Breast 23 (EORTC QLQ BR23), the National Comprehensive Cancer Network Distress Thermometer and Fear of Recurrence scale, and items from the NCI Patient-Reported Outcomes Measurement Information System (PROMIS) in domains of physical, psychological, cognitive, and sexual function. The study will evaluate changes in QOL, distress, and fear of recurrence prior to surgery to two years post-operatively. The study will also allow comparison and validation of QOL measurement using PROMIS, a publicly available Web-based resource supported by the National Cancer Institute, to legacy EORTC QOL instruments. Since initiation of the QOL sub study, 520 patients have participated in the screening phase, with 311 patients initiating I-SPY 2 study treatment. With the accrual goal of 800 patients to the main I-SPY 2 TRIAL, up to 585 may be accrued to the prospective portion of the QOL sub study. Clinical trial information: NCT01042379.

**TPS9657 General Poster Session (Board #306A), Sun, 8:00 AM-11:45 AM**

**POWER-remote: A randomized study evaluating the effect of a remote-based weight loss program on biomarkers in women with early-stage breast cancer.** *Presenting Author: Cesar Augusto Santa-Maria, The Johns Hopkins University School of Medicine and The Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

**Background:** The majority of women diagnosed with breast cancer are overweight or obese, and gain weight with treatment, leading to inferior survival outcomes. The Practice-based Opportunities for Weight Reduction (POWER) investigators reported that, in an obese population with cardiovascular risk factors, a scalable remote-based weight loss intervention was equally effective to an in-person intervention (Appel NEJM 2011). We have adapted the remote intervention for breast cancer survivors. **Methods:** Randomized phase II single-blinded trial. Participants are women with stage 0-III breast cancer and a BMI $\geq$ 25 who have completed local therapy and adjuvant chemotherapy. Objectives:1.) Compare the proportion of participants who lose $\geq$5% of their baseline body weight after 6 and 12 months in the POWER-remote and self-directed (control) arms; 2.) Investigate the effects of weight loss on a panel of biomarkers relevant to obesity, inflammation, and breast cancer risk (insulin, IGF-1, hsCRP, IL-1, IL-6, TNF-$\alpha$, leptin, adiponectin, estradiol, and telomere length); 3.) Investigate the effects of weight loss on patient-reported outcomes (PROs), particularly physical function. Statistical Approach: We hypothesize that the proportion of women who experience $\geq$5% weight loss after 6 months will be greater in POWER-remote and will be similar to the results of the original POWER study (38.2% and 18.8% $\geq$5% weight loss in the remote and control groups, respectively). An interim futility analysis is planned after the first 80 patients are evaluable for the primary endpoint. The final analysis will conclude a significant benefit from POWER-remote if the one-sided p value is greater than 0.10 by Fisher's exact test. Changes in biomarkers and PROs from baseline to 6 months will be calculated and tested for differences by treatment arm and by response. We have enrolled 16 of the planned 200 patients. Future Directions: Results will be used to implement clinically based weight loss programs, and biomarker data will improve our understanding of energy dynamics in breast cancer survivors, leading to future studies investigating weight loss for primary and secondary breast cancer prevention. Clinical trial information: NCT01871116.

**TPS9658 General Poster Session (Board #306B), Sun, 8:00 AM-11:45 AM**

**Prevalence of hypogonadism in previously treated germ cell tumor patients.** *Presenting Author: Trent James Miller, Indiana University, Indianapolis, IN*

**Background:** Germ cell tumors (GCTs) represent a model for a curable malignancy. Most treated patients will live active lives. Patients treated with platinum combination chemotherapy may be left with clinically significant hypogonadism, causing signs and symptoms of erectile dysfunction, muscle weakness, insomnia, depression, increased sweats, and a greater risk for developing metabolic syndrome with resultant cardiovascular disease. It is thus important to identify the prevalence of hypogonadism in survivors of GCT, both in patient populations treated with chemotherapy as well as chemo-naïve patients. We will identify the incidence of hypogonadism and compare patients who have had chemotherapy versus those treated with surgery alone (orchiectomy +/- retroperitoneal lymph node dissection). We will correlate serum testosterone levels with physical & psychological quality of life (QoL) including symptoms of hypogonadism. We will assess these variables over time to determine if symptoms change relative to the time from treatment. Finally, we will develop a database of clinical information for future use. **Methods:** Patients who are at least 8 wks post-treatment with chemotherapy (Group 1) or at least 8 wks post-orchiectomy and/or other surgery for GCT (Group 2), who are between 18 and 50 yrs of age, and who are not receiving supplemental testosterone are eligible for enrollment. 100 patients will be enrolled in each group. Study participants will have a serum total testosterone, fasting lipid panel, serum human chorionic gonadotropin (hCG), and alpha-fetoprotein (AFP) measured at baseline. Testosterone, hCG, and AFP are repeated at 3, 6, and 12 mos. Supplemental testosterone may be prescribed per standard of care. Cancer diagnosis and treatment variables such as stage, type of surgery, chemotherapy, radiation treatment, hormonal treatment, age, and length of time since diagnosis/treatment will be obtained from medical records. Patients will complete a QoL questionnaire composed of items from the Aging Males' Symptoms (AMS) scale and the Patient Reported Outcomes Management Information System (PROMIS) at baseline, which is repeated at 3 and 6 mos. At the time of submission, there are 75 patients enrolled in Group 1, and 34 in Group 2.

**TPS9659 General Poster Session (Board #307A), Sun, 8:00 AM-11:45 AM**

**Phase II trial of inflammation markers and symptom control in metastatic lung cancer: Insync.** *Presenting Author: Chipman Robert Geoffrey Stroud, Leo Jenkins Cancer Center, Brody School of Medicine at East Carolina University, Greenville, NC*

**Background:** Palliative care with focused symptom management and control can improve quality of life outcomes and survival in metastatic non-small cell lung cancer (NSCLC) beyond standard chemotherapy. (Temel et al NEJM 2010) Many symptoms in cancer are related to inflammation. (Laird et al The Oncologist 2013) Smoldering inflammation in the tumor microenvironment is now a recognized 7$^{th}$ hallmark of cancer (Colotta et al Carcinogenesis 2009) as it regulates and escalates cancer invasion, angiogenesis, immune surveillance escape and the metastatic cascade. (Balkwill and Mantovani Lancet 2001) The Veristrat protein test is dominated by inflammatory proteins and is prognostic and predictive in metastatic NSCLC after treatment with platinum based chemotherapy. (Gregorc et al ASCO 2013 #LBA8005) C-reactive protein (CRP) is also a well studied inflammatory marker in cancer. The hypothesis of this study is that the remarkable survival benefit in the Temel study is mediated by reduced inflammation with symptom improvement and control. **Methods:** In this study, patients with metastatic NSCLC will be seen in consultation by our institutional Symptom Management Service PharmD upon presentation to our Thoracic Oncology Program and subsequently managed concurrently with the treating medical oncologist. Inflammatory protein marker studies with Versitrat and CRP will be evaluated at baseline, monitored at 4 and 10 months and correlated with ongoing symptom improvement and a quality of life (FACT-L) study. The primary objective is reduced inflammation markers with Veristrat 'poor' changing to Veristrat 'good' and a decreasing CRP. The secondary objectives are overall survival, quality of life FACT-L improvement and correlation with disease status.

**TPS9660 General Poster Session (Board #307B), Sun, 8:00 AM-11:45 AM**

**Scalp cooling alopecia prevention trial (SCALP).** *Presenting Author: Julie R. Nangia, Baylor College of Medicine, Houston, TX*

**Background:** Adjuvant chemotherapy treats micro-metastatic disease and decreases the risk of breast cancer recurrence. However, it may be associated with distressing adverse effects, including alopecia. Women with breast cancer rate chemotherapy-induced alopecia as one of the most severe, troublesome, and distressing side effects of chemotherapy. In many countries, scalp cooling has been introduced to prevent or reduce chemotherapy-induced alopecia. Scalp cooling causes cutaneous vasoconstriction, which reduces blood flow to the hair follicles during peak plasma concentrations of the chemotherapeutic agents and therefore reduces cellular uptake of these agents. It also results in reduced biochemical activity, which makes hair follicles less susceptible to the damage of the chemotherapy agents. Success rates are variable, but scalp cooling appears to be effective in preventing chemotherapy-induced alopecia especially in more recent studies. **Methods:** We are conducting a multi-center randomized non-blinded controlled prospective trial to demonstrate the safety and efficacy of the Orbis Paxman Hair Loss Prevention System in reducing the incidence of chemotherapy-induced alopecia. Women with stage I-II breast cancer will receive neoadjuvant or adjuvant anthracycline- or taxane-based chemotherapy, for at least four cycles are eligible. Participants will be randomized in a 2:1 ratio to scalp-cooling and will undergo scalp-cooling using the Orbis Paxman Hair Loss Prevention System prior to, during and after each chemotherapy administration. The primary efficacy endpoints are hair preservation, defined as CTCAE v4 alopecia $<2$, and device safety. Two hundred and thirty five (235) patients will be enrolled which will provide 85% power to detect a 20% difference in hair preservation, 15% in control group and 35% in scalp-cooling group . Secondary endpoints include: wig/scarf use and quality of life assessed by the EORTC QLQ-30, HADS and BIS. Study participants will be followed for 5 years post-study for time to first recurrence, overall survival, site of first recurrence, and incidence of isolated scalp metastasis. Clinical trial information: NCT01986140.

**TPS9661 General Poster Session (Board #308A), Sun, 8:00 AM-11:45 AM**

**SELECT-D: Anticoagulation therapy in selected cancer patients at risk of recurrence of venous thromboembolism.** *Presenting Author: Annie Young, Warwick Clinical Trials Unit, University of Warwick, Coventry, United Kingdom*

**Background:** Venous thromboembolism (VTE) in cancer patients is an important and increasingly frequent clinical problem. The impact of VTE on cancer patients can be considerable. Targeted selection by identifying patients with clinically relevant recurrent VTE may have wider health economic benefits whilst reducing patient risk through over-treatment. In the UK, dalteparin is the licensed anticoagulant for the extended treatment and prevention of recurrence of VTE in cancer patients and thus, the gold standard. Rivaroxaban is a highly selective direct Factor Xa inhibitor with oral bioavailability. **Methods:** Select-d is a prospective, randomised, open label, multicentre pilot trial comparing dalteparin (200 IU/kg daily subcutaneously for 1 month and 150 IU/kg months 2-6); and rivaroxaban (15 mg orally twice daily for 3 weeks and 20 mg once daily for 6 months in total) for cancer patients with VTE, with a second placebo-controlled randomisation (rivaroxaban vs placebo) comparing the duration of therapy (6 vs 12 months) in residual vein thrombosis (RVT) positive patients. 70% of patients are estimated to be RVT positive after initial treatment. 530 patients are being recruited toprovide reliable estimates of the primary outcome (VTE recurrence rates) to within the 95% confidence interval of 8% assuming VTE rates are 10% at six months. Secondary objectives include safety, acceptability, biomarker identification and health economics. The trial will recruit for two years with a minimum of one year follow up. Results will support optimal treatment for this key patient group. The independent TSC and DSMC fully support this important trial. At least 40 UK centres will participate in the trial. As of 1$^{st}$February 2014, 23 patients have been recruited from 24 open UK sites. Select-d is amongst the first randomised trials of the new oral anticoagulants in patients with cancer, following recent recommendations from the UK National Institute of Health and Care Excellence.(http://guidance.nice.org.uk/CG144, http://guidance-.nice.org.uk/TA261, http://publications.nice.org.uk/quality-standard-for-diagnosis-and-management-of-venous-thromboembolic-diseases-qs29). Clinical trial information: 86712308.

**TPS9662 General Poster Session (Board #308B), Sun, 8:00 AM-11:45 AM**

**A randomized placebo-controlled phase III study of duloxetine for treatment of aromatase inhibitor (AI)-associated musculoskeletal symptoms in women with early-stage breast cancer: SWOG S1202.** *Presenting Author: N. Lynn Henry, University of Michigan Medical Center, Ann Arbor, MI*

**Background:** Treatment with an aromatase inhibitor (AI) for 5 years improves outcomes for hormone receptor (HR)-positive breast cancer. However, up to 30% of patients discontinue treatment because of AI-associated musculoskeletal symptoms (AIMSS). Preliminary data suggest that treatment with the serotonin norepinephrine reuptake inhibitor duloxetine for 8 weeks decreases AI-associated pain. We are therefore conducting this placebo-controlled, randomized phase III trial of duloxetine for treatment of AIMSS. Specific Aims: To assess if duloxetine as compared to placebo causes a reduction in average pain in women with AIMSS at 12 weeks as measured by the Brief Pain Inventory (BPI). Additional measures include WOMAC, M-SACRAH, FACT-ES, PHQ-9, global rating of change, candidate gene variants, and inflammatory cytokines. Eligibility Criteria: Patients must have stage I-III HR-positive breast cancer and have undergone definitive breast cancer surgery. Patients must be postmenopausal, currently taking an AI (anastrozole, letrozole, or exemestane) for at least 21 days and not more than 36 months prior to registration, and plan to continue for at least 180 days after registration. Patients must have an average joint pain score of at least 4 out of 10 on the BPI, and pain must have started or increased after initiation of AI. Patients must not have a contraindication to duloxetine and must not require antidepressant therapy during study participation. **Methods:** Patients will be randomized to duloxetine 60 mg daily or matching placebo daily for 12 weeks, including a 7 day run-in period of 30 mg daily. Assessments will be performed at baseline, 2, 6, 12, and 24 weeks. Statistical Methods:We stipulate an alpha=0.05 two-sided test, with an estimated 5% non-adherence, 15% dropout, and 10% contamination rate at 12 weeks after randomization. For a one point difference in average joint pain and a 2.3 point SD at 12 weeks, 270 eligible patients would be required for 80% power under a two-arm normal design. To allow for an ineligibility rate of 8%, 294 total patients will be enrolled. The study was activated in May 2013 and is available on the CTSU. Clinical trial information: NCT01598298.

**TPS9663 General Poster Session (Board #309A), Sun, 8:00 AM-11:45 AM**

**Incidence of hypersensitivity reactions (HSR) in patients receiving reduced doses of dexamethasone as prophylaxis for carboplatin and paclitaxel in gynecologic malignancies.** *Presenting Author: Justin Liauw, Maine Medical Center, Portland, ME*

**Background:** Paclitaxel has been used in combination with a platinum agent as part of standard of care for the treatment of gynecologic malignancies. A major clinical concern with the use of paclitaxel is the potential for hypersensitivity reactions (HSRs). Dexamethasone is given in combination with other premedications to decrease the incidence of HSRs. The manufacturer-recommended premedication regimen includes dexamethasone 20 mg orally, taken 12 and 6 hours prior to the paclitaxel infusion. The cumulative dose of dexamethasone may be excessive and may decrease patient's quality of life (QOL). Several studies have omitted oral doses of dexamethasone and used a single 20mg dose of intravenous dexamethasone. These trials suggest that reduced doses of dexamethasone can result in a similar rate of HSRs compared with manufacturer-recommended premedication doses. Our study looks to eliminate the oral dexamethasone premedications, like the aforementioned studies, utilizing a single dose of 20 mg of intravenous dexamethasone. **Methods:** This is a prospective, single arm, interventional, feasibility study. Patients involved in this study will include women with a new diagnosis of ovarian or endometrial cancer that have been selected to receive 3-6 cycles of paclitaxel every 3 weeks with or without carboplatin. The primary endpoint is to document the incidence of paclitaxel HSRs of all grades and HSRs grades 3 and above. Grading of HSRs will be done utilizing the NCI Common Toxicity Criteria for Adverse Events (CTCAE) tool, version 3.0. QOL will be measured as a secondary endpoint using the FACT-O questionnaire, which will be administered prior to beginning paclitaxel chemotherapy, and at the end of paclitaxel chemotherapy. All premedication, excluding dexamethasone, will be chosen and dosed according to standard of care. The results of this study will be analyzed with descriptive statistics.

**TPS9664 General Poster Session (Board #309B), Sun, 8:00 AM-11:45 AM**

**Phase III design for a trial of single-dose fosaprepitant (FA) in preventing chemotherapy-induced nausea and vomiting (CINV) associated with moderately emetogenic chemotherapy (MEC).** *Presenting Author: Stephen Noga, Weinberg Cancer Institute, Baltimore, MD*

**Background:** CINV is a common side effect that may occur in acute (0-24 hours [h]) and delayed (25-120 h) post-chemotherapy phases. Aprepitant is a potent and selective oral NK1 receptor antagonist (RA) indicated for prevention of acute and delayed CINV associated with highly emetogenic chemotherapy (HEC) and MEC using a 3-day regimen combined with a 5HT3 RA and corticosteroid. FA, a water-soluble prodrug rapidly converted to aprepitant after intravenous (IV) administration, is approved as a single dose for HEC-related CINV. To further study FA with MEC, this study will evaluate the efficacy and safety of a single IV dose of 150mg FA given with a 5-HT3 RA and corticosteroid vs a 5-HT3 RA and corticosteroid alone in preventing MEC-associated CINV (NCT01594749). **Methods:** This is a global, phase III, randomized, double-blind, parallel-group study in 990 subjects ≥18 years of age naïve to HEC and MEC scheduled to receive an IV dose of MEC on treatment Day 1. Other moderate and low emetogenic chemotherapy agents may be added to the MEC through Day 3; there are no restrictions on the use of minimally emetogenic agents. Subjects are randomly assigned 1:1 to a control or treatment group. Control group consists of 8mg ondansetron and 20mg dexamethasone on Day 1, followed by 8mg ondansetron PO (by mouth) every 12 h on Days 2 and 3. The treatment group adds 150mg IV FA to the same dose of ondansetron PO and dose-adjusted dexamethasone (12mg PO) before the first dose of MEC on Day 1, followed by 8mg ondansetron PO 8 h after the first dose and no additional antiemetic beyond Day 1. Primary objectives will evaluate the proportion of subjects with a complete response (CR: no vomiting and no rescue medication use) during the delayed phase and FA safety/tolerability. Secondary objectives include CR in acute and overall (0-120 h post MEC) phases. Exploratory objectives further evaluate vomiting, nausea, rescue use, and impact on daily life. Treatment comparisons, stratified by gender, will include a formal test for superiority for the primary efficacy analysis. Primary and secondary efficacy analyses will be tested at a 2-sided significance level of 0.05. Clinical trial information: NCT01594749.

**10000 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Real-time central review: A report of the first 3,000 patients enrolled on the Children's Oncology Group Renal Tumor Biology and Risk Stratification protocol AREN03B2.** *Presenting Author: Elizabeth Anne Mullen, Dana-Farber Cancer Center Institute/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

**Background:** The Children's Oncology Group (COG) Renal Tumor (RT) Biology and Risk Stratification Protocol incorporates real-time central review to direct risk stratification and enrollment on COG therapeutic studies. We assessed the feasibility of the real-time central review process and its impact on the accuracy of risk stratification. **Methods:** 3,000 patients were enrolled on AREN03B2 between 2/2006 and 1/2012, with submissions from 214 COG institutions. Eligible diagnoses included any RT and extra-renal Wilms tumor or non-CNS rhabdoid tumor. Enrollment on AREN03B2 was required to enroll on a RT treatment study. Submission of pathology slides, radiology images, operative reports, and tumor and blood for analysis was required within 7 days of surgery to meet enrollment deadlines stipulated by the therapeutic studies. Central pathology review for histology and stage, radiology review for presence of bilateral lesions and pulmonary metastases, and surgical review for operative stage were completed electronically by a panel of expert reviewers. An initial risk assignment (IRA) was made by the study chairs based on the multidisciplinary central reviews. **Results:** 2,913/3,000 met all eligibility and submission requirements. The median time from enrollment to IRA was 8 days. 1,205 discrepancies between central and institutional review potentially impacting IRAs were observed; including differences in initial histology in 253 unilateral and 69 bilateral tumors, pathologic staging of 294 tumors, diagnostic imaging of 92 bilateral cases and 112 cases of pulmonary metastases, and the surgical review of 244 cases of rupture and 141 instances of node sampling. **Conclusions:** Real time central review is feasible in a large multi-center study. Discrepancies between local and central risk stratification were identified in a substantial number of participants. Communication of these findings in real time supported increased accuracy of enrollment on appropriate clinical trials and strengthened the comprehensive annotation of a rich RT biorepository. Expansion of this process to other pediatric tumor registry protocols should be strongly considered.

**10001 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Treatment of stage IV favorable histology Wilms tumor with incomplete lung metastasis response after chemotherapy: A report from Children's Oncology Group study AREN0533.** *Presenting Author: David B. Dix, British Columbia Childrens Hospital, Vancouver, BC, Canada*

**Background:** National Wilms Tumor Study-5 showed that patients with stage IV Favorable Histology Wilms Tumor (FHWT) had 4-year event-free survival (EFS) and overall survival (OS) estimates of 75% and 86% when treated with Regimen DD4A (vincristine/dactinomycin/doxorubicin) and whole lung irradiation (XRT). To decrease relapse rates while subjecting fewer patients to XRT, the AREN0533 study evaluated whether therapy can be tailored based on the completeness of lung metastasis response after 6 weeks of DD4A chemotherapy. Patients showing complete resolution of lung metastases at week 6 continued DD4A without lung XRT. Patients with incomplete lung metastasis response ("slow incomplete response"=SIR) continued DD4A with the addition of cyclophosphamide/etoposide (Regimen M) and lung XRT. Interim analysis for the SIR group is the subject of this report. **Methods:** Patients were enrolled between February 2007 and February 2013 after undergoing risk assignment on the AREN03B2 Renal Tumor Biology and Classification study. The completeness of lung metastasis response was determined by central radiology review after 6 weeks of chemotherapy. The null hypothesis was that 4-year EFS for SIR when treated with DD4A therapy is 75%. The study was designed to detect a decrease in the risk of failure corresponding to 4-year EFS of 84%. **Results:** Among 391 patients enrolled, 279 had isolated lung metastases, of which 163 (58%) had SIR. At interim analysis in June 2013, the number of expected events under the null hypothesis was 38.6, yet only 15 events were observed. This difference was sufficient to reject the null hypothesis and conclude that Regimen M is superior to the historical standard ($p=0.0001$, Woolson 1-sample log rank test). The 3-year EFS and OS estimates for SIR patients were 88% (95% CI: 81%, 93%) and 92% (95% CI: 86%, 96%). Grade 3 or higher hematological toxicity was the most common toxicity observed with Regimen M, affecting 60% of patients. There were no unexpected toxicities. **Conclusions:** Patients with stage IV FHWT with SIR of lung metastases showed superior EFS with the addition of cyclophosphamide/etoposide compared to the historical standard. Clinical trial information: NCT00379340.

**10002 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Outcome of localized blastemal-type nephroblastoma patients treated according to intensified treatment in the SIOP 2001 protocol: A report of the SIOP-RTSG.** *Presenting Author: Marry M van den Heuvel-Eibrink, Department of Pediatric Hematology and Oncology, Erasmus MC - Sophia Children's Hospital, Rotterdam, Netherlands*

**Background:** From previous pre-surgery chemotherapy based SIOP protocols, blastemal type Wilms tumor (BT-WT) has been identified as a poor prognostic subgroup. Therefore in SIOP 2001, post-operative treatment for BT-WT was prolonged and intensified (VCR/Act/Dox in stage I, VP16/Carbo/Cyclo/Dox in stage II-IV) aiming to improve survival. Here, we present characteristics and outcome of BT-WT patients treated on intensified regimen in SIOP 2001. **Methods:** Response and survival analysis of unilateral BT-WT (n = 238) patients treated from 2001-2012 (SIOP 2001) were compared with SIOP 93-01 (n = 113). **Results:** In SIOP 93-01 and SIOP 2001 trials, among 4061 unilateral non-metastatic Wilms tumor patients registered, 351 (8.6%) were BT-WT. Median age at diagnosis was 43 months (IQR 24-68). Stages were: I (n = 140, 40%), II (n = 106, 30%), III (n = 105, 30%). Pre-surgery chemotherapy reduced tumor volume from median 359 ml (IQR 174-611) to 123 ml (IQR 41-291). BT-WT were older, higher staged and showed less markedly volume decrease after pre-surgery chemotherapy. Univariate analysis of localised unilateral BT-WT cases in SIOP 2001 showed a 5-year event-free survival (EFS) of 80% (95% CI 75-86%) (67% in SIOP 93-01 (95% CI 59-76; p = 0.006)) and an overall survival (OS) of 88% (95% CI 83-93) (84% (95% CI 77-91; p = 0.4) in SIOP 93-01). Treatment protocol, volume at surgery, age and stage were prognostic variables for EFS in uni- and multivariate Cox regression analysis. Independent prognosticators for OS were stage, age and tumor volume at surgery. The most significant benefit of intensified treatment was found in Stage I BT-WT with 96% EFS in SIOP 2001 (OS 100%), compared to 71% EFS in SIOP 93-01 (OS 96%). **Conclusions:** BT-WT, defined after pre-operative chemotherapy, benefits from more intensive chemotherapy as reflected by reduction of relapse risk. However, OS mainly seems to be enhanced in stage I BT-WT patients underscoring the value of doxorubicin for relapse prevention in these tumors.

**10003 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Randomized phase II trial of bevacizumab and temsirolimus in combination with vinorelbine (V) and cyclophosphamide (C) for first relapse/disease progression of rhabdomyosarcoma (RMS): A report from the Children's Oncology Group (COG).** *Presenting Author: Leo Mascarenhas, Children's Hospital Los Angeles, Saban Research Insititute, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA*

**Background:** Patients with RMS have a poor prognosis at first relapse/disease progression. VC has activity in RMS and preclinical data supports the use of bevacizumab and temsirolimus in RMS. **Methods:** Patients with biopsy proven RMS, $<$ 30 years of age and unfavorable prognosis at first relapse/progression were eligible. Entry criteria were: life expectancy $>$ 8 weeks, performance status $<$ 2, adequate organ function and written informed consent. Patients were randomized between two regimens administered every 3 weeks for a maximum of 12 cycles: Regimen A- V 25 mg/m$^2$ intravenously (IV) days 1 & 8, C 1.2 gms/m$^2$ IV day 1, bevacizumab 15 mg/Kg IV day 1; b) Regimen B- VC identical to regimen A, temsirolimus 15 mg/m$^2$ IV days 1, 8 & 15. Primary endpoint was event free survival (EFS) at 6 months. Disease response at week 6 was assessed using RECIST. The study had a phase 2 screening design and was powered to detect a 15% difference in EFS between the two regimens ($\alpha=0.2$, 1-$\beta=0.8$, 2-sided test). Interim analysis was planned when 30%, 50% and 75% of the expected events occurred. **Results:** 87 of the 100 planned patients were enrolled when the trial was closed following the second interim analysis after 46 events occurred in 68 patients with sufficient follow-up. The O'Brien Flemming boundary at this analysis corresponded to a 2-sided p value of 0.0582 with an observed 2-sided p value of 0.0031 favoring the regimen with temsirolimus. The 6 month EFS for regimen A was 50% (95% CI 32%, 66%) and for regimen B was 65% (95% CI 44%, 79%). The response rate observed for regimens A and B were 32% and 47% respectively ($p=0.22$). The rate of progressive disease on regimen A was 26% compared with 9% on regimen B. Treatment was well tolerated. No unexpected toxicities were observed. Febrile neutropenia was the most common adverse event on both regimens. Oral mucositis and hypertriglyceridemia were noted only on regimen B. **Conclusions:** Patients randomized to VC+ temsirolimus had a superior EFS compared to VC+ bevacizumab. Temsirolimus has been selected by COG for further investigation in newly diagnosed patients with intermediate risk RMS. Clinical trial information: NCT01222715.

**10004 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Vincristine, dactinomycin, cyclophosphamide (VAC) versus VAC/V plus irinotecan (VI) for intermediate-risk rhabdomyosarcoma (IRRMS): A report from the Children's Oncology Group Soft Tissue Sarcoma Committee.** *Presenting Author: Douglas S. Hawkins, Seattle Children's Hospital, Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA*

**Background:** The long-term event free survival (EFS) for IRRMS is 65%. Since VI had significant activity in metastatic and recurrent RMS, we tested whether adding VI to VAC would improve EFS for IRRMS. **Methods:** Patients (pts) with alveolar (A)RMS or incompletely resected (Group III) embryonal (E)RMS arising in an unfavorable primary site (Stage 2/3), both without distant metastases, < 50 years, and adequate organ function were eligible to be randomized to 42 weeks of VAC (V=1.5 mg/m$^2$, A=0.045 mg/kg, C=1.2 g/m$^2$ every 3 weeks) vs VAC/VI (I=50 mg/m$^2$/day x 5 days) intravenously; doses were adjusted for children < 3 years; radiation therapy (36-50.4 Gy) was started at week 4, with individualized local control for children < 2 years allowed. The primary study endpoint was EFS. The study was designed with 80% power (5% 1-sided alpha level) to detect an increase in 5 yr EFS from 65% to 76%, a relative risk of 0.64. **Results:** 481 pts were entered between 12/2006-12/2012, with 461 confirmed eligible. Clinical features included ERMS 53%, ARMS 43%; age < 1 year 6%, 1-9 years 62%, 10+ years 32%; Group III 85%; Stage 3 61%. The most common primary tumor sites were parameningeal (44%), extremity (13%), and bladder/prostate (13%). With median follow up of 2.46 years in surviving pts, EFS and overall survival (OS) with 95% confidence intervals (CI) were similar overall and by histologic subtypes (Table). Grade 3/4 febrile neutropenia, anemia, and thrombocytopenia were less common with VAC/VI, particularly after the first 15 weeks of therapy, while diarrhea was more common with VAC/VI. **Conclusions:** The addition of VI to VAC did not significantly improve EFS or OS compared to VAC alone for IRRMS. The lower rate of hematologic toxicity and cumulative C dose with VAC/VI (8.4 g/m$^2$ vs 16.8 g/m$^2$) support the use of VAC/VI as the standard arm in future IRRMS trials. Clinical trial information: NCT00354835.

| Treatment | n | 2-year EFS (95% CI) | 2-year OS (95% CI) |
|---|---|---|---|
| VAC | 227 | 64% (56%, 70%) | 84% (78%, 89%) |
| VAC/VI | 234 | 64% (56%, 70%) | 86% (80%, 90%) |
| ERMS: VAC | 118 | 67% (56%, 76%) | 86% (76%, 92%) |
| ERMS: VAC/VI | 128 | 68% (58%, 76%) | 89% (81%, 93%) |
| ARMS: VAC | 102 | 58% (48%, 69%) | 81% (71%, 88%) |
| ARMS: VAC/VI | 95 | 57% (45%, 67%) | 83% (72%, 90%) |

**10005 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Which patients with rhabdomyosarcoma (RMS) do need radiotherapy (RTX)? The long-term results of the CWS studies -81, -86, -91, and -96.** *Presenting Author: Ewa Koscielniak, Olgahospital Klinikum Stuttgart, Stuttgart, Germany*

**Background:** RTX is an essential therapy modality in the treatment of RMS. However, RTX is associated with severe late effects, therefore the indication and the optimal dose are still a matter of controversy. The stratification for the RTX indication and cumulative dose has been optimized in the consecutive CWS trials. Here we report the long-term results of four consecutive prospective trials. **Methods:** A total of 998 patients enrolled in the CWS-81, 86, -91 and -96 met the inclusion criteria for this analysis: 1) RMS histology 2) localized tumor (IRS Group I-III) 3) complete RTX data set and 4) follow up of minimum 10 yrs. 171 patients were classified as IRS Group I, 171 as IRS Group II and 656 as IRS Group III. 200 tumors (20%) had alveolar histology (RMA). The indication for RTX and the doses of 32Gy, 40Gy, 45Gy, 48Gy, 50Gy and 54Gy were stratified according to patient and tumor related factors. **Results:** The 5yrs event free survival (EFS) and overall survival (OS) did not differ between the trials included in the analysis. 630 pts were irradiated (63%).There was no major difference in proportion of irradiated patients between the trials 81-96 (62%, 59%, 71%, 61%). The 5yrs EFS by IRS Groups and RTX vs. no RTX were as follows: IRS I 60% vs. 84%, IRS II 73% vs. 72%, IRS III 62% vs. 57% (n.s.). The 5yrs EFS by RTX dose (32±2Gy vs. > 34Gy) were: IRS II 80% vs. 69%, IRS III 70% vs. 61%. Restricting the analysis to alveolar type: the 5 yrs EFS of patients irradiated with 32±2Gy vs. > 34Gy were as follows: IRS II 50% vs. 59%(n.s.), IRS III 30% vs. 41% (n.s.). There was no difference in EFS when splitting the RMS patients irradiated with > 34Gy into 40Gy vs. 45Gy, vs. 48Gy vs. 50 vs. 54Gy. **Conclusions:** The stratification criteria for RTX seem to compensate for different risk factors and allowed for reducing the cumulative dose to 32Gy in the lower risk group. However, the proportion of irradiated patients could not be reduced significantly. Further improvement in identification of patients who do not need RTX is needed.

**10006 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Maintaining outstanding outcomes using response- and biology-based therapy for intermediate-risk neuroblastoma: A report from the Children's Oncology Group study ANBL0531.** *Presenting Author: Clare Twist, Stanford University, Palo Alto, CA*

**Background:** This Phase III prospective reduction of therapy study used tumor biologic features to determine the minimal treatment needed to achieve excellent outcomes in patients with intermediate risk (IR) neuroblastoma (NB). **Methods:** Between 10/8/2007 and 6/30/2011, 464 patients enrolled; 401 had evaluable IR NB. Eligibility included newly diagnosed single copy *MYCN* NB and: age <12 years with stage 2A/B <50% resected or stage 3 with favorable biology, age <365 days with stage 3 or 4, and all patients <365 days with stage 4S, including those too ill to undergo biopsy. Toddlers age 365-<547 days with favorable biology stage 4 NB and age 365-<547 days with stage 3 and unfavorable histology (UH) received isotretinoin in addition to chemotherapy. Risk-stratification and therapy assignment utilized age, INSS stage, INPC, *MYCN*, and tumor ploidy. Therapy reduction was prescribed for tumors without loss of heterozygosity (LOH) at 1p36 and/or 11q23. Therapy included 2-8 courses of chemotherapy +/- surgery. Treatment endpoint for localized favorable biology tumors was partial response. **Results:** The 3-year EFS/OS for all IR patients was 83±3%/95±2%. The presence of 1pLOH and/or unbalanced 11qLOH was detected in 18% of IR tumors. To date, there were no deaths due to disease in patients with localized favorable biology tumors. Among 124 stage 4 patients <365 days, 3-year EFS/OS for favorable biology (n=60) was 90±5%/95±4%; for unfavorable biology (diploid and/or UH, irrespective of LOH, n=24) was 63±16%/76±13% and 65±14%/95±7% for tumors with LOH (n=20). Among 9 stage 4 toddlers there were 3 relapses; 3-year OS 100%. Eight of 46 patients with stage 4S NB died; 5 were due to complications of hepatomegaly. **Conclusions:** Further reduction of therapy and prospective refinement of treatment using genomic stratification achieved excellent survival in the majority of IR NB patients. Some unfavorable biology IR tumors may benefit from novel treatment strategies. Clinical trial information: NCT00499616.

**10007 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Tandem high-dose chemotherapy with stem cell rescue followed by risk-adapted radiation in children with high-risk cerebral primitive neuroectodermal tumor: Results of the prospective SFCE-trial PNET HR+5.** *Presenting Author: Christelle Dufour, Gustave Roussy, Villejuif, France*

**Background:** To assess the 3-year progression-free survival (PFS) rate of patients with newly diagnosed high-risk medulloblastoma (MB) or supratentorial primitive neuroectodermal tumor (sPNET) between 5-20 years treated according to the prospective multicenter trial PNET HR+5. **Methods:** Children received as postoperative induction chemotherapy two cycles of etoposide (500mg /m$^2$) - carboplatine (800mg/m$^2$), followed by two courses of thiotepa (600mg/m$^2$ per course) with autologous stem cell rescue. Risk-adapted conventional radiotherapy (RT) was delivered around day 45 after second transplantation. Craniospinal RT dose was 36 Gy for patients with metastatic disease or with unfavourable histology (anaplastic MB, large cell MB, MB with *myc* amplification) followed by a tumor bed boost of 18 Gy. Patients with localized sPNET received focal RT at the dose of 54 Gy. Maintenance treatment with 6 cycles of temozolomide was planned to start between 1-3 months after the end of RT. **Results:** From January 2009 to February 2012, 64 patients (MB=51; sPNET=13) between 5 and 19 years (median age, 9 years) were enrolled. Five patients didn't received RT due to progressive disease. Maintenance treatment was administered in 44 patients. The median follow-up was 32 months (range, 16-54 months). The 3-year PFS and overall survival (OS) were 80% (95% CI: 68-88%) and 85% (95% CI: 74-92%), respectively. The 3-year PFS was 79% (95% CI: 65-88%) for children with MB and 85% (95% CI: 58-96%) for those with sPNET. No major unexpected toxicities and no treatment-related deaths were reported. **Conclusions:** This treatment based on high-dose chemotherapy and conventional RT resulted in a high overall survival rate in children and adolescent with newly diagnosed high-risk cerebral PNET. Clinical trial information: NCT00936156.

**10008** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Risk-based treatment for nonrhabdomyosarcoma soft tissue sarcomas (NRSTS) in patients under 30 years of age: Children's Oncology Group study ARST0332.** *Presenting Author: Sheri L. Spunt, Lucile Packard Children's Hospital at Stanford, Palo Alto, CA*

**Background:** NRSTS comprise ~4% of childhood cancer but only 3 prospective clinical trials have been performed in the U.S. in the past 40 years. Tumor grade, size, resection potential, and extent of disease influence outcome. ARST0332 evaluated a risk-based treatment strategy for young NRSTS patients designed to limit therapy for low-risk disease and to test a combined chemoradiotherapy approach for unresected higher risk disease. **Methods:** Newly diagnosed NRSTS patients < 30 years old were assigned to 4 treatment arms based on risk: A (surgery only): grossly excised low-grade and ≤ 5 cm widely excised high-grade tumor; B (55.8 Gy radiotherapy [RT]): ≤ 5 cm marginally resected high-grade tumor; C (ifosfamide/doxorubicin chemotherapy + 55.8 Gy RT): > 5 cm grossly resected tumor ± metastases; D (neoadjuvant ifosfamide/doxorubicin chemotherapy and 45 Gy RT, then surgery and an RT boost based on margins): > 5cm unresected tumor ± metastases. **Results:** 551 eligible patients were enrolled on Arm A (212), B (19), C (120), and D (200). Most common subtypes were synovial sarcoma (149), malignant peripheral nerve sheath tumor (60), and undifferentiated sarcoma (48). Tumors were 53% extremity, 72% high grade, 76% > 5 cm, and 14% metastatic. There were no toxic deaths; 2% had unexpected grade 4 adverse events. By treatment arm, at a median follow-up of 2.6 years, estimated 3-year event-free survival was: A 91%, B 79%, C 68%, D 52% and overall survival was: A 99%, B 100%, C 81%, D 66%. **Conclusions:** This novel risk-based treatment strategy segregated patients into clinically meaningful risk groups and produced outcomes similar to or slightly better than historical controls while using RT less frequently and at lower doses. This study defines the new standard of care for pediatric NRSTS against which future interventions should be compared. Clinical trial information: NCT00346164.

**10009** **Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**Breast cancer in childhood cancer survivors not treated with chest-directed radiation in the Childhood Cancer Survivor Study (CCSS).** *Presenting Author: Tara O. Henderson, Pritzker School of Medicine, The University of Chicago, Chicago, IL*

**Background:** While chest radiation (CRT) is strongly associated with risk of breast cancer (BC) in childhood cancer survivors (CCS), there are BC cases among survivors not exposed to CRT. We sought to examine if BC risk is elevated in non-CRT exposed women to inform surveillance recommendations. **Methods:** Using the CCSS cohort, BC risk was assessed among 3,768 female 5-yr CCS (median follow-up 25.5 yr, range 8-39) not treated with CRT. Cumulative incidence was examined treating death as a competing risk. BC risk was assessed using standardized incidence ratios (SIR) and 95% confidence intervals (CI) using incidence from the Surveillance, Epidemiology, and End Results Program, and by calculation of absolute excess risk (AER) per $10^4$person-yrs (py). **Results:** 47 CCS developed BC at a median age of 38 yrs (range 22-47) and median of 24 yrs (range 9.6-34.3) from primary diagnosis. Primary cancers included: 14 leukemia; 10 bone tumor; 10 soft tissue sarcoma; 6 Ewing's sarcoma (EWS); 2 CNS; and, 1 each of neuroblastoma, Wilms, Hodgkin, NHL. Among non-CRT exposed survivors, the cumulative incidence of BC was 2.5% (CI 1.6-8.8) at 35 yrs from diagnosis and 1.6% (CI 1.0-2.3) by age 40 yrs. Non-CRT survivors had a 3.8-fold increased risk of BC (SIR=3.8, CI 2.8-5.0) with an AER of 4.8/$10^4$ py, CI 2.9-6.2. Survivors with potential Li-Fraumeni (LF)-associated malignancy (leukemia, CNS, sarcoma except EWS) had an SIR of 3.8 (CI 2.7-5.2) and AER of 5.1/$10^4$ py (CI 3.0-7.4). Leukemia and sarcoma survivors were at highest risk (SIR=3.9, CI 2.3-6.6 and AER=3.5/$10^4$ py, CI 1.0-5.9 and SIR 5.3, CI 3.6-7.8; AER=14.2/$10^4$ py, CI 7.5-20.9, respectively). Among sarcomas, EWS survivors had a significant risk (SIR=9.5, CI 4.3-21.7; AER=29.3/$10^4$ py, CI 3.2-55.3). Survivors of all other cancers (excluding EWS and LF cancer) did not have an elevated BC risk (SIR=2.2, CI 0.9-5.3; AER 1.5/$10^4$py, CI -0.8 – 2.3). **Conclusions:** Although overall incidence is low, CCS not treated with chest-directed radiation are at increased risk for BC. The elevated BC risk is predominantly among leukemia and sarcoma survivors, potentially due to a genetic risk, and support consideration of early BC surveillance and genetic risk assessment.

**10010** **Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**Alkylating agent exposure and sperm concentration in adult survivors of childhood cancer: A report from the St. Jude Lifetime (SJLIFE) Cohort Study.** *Presenting Author: Daniel M. Green, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Male survivors of childhood cancer treated with alkylating agents (AA) are at risk for azoospermia; however, the long-term dose-risk relationship is unknown. **Methods:** Of the 287 SJLIFE participants treated with AA but no radiation therapy, 214 provided an evaluable semen sample (mean age at diagnosis: 7.9 years, mean age at evaluation: 29.8 years, and mean years from diagnosis to evaluation: 21.6 years). Survivors were categorized as azoospermia, oligospermia (sperm concentration > 0 and < 15 million/ml), or normospermia (sperm concentration ≥ 15 million/ml). AA exposure was estimated using the cyclophosphamide equivalent dose (CED). Risks were estimated using the odds ratio (OR) and 95% confidence intervals (CI) from multinomial logistic regression analyses. **Results:** Among survivors 24.8% had azoospermia, 27.6% oligospermia, and 47.6% normospermia (Table). CED was negatively correlated with sperm concentration ($r = -0.25$, $p < 0.001$). Neither age at diagnosis nor age at evaluation was significantly associated with increased risk for azoospermia. Treatment with cis-platinum or carboplatinum did not increase the risk of azoospermia or oligospermia. Adjusting for age at diagnosis and at follow-up, CED was statistically significantly associated with azoospermia (OR= 1.22, 95% CI 1.11, 1.34) and oligospermia (OR=1.14, 95% CI, 1.04, 1.25) for each 1000 mg/m$^2$increase of CED. **Conclusions:** We identified neither a threshold dose, below which impaired spermatogenesis was unlikely, nor a dose above which azoospermia was uniformly present. This result suggests that other factors, including genetic variation in drug metabolizing pathways, may modulate the impact of AA exposure on spermatogenesis.

| | | CED (mg/m$^2$) | | | | |
|---|---|---|---|---|---|---|
| Outcome | No. | Mean | SD | Range | Median | Interquartile range |
| Azoospermia | 53 | 10,830 | 7,274 | 1,000 - 41,311 | 9,234 | 6,354-10,916 |
| Oligospermia | 59 | 8,480 | 4,264 | 2,100 - 31,894 | 8,000 | 5,650-9,872 |
| Normospermia | 102 | 6,626 | 3,576 | 1,016 - 15,645 | 6,137 | 3,386-9,396 |

**10011** **Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**Multicenter study assessing tumor molecular profiles in advanced pediatric solid tumors.** *Presenting Author: Katherine A. Janeway, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The role of molecular profiling in the clinical care of children with advanced solid tumors is unknown. Key questions are: do pediatric solid tumors have a sufficient rate of actionable alterations to warrant prospective assessment for clinical use; and, if potentially actionable alterations are identified are targeted drugs accessible for use in children with recurrent solid tumors? **Methods:** We conducted a multi-institution study to determine whether it is feasible to identify actionable alterations and make an individualized cancer therapy (iCat) recommendation using currently available clinical genomic technologies. Patients(pts) were eligible if they had a diagnosis of a high risk or recurrent/refractory solid tumor. Tumor profiling consisted of: a)mutation detection by either a Sequenom assay or targeted next-generation sequencing; b)copy number assessment by array CGH; and c)validation with IHC/FISH in some cases. Tumor profiling results were reviewed by a multi-disciplinary expert panel. iCat recommendations were made if an actionable alteration was present and if a targeted drug was available. Recommendations were tiered from 1 (strongest) to 5 (weakest) based upon strength of supporting evidence. **Results:** 100 pts were enrolled in 14 months. The most common diagnoses were neuroblastoma and Ewing sarcoma. 43% of pts had rare solid tumors. With 54 pts resulted and reviewed at the time of submission, profiling was technically feasible in 81%. Overall, 16 of 54 (30%) pts received an iCat recommendation (1 tier 1; 5 tier 3; 8 tier 4; 2 tier 5). The most common molecular aberrations in the 16 pts receiving an iCat recommendation were cancer-associated signaling pathway gene mutations (n=9), *MYC*/*MYCN* high copy number gain (n=4), and Cyclin D/CDK4/Rb pathway gene alterations (n=3). Additional pts had a potentially actionable alteration, but an iCat recommendation was not made due to lack of available drug. **Conclusions:** It is feasible to conduct a multi-institution clinical genomics study. A substantial proportion of relapsed, refractory pediatric solid tumors have actionable alterations. Additional research is required to determine whether applying genomics in this setting has an impact on pt outcome.

**10012 Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**What's in an exome? Diversity of diagnostic and incidental findings revealed by clinical tumor and germline sequencing of 100 children with solid tumors.** *Presenting Author: D. Williams Parsons, Texas Children's Cancer Center, Houston, TX*

**Background:** Whole exome sequencing (WES) can identify a wide spectrum of tumor and germline genetic findings. Before WES is incorporated into oncology practice, it is necessary to gain an understanding of the nature and frequency of these genetic results in cancer patients. **Methods:** The BASIC$^3$ (Baylor Advancing Sequencing in Childhood Cancer Care) study investigates the clinical implementation of CLIA-certified WES for sequentially diagnosed children with CNS and non-CNS solid tumors. Blood and frozen tumor samples undergo WES, with the resulting germline and tumor reports deposited into the medical record and disclosed to families by their oncologist and a genetic counselor. Germline reports include: (1) deleterious mutations and variants of uncertain significance (VUS) in disease genes related to cancer or other patient phenotypes, (2) incidental medically-actionable mutations, (3) FDA-approved pharmacogenetic (PGX) variants, (4) mitochondrial (mtDNA) mutations, and (5) carrier status for recessive disorders if requested by parents. **Results:** Of the first 124 eligible families, 100 (81%) consented to participate. At least one somatic mutation of proven or potential clinical relevance was reported in 22/80 (28%) patients with tumor available (e.g. *ALK, CTNNB1*, *BRAF*, *KRAS*, *KIT, TSC2*). Diagnostic germline findings were found in 11 cases: 8 pathogenic mutations in dominant cancer susceptibility genes (*TP53* x 2, *MSH2*, *BRCA1*, *WT1*, *BRCA2*, *DICER1*, *VHL*) and 3 mutations underlying non-oncologic diagnoses. There were 7 patients with medically-actionable incidental findings (2 in mtDNA). Nearly all patients harbored VUS in cancer genes (98%; median of 3) and PGX variants (89%; median of 1). Carrier mutations were reported in 76/89 (85%; median of 2) patients. **Conclusions:** Clinical tumor and germline WES revealed diagnostic and potentially actionable results in nearly 40% of pediatric solid tumor patients, including both cancer and non-cancer-related findings. Successful incorporation of genomic methods into the care of oncology patients will require preparation of clinicians to disclose and manage these diverse results. Supported by 1U01HG006485.

**10013 Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**Factors associated with nonadherence to oral 6-mercaptopurine (6MP) in children with acute lymphoblastic leukemia (ALL): A report from Children's Oncology Group (COG) study AALL03N1.** *Presenting Author: Wendy Landier, City of Hope, Duarte, CA*

**Background:** We have previously shown that poor adherence (adherence rate <95%) to oral 6MP is prevalent in children with ALL, and increases relapse risk (JCO 30[17]:2094-101). However, behavioral predictors of non-adherence to oral 6MP have not been examined. **Methods:** We addressed this gap in 462 children (non-Hispanic Whites: 34%; Hispanics: 36%, Asians: 15%, African-Americans: 15%) with ALL diagnosed at age ≤21 years, and receiving maintenance therapy. 6MP adherence was measured over 6 months using Medication Event Management System (MEMS) that recorded dates/times of 6MP bottle opening (adherence rate=days bottle opened/days 6MP prescribed). A 37-item questionnaire assessed barriers/facilitators (addressing the Health Belief Model [HBM]) to adherence. **Results:** Median age at study was 6 years (2-20); 67% were males; 40% had high-risk disease. MEMS monitoring for 76,174 person-days yielded a non-adherence rate of 44.4%. Multivariable analysis identified the following predictors of non-adherence: i) age ≥12 years (Odds ratio [OR]=2.2, p=0.02); ii) Hispanic ethnicity (OR=2.1, p=0.005); iii) African-American race (OR=4.2, p<.001); iv) parental education ≤high school (OR=1.8, p=0.02); v) annual household income <$50,000 (OR=1.6, p=0.05); vi) involvement of ≥2 adults in 6MP supervision (OR=2.4; p=.004); vii) failure (on part of parents/patients) to understand the purpose of 6MP (OR=2.8; p<.001); viii) failure to take 6MP at the same time each day (OR=1.8; p<.01); and ix) taking 6MP with milk/dairy (OR=1.9; p=.03). **Conclusions:** In addition to sociodemographic predictors, we identified behavioral determinants of 6MP non-adherence that align with HBM. Lack of perceived benefits (not understanding the purpose of 6MP), absence of cues to action (not taking medication at same time each day), low self-efficacy (absence of a designated adult assuming primary responsibility for 6MP administration), and presence of barriers (dietary restrictions) contributed to non-adherence. These findings identify vulnerable populations that could benefit from targeted interventions to improve adherence in pediatric ALL. Clinical trial information: NCT00268528.

**10014 Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**The significance of minimal residual disease (MRD) in relapsed childhood B-lymphoblastic leukemia (B-ALL): A report from Children's Oncology Group (COG) protocol AALL0433.** *Presenting Author: Glen Lew, Emory University School of Medicine, Atlanta, GA*

**Background:** Relapsed childhood B-ALL has a poor prognosis. Few risk factors beyond immunophenotype, timing, and site of relapse are known to affect outcome. MRD is a powerful predictor of outcome in newly diagnosed ALL, but its significance after relapse is less clear. We report an analysis of MRD and outcome from the AALL0433 protocol for childhood B-ALL with intermediate-risk relapse. **Methods:** AALL0433 is a Phase 3 study of intermediate-risk relapsed childhood B-ALL, defined as CNS/testicular relapse <18 mo. or bone marrow (BM)/combined relapse >36 mo. from diagnosis. Therapy is based upon the AALL01P2 / 9412 platforms. BM MRD was measured by flow cytometry at end-induction; results were blinded to investigators. Only matched family donor SCT was allowed on protocol. 271 eligible patients were enrolled. Outcome by treatment received remains blinded at this time. **Results:** The 3-yr. EFS/OS for the entire cohort of 271 patients were 60.7 ± 4.6% and 71.3 ± 4.3%, respectively. All 29 patients with isolated extramedullary relapse had MRD <0.01% at end-induction. Further analyses focused on patients with BM/combined relapse (n=242). The 3-yr. EFS/OS for this group of patients was 62.8 ± 4.8% and 73.6 ± 4.4%, respectively. 175 patients had available end-induction MRD data: 84 patients had MRD levels <0.01%, 28 were between 0.01-0.1%, and 63 had MRD > 0.1%. These three groups had 3-yr. EFS of 83.4 ± 5.4%, 70.4 ± 12.8%, and 40.9 ± 8.4% respectively (p=0.001), and 3-yr. OS of 88.5 ± 4.6%, 83.0 ± 10.3%, and 56.2 ± 9.0%, respectively (p = 0.0019). An MRD cutoff of 0.1% provided the best discriminator of outcome, with 3-yr. EFS 80.2 ± 5.2% vs. 40.9 ± 8.4%, and 3-yr. OS of 87.1 ± 4.3% vs. 56.2 ± 9.0% for those below (n=112) or above (n=63) this cutoff. **Conclusions:** Preliminary efficacy of the AALL0433 platform for intermediate-risk relapse of childhood B-ALL is encouraging. An end-induction MRD cutoff of 0.1% was the best predictor of outcome for patients with late BM/combined relapse. Because of the major survival difference at the 0.1% MRD cutoff, it will be used to stratify late BM relapse patients to receive chemotherapy vs. SCT in the next COG relapsed ALL trial. Clinical trial information: NCT00381680.

**10015 Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**Outcome of childhood T-cell acute lymphoblastic leukemia (T-ALL): Results from DFCI protocol 05-001.** *Presenting Author: Andrew E. Place, Dana-Farber Cancer Institute, Boston, MA*

**Background:** T-ALL accounts for ~ 15% of pediatric ALL; in general, outcomes have been less favorable than those for B-ALL. Methods: Between 2005-11, 97 evaluable patients (pts) aged 1-18 years (yrs) with newly diagnosed T-ALL were enrolled on DFCI ALL Consortium Protocol 05-001. Early T-cell precursor (ETP) subtype was retrospectively assessed in 90 pts by flow cytometry. End-Induction minimal residual disease (MRD) was assessed by PCR. All 97 pts were initially treated as high-risk regardless of other presenting features; 2 pts were assigned more intensive post-induction therapy based on cytogenetics (MLL-R:1; BCR-ABL: 1). **Results:** Presenting features and outcomes are shown in Table 1. The 4-yr EFS and OS for all T-ALL pts was 83% and 89%, respectively (median follow-up: 4.3 yrs). End-induction MRD was evaluable in 58 (67%) pts achieving CR; high MRD (>0.001) was associated with an inferior DFS (high MRD (N=15): 79%, low MRD (N=43): 95%, p=0.047). ETP subtype was identified in 16 pts (18%). ETP pts had a higher rate of induction failure (31% vs. 4%, p<0.01) and an inferior EFS (62% vs. 89%, p<0.01). None of the ETP pts who achieved CR after the 1$^{st}$ month of treatment subsequently relapsed. **Conclusions:** Overall outcome for T-ALL pts on Protocol 05-001 was favorable, especially for non-ETP pts with low MRD (4-yr DFS 98%; 95% CI:[84-99%]). Future studies should focus on intensifying post-induction treatment for pts with high end-induction MRD and modifying induction regimens for ETP pts. Clinical trial information: NCT00400946.

**Outcome and presenting features for T-ALL on DFCI 05-001.**

**10016 Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**The impact of initial cerebrospinal fluid (CSF) findings on outcome among patients with NCI standard (SR) and high-risk (HR) B-lymphoblastic leukemia (ALL): A report from the Children's Oncology Group (COG) Studies AALL0331 and AALL0232.** *Presenting Author: Naomi Joan Winick, The University of Texas Southwestern Medical Center; Center for Cancer and Blood Disorders, Children's Medical Center Dallas, Dallas, TX*

**Background:** To determine the prognostic significance of variable numbers of white cells (WBC), blasts and/or red cells (RBC) in diagnostic CSF samples of ALL patients, COG protocols, AALL0331 (SR)/AALL0232 (HR) incorporated a uniform CSF and risk group classification schema for all newly diagnosed patients. **Methods:** Patients, 1-31 years, were enrolled on the classification protocol, AALL03B1. CSF status was designated as: CNS1-no blasts; CNS2a- < 5 WBC + blasts + < 10 RBC/ml; CNS2b-< 5 WBC + blasts + > 10 RBC/ml; CNS2c- > 5 WBC + blasts, with excess WBC proportional to RBC; CNS3a- > 5 WBC + blasts + < 10 RBC/ml; CNS3b - > 5 WBC + blasts + > 10 RBC/ml, with excess WBC not proportional to RBC; CNS3c- clinical signs of CNS leukemia (e.g. cranial nerve deficits, hypothalamic disease). Only CNS1 patients could be allocated to the SR-low risk arm. CNS2 status did not impact therapy but CNS3 patients received augmented therapy and 1800 cGY cranial radiation. **Results:** In multivariate analysis that includes age and WBC at diagnosis and Day 29 MRD < 0.1%, the presence of CSF blasts, regardless of the number of CSF WBC or RBC is an independent adverse predictor of outcome for NCI SR (all of whom received dexamethasone) and HR patients. The EFS difference reflects a significant difference in the incidence of CNS, not marrow relapse in CNS1vs CNS2/3 patients (see Table). Conclusion: Even low levels of CNS leukemia, regardless of the number of RBCs, are associated with a lower EFS/OS and an increase in the likelihood of CNS relapse. The use of dexamethasone in NCI SR patients did not negate the impact of CSF blasts. Further augmentation of CNS directed therapy is needed for patients with CNS2/3 disease. Clinical trial information: NCY00482352.

**10017 Oral Abstract Session, Sun, 9:45 AM-12:45 PM**

**The effects of sodium thiosulfate (STS) on cisplatin-induced hearing loss: A report from the Children's Oncology Group.** *Presenting Author: David Robert Freyer, Children's Hospital Los Angeles, Los Angeles, CA*

**Background:** Cisplatin frequently causes irreversible hearing loss in children treated for cancer. STS is a thiol reducing agent shown in preclinical studies to protect hearing but not the tumor with its timed administration post-cisplatin. **Methods:** The primary aim of ACCL0431 was to evaluate the efficacy of STS, compared with observation (Obs), for preventing cisplatin-induced hearing loss. Eligible subjects were 1–18 years old with normal audiometry and planned cisplatin infusions of ≤ 6 hours with cumulative dose ≥ 200 mg/m$^2$. Subjects were randomized either to Obs or treatment with STS 16 grams/m$^2$ IV over 15 minutes 6 hours after each cisplatin dose. Hearing was measured using standard audiometry for age; data were reviewed centrally using American Speech-Language-Hearing Association criteria. The proportion of subjects with hearing loss ($\chi^2$ test) assessed at 4 weeks post the final cisplatin dose (primary endpoint) and EFS/OS (log-rank test, 2-year cumulative estimates and Cox proportional hazards model) were compared between the two groups. **Results:** 126 eligible subjects were enrolled with germ cell tumor (32), osteosarcoma (30), neuroblastoma (26), medulloblastoma (26), hepatoblastoma (7) or other (5). 105 subjects (64 male, 30 <5 years old) were evaluable for the primary aim. The proportion of hearing loss for STS vs. Obs was 28.6% vs. 55.4%, respectively (p=0.006). Including all 126 subjects at median post-diagnosis follow-up of 2.1 years, EFS for STS vs. Obs was 60.1% vs. 70.0% (p=0.53); OS was 74.5% vs. 88.8% (p=0.050). Subset analysis by extent of disease (determined post hoc) was performed. For subjects with localized disease, EFS was 72.5% vs. 67.1% (p=0.61); HR (hazard ratio) 0.81 (p=0.61); OS was 89.7% vs. 89.2% (p=0.73); HR 1.26 (p=0.73). For those with disseminated disease, EFS was 35.8% vs. 75.0% (p=0.047); HR 2.51 (p=0.055); OS was 49.0% vs. 88.3% (p=0.010); HR 4.03 (p=0.017). **Conclusions:** STS protects against cisplatin-induced hearing loss in children. However, the potentially lower survival seen in those with disseminated disease receiving STS raises the concern of a tumor protective effect when the drug is administered on this dose and schedule. Clinical trial information: NCT00716976.

**10018 Poster Highlights Session (Board #319), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Phase I study of the MEK1/2 inhibitor selumetinib (AZD6244) hydrogen sulfate in children and young adults with neurofibromatosis type 1 (NF1) and inoperable plexiform neurofibromas (PNs).** *Presenting Author: Brigitte C. Widemann, Pediatric Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD*

**Background:** Lack of functional neurofibromin in NF1 leads to dysregulated Ras and tumorigenesis. Selumetinib (AZD6244; ARRY-142886), an oral selective inhibitor of MEK1/2, may inhibit PN growth by blocking Ras signaling. **Methods:** We are conducting a phase 1 trial (NCT01362803) to determine the maximum tolerated dose (MTD) and plasma pharmacokinetics (PK) of selumetinib in patients (pts) 3-18 years old with NF1 and inoperable PNs. The MTD is determined based on cycle (C) 1-3 toxicities. Selumetinib is administered BID on a continuous dosing schedule (1 C = 28 days) at dose level (DL) 1: 20 mg/m$^2$/dose, and 2: 30 mg/m$^2$/dose. Response evaluation with volumetric MRI analysis occurs after C 5, 10, and then after every 6 C (partial response [PR] = ≥20% decrease in the PN volume). **Results:** Eighteen pts (10 M:8 F, median age 12.9 years, range 5.3-18.5) with a median PN volume of 1204 mL (range 47-10,269 mL) have enrolled. DL2 exceeded the MTD with DLT in 2/6 pts: grade (gr) 3 creatine kinase (CK) elevation (n=1), and gr 3 decrease in left ventricular ejection fraction (n=1). DL1 was tolerated with DLT in 2/12 pts: gr 3 cellulitis (n=1), and grade 3 urticaria (n=1). The most frequent toxicities (all grades) are acneiform rash, asymptomatic CK elevation, nausea, vomiting, abdominal pain, diarrhea, and fatigue. All DLTs have been reversible. Preliminary median (range) selumetinib C1 day 1 PK parameters [DL1 (n=2), DL2 (n=5)] were: $C_{max}$ DL1 513 ng/mL (487-539), DL2 841 ng/mL (576-1770); $AUC_{0\text{-}24h}$DL1 2068 (2046-2089) ngxh/mL, DL2 2702 (2088-6008) ngxh/mL; half-life DL1 7.7 h (6.8-8.5), DL2 7.6 h (5.4-9.8). Of 11 pts with ≥ 1 restaging MRI, all had a decrease in PN volume (median maximal decrease 24%, range 8-39), and 3/5 at DL1, and 3/6 at DL 2 had a PR. All pts remain on trial after a median of 9 C (range 4-30). **Conclusions:** In children with NF1 PNs selumetinib is tolerated at 20 mg/m$^2$/dose BID on a continuous dosing schedule, approximately 50% of the adult recommended dose (75 mg BID). Preliminary activity is observed at DL1 and DL2. Enrollment is being expanded at 25 mg/m$^2$/dose, the MTD in study PBTC-029 for pediatric low grade gliomas, and a phase II trial is in development. Clinical trial information: NCT01362803.

**10019 Poster Highlights Session (Board #320), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**A phase I study of ruxolitinib in children with relapsed/refractory solid tumors, leukemias, or myeloproliferative neoplasms: A Children's Oncology Group Phase I Consortium study (ADVL1011).** *Presenting Author: Sarah K. Tasian, The Children's Hospital of Philadelphia, Philadelphia, PA*

**Background:** Ruxolitinib, an orally bioavailable inhibitor of the JAK family of kinases, may play a role in the treatment of childhood cancers with *JAK1*, *JAK2*, *CRLF2,* or other *BCR-ABL1*-like (Ph-like) alterations. We performed a phase 1 and pharmacokinetic (PK) study of ruxolitinib in children with relapsed/refractory solid tumors (STs) or hematologic malignancies (HMs; leukemias or myeloproliferative neoplasms). **Methods:** Ruxolitinib was administered orally twice daily (BID) continuously in 28 day cycles. The starting dose (15 mg/m$^2$; dose level 1, DL1) was equivalent to the recommended adult dose of 25 mg/dose BID. Using the rolling six design, subsequent 20% dose escalations were 21 (DL2), 29 (DL3), 39 (DL4), and 50 (DL5) mg/m$^2$/dose. Patients with HMs were enrolled at one dose level below ST patients. PK and pharmacodynamic analyses of phosphorylated (p) JAK2, STAT5, and S6 were performed in Cycle 1. **Results:** Twenty-eight ST and 21 HM patients were enrolled (median age 14.4 years; range 2.4 - 21.4). Twenty-seven ST and 10 HM patients were evaluable for toxicity. Ruxolitinib was generally well-tolerated, although there was 1 grade 5 event at DL2 in a ST patient (multi-system organ failure). During the dose escalation phase in STs, there was 1 dose-limiting toxicity at DL3 (neutropenia), DL4 (neutropenia), and DL5 (increased CPK). Grades 3 and 4 non-dose-limiting adverse events related to therapy in STs included cytopenias, nausea, and elevated transaminases and creatinine. PK parameters were similar to those in adults with marked inter-patient variability in the $C_{max}$ and AUC. Median peak plasma inhibitory activity of pJAK2 (44.8%), pSTAT5 (58.9%), and pS6 (62.3%) appeared generally dose-independent with the exception of greater pSTAT5 inhibition at DL5. **Conclusions:** The recommended phase 2 dose of ruxolitinib is 50 mg/m$^2$ orally BID. A trial of ruxolitinib with chemotherapy for children with acute lymphoblastic leukemia harboring activating JAK mutations or fusions or other Ph-like alterations is in development. Clinical trial information: NCT01164163.

**Results of nimotuzumab and vinorelbine, radiation, and re-irradiation for diffuse pontine glioma in childhood.** *Presenting Author: Maura Massimino, Pediatric Oncology Unit, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

**Background:** Radiotherapy is the only treatment definitely indicated for diffuse pontine gliomas (DIPG). Findings on the role of EGFR signaling in the onset of childhood DIPG has prompted the use of nimotuzumab, an anti-EGFR monoclonal antibody. Assuming a potential synergy with vinorelbine and radiotherapy, a pilot phase 2 protocol launched in 2009 combined nimotuzumab with concomitant radiation and vinorelbine. A protocol amendment in July 2011 introduced re-irradiation at relapse. The primary endpoint for first-line treatment was objective response rate (CR+PR+SD) according to the RECIST. This report concerns the outcome of this whole strategy. **Methods:** Vinorelbine 20 mg/m$^2$ was administered weekly, with nimotuzumab 150 mg/m$^2$ in the first 12 weeks of treatment; radiotherapy was delivered from weeks 3 to 9, for a total dose of 54 Gy. Then vinorelbine 25 mg/m$^2$and nimotuzumab were given every other week until the tumor progressed or for up to two years. Re-irradiation consisted of 19.8 Gy, fractionated over 11 days. Baseline and latest MRIs were assessed blindly by an outside neuroradiologist. **Results:** 25 children (mean age 7.4 years) were enrolled from August 2009 (median follow-up 29 months). A response was observed in 24/25 patients (96%). The nimotuzumab/vinorelbine combination was very well tolerated, with no acute side-effects. Eleven of 16 locally-relapsing patients were re-irradiated. One-year PFS and OS rates were 30±10% and 76±9%, respectively; 2-year OS was 27±9%; the median OS was 15 months. **Conclusions:** This strategy generated interesting results and warrants further investigation.

**Hearts too small for body size after doxorubicin for childhood ALL: Grinch syndrome.** *Presenting Author: Steven E. Lipshultz, Children's Hospital of Michigan, Wayne State University, Detroit, MI*

**Background:** Cross sectional studies show that cardiac abnormalities are common in survivors of doxorubicin (DOX)-treated childhood cancers. Longitudinal data, however, are rare. **Methods:** Serial echocardiograms (N = 900) from 115 DOX-treated childhood ALL (DFCI protocols 72-01 – 85-01) survivors were reported as indexed Z scores, indicating SDs above or below the normal mean for body size. Central single observer remeasurement minimized variability. Median individual and cumulative DOX doses were 30 mg/m$^2$/dose and 352 mg/m$^2$, respectively. **Results:** During 21 yrs median follow up (range 3-39), left ventricular (LV) fractional shortening remained decreased after DOX (mean LVFS >24 yrs: -2.42 [P<.05]). Both reduced LVFS and wall thickness related to cumulative dose (P<.05). LV dimension was initially above normal, but fell to become significantly decreased by last follow up (≤ 3yrs: +.53 [P<.05], > 12, ≤ 15yrs: +.08, > 24yrs: -.62 [P<.05], change over time: P<.001). The LV thickness-dimension ratio was significantly reduced until 21 yrs of follow up, following which it increased secondary to a fall in dimension and increasing wall thickness. However, the rise in wall thickness was accompanied by a progressive significant reduction in LV mass (≤ 3yrs: -.09 [NS], ≤ 24 yrs: -1.65 [P<.05]), indicating that increasing wall thickness was secondary to decreasing chamber size rather than myocardial hypertrophy. **Conclusions:** Progressive DOX cardiotoxicity transitions from an early subclinical dilated cardiomyopathy to a potentially restrictive cardiomyopathy detectable by 15+ years after exposure. The restrictive phase manifests as a relative decrease in LV dimension with a geometrically consequent rise in wall thickness leading to a normal thickness-dimension ratio at latest follow up. There is also a progressive fall in LV mass and cavity size that becomes inadequate for body size. Cardiomyopathy marked by shrinking myocardial and cavity size (Grinch Syndrome) appears to be a long term risk in this population. Monitoring for late clinically significant cardiotoxicity is essential. Symptomatic restrictive cardiomyopathy medical management failures are common, requiring use of early surgical therapeutic options.

**10022 Poster Highlights Session (Board #323), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Risk and impact of pulmonary complications in survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS).** *Presenting Author: Andrew Charles Dietz, Rady Children's Hospital San Diego, University of California, San Diego, San Diego, CA*

**Background:** Pulmonary complications from exposure to radiation, bleomycin and the nitrosureas have been well-documented among adult survivors of childhood cancer. However, the magnitude of condition-specific risks, compared to a non-cancer population, and the long-term impact on physical activity have not been well described. **Methods:** This analysis includes 13,208 five-yr survivors of childhood cancer (53% male, age 8 yrs [range: 0-21] at diagnosis, 33 yrs [6-59] at last follow-up), diagnosed ≤ 21 yrs between 1970-1986. Self-reported pulmonary outcomes were compared to a sibling control group (N=4,023) using Poisson regression to estimate rate ratios (RR) and 95% confidence intervals (CI) adjusted for attained age, sex, race, body mass index, congestive heart failure, and smoking status. Logistic regression was used to estimate associations (odds ratios, OR) between pulmonary outcomes and daily physical activity (walk one block, carry groceries, climb stairs, etc). **Results:** Compared to siblings, fewer survivors ever smoked (21.2% vs. 34.3%, p<0.001) but were more likely to report asthma (RR 1.4, CI 1.2-1.6), bronchitis (RR 1.2, CI 1.1-1.3), chronic cough (RR 2.2, CI 1.9-2.5), emphysema (RR 2.5, CI 1.2-5.2), need for extra oxygen (RR 2.2, CI 1.8-2.6), pulmonary fibrosis (RR 3.9, CI 2.7-5.8), pleurisy (RR 1.3, CI 1.1-1.7), and recurrent pneumonia (RR 2.8, CI 1.9-4.0). Cumulative incidence of any pulmonary condition by age 40 was 78.7% (CI 78.3-79.2). Lung cancer was reported in 17 (0.1%) with a standardized incidence ratio of 3.9 (CI 2.3-6.2). The standardized mortality ratio for death due to a pulmonary condition was 9.1 (CI 7.4-11). Limited daily physical activities were more likely among survivors with a pulmonary condition vs. those without: asthma (OR 1.6, CI 1.4-1.8), bronchitis (OR 1.5, CI 1.4 - 1.7), chronic cough (OR 2.8, CI 2.5 - 3.1), emphysema (OR 2.6, CI 1.5 - 4.3), need for extra oxygen (OR 3.3, CI 2.9 - 3.7), lung fibrosis (OR 2.3, CI 1.9 - 2.8), pleurisy (OR 1.9, CI 1.6 - 2.3), and recurrent pneumonia (OR 3.6, CI 2.9 - 4.4). **Conclusions:** Pulmonary complications are substantial among cancer survivors, significantly impacting daily activity and increasing risk of death.

**10023 Poster Highlights Session (Board #324), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Exercise and risk of major cardiovascular events in adult survivors of childhood Hodgkin lymphoma: A report from the Childhood Cancer Survivor Study (CCSS).** *Presenting Author: Lee Jones, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Adult survivors of childhood Hodgkin's lymphoma are at elevated risk of treatment-related major cardiovascular (CV) events. We investigated whether exercise modified this association in HL survivors participating in the CCSS. **Methods:** HL survivors (n=1,187), median age 31.2 (range 18.0-48.9 years) and free of CV disease at baseline completed a questionnaire evaluating vigorous-intensity exercise behavior over the past week. Subsequent CV events were collected in follow-up questionnaires and graded according to the CTCAE (v. 4.03). The primary end point was incidence of any major (grade 3 to 5) CV event. Secondary end points were incidence of grade 3 to 5 CV events [coronary artery disease (CAD), heart failure, valve replacement, arrhythmia, and CV death]. Poisson regression analyses were used to estimate the association between exercise exposure [metabolic equivalent task-hrs·wk$^{-1}$(MET)] and risk of major CV events after adjustment for important clinical covariates (age, smoking, education, CV risk factors, and baseline grade 3-4 health conditions) and cancer treatment (anthracycline exposure and chest radiation). **Results:** A total of 135 major CV events were reported after median follow-up of 11.9 (range 1.7 - 14.3) years. In multivariable-adjusted analyses, the incidence of any CV event declined across increasing MET categories ($P_{trend}$=0.002). Compared with survivors reporting 0 METs, the adjusted RR for any CV event was 0.87 (95% CI, 0.56 to 1.34) for 3 to 6 METs, 0.45 (95% CI, 0.26 to 0.80) for 9 to 12 METs, and 0.47 (95% CI, 0.23 to 0.95) for 15 to 21 METs. A similar pattern was observed for the incidence of CAD (adjusted $P_{trend}$=0.005). The cumulative incidence of any CV event was 12.2% at 10 years for survivors reporting 0 METs, compared to 5.2% for those reporting ≥9 METs. Adherence to national exercise guidelines (i.e., ≥9 METs) was associated with a 51% reduction in the risk of any CV event, in comparison with not meeting the guidelines (p=0.002). **Conclusions:** Vigorous exercise reduces the incidence of CV events in a dose-dependent mannerbeyond CV risk profile and treatment exposure in adult survivors of childhood HL.

**10024 Poster Highlights Session (Board #325), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Late mortality and relapse after dexrazoxane (DRZ) treatment: An update from the Children's Oncology Group (COG).** *Presenting Author: Eric Jessen Chow, Fred Hutchinson Cancer Research Center, Seattle Children's Hospital, Seattle, WA*

**Background:** DRZ use as a cardioprotectant in pediatric oncology has been limited by concerns regarding its efficacy and possible induction of second cancers, both of which may compromise overall long-term survival. **Methods:** COG protocols P9404 (T-cell acute lymphoblastic leukemia/lymphoma, n=537), P9425 (advanced stage Hodgkin lymphoma, n=216), and P9426 (low/intermediate stage Hodgkin, n=255) were conducted between 1996 and 2001. Patients were randomly assigned to treatment with or without DRZ (10:1 DRZ:doxorubicin alone given as IV bolus before each doxorubicin dose); cumulative protocol-specified doxorubicin dose: 100-360 mg/m$^2$. Data from all 3 trials were aggregated to examine overall relapse rates, and also linked with the US National Death Index to determine overall and cause-specific mortality by DRZ status (intent-to-treat). The combined sample had 80% power to detect differences in mortality and relapse rates of 5-7% and 6-8%, respectively. **Results:** Among 1,008 patients (DRZ+, n=507) with a median follow-up of 8.3 years (range 0-16.7), 132 died (DRZ+ n=67). With similar duration of follow-up by DRZ status, DRZ did not affect overall mortality (DRZ+, 12.8% vs. DRZ-, 12.2% at 10 years; HR 1.02, 95% CI 0.72-1.43) or relapse (10-year cumulative incidence: DRZ+, 15.6% vs. DRZ-, 18.8%; HR 0.82, 95% CI 0.60-1.10). Findings were similar when each protocol was examined separately. DRZ also was not associated with differential causes of death, with the original cancer accounting for 75.8% of all deaths (DRZ+/-, n=48/52; HR 0.91, 95% CI 0.61-1.34), followed by second cancers (DRZ+/-, n=10/9; HR 1.08, 95% CI 0.44-2.67), toxicity (DRZ+/-, n=7/3; HR 2.30, 95% CI 0.60-8.91), and other/unknown causes (DRZ+/-, n=2/1). There was no detectable difference in deaths due to acute myeloid leukemia/myelodysplasia (DRZ+/-, n=6/5) or with a cardiovascular event as a contributing cause (DRZ+/-, n=4/2). **Conclusions:** DRZ was not associated with a differential risk of mortality or relapse among randomized pediatric leukemia and lymphoma patients. Whether DRZ reduced cardiotoxicity is the focus of an ongoing prospective study. Clinical trial information: NCT01230983, NCT00005578, NCT00002827.

**10025 Poster Highlights Session (Board #326), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Cardiac outcomes in aging survivors of childhood cancer exposed to cardiotoxic therapy: A report from the St. Jude Lifetime (SJLIFE) Cohort Study.** *Presenting Author: Daniel A. Mulrooney, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Cardiac studies among adult survivors of childhood cancer have generally relied on self-report or registry data; few have systematically performed comprehensive clinical assessments. **Methods:** We assessed 1,831 childhood cancer survivors, ≥ 18 yrs. of age and ≥10 yrs. from cardiotoxic therapy (radiation and/or anthracyclines). Cardiomyopathy (CMP), coronary artery disease (CAD), valve and conduction abnormalities, poor fitness (6-minute walk test < 490 minutes) and health status (SF-36 Physical Component score ≤ 40) were assessed. Cumulative prevalence was calculated by the Kaplan-Meir method. Cox proportional hazard models were used to calculate rate ratios (RR) and 95% confidence intervals (CI). **Results:** Survivors (52% male) were on average 8.3 yrs. (range: 0-21) at diagnosis and 32 yrs. (18-60) at evaluation. CMP was diagnosed in 6.7% (yield from screening 3.4%), CAD in 7.1% (yield 4.5%), valve disorders in 52% (yield 44%), and conduction abnormalities in 11% (yield 8%). By age 50 yrs. the estimated cumulative prevalence of CMP, CAD, valve and conduction disorders was 24% (CI 18-30%), 25% (CI 18-32%), 86% (CI 81-90%), and 42% (CI 34-49%), respectively. Diastolic dysfunction was present in 12%, and 18% of survivors had > 1 cardiac condition. Anthracycline exposure ≥ 250 mg/m$^2$ increased the risk of CMP (RR 4.1, CI 2.3-7.2), valve disorders (RR 1.4, CI 1.1-1.9), and conduction abnormalities (RR 2.0, CI 1.3-3.2) compared to unexposed survivors. Radiation to the heart increased the risk of CAD (RR 3.5, CI 1.8-6.7), valve disorders (RR 1.3, CI 1.1-1.6), and conduction abnormalities (RR 1.5, CI 1.1-2.1) compared to those unexposed. Survivors with CMP and CAD had poorer physical fitness compared to those without (31% vs. 19%, p=0.006 and 37% vs. 20%, p=0.003), and lower health status among those with CMP (46% vs. 16%, p<0.001), CAD (49% vs. 16%, p<0.001), valve (27% vs. 18%, p<0.002) and conduction abnormalities (36% vs. 15%, p<0.001). **Conclusions:** A substantial proportion of survivors exposed to cardiotoxic therapy have cardiac disease by 50 years of age. Systematic screening of adult survivors of childhood cancer identified considerable subclinical disease.

**10026 Poster Highlights Session (Board #327), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Immunotherapy (IT) with ch14.18/CHO for high-risk neuroblastoma: First results from the randomised HR-NBL1/SIOPEN trial.** *Presenting Author: Ruth L Ladenstein, St. Anna Children's Cancer Research Institute, Vienna, Austria*

**Background:** The HR-NBL1/SIOPEN trial randomised 2 essential treatment concepts: Randomisation R1 investigated BUMEL superiority (plenary session ASCO 2012), whilst the R2 randomisation tested the benefits of adding subcutaneous interleukin 2 (scIL2) to ch14.18/CHO mAB immunotherapy(IT) and 13 cis retinoic acid (13-cis RA). The R2 population reached the target population of 400 patients (pts) in August 2013. **Methods:** After Rapid Cojec induction pts were randomised in R1 (296 BuMel, 302 CEM) till 09/2010. Median follow up is 6.2 years. Eligibility included complete bone marrow remission and ≤3, but improved mIBG positive spots. Local control included surgery and radiotherapy of 21 Gy. Eligibility to R2 included previous R1 eligibility. R2 was initiated in 2009 aiming at 400pts receiving ch14.18/CHOmAB as 8-hour infusion with 20mg/m$^2$ over 5 days and 13 cis RA over a total of 5 IT cycles. The schedule requires high dose morphine to control for neuropathic pain. R2 addressed a scIL2 question, using a dose of 6x10E6/m$^2$/day over 5 days twice in a weekly interval, given in week 2 in parallel with ch14.18/CHOmAb. **Results:** The superiority of BuMel in EFS and OS over CEM (3-years EFS&OS 50%/61% vs. 38%/52%; p<0.001) is maintained with a significantly lower relapse and progression rate with BuMel (48% vs. 58%) as major factor. Severe toxicity rates (ICU, toxic deaths) are below 10%, but are higher for CEM (p=0.012). Hence the MAT toxicity profile still favours BuMel in spite of a VOD rate of 24% (grade 3: 4%) vs. 10% in CEM (Grade3: 1%). Having reached the R2 target in August 2013, the randomisation is currently suspended expecting "last patient out" in 02/2014 with liberation of the randomised R2 data by the DMC thereafter. The R2 population undisclosed for treatment arms currently reveals a 2 year EFS/OS of 56%/68%. The scIL2 arm carries a significantly higher toxicity burden related to IL2 associated side effects like fever and capillary leak with a number of pts in the IL2 arm stopping treatment early. **Conclusions:** BuMel is maintained as SIOPEN standard treatment whilst R2 results will have a major impact on the future management of immunotherapy. Clinical trial information: NCT01704716.

**10027 Poster Highlights Session (Board #328), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Genetic modification of T cells with a novel bispecific chimeric antigen receptor to enhance the control of high-grade glioma (HGG).** *Presenting Author: Meenakshi Hegde, Texas Children's Cancer Center, Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX*

**Background:** Highly targeted immunotherapy with adoptively transferred chimeric antigen receptor (CAR) T cells has shown considerable efficacy against some refractory childhood malignancies. Downregulation/mutation of targeted antigen can however create antigen loss escape variants. Multispecific T-cell approach could therefore further improve their therapeutic efficacy. **Methods:** We created a novel bispecific CAR that incorporates two extracellular antigen-recognition domains; one for HER2 (from HER2 monoclonal antibody FRP5) and the other for IL-13R$\alpha$2 (a mutated IL-13 molecule), in tandem (TanCAR). TanCAR was rationally designed by in silico modeling. Intracellular domain consists of a CD28/zeta-signaling chain. TanCAR encoding DNA was then synthesized and force expressed on T cells using retroviral system. Surface expression of extracellular domain of the TanCAR in its entirety was confirmed using HER2/IL-13R$\alpha$2 specific methods on flowcytometry. Functionality of TanCAR T cells was evaluated using standard immunoassays. Orthotopic murine model of HGG was used for in vivoexperiments. **Results:** 50-80% of T cells expressed the TanCAR on cell surface. In cytotoxicity assays, bispecific TanCAR T cells showed improved killing of IL-13R$\alpha$2 and HER2 positive HGG cell lines and autologous HGG cells over the control T cells from the same donor. Though TanCAR T cells were effectively activated and secreted immunostimulatory cytokines on recognizing HER2 and IL-13R$\alpha$2 proteins individually, cytokine secretion was significantly higher on simultaneous exposure to both target antigens. Adoptively transferred TanCAR T cells induced regression of established HGG xenografts. **Conclusions:** TanCAR T cells can distinctly target HER2 or IL-13R$\alpha$2 individually as well as both antigens simultaneously.TanCAR T cells exhibit enhanced effector functionality in vitro and anti-tumor activity in vivo, demonstrating their potential for therapeutic application. Targeting the heterogeneity in HGG with such a multi-specific T-cell approach could potentially achieve near complete targeting of tumor subpopulations and reduce the risk of recurrence.

**10028 Poster Highlights Session (Board #329), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Immune activation and clinical responses following long-term infusion of anti-$GD_2$ antibody ch14.18/CHO in combination with interleukin-2 in high-risk neuroblastoma patients.** *Presenting Author: Holger N. Lode, University Medicine Greifswald, Greifswald, Germany*

**Background:** A less toxic treatment using long-term infusion (LTI) of anti-$GD_2$antibody ch14.18/CHO and subcutaneous interleukin-2 (IL-2) may improve outcome in high risk neuroblastoma (NB). **Methods:** 53 NB patients received 5/6 cycles of $6x10^6$ IU/$m^2$ s.c. IL-2 (d1-5; 8-12), LTI of 100 mg/$m^2$ ch14.18/CHO (d8-17) and 160 mg/$m^2$ oral 13-cis-RA (d19-32) in a single center program. Usage of i.v.-morphine and scores established for pediatric pain assessment were documented. Effector cells (NK- and T-cell subsets), ch14.18/CHO levels and $GD_2$ specific killing of neuroblastoma cells by ADCC, CDC, and whole blood were analyzed. KIR/KIRL mismatch and Fc$\gamma$-receptor polymorphisms were determined with a validated PCR-based method for KIR, HLA, FCGR2A (H131R), -3A (V158F) and -3B (NA1/NA2). Clinical response was assessed following INRG criteria by mIBG, MRI/CT, BM and catecholamines. **Results:** LTI of ch14.18/CHO translated into a decreasing degree of i.v. morphine usage allowing for treatment in the outpatient setting. The expansion of effector NK- (3x) and T-cells (2x) was combined with a pro-inflammatory cytokine response (IL-2, IL-6, IL-8, IFN$\gamma$). Effective levels of ch14.18/CHO (12.48 $\pm$ 0.93 $\mu$g/ml) at the end of antibody infusion translated into $GD_2$specific activity against NB cells in functional assays (CDC, ADCC, WBT). Interestingly, ch14.18/CHO levels and functional parameters before subsequent treatment cycles indicate persistent anti-NB activity measurable for the entire treatment period of 6-7 months. Response rates were 41.7 % in mIBG (15/36), 31.8 % MRI/CT (7/22), 28.6 % bone marrow- (6/21) and 38.1 % in catecholamines (8/21). An overall response of 30% (12/40), EFS of 32.4 % (observation 3.2 years, mean: 1.6 years) and an OS of 66.8% (observation 3.9 years, mean: 3.1 years) was observed. Patients with KIR/KIRL mismatch and high affinity FCGR alleles are associated with a longer event-free survival (P = 0.025), which supports NK-cell mediated ADCC as the mechanism of action. **Conclusions:** LTI of ch14.18/CHO shows anti-NB activity over the entire treatment period and objective clinical responses.

**10029 Poster Highlights Session (Board #330), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Validation of the MIBG SIOPEN scoring method in two independent high-risk neuroblastoma trials.** *Presenting Author: Ariane Boubaker, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland*

**Background:** Harmonised evaluation standards of MIBG scintigraphy for (re)staging of neuroblastoma (NB) are an international aim. In the HR-NBL1/SIOPEN trial population a SIOPEN score (SISCO) >3 was associated with a significantly poorer event free survival (EFS) on pre and post induction mIBG. This analysis validates the SISCO prognostic value in the independent dataset (DS) of the Children's Oncology Group (COG) protocol A3973. **Methods:** SIOPEN scoring evaluates mIBG uptake over 12 skeletal regions (scored 0-6/region, maximum of 72), not considering extra-osseous disease nor the primary site. MIBG scans from mIBG-avid stage 4 NB pts in 2 collaborative trials were reviewed and judged evaluable by the SIOPEN Nuclear Medicine review committee: the COG-A3973 (DSA; n=216) and SIOPEN HR-NBL1 trial (DSB; n=343). Predefined categories from DSB were used with a SISCO of 0, 1-3, 4-17 and ≥18. In addition, the YOUDEN index was used to identify single cut points (CPY). The median follow-up time was 7.1 and 5.5y, respectively. **Results:** Both DS showed a significantly superior EFS with a SISCO ≤3 at diagnosis [5-yr EFS in DSA: 51%±7% vs 34%±4%, p= 0.047 and in DSB 47%±7% vs 26%±3%, p=0.007]. However, the YOUDEN index yielded different results at diagnosis with a CPY of 40 in DSA and 10 in DSB and failed to identify a consistent poor prognosis group. A post induction SISCO of ≤3 also revealed a significant superior outcome [5-yr EFS in DSA: 43%±5% vs 16%±6%, p=0.004 and in DSB 36%±4% vs 14%±4%, p< 0.001]. The post induction CPY was 3 in DSB (in line with the DSB stratification criterion of ≤3 mIBG positive spots to proceed to high dose chemotherapy) and 0 in DSA. Pts with a SISCO of 0 post induction have the best outcome in both DS. In MYCN amplified pts, the pre and post-induction SISCO of ≤3 showed a significant impact in both groups, whilst in MYCN non-amplified pts this effect is only seen post induction. A SISCO ≤3 has independent statistical significance in Cox models including age and MYCN. **Conclusions:** A SIOPEN score ≥ 3 of mIBG scans carries relevant prognostic significance for the management of patients with high-risk NB at diagnosis and at the end of induction chemotherapy in the HRNBI1/SIOPEN trial and was confirmed in the independent COG A3973 data set. Clinical trial information: NCT01704716.

**10030 Poster Highlights Session (Board #331), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**A neuroblastoma risk classification model for developing countries: A study from the International Neuroblastoma (NB) Risk Group (INRG) database.** *Presenting Author: Wendy B. London, Dana-Farber Cancer Institute/Boston Children's Hospital, Boston, MA*

**Background:** Current methods for stratifying NB patients (pts) at diagnosis to INRG risk/pre-treatment groups are based on prognostic clinical, genomic, and histologic factors [Cohn et al, JCO 2009]. In developing countries, testing tumors for genomic biomarkers or histologic features is not possible; however, clinical tests serum ferritin and serum lactate dehydrogenase (LDH) are likely available. **Methods:** Retrospective analysis included INRG pts with sufficient data for clinical risk factors and event-free survival (EFS). Survival tree regression was performed, considering only age (<18 months; ≥18 months), INSS stage (4; not 4), ferritin (<92; ≥92ng/mL), and LDH (<587; ≥587U/L). Pts were categorized into clinical pre-treatment risk groups, categorized by 5-yr EFS: very low (>85%), low (>75-≤85%), intermediate (≥50-≤75%), or high risk (<50%). EFS time was calculated from diagnosis until first event (relapse/progression, second malignancy, death), or until last contact if no event occurred. **Results:** From 8,800 INRG pts, 7,679 were able to be risk classified according to INRG definitions, including genomic and histological factors. Of 7,679, 3,509 had known age, stage, LDH and ferritin and a clinical pre-treatment risk group was assigned: very low (n=1319), low (n=379), intermediate (n=550), and high (n=1261). 5-yr EFS for very low-, low-, intermediate-, and high-risk groups were 90±1%, 80±3%, 65±3%, 27±2%, respectively. The clinical risk classification was the same as (58.1%) or similar to (12.8%) the INRG in 70.9% of pts. Based on 5-year EFS: INRG overestimated risk but clinical factors correctly assigned risk in 18.9% of pts; clinical factors overestimated (3.7%) or underestimated (6.4%) risk but INRG correctly assigned risk in 10.1% of pts. **Conclusions:** In 89.9% of pts, clinical factors (age, stage, ferritin, LDH) do as well or better than clinical, genomic, and pathologic factors currently used in INRG risk/pre-treatment group assignment. The INRG-clinical pre-treatment risk stratification shows promise for developing countries to assign treatment intensity, whereby very low-risk pts can be spared unnecessary, expensive chemotherapy.

**10031 Poster Highlights Session (Board #332), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Validation of postinduction Curie scores in high-risk neuroblastoma.** *Presenting Author: Gregory A Yanik, University of Michigan Medical Center, Ann Arbor, MI*

**Background:** A semi-quantitative MIBG scoring method (Curie scoring, CS) has been previously examined in the Children's Oncology Group (COG) high-risk neuroblastoma trial, COG A3973, with a post-induction CS >2 associated with poor event-free (EFS) and overall survival (OS). We now examine the impact of Curie scoring in an independent data set, the SIOPEN-HR-NBL1 (SIOPEN-NB) high-risk study. **Methods:** MIBG scans from patients with MIBG avid, INSS stage 4 neuroblastoma enrolled on SIOPEN-NB were evaluated at diagnosis (n=345) and post-induction (n=330). Scans were evaluated in 10 different anatomic regions by 2 reviewers, including 9 skeletal and 1 soft issue region, with each region scored 0-3 based upon disease extent, and a cumulative consensus score generated. Optimal cut-points at diagnosis (Dx) and post-induction were determined using the Youden index, with outcomes determined. Curie scores from patients enrolled on COG A3973 at diagnosis (n= 280) and post-induction (n= 237) were used for comparison. **Results:** The optimal CS cut-points at Dx were 12 in SIOPEN-NB and 9 in COG A3973. There was a significant outcome difference by CS (≤ 12 vs > 12) at Dx [5-yr EFS: 43.0±5.7 vs 21.4±3.6%, p<0.0001] in the SIOPEN-NB cohort. By comparison, CS at Dx were not prognostic in COG A3973, with no outcome difference identified at any cut-point. The optimal CS cut-point post-induction was 2 in both SIOPEN-NB and COG A3973, with a post-induction CS > 2 associated with inferior outcomes (Table). A post-induction CS > 2 carried prognostic significance for both MYCN amplified and MYCN non-amplified tumors, in both COG A3973 and SIOPEN-NB. The Curie score at Dx and post-induction maintained independent statistical significance in Cox models when compared to standard predictive covariates age and MYCN. **Conclusions:** The prognostic significance of post-induction Curie scores has now been validated in an independent cohort of patients, with a post-induction Curie score > 2 associated with inferior outcome in two cooperative group trials, SIOPEN-HR-NBL1 and COG A3973.

| | | Post-induction Curie score | | | | | |
|---|---|---|---|---|---|---|---|
| | | 5-year EFS (± SE) | | | 5-year OS (± SE) | | |
| | No. | CS ≤ 2 | CS > 2 | p | CS ≤ 2 | CS > 2 | p |
| SIOPEN | 330 | 39.2 ± 4.7 | 16.4 ± 4.2 | <0.001 | 48.0 ± 4.7 | 29.5 ± 5.1 | <0.001 |
| COG | 237 | 42.0 ± 5.8 | 10.5 ± 10.0 | <0.001 | 55.4 ± 6.3 | 26.7 ± 11.4 | 0.02 |

**10032 Poster Highlights Session (Board #333), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**A phase 2 study of vincristine and irinotecan in metastatic diffuse anaplastic Wilms tumor: Results from the Children's Oncology Group AREN0321 study.** *Presenting Author: Najat C. Daw, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Patients with metastatic diffuse anaplastic histology Wilms tumor (DAWT) had an unacceptably low 4-year event-free survival (EFS) and overall survival of 33% on the National Wilms Tumor Study-5. Preclinical and clinical data showed promising antitumor activity of the camptothecins in Wilms tumor. **Methods:** AREN0321 evaluated the activity of vincristine (Vinc) and irinotecan (Irino) in a phase 2 window in newly-diagnosed patients with Stage IV DAWT. Patients received Vinc (1.5 mg/m$^2$/day) intravenously (IV) on days 1 and 8, and Irino (20 mg/m$^2$/day) IV on days 1-5 and 8-12 of a 21-day cycle. In the absence of progressive disease (PD), a second cycle was administered. Tumor responses after 2 cycles of therapy were centrally reviewed and assessed using the RECIST criteria. Patients with partial response (PR) had Vinc/Irino incorporated into a chemotherapy regimen consisting of Vinc, doxorubicin, cyclophosphamide, carboplatin, and etoposide, plus local and whole lung radiation therapy. Patients with stable disease or PD did not receive additional cycles of Vinc/Irino. A 2-stage design was used with the aim to accrue 10 patients in the first stage and continue accrual if an adequate number of responses was observed. The window study closed after other strata of AREN0321 reached their accrual targets. **Results:** Twenty-four patients with stage IV DAWT were enrolled from June 2006 to December 2012. Five patients did not have measurable disease and were ineligible for window therapy. Nineteen had measurable disease, 14 of whom elected to participate in the window. Of these 14 patients, 11 (79%) had PR and 3 had PD. Two of the 3 non-responders also did not achieve complete response to the other agents in the chemotherapy regimen. The most common grade 3-4 toxicities during the window were diarrhea (n=3), hypoxia (n=2), elevation of aspartate aminotransferase (n=2), hypoalbuminemia (n=2), and hyperglycemia (n=2). **Conclusions:** The Vinc/Irino combination was well tolerated and produced a high response rate in patients with metastatic DAWT. Its incorporation into Wilms tumor treatment regimens deserves further evaluation. Clinical trial information: NCT00335556.

**10033 Poster Highlights Session (Board #334), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Phase II study of $^{131}$I-MIBG with vincristine and 5 days of irinotecan for patients with relapsed or refractory neuroblastoma.** *Presenting Author: Steven G. DuBois, University of California, San Francisco, San Francisco, CA*

**Background:** $^{131}$I-metaiodobenzylguanidine (MIBG) is a targeted radiopharmaceutical active in neuroblastoma. A previous study demonstrated that MIBG (18 mCi/kg) could be combined with vincristine and irinotecan (20 mg/m$^2$/dose for 5 days/week x 2 weeks) as a radiation sensitizer. However, 25% of courses were associated with grade 3 diarrhea. To reduce the incidence of diarrhea, the current study evaluated MIBG together with vincristine and 5 days of higher-dose irinotecan, a standard schedule in recent pediatric trials. This report describes the experience with this regimen at maximum tolerated MIBG dose of 18 mCi/kg. **Methods:** Patients $<$ 30 with relapsed or refractory MIBG-avid neuroblastoma were eligible for this multicenter trial (NCT01313936). Prior MIBG therapy was allowed if $>$ 6 months from prior MIBG and $<$ 18 mCi/kg cumulative prior dose. Patients received cefixime on days -1 to +6, irinotecan (50 mg/m$^2$/dose IV) on days 0-4, and vincristine (2 mg/m$^2$) on day 0. MIBG (18 mCi/kg) was given on day 1 and peripheral blood stem cells on day 13. Up to two courses of therapy were allowed. Response was assessed at day 42 and was the primary endpoint of this phase II portion. Consenting patients provided germline DNA for *UGT1A1* genotyping. **Results:** 26 patients received 37 courses of therapy. Myelosuppression was the most common toxicity, with 55% of patients with grade 4 thrombocytopenia and 65% of patients with grade 4 neutropenia in course 1. No patients had failure to engraft. Only 4.5% of first courses were associated with grade 3 diarrhea. Correlation of *UGT1A1* genotype with toxicity is ongoing. Centrally reviewed best response after course 1 is available for 17 patients at the time of this submission. Of these, the overall response rate was 23.5% (2 CR and 2 PR). The response rate by MIBG scan was 37.5%, including 4 CR. **Conclusions:** MIBG at doses of 18 mCi/kg with vincristine and 5 days of irinotecan is tolerable and active. This regimen is now being compared to single-agent MIBG in a randomized phase II trial. Clinical trial information: NCT01313936.

**10034 Poster Highlights Session (Board #335), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Historical gold standard for time-to-progression (TTP) and progression-free survival (PFS) from relapsed/refractory neuroblastoma modern era (2002-2014) patients.** *Presenting Author: Wendy B. London, Dana-Farber Cancer Institute/Boston Children's Hospital, Boston, MA*

**Background:** Early phase trials of investigational agents in pediatric patients (pts) with relapsed neuroblastoma (NB) historically used "response" per RECIST as the primary endpoint; response rate determined whether to test agents in Phase 3. Response assessment is challenging because NB in bone and bone marrow is not 'measureable'. TTP and PFS endpoints are better suited to measure potential therapeutic benefit in NB, especially for targeted biologic agents and immunotherapies. Historical data on PFS or TTP exist only in small potentially biased NB cohorts. Herein, we study the largest cohort to date of relapsed/refractory NB pts, treated with modern era frontline and relapse therapy. We determined PFS, OS, & TTP, for use as historical comparators in future Phase 2 studies. **Methods:** 489 NB enrollments (consecutive 11/2002-1/2014), from 384 distinct pts, on 36 Phase 1 (27) or 2 (9) Children's Oncology Group trials were analyzed for PFS (relapse, progression, death from disease), overall survival (OS) (death- any cause), & TTP, starting from Phase 1,2 trial enrollment. If pts were on multiple trials, enrollments were analyzed as if they were independent. For PFS, non-disease deaths were censored. Using RECIST, only 2 Phase 2 trials met the prospective response rate bar for success. For high-risk pts, planned frontline therapy included HSCT; 11.6% received ch14.18 antibody. **Results:** From relapse study enrollment: 1-year & 4-year PFS were 19±2% & 8±3%, respectively; 56±3% & 14±4% for OS; median TTP was 63 days (95% CI: 56,79). Median follow-up time in pts without progression was 9.7 mos. Risk factors at diagnosis were known in pt subsets: 88% of 230 - INSS stage 4; 92% of 230 - ≥18 mos old; 18% of 189 - *MYCN* amplified; 49% of 180 - diploid; 94% of 172 - unfavorable histology. Only *MYCN* amplification was prognostic of worse PFS after relapse study enrollment ($p<0.001$). Median time from diagnosis to first relapse/progression was 22 mos (95% CI: 19,25) (n=214). **Conclusions:** PFS/TTP/OS from this representative comprehensive historical COG early-phase trial NB cohort should be used in Phase 2 trials as the gold standard comparator to identify promising new agents for NB.

**10035 Poster Highlights Session (Board #336), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Clinical application of comprehensive next-generation sequencing-based genomic profiling for identification of actionable genomic alterations in pediatric solid tumors and hematolymphoid malignancies: The Foundation Medicine pediatric experience.** *Presenting Author: Matthew J. Hawryluk, Foundation Medicine, Inc., Cambridge, MA*

**Background:** Oncology is undergoing a paradigm shift with the advent and increasingly successful utilization of targeted therapies. Unfortunately, many pediatric tumors lack approved targeted therapies, and routine genomic profiling of pediatric tumors has yet to be broadly applied. Comprehensive testing platforms are required to determine the landscape of genomic alterations in pediatric solid tumors and thereby broaden therapeutic options. We have developed a next-generation sequencing-based test, optimized for routine clinical FFPE specimens, and report here on over 340 pediatric patients' tumors analyzed to date in our CLIA-certified, CAP-accredited laboratory. **Methods:** Hybridization capture of 3,320 exons from 182 cancer-related genes and 37 introns of 14 genes commonly rearranged in cancer (previous version of the test) or 3,769 exons from 236 cancer-related genes and 47 introns of 19 genes commonly rearranged in cancer (current version of the test) was applied to ≥ 50ng of DNA extracted from over 340 pediatric tumors. Genomic alterations were identified and reported for these patient samples. **Results:** Successful profiles were generated from 343 pediatric patient specimens from individuals ≤21 years old at the time of sample procurement. The pediatric clinical experience consists of: adrenal and soft tissue neuroblastomas (n=83), sarcomas (n=53), brain (n=42), bone sarcomas (n=26), leukemias (n=30), rhabdomyosarcomas (n=17), liver (n=16), kidney (n=14), lung (n=13), lymphomas (n=7), and other tumors (n=42). **Conclusions:** Comprehensive NGS-based genomic profiling identified alterations in a majority of 343 unselected pediatric cancer clinical cases and more than half of these patients were found to have at least one alteration targeted by a therapeutic on the market or in clinical trials. Widespread deployment of this approach may provide treatment options for pediatric cancer patients requiring systemic approaches.

**10036 Poster Highlights Session (Board #337), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Molecular analysis of solid tumors (MAST): A protocol for comprehensive preclinical evaluation of pediatric solid tumors.** *Presenting Author: Sara Michele Federico, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** The genomic landscape of pediatric solid tumors is actively being investigated and to date, few recurrent actionable mutations have been identified. Using orthotopic xenografts, we developed MAST to better characterize the genetic lesions of these tumors as well as investigate the correlations between drug sensitivity, gene expression and genomic and epigenetic findings. **Methods:** We obtained tumor samples from 24 pediatric solid malignancies including neuroblastoma (n=5), rhabdomyosarcoma (n=7), osteosarcoma (n=9), Ewing sarcoma (n=1) and high grade sarcoma NOS (n=2). Fresh tumor samples were extensively analyzed including histology, electron microscopy, gene expression profiling, single nucleotide polymorphism (SNP) microarrays, whole genome sequencing, exome sequencing, RNA-seq and DNA methylation. Orthotopic xenografts were developed, characterized and compared to the original patient tumors. High-throughput screening of primary cultures derived from the xenografts was performed to test drug sensitivity. Clonal evolution, for tumors with banked tissue from diagnosis, was studied in tumor samples obtained at the time of disease recurrence. **Results:** Our analysis demonstrated that the xenografts closely recapitulate the molecular features of their primary tumors. Drug screening demonstrated that there was little, if any, correlation between the identified genetic lesions, molecular markers and drug hits. Clonal analysis of recurrent tumors identified variability of major and minor clones present at the time of diagnosis and recurrence and specific to the site(s) of disease. **Conclusions:** Through the MAST protocol we developed a diverse panel of pediatric solid tumors for preclinical testing.Our data suggests that up front genetic profiling of tumor tissue may not be predictive of response to targeted therapies for many patients with pediatric solid tumors. Further studies on clonal evolution are necessary as mutations present at diagnosis may differ from those present at recurrence. The MAST model sets a new standard for preclinical testing in which we will use cell biology studies combined with genomic analysis to identify new therapies.

**10037 Poster Highlights Session (Board #338), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Molecular profiling of 267 pediatric cancers to identify potential clinically relevant targets.** *Presenting Author: Todd Maney, Caris Life Sciences, Phoenix, AZ*

**Background:** Even though only 1% of cancers occur in children, it is the 2nd leading cause of death in children. Survival rates depend on the type of cancer, the majority of which arise from the central nervous system, bone, or neuroblasts. **Methods:** 267 cases referred to Caris Life Sciences were tested per physician request, including sequencing (Sanger, next generation [NGS]), protein expression (immunohistochemistry [IHC]), gene amplification (CISH or FISH), and/or MGMT methylation. Diagnoses were collected from referring physicians at intake; for this analysis, cases were initially grouped into carcinomas (CA), n=40, sarcomas (SA), n=117, neuroendocrine (NET), n=12, germ line (GL), n=11, or central nervous system (CNS), n=37. Within those groups the specific diagnoses were further delineated. **Results:** In this pediatric cohort, biomarker alterations included higher AR protein expression in CA and SA, higher ER expression in CA, GL, and NET, and EGFR amplification in all but GL. MGMT loss was highest in CNS, PTEN loss was highest in GL and both were lowest in CA. PGP was expressed at less than 15% in CNS and SA and 68% in CA. No HER2 protein overexpression, amplification, or gene mutations were seen. TP53 mutations were lowest in SA (9%) and varied between 25 and 50% in the others. Of the gene panel tested, CTNNB1 was mutated in 1 patient in CA and SA, while AKT1, CSFIR, and MPL were mutated in 1 patient each in GL. KRAS was mutated at least once in all but CNS. All other mutations (MT) were exclusive to the CNS group, and included PTEN, SMO, VEGF, ERBB4, EGFR, ALK, and APC. These were specific to the astrocytomas, which also had the only MGMT methylation event, except for ALK MT (neuroblastoma) PTEN MT (medulloblastoma), and EGFR MT (ganglioglioma). **Conclusions:** The mutations in the CNS group suggest MEK and mTOR pathway involvement. Biomarker profiling to identify therapeutic targets has potential in pediatric patients and warrants further investigation. Comparison to adult onset of these types of cancers may yield different molecular profiles for a subset of these cancers. Because children typically respond well to chemotherapy, targeting specific molecular alterations identified in childhood cancer could prove very effective.

**10038 Poster Highlights Session (Board #339), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Association of genetic variants involved in drug metabolism and transport with efficacy and toxicity of chemotherapeutic treatment in osteosarcoma patients.** *Presenting Author: Hanneke I. Vos, Laboratory of Pediatric Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** Despite multiagent chemotherapeutic treatment, osteosarcoma patients relapse frequently and survival has reached a plateau in the past decades. A poor response to chemotherapy seems to be the predominant risk factor for an unfavorable outcome. We have previously identified several genetic polymorphisms in genes in the metabolic pathways of cisplatin and doxorubicin which might be used for risk stratification of patients in relation to treatment response. However, as the complex metabolism of drugs used in the treatment of osteosarcoma involves a broader range of genes, we have performed a DMET analysis including 1,936 genetic variants in 231 genes known to be involved in drug metabolism and transport. **Methods:** We used a two-stage design, including 135 osteosarcoma patients in the discovery stage. Germline DNA was genotyped using the DMET Plus array. Associations between the presence of genetic variants and histological response (HR) to preoperative cisplatin and doxorubicin based chemotherapy, 5-year Disease Free Survival (DFS) and ototoxicity (SIOP grade 1-3) were assessed by logistic regression models in PLINK. In the replication cohort 185 osteosarcoma patients will be included. **Results:** 734 markers and 131 patients passed quality control (call rates $> 0.9$, minor allele frequency $> 0.01$) in the discovery cohort. A total of 21 markers showed association ($p < 0.05$) with HR and 20 markers with 5-year DFS, with overlap of associated markers in the transporter *SLCO4A1* and Phase I enzyme *CYP8B1* genes. In addition, 21 markers were significantly associated with ototoxicity, the majority was located in cytochrome p450 genes. **Conclusions:** To the best of our knowledge, the present pharmacogenetic study is the first in osteosarcoma patients using the DMET analysis. Significant associations of treatment response and ototoxicity with genes previously unknown to impact cisplatin and doxorubicin metabolism and transport were explored. Following replication and validation in functional studies and in larger prospective studies, these markers are of potential interest for the development of new treatment strategies and optimizing current therapy.

**10039 Poster Highlights Session (Board #340), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Subsequent neoplasms in the fifth and sixth decades of life in the Childhood Cancer Survivor Study cohort.** *Presenting Author: Lucie Marie Turcotte, University of Minnesota, Minneapolis, MN*

**Background:** The risk of subsequent neoplasms (SN) in childhood cancer survivors increases over time, but only limited data exist on risk beyond 40 years of age. **Methods:** Occurrence of SN was evaluated in 3171 5-year adult survivors of childhood cancer ≥40 years of age (median 44 years, range 40-58) following cancer diagnosed <21 years of age, between 1970-1986. Cumulative incidence and standardized incidence ratio (SIR), with corresponding 95% confidence intervals (CI) were used to evaluate risk of SN and subsequent invasive malignant neoplasm (SMN), respectively. SIR were calculated using age-, sex- and calendar year-specific incidence from the NCI Surveillance, Epidemiology and End Results program. Survivors with a history of SN prior to age 40 ($SN_{pos}$) were also compared to those without previous SN ($SN_{neg}$). **Results:** A total of 371 SN were diagnosed ≥40 years of age, including 136 SMN (SIR=2.2, CI 1.9-2.5), 191 non-melanoma skin cancers (NMSC), and 44 meningiomas and other non-invasive neoplasms. Cumulative incidence of a new SN after age 40 was 34.6% (CI 28.7-40.6) at age 55, with $SN_{pos}$ having a higher incidence compared to $SN_{neg}$ 57.6% (CI 46.7-68.6) versus 30.4% (CI 23.8-37). While cumulative incidence of new SMN at age 55 was similar for $SN_{neg}$ and $SN_{pos}$ (15.4% (CI 10.2-20.5) vs. 20.8% (CI 12.5-29.1)), $SN_{pos}$ experienced more NMSC compared to $SN_{neg}$ (cumulative incidence 16.2% (CI 10.8-21.6) vs. 38.2% (CI 27.9-48.5)). Compared to the U.S. population, risk of a SMN was elevated for both $SN_{neg}$ and $SN_{pos}$ (SIR=2.0, CI 1.7-2.4 vs. SIR=3.0, CI 2.2-4.0). Breast cancer was the most common SMN beyond age 40, and also carried the largest risk (SIR=5.5, CI 4.5-6.7). Significantly elevated risks were also seen for renal cancer (SIR=3.9, CI 2.0-7.5), soft tissue sarcoma (SIR=2.6, CI 1.5-4.4) and thyroid carcinoma (SIR=1.9, CI 1.0-3.5). Hodgkin lymphoma (SIR=3.6, CI 3.0-4.4) and radiation therapy (SIR=2.6, CI 2.2-3.1) were associated with high risk of SMN although the magnitude of risk for $SN_{neg}$ and $SN_{pos}$did not differ substantially. **Conclusions:** Risk of SN remains significantly elevated after age 40. These data have important implications for screening and should inform anticipatory guidance provided to childhood cancer survivors.

**10040 Poster Highlights Session (Board #341), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Influence of polymorphisms discovered in cell-based model of cytarabine sensitivity on outcome in pediatric AML: A Children's Oncology Group Study.** *Presenting Author: Christine L. Phillips, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

**Background**: Genetic variability of patients with AML contributes to the success and tolerability of cytarabine-based therapy. **Methods**: We investigated 120 genetic polymorphisms (SNPs) associated with cytarabine sensitivity ($p<0.0001$) that were discovered in a previous cell-based genome wide association study using Hap Map lymphoblastoid cell lines. We tested these variants for impact on outcome in 412 children with de novo AML treated on Children's Oncology Group protocols, CCG 2941 and 2961. Therapy consisted of intensive cytarabine based induction and a randomization to consolidation with different cumulative doses of cytarabine; IDA-DCTER (3200 mg/m$^2$) or IDA-FLAG (9190 mg/m$^2$) in 2961. **Results**: The homozygous variant genotypes of rs 2025501 and rs 6661575 had increased in vitro cytarabine sensitivity and were also associated with increased treatment related mortality (TRM). TRM was most markedly increased in children randomized to the high dose cytarabine arm IDA-FLAG (rs 2025501: TRM 29 ± 7 % AA vs. 8 ± 3% GA, 17 ± 6% GG, p= 0.007 and rs 6661575: TRM 60 ± 20% T/T vs. 14 ± 5% C/T, 14 ± 4% CC, p=0.011) compared to the IDA-DCTER arm where no significant differences were observed. Improvement in three-year cumulative incidence of relapse was not statistically significant for either variant genotype. These SNPs are intragenic, but search in relevant databases indicate they are eQTLs with influence on expression of other genes. **Conclusions:** These findings warrant further exploration and validation in an independent dataset, but suggest cytarabine sensitivity genotypes may predict treatment related mortality and could be used to stratify to standard vs. high dose cytarabine regimens.

| rs 2025501 | 1-year cumulative incidence of TRM | TRM randomized to IDA-FLAG arm | 3-year relapse rate (RR) |

**10041 Poster Highlights Session (Board #342), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Treatment and outcome of patients with relapsed clear cell sarcoma of the kidney (CCSK): A combined SIOP and AIEOP study.** *Presenting Author: Saskia L Gooskens, Department of Pediatric Hematology and Oncology, Erasmus MC - Sophia Children's Hospital, Rotterdam, Netherlands*

**Background:** Clear Cell Sarcoma of the Kidney (CCSK) is an uncommon pediatric renal tumor. Relapses occur in about 15% of the patients. Detailed clinical information on relapsed CCSK is scarce. The current study aims to describe outcome of patients with relapsed CCSK treated according to recent European protocols, in order to find a rational for creating future international CCSK relapse treatment protocols. **Methods:** We analysed prospectively collected data of all CCSK patients who developed a relapse after complete response to initial therapy, entered onto International Society of Pediatric Oncology (SIOP) and Associazione Italiana Ematologia Oncologia Pediatrica (AIEOP) trials between 1992 and 2012. **Results:** Thirty-seven of 237 CCSK patients (16%) treated according to SIOP and AIEOP protocols developed a relapse. Median time from initial diagnosis to relapse was 17 months (range, 5.5 months - 6.6 years). 35/37 relapses (95%) were metastatic; the most common sites of relapse were brain (n = 13), lungs (n = 7) and bone (n = 5). Relapse treatment consisted of chemotherapy (n = 30), surgery (n = 19) and/or radiotherapy (n = 18), followed by high dose chemotherapy and autologous bone marrow transplantation (ABMT) in 14 patients. 22/37 patients (59%) achieved a second complete remission (CR); 15 of whom (68%) developed a second relapse. Five-year event-free survival (EFS) after relapse was 18% (95% CI: 4-32%) and 5-year overall survival (OS) was 26% (95% CI: 10-42%). **Conclusions:** In this largest series of relapsed CCSK patients ever described, overall outcome is poor. Relapses tend to occur late, so extensive follow-up is desirable. Most relapses are metastatic and brain relapses are more common than previously recognized. Intensive treatment aiming for local control, followed by high dose chemotherapy and ABMT, seems to be of benefit to enhance survival. Novel development of targeted therapy is urgently required.

**10042 Poster Highlights Session (Board #343), Mon, 8:00 AM-11:45 AM and 11:30 AM-12:45 PM**

**Increased risk of second malignant neoplasms (SMN) in young children with embryonal rhabdomyosarcoma (ERMS): Evidence for a cancer predisposition syndrome?** *Presenting Author: Renata Parada Amorim, Faculdade de Ciências Médicas da Santa Casa de São Paulo, Sao Paulo, Brazil*

**Background:** Germline TP53 mutations have been recently described in children with anaplastic EMRS, suggesting a possible association with Li-Fraumeni syndrome (LFS). In this population-based study we aimed to assess the risk of SMN according to distinct rhabdomyosarcoma (RMS) subtypes and age groups that could identify high-risk individuals who warrant close surveillance. **Methods:** Data from SEER-9 (1973-2010) from children ages 0-19 with RMS were analyzed. Standardized incidence ratios (SIR) and corresponding 95% confidence intervals (95% CI) were calculated using SEERStat 8.1.2. **Results:** 1,151 children (median age=7 years) with RMS were included. Histologies were embryonal (58.2%), alveolar (24.8%), not otherwise specified (NOS) (14.3%), mixed (1.4%), and pleomorphic (1.3%).Twenty-nine SMN were identified, resulting in five-fold increased risk (SIR= 5.69, 95% CI 3.81-8.17). The increase in risk was attributable to second solid tumors, which were consistent with the LFS spectrum, and it was higher for pleomorphic type (SIR=15.77, 95% CI 1.91-56.96). Risk of SMN was higher among those treated at a younger age [children < 2 yrs at diagnosis (SIR=13.38, 95% CI 4.34-31.22) vs. children > 10 yrs (SIR=3.35, 95% CI 1.53-6.35)]. Among children < 2 yrs, those with ERMS histology were at greatest risk (SIR=14.72, 95% CI 4.01–37.70), and it increased when embryonal and NOS histologies were combined (SIR=19.08, 95% CI 6.20-44.54). Among children ages 5-9, the risk was the highest for children 5-9 yrs with pleomorphic type (SIR=314.95, 95% CI 7.91-1,754.80). The risk of SMN was independent of the use of radiation (RT) to the primary (RT: SIR=6.50, 95% CI 3.97–10.03 vs. no RT SIR=4.57, 95% CI 2.09-8.68,). Patients < 5 years receiving RT had higher risk than older patients (SIR=10.52, 95% CI 4.23-21.68 vs. SIR=3.07, 95% CI 1.46-8.65 for > 10 years, respectively). **Conclusions:** Children with RMS are at high risk of developing SMN. This risk is particularly higher for a subgroup of young children with embryonal or pleomorphic histology, and is independent of the use of RT, suggesting a constitutional predisposition.

**10043 General Poster Session (Board #344), Mon, 8:00 AM-11:45 AM**

**Correlation of childhood acute lymphoblastic leukemia subclones carrying intragenic *IKZF1* deletions with relapse.** *Presenting Author: Peter Hoogerbrugge, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands*

**Background:** Relapse is the major cause of treatment failure in childhood acute lymphoblastic leukemia (ALL), and further improvement of risk stratification is essential for obtaining better cure rates. We and others demonstrated that the presence at diagnosis of deletions in *IKZF1*, the gene encoding the lymphoid transcription factor IKAROS, is a strong risk factor for relapse. Furthermore, preliminary results show that these deletions can be present at subclonal levels, often undetectable by routine methodologies. These findings are in line with recent studies, which have shown a complex, dynamic architecture of clonal diversity in ALL, both at diagnosis and at relapse. This multiclonal diversity likely contributes to the selective outgrowth of therapy-resistant leukemic cells during or after chemotherapy treatment, resulting in relapse. Whether subclonal deletions in *IKZF1* are also associated with relapse has not been thoroughly investigated. **Methods:** Several recurrent intragenic deletions in *IKZF1* show clustering of their genomic breakpoints, which allows efficient detection of subclonal deletions by sensitive semi-quantitative breakpoint-spanning PCR. Using this method, we screened a cohort of 331 B-cell precursor ALL patients, treated according to the DCOG-ALL9 and ALL10 protocols, for the presence of subclonal exon 4-7 *IKZF1* deletions (*IKZF1*Δ4-7) at diagnosis. The cohort was slightly enriched for relapsed cases (36.6%). **Results:** A total of 34 *IKZF1*Δ4-7 deletions were found, of which 17 were not detected by routine MLPA. All deletions carried unique breakpoints and TdT-mediated non-templated sequences. The 17 MLPA-negative cases had an allelic burden of the *IKZF1*Δ4-7 deletion varying from 28% to <1%. Whereas 12 cases with full clonal *IKZF1*Δ4-7 deletions eventually relapsed, only 6 cases with subclonal *IKZF1*Δ4-7 deletions developed a relapse. Remarkably, in none of the cases for which material was available for testing (n=4), these subclonal lesions were detected in the relapsed clone. **Conclusions:** Our data suggest that, in contrast to clonal *IKZF1*Δ4-7 deletions, subclonal deletions of *IKZF1*Δ4-7 rarely contribute to relapse development in ALL.

**10044 General Poster Session (Board #345), Mon, 8:00 AM-11:45 AM**

**A comprehensive safety trial of chimeric antibody 14.18 (ch14.18) with GM-CSF, IL-2, and isotretinoin in high-risk neuroblastoma patients following myeloablative therapy: A Children's Oncology Group study.** *Presenting Author: Mehmet Fevzi Ozkaynak, New York Medical College, Valhalla, NY*

**Background:** In a Phase 3 randomized study (COG ANBL0032), we demonstrated that the addition of ImmRx to standard therapy isotretinoin for high-risk neuroblastoma (NB) patients in CR or VGPR after intensive induction and consolidation significantly improved outcome (Yu*, NEJM*, 2010). ANBL0931 study was designed to collect FDA-required comprehensive safety/toxicity data for ImmRx to support a new Biological License Application. Efficacy data were collected as a secondary endpoint. **Methods:** Newly diagnosed high-risk NB patients who achieved ≥PR to induction therapy and received myeloablative consolidation with stem cell rescue then received isotretinoin x 6 with 5 concomitant cycles of ch14.18 combined with GM-CSF (cycles 1,3,5) or IL2 (cycles 2,4). Ch14.18 infusion time was 10 hrs. which was prolonged compared to 5.75 hrs for the initial 245 patients on ANBL0032. Toxicity data were collected. **Results:** Of105 patients enrolled (none ineligible), five patients developed protocol-defined unacceptable toxicities and came off study (four grade 4 allergic reactions, one sudden death - sudden onset of abdominal pain and arrest). The most common grade 3 or higher non-hematologic toxicities of ImmRx were neuropathic pain (cycles 1, 2, 3, 4, 5 were 30.9%, 22%, 13.3%, 20%, 17%, respectively), hypotension (9.6%, 17%, 3.1%, 12.2%, 5.7%), allergic reactions (2.9%, 9%, 3%, 6.6%, 2.2%), capillary leak syndrome (1%, 4%, 0, 2.2%, 0), fever (21%, 58%, 6.1%, 31.1%, 4.5%). Toxicities occurred more frequently during IL-2 cycles compared to GM-CSF cycles. Dose modifications were reported in 73 patients (69%) most of which are thought to be prolongation of the ch14.18 infusion time beyond 10 hrs. The 2-year EFS and OS were 74±6% and 84±5%, respectively (n=105). **Conclusions:** This study has confirmed the significant, but manageable treatment-related toxicities of the ImmRx including pain, allergic reactions, hypotension and capillary leak syndrome. Decreased toxicity compared to ANBL0032 may be due to the 10 hr minimum ch14.18 infusion time for all patients in this study. EFS and OS appear similar to that observed on ANBL0032.

**10045 General Poster Session (Board #346), Mon, 8:00 AM-11:45 AM**

**IGF-1R inhibition effect on a yes/SFK bypass resistance pathway: Rational basis for cotargeting IGF-1R and yes/SFK kinase in rhabdomyosarcoma.** *Presenting Author: Xiaolin Wan, Pediatric Oncology, CCR, NCI, NIH, Bethesda, MD*

**Background:** The insulin-like growth factor 1 receptor (IGF-1R) has surfaced as a significant target in multiple solid cancers due to its fundamental roles in pro-survival and anti-apoptotic signaling. However, development of resistance to IGF-1R blockade represents a significant hindrance and limits treatment efficacy in the clinic. Thus, identifying the mechanisms of acquired resistance to IGF-1R blockade is a major goal. The aim of this study was to identify the molecular mechanisms responsible for acquired resistance to IGF-1R targeted therapy in rhabdomyosarcoma. **Methods:** Expression profiles of IGF components and Src family kinases (SFKs) were analyzed by cDNA microarray. Antiproliferative effects of anti-IGF-1R agents and SFK inhibitors alone or in combination were tested in vitro in multiple rhabdomyosarcoma (RMS) cell lines and in vivousing xenografts. Western blot and immunoprecipitation were performed to identify protential resistance mechanisms to IGF-1R inhibition. **Results:** We identified acquired resistance to IGF-1R blockade with R1507, an antibody against IGF-1R, and with BMS-754807, a small molecular inhibitor against IGF-1R/IR. In both cases, resistance was associated with increased activation of Yes/SFK in RMS. Combining anti-IGF-1R agents with SFK inhibitors resulted in blockade of IGF-1R inhibition induced activation of Yes/SFK and displayed enhanced antitumor activity in vitro and in vivo. **Conclusions:** Our data provide evidence that IGF-1R blockade results in activation of the Yes/Src family kinases (SFKs) by-pass resistance pathway in vitro and in vivo, and that co-targeting both IGF-IR and SFK shows advantageous antitumor activity in vitro and in vivo. Our preclinical data support consideration of clinical trials to test this combination in pediatric sarcomas.

**10046 General Poster Session (Board #347), Mon, 8:00 AM-11:45 AM**

**Identification of PDGFR-$\beta$ activation as a potential bypass resistance pathway in a rhabdomyosarcoma (RMS) model of acquired resistance to IGF-1 receptor blockade.** *Presenting Author: Christine Heske, National Cancer Institute, National Institutes of Health, Bethesda, MD*

**Background:** IGF-1R and its ligands have been shown to be potentially important therapeutic targets for sarcomas. Phase II sarcoma trials using IGF-1R blockade yielded clinically meaningful responses in unselected patients with pediatric type sarcomas. However, most responses were short-lived with rapid onset of resistance. Similarly, data from mouse xenograft RMS models showed initial response with subsequent resistance. Evaluation of tumor samples from treated mice showed persistently down-regulated IGF-1R, but rebound AKT phosphorylation, suggesting that resistance was not from loss of antibody activity against IGF-1R, but rather the result of a bypass pathway. We therefore sought to model acquired resistance in human RMS cells. **Methods:** Human RMS cell lines resistant to IGF-1R blockade were generated in xenografts from a highly sensitive parent cell line. Additional cell lines were selected for in vitro resistance. Parental and resistant lines were screened with a receptor phosphotyrosine array. Differences in expression were confirmed with Western Blot analysis and electrochemiluminescence detection. Cell growth under dual pathway inhibition was tested in vitro using IGF-1R antibody and several kinase inhibitors. **Results:** Screening of parental and resistant lines revealed increased phosphorylation of PDGFR-$\beta$ in resistant cells. PDGFR-$\beta$ and IGF-1R share several signaling pathways (PI3K, MAPK/ERK), suggesting that PDGFR-$\beta$ activation may act as a bypass mechanism to activate AKT. Target inhibition of PDGFR-$\beta$ in resistant cells was achieved with pazopanib. Proliferation assays have shown that dual inhibition of IGF-1R and PDGFR-$\beta$ in resistant clones enhances cell growth inhibition in vitro. Similar studies are ongoing using xenografted tumors. **Conclusions:** Activation of PDGFR-$\beta$ may be responsible for resistance to IGF-1R blockade in some RMS. This mechanism may also explain the rapid onset of resistance seen in clinical trials using IGF-1R blockade. Therapy targeting both IGF-1R and PDGFR-$\beta$ may be a rational combination to treat RMS and prevent onset of resistance in some patients.

**10047 General Poster Session (Board #348), Mon, 8:00 AM-11:45 AM**

**Preclinical evidence of craniofacial adverse effect of zoledronic acid in newborn mice: Potential consequences in pediatric osteosarcoma and Ewing's sarcoma patients.** *Presenting Author: Francoise Redini, INSERM UMR957, Nantes, France*

**Background**: Oncologic doses of zoledronic acid (ZOL) are currently evaluated in phase III clinical trials in Europe for the treatment of malignant primary bone tumors in children and adolescents. The impact of such an intensive treatment on the craniofacial skeleton growth is a critical question in the context of patients with actively growing skeleton. **Methods**: Two protocols adapted from pediatric treatments were developed for newborn mice (5 or 10 injections of ZOL 50 $\mu$g/kg every two days). Their impact on skull bones and teeth growth was analyzed by micro-CT and histology up to 3 months after the last injection. In parallel, panoramic radiographs of pediatric patients from the French OS2006 trial (chemotherapy +/- zoledronic acid) were analyzed for potential orofacial consequences. **Results**: In mouse, ZOL administrations induced a transient delay of skull bone growth and an irreversible delay in incisor, first molar eruption and root elongation. Root histogenesis was severely impacted for all molars and massive odontogenic tumor-like structures were observed in lower incisors. Panoramic radiograph analysis of 23 pediatric patients treated by chemotherapy + zoledronic acid in the OS2006 protocol showed not significant increase of tooth eruption delay comparatively to 21 patients treated by chemotherapy alone. **Conclusions**: In mouse, oncologic doses of ZOL irreversibly disturbed teeth eruption and elongation, and delayed skull bone formation. In human, ZOL treatment may impact the permanent teeth eruption. These observations are crucial for the follow-up of pediatric patients with bone tumors (osteosarcoma, Ewing's sarcoma) treated with zoledronic acid in several European and American protocols. Clinical trial information: NTC00470223.

**10048 General Poster Session (Board #349), Mon, 8:00 AM-11:45 AM**

**Preclinical evidence of positive effect of I-MTP-PE alone or combined with zoledronic acid in osteosarcoma.** *Presenting Author: Francoise Redini, INSERM UMR957, Nantes, France*

**Background**: Zoledronic Acid (ZA), a potent inhibitor of bone resorption is currently evaluated in phase III clinical trials in Europe for the treatment of malignant primary bone tumors. The beneficial effect of the liposomal form of MuramylTriPeptide-Phosphatidyl Ethanolamine (MTP-PE, mifamurtide), activating the macrophage population in tumors, has also proved its efficacy in osteosarcoma. The objective of our study was to evaluate the safety of the combination of zoledronic acid and liposomal mifamurtide in pre-clinical models of osteosarcoma before transfer to patients. **Methods**: Two protocols were developed in mouse syngenic models of osteosarcoma: (1) 1 or 2.5 mg/kg mifamurtide alone in primary tumor progression and pulmonary metastasis dissemination (experimental model induced by paratibial injection of murine osteosrcoma cells), (2) the potential interference of mifamurtide on ZA induced effect on osteosarcoma. These effects were evaluated at clinical, radiological (bone microarchitecture by microCT analysis), biological and histological levels. **Results**: Mifamurtide alone induced slight but not significant inhibitory effect on primary osteosarcoma growth. However, it significantly inhibits spontaneous (lung metastasis dissemination from primary bone tumor) and experimental (lung colonization after intraveinous injection of osteosarcoma cells) metastases at pulmonary site. Combinatory studies of mifamurtide associated with zoledronic acid showed no significant interference on specific effect on primary bone tumor growth, but rather synergism. **Conclusions**: In mouse, mifamurtide alone has a potent inhibitory effect on lung metastasis development, probably due to high macrophage infiltration in the lung parenchyma. Preliminary data did not evidence any interference of mifamurtide with ZA potential therapeutic activity in preclinical models of osteosarcoma.

**10049 General Poster Session (Board #350), Mon, 8:00 AM-11:45 AM**

**Regorafenib antitumor activity alone and in combination with radio or chemotherapy in preclinical models of pediatric solid tumors.** *Presenting Author: Estelle Daudigeos-Dubus, Institut Gustave Roussy, Villejuif, France*

**Background:** Angiogenesis plays a pivotal role in tumor growth and metastatic spread in children. High VEGF expression is correlated with invasion, metastases and risk for recurrence. In several pediatric tumors, angiogenesis is further driven by PDGFR and FGFR signaling. We evaluated the novel potent oral multikinase inhibitor regorafenib (BAY-73-4506) against pediatric cell lines and xenografts. **Methods:** Inhibition of cell proliferation and migration was explored in vitro against the Innovative Therapies for Children with Cancer (ITCC) cell line panel by MTS assay and against neuroblastoma cells by phase-contrast with Incucyte. In vivo, athymic mice bearing subcutaneous PDGFRA gene amplified IGRG93 glioma (derived from an adult patient) and IGRM57 medulloblastoma, and orthotopic IGR-N91-Luc neuroblastoma xenografts were treated with regorafenib at 10 or 30 mg/kg orally during at least 21 days alone or in combination with irradiation or irinotecan. **Results:** Regorafenib inhibited cell proliferation in vitro at GI50s of 1.85 – 31.8 $\mu$M in pediatric cell lines. It exhibited a dose-dependent effect on proliferation and migration of IMR-32-Luc and IGR-N91-Luc neuroblastoma cells with IC50s of 0.8 $\mu$M and 2.6 $\mu$M respectively. In IGR-N91-Luc neuroblastoma, IGRG93 glioma and IGRM57 medulloblastoma xenografts, regorafenib at 10 or 30 mg/kg resulted in significant tumor growth inhibition associated with decreased tumor vascularisation. In IGRG93 glioma, regorafenib resulted in significant tumor growth delay and 100% tumor regression (3/10 complete responses (CR) and 7/10 partial responses (PR) at 10 mg/kg; 5/11 CR and 6/11 PR at 30 mg/kg) when combined with irradiation which alone resulted in 3 PR in 11 tumors. Equivalent effects were observed against IGRM57 medulloblastoma when regorafenib was combined with irinotecan (5/7 CR and 2/7 PR versus 2/7 CR and 5/7 PR respectively). Inhibition of angiogenesis was associated with induction of tumor cell death, particularly in the combination strategies. **Conclusions:** Regorafenib exhibits significant antitumor activity alone and increased effects when combined with standard of care treatments.

**10050 General Poster Session (Board #351), Mon, 8:00 AM-11:45 AM**

**Molecular screening for cancer treatment optimization (MOSCATO 01) in pediatric patients: First feasibility results of a prospective molecular stratification trial.** *Presenting Author: Birgit Geoerger, Institut Gustave Roussy, Villejuif, France*

**Background:** This feasibility study intends to characterize genomic alterations in recurrent tumors of an individual pediatric patient in order to select a targeted therapy approach. **Methods:** Pediatric patients with recurrent or refractory solid tumor were proposed to undergo on-purpose tumor biopsy or surgical resection for molecular characterization. Biopsies were obtained using 18G needles under ultrasound, CT or MRI control from primary tumor or metastatic sites. DNA extracted from fresh samples was analyzed by CGHarray 180K (if $\geq$ 50% tumor cells in the sample) and by sequencing for 74 target genes (if $\geq$ 30% tumor cells). A panel of scientists and clinicians reviewed results to determine biological signification of the alteration and match patients to the most relevant targeted therapy available (mainly in early clinical trials). **Results:** From December 2012 to January 2014, 12 patients were consented; 3 were screening failures. Nine enrolled patients with a median age of 7 years (range, 3-18) and a median of 3 previous treatment lines underwent dedicated intervention. Six patients (rhabdomyosarcoma (2), osteosarcoma, angiosarcoma, cervical clear cell adenocarcinoma, high-grade glioma) had biopsy, two (medulloblastoma, PNET) underwent neurosurgical resection; one with leukemic Burkitt lymphoma had blood sample for analysis. Percentage of tumor cells per sample ranged between 50 and 90% in 8 out of 9 patients. Median time between biopsy/surgery and molecular results was 21 days (14-46). At least one actionable target was identified in 6 patients (75%). Genetic alterations encompassed *CDK4, EGFR, MYCN, MDM2, AR* amplification, *ERBB4, FGF, FGFR2, TCR* gain, *PTEN* loss, *PI3K* and *TP53*mutation/deletion. Two patients received an adapted targeted therapy; the others could not be treated with a matched therapy due to rapid tumor progression (1) or lack of a pediatric trial (3). **Conclusions:** High throughput molecular analysis of recurrent/refractory malignancies in pediatric patients is feasible. Presence of multiple alterations and limited access to targeted agents within pediatric clinical trials remain the main limiting factors. Clinical trial information: NCT01566019.

**10051 General Poster Session (Board #352), Mon, 8:00 AM-11:45 AM**

**Phase I study of proteasome inhibitor bortezomib in combination with irinotecan in patients with relapsed/refractory neuroblatoma.** *Presenting Author: Rajen Mody, University of Michigan Medical Center, Ann Arbor, MI*

**Background:** Despite recent progress in neuroblastoma (NBL) therapy, prognosis for relapsed/ refractory NBL remains poor. Bortezomib, a proteasome inhibitor has been shown to be effective by our group and others, against NBL in vitro and in vivo, either as a single agent or in combination with cytotoxic agents including irinotecan. **Methods:** Eligible patients high risk NBL, with primary refractory (n=8) or relapsed (n=10) disease. Bortezomib (1.2 mg/m2/day) was administered on days 1, 4, 8 and 11 intravenously (IV), with irinotecan 35, 40, or 45 mg/m2/day (Dose Level (DL) 1,2, and 3 respectively) administered IV days 1-5 of each 21day course. The maximum tolerated dose (MTD), dose limiting toxicity (DLT), and response were examined. **Results:** Eighteen patients with relapsed/ refractory, high risk NBL were treated, of which17 were evaluable. Three patients were treated at DL-1, 9 patients at DL-2 and 6 patients at DL-3. A total of 149 courses were delivered (mean of 8.2 and median of 2) with 2 patients receiving $>$ 40 courses of therapy. Therapy was very well tolerated and MTD was not reached. Two dose limiting toxicities (DLT) were reported, including grade 3 thrombocytopenia (n=1) and grade 3 irritability (n=1), at dose levels 2 and 3 respectively. Other grade 3 toxicities included neuropathy (n=1) after 34 cycles of therapy, and reversible hematologic toxicities (n=9). None of the patients experienced serious infection. DL-3 is the recommended dose for Phase-II studies. Two out of seventeen (12%) evaluable patients showed sustained objective responses lasting $>$ 40 courses, including 1 partial remission (PR) and 1 complete remission (CR). Four additional patients (23%) had prolonged stable disease (SD) lasting 6 courses or more with a total of 35% patients having prolonged SD or better. **Conclusions:** The combination of bortezomib with irinotecan was extremely well tolerated by patients with relapsed/ refractory NBL and exhibited very favorable toxicity profile. It showed promising clinical activity with 35% patients experiencing prolonged clinical benefit and merits further testing in Phase-II studies. Clinical trial information: NCT00644696.

**10052 General Poster Session (Board #353), Mon, 8:00 AM-11:45 AM**

**Phase 1 study of sorafenib and irinotecan in pediatric patients with relapsed or refractory solid tumors.** *Presenting Author: Holly Jane Meany, Children's National Medical Center, Washington, DC*

**Background:** Sorafenib, an orally bioavailable, multi-target tyrosine kinase inhibitor, and irinotecan, a topoisomerase I inhibitor, have demonstrated single agent activity in various malignancies. This study was designed to determine the maximum tolerated dose of sorafenib in combination with irinotecan and assess the feasibility of incorporating patient reported outcome (PRO) measures into a phase I trial in children with relapsed or refractory solid tumors. **Methods:** Sorafenib was administered orally twice daily, continuously, beginning at 150 mg/m$^2$/dose with irinotecan, 70 mg/m$^2$/dose orally, once daily for 5 days to complete a 21-day cycle (dose level 1). Sorafenib was escalated to 200 mg/m$^2$/dose (dose level 2) followed by escalation of irinotecan to 90 mg/m$^2$/dose (dose level 3). Three patients enrolled initially at each dose level. Secondary aims included evaluating PRO measures as an adjunct to traditional phase 1 endpoints and determining the pharmacokinetic profile of sorafenib and irinotecan in children. **Results:** Twelve evaluable patients [6 male, 6 female; median age 13 years (range 4.6-19.8)] with Wilms tumor (n= 4), osteosarcoma (n=3), neuroblastoma (n=1), CNS tumor (n=1), desmoplastic small round cell tumor (n=1), soft tissue sarcoma (n=1) and germ cell tumor (n=1) have enrolled to date. No dose limiting toxicities (DLT) were seen at dose level 1 (n=3). Two of 3 patients at dose level 2 experienced DLT (grade 3 diarrhea with dehydration, grade 3 hyponatremia). Dose level 1 was expanded to evaluate up to 12 patients. Of 9 patients who have completed therapy at this dose level, one patient had DLT, grade 4 thrombocytopenia. Three patients received ≥6 cycles with stable disease prior to disease progression. Two additional patients were removed from protocol therapy after experiencing responses that rendered them eligible for surgical resection. All eligible patients (n=4) completed PRO measures. **Conclusions:** The recommended dose for children is anticipated to be sorafenib 150 mg/m$^2$/dose, twice daily, continuously with irinotecan 70 mg/m$^2$/dose, once daily for 5 days, repeated every 21 days. This convenient, oral outpatient regimen is well tolerated in pediatric patients. Clinical trial information: NCT01518413.

**10053 General Poster Session (Board #354), Mon, 8:00 AM-11:45 AM**

**Prospective assessment of renal function using cystatin C and functional MRI in children with newly diagnosed renal tumors.** *Presenting Author: Elizabeth Fox, The Children's Hospital of Philadelphia, Philadelphia, PA*

**Background:** Serum creatinine (sCr) is an imprecise renal function marker in children. Serum cystatin C (cysC) is a more sensitive marker to estimate glomerular filtration rate (GFR). Functional MRI (*f*MRI) measures the contribution of each kidney to overall renal function. **Methods:** Renal function was serially evaluated in children with renal tumors. sCr, cysC and contrast enhanced *f*MRI were obtained at baseline and during therapy in children [n=11,median (range) age 3y (0.5-7.8y)] with newly diagnosed renal tumors. Three children had a tumor predisposition syndrome, one had horseshoe kidney. Diagnoses were Wilms tumor [unilateral (n=5), multifocal/bilateral (n=4)] metanephric stromal tumor (n=1) and no tumor (n=1). Therapy included unilateral total nephrectomy (n=5), partial nephrectomy (n=3), bilateral partial nephrectomy (n=2), chemotherapy (n=9), flank/abdomen radiation (n=4). GFR was estimated using the Schwartz formula ($GFR_{Cr}$) and cysC ($GFR_{cycC}$). **Results:** At baseline, median (range) $GFR_{Cr}$ was 138 (81-198)$_2$ mL/min/1.73m$^2$ including 3 patients with $GFR_{Cr}$ <100 ml/min/1.73m$^2$ and one had progressive acute kidney injury during therapy; $GFR_{cycC}$ was 108 (77-136) mL/min/1.73m$^2$. Pre- vs post-surgery (n=8), median $GFR_{Cr}$ was 142 vs 104 mL/min/1.73m$^2$ (P=0.04), $GFR_{cycC}$ was 114 vs 88 mL/min/1.73m$^2$ (P=0.01). At end of therapy, median (range) percent change from baseline in $GFR_{Cr}$ was -23% (-64 to +23%), $GFR_{cycC}$ was -25% (-60 to +24%). *f*MRI analysis was completed in 26/27 scans. Using *f*MRI, median (range) percent of total renal function contributed by the involved kidney at diagnosis was 35% (23-48%) and the percent change in total parenchymal volume pre- and post-surgery was -50% (-17 to +63%) after unilateral nephrectomy (n=3) and -9% (-40 to +5%) after partial nephrectomy (n=4). **Conclusions:** Some children with Wilms tumor have decreased GFR at diagnosis. At end of therapy, median decrease in GFR was 25%. $GFR_{cysC}$ may be more sensitive to changes in renal function after complete or partial nephrectomy. *f*MRI is feasible and quantifies the contribution of tumor-involved kidney to overall renal function. Partial nephrectomy spared 90% of renal parenchymal volume in this small cohort of children.

**10054 General Poster Session (Board #355), Mon, 8:00 AM-11:45 AM**

**Effect of nerve growth factor administered as eye-drop on visual function in children with optic glioma-associated visual impairement: A controlled, cross-over clinical trial.** *Presenting Author: Riccardo Riccardi, Department of Pediatric Oncology, Catholic University of Sacred Heart, Rome, Italy*

**Background:** To date, no specific therapy is available for visual dysfunction associated with optic pathway glioma (OPG). The aim of this study was to evaluate the effects on visual function of murine nerve growth factor (NGF) administered as eye drop in children with OPG and visual impairment. **Methods:** A controlled randomized double-blind study (EudraCT 2011-003030) was conducted in 18 pts (age range 2-23 yrs , median age 10 yrs) with OPG, off-therapy with stable disease, and visual impairment. NGF eye-drop was prepared with standards required for human use by Policlinico Gemelli Pharmacy. A single 10-day course of 1 mg topical murine NGF or placebo was administered. Assessment included visual acuity, visual field, optical coherence tomography, Ganzfeld electroretinogram photopic negative response (PhNR), and visual evoked potentials (VEPs) at baseline and 15, 30, 90 and 180 days post treatment. Brain MRI was performed at baseline and at 180 days post-treatment. Following the double-blind trial, a cross-over treatment with NGF was also performed, in open label, for patients originally receiving placebo. **Results:** Ten pts received placebo and eight NGF. Drug was always well tolerated. In treated pts there was an improvement of visual field by 50% (p=0.02) and 40% (p=0.05), compared to a 14% and 5% increase in the placebo group, at 30 and at 90 days post-treatment, respectively. There was a median VEP amplitude increase from baseline, compared to placebo group, at 30 days ($p < 0.05$). In the cross-over testing, following NGF treatment, visual field and VEP amplitudes improved from either baseline or from the values recorded after placebo . The overall NGF response rate in all 18 patients was 75% (95% CI : 65-80 % ) for visual field improvement. **Conclusions:** NGF administration appears to be an effective and safe treatment in patients with OPG-associated visual impairment. Clinical trial information: 2011-003030.

**10055 General Poster Session (Board #356), Mon, 8:00 AM-11:45 AM**

**A combination chemotherapy, temozolomide (TMZ) with etoposide (VP), in relapsed or refractory pediatric solid cancer: Preliminary report of randomized phase II study of two different outpatient setting regimens (rPII).** *Presenting Author: Atsushi Ogawa, Niigata Cancer Center Hospital, Niigata, Japan*

**Background:** Each of TMZ and VP has been shown its own anti-cancer activity and they have oral formulation. Although there are established active combinations comprising alkylating agent and topoisomerase inhibitor, TMZ and VP combination (TE), has never been evaluated in pediatric solid cancer. We report efficacy, safety, feasibility of outpatient setting of TE in advance of final analysis of rPII. **Methods:** This multicenter rpII included children and young adults with recurrent or refractory pediatric solid cancer, who received disease-specific standard chemotherapies. The study design has been reported in ASCO2010 (TPS328). TMZ (150 mg/m2) and VP (50 mg/m2) were administered orally on d1-5 and d1-12 respectively every 28 days, repetitively. The main efficacy endpoint, DSMC approved to be published, was response rate. Response was evaluated according to RECIST 1.1 and toxicity was assessed by CTCAE v4.0. **Results:** Thirty-four patients(pts) from 13 centers, median age 14 years (range 3-30), received TE: 8 neuroblastoma (NB), 5 rhabdomyosarcoma, 6 Ewing sarcoma family tumor, 8 osteosarcoma (OS), 3 CNS tumors and 4 others. Overall 114 cycles were administered (median 3 per patient; range 1-20). Seventeen pts experienced grade 3-4 neutropenia, but none developed febrile neutropenia. Eight pts had grade 3-4 thrombocytopenia and twelve pts developed grade 3-4 anemia. No grade 4 non-hematological toxicity occurred. Hospitalization was required only in two pts due to VZV infection and grade 2 fever episode, respectively. Response rate (RR) was 14.7% with CR 1 and PR4. Disease control rate (CR+PR+ more than two courses stable disease (SD)) was 38.2% with eight SD. Clinical benefit ratio (CBR, CR+PR+long SD) was 29.4% with five long SD (stable disease during more than 4 course). In NB, CBR was 62.5% with 1 CR, 1 PR and 3 long SD. In OS, RR was 40.7% with 3 PR/7 (one who terminated therapy first 2-3 days due to tumor hemorrhage was excluded). **Conclusions:** TE is a promising regimen for heavily pretreated recurrent pediatric solid cancer, especially in NB and OS, with acceptable toxicities in outpatient setting. Clinical trial information: 000003002.

**10056 General Poster Session (Board #357), Mon, 8:00 AM-11:45 AM**

**Complete radiographic responses in pediatric patients with *BRAF*$^{V600}$-positive tumors including high-grade gliomas: Preliminary results of an ongoing phase 1/2a safety and pharmacokinetics (PK) study of dabrafenib.** *Presenting Author: Mark W. Kieran, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Dabrafenib is a selective inhibitor of V600 mutant BRAF kinase activity with a mechanism of action consistent with adenosine triphosphate-competitive inhibition. Dabrafenib has demonstrated anti-tumor efficacy in adult patients (pts) with *BRAF*$^{V600}$ mutant tumors, including melanoma, papillary thyroid cancer (PTC), and non-small cell lung cancer. **Methods:** This 2-part study was designed to identify phase 2 recommended dose, safety, PK, and clinical activity in pediatric pts who have had ≥1 previous therapy. Part 1 is a PK-driven dose escalation. Part 2 is an expansion study to evaluate the safety and activity of dabrafenib in pediatric pts with 1 of 4 pre-specified tumor types. Pts are treated with dabrafenib orally twice daily, using capsules or a powder for oral suspension. Serial PK samples are obtained on days 1 and 15. Imaging is performed every 2 cycles, and responses require confirmation on a follow-up scan at least 4 weeks later. **Results:** From May 2013 to Jan 2014, 8 pts (median age, 11 y; range 3-17 y) with recurrent/refractory *BRAF*$^{V600}$ mutant solid tumors including 6 high grade glioma (HGG), 1 each of Langerhans cell histiocytosis (LCH), and PTC were enrolled at dose levels 3mg/kg (n=3) and 3.75mg/kg (n=5). Radiographic responses for the HGG pts included 3 complete responses (2 confirmed and maintained at the 6 month assessment [both anaplastic astrocytoma], 1 unconfirmed [pleomorphic xanthoastrocytoma]), and 2 progressive disease. The LCH pt continues to exhibit stable disease at week 16. Data are not yet available for a PTC pt and 1 HGG pt. There were no DLTs or drug-related grade 3/4 toxicities in these 8 pts. No dose reductions have been required, and PK data analysis and dose escalation continues. Two pts (1 in each cohort) achieved plasma dabrafenib concentrations associated with clinical efficacy in adults. **Conclusions:** Dabrafenib shows encouraging initial clinical activity in this small number of evaluable pediatric pts with *BRAF*$^{V600}$ mutant solid tumors, including primary brain tumors. The preliminary safety profile in pediatric pts is consistent with that in adults. Clinical trial information: NCT01677741.

**10057 General Poster Session (Board #358), Mon, 8:00 AM-11:45 AM**

**Heat-shock protein 90 inhibition in pediatric sarcomas.** *Presenting Author: Fernanda Irene Arnaldez, Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD*

**Background:** Hsp90 is a molecular chaperone that regulates post-translational folding, stability, and function of many client proteins, which play critical roles in key signal transduction pathways implicated in cell growth, differentiation, and survival. Several relevant oncogenic proteins are described as clients, such as IGF1R, AKT/PKB, and Src-family kinases. Signaling through these molecules is critical in the biology of rhabdomyosarcoma (RMS) and Ewing's sarcoma (ES). Novel therapies for these tumors are clearly needed since patients with relapsed and metastatic disease continue to have poor outcomes. Ganetespib (Synta Pharmaceuticals) is a small molecule Hsp90 inhibitor that binds to the ATP pocket in the N-terminus of Hsp90, leading to down-regulation of Hsp90 client protein levels. **Methods:** We sought to evaluate the preclinical activity of ganetespib in a panel of ES and RMS cell lines. We evaluated in vitro activity of ganetespib in ES cell lines (TC71, TC32, EW8, RDES) and in RMScell lines (RD, RH30) using kinetic proliferation assays and MTS. **Results:** In all cases, a marked inhibition of cell growth was achieved in a dose-dependent manner with drug concentrations in the low nanomolar range (3-6 nM). We found that ganetespib exposure is associated with induction of apoptosis using caspase 3/7 assay; as well as alterations in cell cycle progression. In addition to upregulation of Hsp70, which is considered a biomarker of Hsp90 inhibition, ganetespib treatment was associated with loss of expression of IGF1R-beta as well as downregulation of key signaling pathways such as mammalian target of rapamycin (mTOR), pAKT, and Src-family kinases, particularly YES1, a kinase we identified as critical in RMS biology. Moreover, we observed a cooperative effect between Hsp90 inhibition and IGF1R blockade with R1507, a monoclonal antibody targeting this receptor (Hoffman-La Roche). Furthermore, a synergistic effect was seen when ganetespib treatment was combined with SFK inhibition using dasatinib. **Conclusions:** Ganetespib exhibited activity alone and in combination in ES and RMS cell lines and is an attractive strategy to explore in the therapy of pediatric sarcomas; possibly in combination with other targeted therapies.

**10058 General Poster Session (Board #359), Mon, 8:00 AM-11:45 AM**

**Adolescent and young adult oncology (AYAO) patient enrollments onto National Cancer Institute (NCI)-supported trials from 2000 to 2010.** *Presenting Author: Nita Seibel, Cancer Therapy Evaluation Program, National Cancer Institute, Bethesda, MD*

**Background:** Lack of participation in clinical trials has been proposed as a key explanation for the survival deficit of AYAO patients. We compared the proportion of newly diagnosed AYAO patients (out of all patients) enrolled on NCI-sponsored cooperative group therapeutic trials from 2000 to 2010 to the proportion that would be expected based on SEER incidence data. Location of care was also assessed. **Methods:** We studied AYAO accrual to all open trials by evaluating two age groups (15-19 and 20-39 years) and two time periods (2000-2005 and 2006-2010). For each cancer type, the observed proportion of AYAO patients was calculated by dividing the total number of AYAO participants accrued by the total number of trial participants. This was compared to SEER 17 data by calculating the same proportion using the cancer specific incidence for the same age and year groupings. The proportion of community based (CCOP) accrual to non-CCOP accrual was compared for the AYAO patients. **Results:** Of 116,665 patients enrolled from 294 NCI-sponsored studies with eighteen cancer types, 12,392 were aged 15-39 years. For both time periods, the observed proportion of 15 - 19 year olds was greater than the SEER data for ALL, AML, CNS, Hodgkins, and bone cancers while the clinical trial proportion of 20-39 year olds exceeded the SEER data for AML, colon, NHL, and breast cancer. Among CCOPs, the proportion of AYAO accrual was greater for younger than older patients in ALL, bone cancer, Hodgkin, and STS. **Conclusions:** For many cancer types, both adolescent and young adult patient enrollments onto NCI studies exceed what would be expected based on SEER incidence data. Although AYAO patients are represented on clinical trials, recruiting and ensuring trials are available for this age group should remain a priority.

**10059 General Poster Session (Board #360), Mon, 8:00 AM-11:45 AM**

**Evaluation of ciclopirox efficacy in rhabdomyosarcoma.** *Presenting Author: Alaa Altahan, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma in the pediatric age group. Despite current multimodal treatment, a significant portion of patients still have poor outcomes. Recent studies have shown that ciclopirox (CPX), an antifungal agent, has antitumor activity in some types of cancers like leukemia and breast cancer. The aim of this study is to evaluate the therapeutic efficacy of ciclopirox in treating rhabdomyosarcoma both in-vitro and in-vivo. **Methods:** The effect of ciclopirox on RMS in-vitro was evaluated by performing dose and time response curves in 4 RMS cell lines (Rh30, Rh41 alveolar and Rh18, RD embryonal). Flow cytometry was used to evaluate cell cycle status and degree of apoptosis. Western blotting was used to evaluate protein changes. Levels of N-MYC and C-MYC in RMS were analyzed using R2: microarray analysis and visualization platform (http://r2.amc.nl). The efficacy of CPX in-vivowas tested in a subcutaneous RMS xenograft model in SCID mice. Once tumors were established, mice were randomized to treatment or control groups. **Results:** In-vitro studies showed high sensitivity of all the RMS cell lines to CPX with IC50 = 0.5-2.5uM. In contrast, normal human fibroblasts were minimally affected in this dose range. Cell cycle and apoptosis analysis showed different responses to CPX in different cell lines. Interestingly, western blot analysis showed a significant reduction of N-MYC and C-MYC levels with CPX treatment. Analysis of public data sets showed increased expression of N-MYC and C-MYC in RMS compared to normal muscle. In-vivoresults showed that CPX treatment leads to significant delay in tumor growth, with 47% reduction in tumor volume after 26 days of starting treatment (p-value 0.005), compared to the control group. **Conclusions:** Our results show that ciclopirox is effective at inhibiting rhabdomyosarcoma cell proliferation. Interestingly, we found that CPX significantly reduces N-MYC and C-MYC expression. Further studies are being done to better understand the mechanism behind this change. Finally, in-vivo results demonstrated therapeutic efficacy of CPX in treating RMS tumors. Results of our study suggest a potential therapeutic role for ciclopirox in the treatment of rhabdomyosarcoma.

**10060 General Poster Session (Board #361), Mon, 8:00 AM-11:45 AM**

**IVADo treatment of type II and type III pleuropulmonary blastoma (PPB): A report from the International PPB Registry.** *Presenting Author: Leslie Ann Doros, Children's National Medical Center, Washington, DC*

**Background:** Pleuropulmonary blastoma (PPB) is a rare malignancy of the lung presenting in young children. The International PPB Registry (IPBBR) has pathologically confirmed more than 400 cases of PPB. Three pathologic subtypes correlate with age and outcome: Type I, a purely cystic lesion often cured by surgery alone; Type II, a combined cystic and solid lesion; and Type III, a purely solid high-grade sarcoma. Previously reported five-year survival rates for Types II and III PPB are 67% and 51%, respectively. Historically, treatment for Types II and III PPB has not been uniform. The IPPBR conducted the first prospective treatment study to evaluate the response of Type II and III PPB to a standardized chemotherapy regimen. **Methods:** Treatment records were obtained forpatients with Type II and III PPB who enrolled on the IPBBR Treatment and Biology registry. A regimen of 36 weeks of ifosfamide, vincristine, actinomycin and doxorubicin (IVADo) was recommended. Sixty-two patients were treated on the IVADo regimen; 42 completed 3 or more cycles of induction IVADo and were considered fully assessable for analyses. The IVADo group was compared as a group to 200 historical IPPBR confirmed PPB patients who received regimens other than IVADo for both event-free survival (EFS) and overall survival (OS). **Results:** Of the 42 patients, 25 (60%) were males and 17 (40%) females; median age at diagnosis was 35 months (range 19-83). There were 24 (57%) Type II; 4 (10%) Type II/III, and 14 (33%) Type III. At a median follow-up of 28 months (range 2-71), 10 (24%) relapsed; 6 (14%) died at 12-24 months. Compared to the historical group, the IVADo group had better EFS (Log-rank test, p=0.008) and better OS (p=0.04). At 5 years, IVADo had better EFS: 70.8% (95% CI 55.3-86.3%) vs. 44.7% (95% CI 37.1-52.4%), and better OS 79.2% (64.1-94.2%) vs. 60.1% (52.3-67.9%). **Conclusions:** To date, the IPPBR treatment study represents the only cohort of patients with Type II and Type III PPB that have been treated uniformly. The standardized use of IVADo showed improvement in EFS and OS compared to the historical group. Importantly, the follow-up of the IVADo cohort is shorter, and there are late events and deaths in the historical group, limiting our conclusion. Clinical trial information: NCT01464606.

**10061 General Poster Session (Board #362), Mon, 8:00 AM-11:45 AM**

**A phase I study of panobinostat in pediatric patients with refractory solid tumors, including CNS tumors.** *Presenting Author: Paul James Wood, Monash Health, Children's Cancer Centre, Melbourne, Australia*

**Background:** Deregulated acetylation of histones plays a key role in the pathogenesis of haematological and solid tumors by changing the transcription of genes involved in cell cycle control, differentiation or apoptosis. Thus, there is considerable interest in HDAC inhibition as a potential therapeutic modality in the treatment of hematological and solid tumor malignancies, including pediatric malignancies. **Methods:** This is an open label, Phase I, multi-centre study evaluating panobinostat in pediatric patients with refractory solid tumours. Primary endpoints were to define and describe associated toxicities, and to characterize its pharmacokinetics (PK). Secondary endpoints included assessing the anti-tumour activity of panobinostat, and also to assess its biologic activity by measuring the histone acetylation status in peripheral blood mononuclear cells (PBMNC). **Results:** Nine patients were enrolled and treated with intravenous panobinostat at a dosing level of 15mg/m$^2$. Three patients were removed from study prior to completion of course one due to tumour progression. A dose of 15mg/m$^2$ was tolerated with one dose limiting toxicity (DLT) observed in the six patients evaluated for DLT. Two (22%) patients experienced grade 3-4 thrombocytopenia, 1 (11%) experienced grade 3 anemia, and 2 (22%) experienced grade 3 neutropenia. Grade 4 drug related pain occurred in 2 (22%) of patients studied. Vomiting (44%), nausea (33%) and hypokalaemia (22%) were also common adverse events. Two (22%) of patients experienced a Grade II QTcF change (0.478 +/- 0.006 msec). One cardiac DLT (T wave changes) was reported. PK values for 15mg/m$^2$ (n=9) dosing were: Tmax 0.8 hours, Cmax 235.2 ng/ml, $AUC_{0\text{-}t}$ 346.8h.ng/ml and $t_{1/2}$ 7.3 hours. Pooled flow cytometry results of all nine patient samples confirm that panobinostat significantly induced acetylation of histone H3 and H4 at 6 hours ($p< 0.001$), 24 hours ($P<0.01$) and 28-70 hours ($p<0.05$) post dose. **Conclusions:** A significant, sustained, biological effect of panobinostat, as measured by acetylation status of histone H3 and H4, was achieved at a dosing level of 15mg/m$^2$. PK data and drug tolerability at 15mg/m$^2$ was very similar to that seen in adults at an equivalent dosing level. Clinical trial information: ACTRN12609000978268.

**10062 General Poster Session (Board #363), Mon, 8:00 AM-11:45 AM**

**Similar exposure and pharmacokinetics of bevacizumab in pediatric and adult cancer patients: Analysis of individual data of 152 pediatric patients.** *Presenting Author: Kelong Han, Genentech, Inc., South San Francisco, CA*

**Background:** Bevacizumab (BEV) is approved for various cancers. BEV pharmacokinetics (PK) is well established by a population PK (PPK) model in adults, but has not been comprehensively evaluated in children. Four pediatric studies have been conducted to assess BEV exposure (EXP) and PK in children, to explore the influence of patient variables on BEV PK and to compare BEV EXP and PK between pediatric and adult patients. **Methods:** BEV was administered at 5, 7.5, 10 or 15 mg/kg (Q2W or Q3W) with chemotherapy to children with primary CNS tumor (n=76), metastatic soft tissue sarcoma (n=39), osteosarcoma (n=27), or other refractory solid tumors (n=10). A nonlinear mixed effects PK model was fitted to BEV serum concentrations (Cs). Pediatric BEV EXP (trough Cs) were simulated by the pediatric PPK model under the same BSA-based or WT-based dose, and compared to adult EXP simulated by the adult PPK model. **Results:** Totally 1,464 BEV Cs from 152 patients between 6 months and 21 years old (median 10.8) were analyzed, with 9 patients under the age of 3 years. Body weight (WT) ranged from 5.9 to 125 kg (median 43.8 kg). Typical BEV clearance (CL), central volume of distribution (V1) and half life for a 75 kg individual are 9.47 mL/h, 2.98 L and 18 days in children (vs. 9.31 mL/h, 2.91 L and 20 days in adults based on the adult PPK model). In pediatric patients, CL and V1 increase with WT and are lower in females and primary CNS tumor, and CL decreases with albumin. Age is not correlated with WT-normalized CL or V1. BEV EXP in children decreases with decreasing WT given the same mg/kg dose. BEV EXP under BSA-based dose (mg/m$^2$) and WT-based dose both generally fall within the 90% predictive interval of adult EXP across pediatric age and WT range. **Conclusions:** A robust BEV PPK model for children that can be used to perform simulations was developed based on this large pediatric population with a wide range of age (0.5~21 years) and WT (5.9~125 kg). BEV PK is similar across pediatric age range when corrected for WT. BEV PK and factors correlated with BEV PK are similar in pediatric and adult patients. Pediatric BEV EXP is similar to adult EXP across pediatric WT range. BSA-based dose offers no substantial advantage over WT-based dose.

**10063 General Poster Session (Board #364), Mon, 8:00 AM-11:45 AM**

**Protein network mapping of retinoblastomas for the identification of therapeutic targets.** *Presenting Author: Elisa Baldelli, George Mason University, Manassas, VA*

**Background:** Retinoblastoma is the most common ocular tumor of childhood. Diagnosis times differ across the word, with diagnosis occurring significantly earlier in developed countries. Necrosis and invasion of the optic nerve are usually associated with poor prognosis and higher incidence of recurrence and metastases. Treatment options include surgery, radiotherapy, and chemotherapy while targeted therapies are still not available. The aim of this study was to investigate the protein signaling architecture of retinoblastomas to identify new druggable targets for personalized therapy. **Methods:** Six paraffin embedded retinoblastomas collected at the Bugando Medical Center (Mwanza, Tanzania) were analyzed in this feasibility study. Samples were collected from patients aged 2 to 10. Two tumors presented invasion of the optic nerve, 2 were free of invasion, and 2 tumors were unclassified. Four tumors were necrotic, while 2 displayed no signs of necrosis. Samples were subjected to laser capture microdissection to isolate the cancer cells from the surrounding microenvironment and analyzed by Reverse Phase Protein Microarray to evaluate the activation status of 52 drug targets and downstream effectors. **Results:** Unsupervised hierarchical clustering analysis identified 2 major clusters, one with high and one with low activation of the drug targets. Stratification based on age, invasion of the optic nerve, and necrosis showed no clustering based on the signaling network. A clear distinction between the 2 groups was detected for the activation of ErbB family members, IGF-1R, Mek and c-Met. The activation of PDGFR$\alpha$, PDGFR$\beta$ and VEGFR2 was more heterogeneous across all samples and revealed high activation only in a small portion of patients. **Conclusions:** Based on these preliminary results there is an indication that retinoblastoma has several sub-populations that exhibit different activation of drug targets. Patients whose tumors present with high activation levels for these proteins may benefit from a more targeted and specific treatment. Further analysis is needed to explore the underlying architecture and robustness of these two groups to provide evidence for the use of more targeted therapies in retinoblastoma.

**10064 General Poster Session (Board #365), Mon, 8:00 AM-11:45 AM**

**First-in-pediatrics phase I study of crenolanib besylate (CP-868,596-26) administered during and after radiation therapy (RT) in newly diagnosed diffuse intrinsic pontine glioma (DIPG) and recurrent high-grade glioma (HGG).** *Presenting Author: Cynthia Wetmore, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Children diagnosed with DIPG have a median survival of less than one year despite RT, the primary modality of therapy. PDGF pathway activation has been noted in tumor analyzed from approximately 70 % of pediatric DIPG and 50% of HGG patients, suggesting inhibition of this pathway may be of clinical benefit. Crenolanib is a highly selective and potent antagonist of the PDGF pathway with in vitro $IC_{50}$of 35- and 185-fold lower than observed with dasatanib and imatinib, respectively. **Methods:** We used a rolling-6 design to study the MTD of once-daily crenolanib administered during and after local RT in children with newly diagnosed DIPG (Stratum A), and in recurrent/progressive HGG, including DIPG (Stratum B). We have completed accrual of 55 patients, 29 and 20 evaluable in Stratum A and B, respectively. Serum pharmacokinetic analyses were performed using non-compartmental techniques on all patients for samples collected on days 1 and 28 of course 1. Pharmacodynamic and mutational analyses of peripheral blood mononuclear cells and tumor tissue are ongoing. **Results:** Forty-nine evaluable patients have been enrolled to the following dose levels: 100, 130, 170 and 220 mg/m$^2$. Dose limiting toxicities (DLTs) were primarily elevated liver enzymes in both strata, and the most common Grade 3 toxicity seen on Stratum A was leukopenia that resolved with drug interruption. Mild (Grade 2) elevation in liver enzymes was observed in fewer than 15% of patients. The maximum tolerated dose (MTD) of 170 mg/m$^2$ has been established in each stratum. On day 1, median crenolanib non-compartmental $AUC_{0-\infty}$ values for 170 mg/m$^2$dosage on Stratum A was 13,942 nM*hr (6,314-24,369), which was comparable to adult Phase I data at the 280mg flat dose. **Conclusions:** We have established an MTD in pediatric patients. The PK and current preliminary toxicity data indicate that crenolanib is well tolerated in children at doses slightly higher than the established MTD from Phase I trial in adults (280 mg/day). The spectrum of toxicities observed in children is similar to those observed in adults, though leukopenia is a novel toxicity. Clinical trial information: NCT01393912.

**10065 General Poster Session (Board #366), Mon, 8:00 AM-11:45 AM**

**A phase 1 study of AZD6244 in children with recurrent or refractory low-grade gliomas: A Pediatric Brain Tumor Consortium report.** *Presenting Author: Anuradha Banerjee, University of California, San Francisco, San Francisco, CA*

**Background:** Pathway activating genetic aberrations of the Ras-MAP kinase signaling pathway have been observed in pediatric low grade glioma (LGG), most commonly a fusion gene, BRAF-KIAA1549 or a mutation of BRAFV600E. MEK is a downstream target of BRAF; thus, MEK inhibition may represent a promising treatment strategy for patients with LGGs. **Methods:** AZD6244 was administered orally BID to children $\geq$ 3yrs and $\leq$21 years with refractory or recurrent LGG. The starting dose was 33 mg/m$^2$/day BID and continual reassessment method was used for dose finding. Pre-treatment tissue was assessed for BRAF aberrations by FISH and IHC. Serial PK studies were obtained on day 1 cycle 1. **Results:** Thirty eight eligible patients were enrolled. Initially, only patients $>$12 and $\leq$21 years were eligible. Dose levels 1 and 2 (33 and 43 mg/m$^2$/dose, BID) were deemed intolerable with dose limiting toxicities (DLTs) of headache, rash and mucositis. Following de-escalation to dose level 0 (25mg/m$^2$/dose BID), eligibility was extended to patients $<$12 years. Among the 24 patients treated at dose level 0, no patient $<$12 years and 3 of 12 patients $\geq$12 years experienced DLTs of elevated amylase/lipase, rash and mucositis. The MTD/RP2D for both cohorts was 25 mg/m$^2$/dose BID. Non-compartmental pharmacokinetic analysis in 23 patients at 25 mg/m2/dose BID indicated the median (range) $AUC_{0-\infty}$ and CL/F were 3,855 ng*hr/mL(1,780 to 7,250 ng$\times$hr/mL) and 6.5 L$\times$hr$^{-1}\times$m$^{-2}$ (3.4 to 14.0 L$\times$hr$^{-1}\times$m$^{-2}$), respectively. Similar plasma exposures of AZD6244 are known to inhibit ERK phosphorylation in peripheral blood cells. Nineteen patients had sufficient tissue for BRAF studies. Eleven patients had KIAA1549:BRAF fusion products, 3 had BRAF-V600E mutations; and 1 patient had both. ERK1/2 phosphorylation immunohistochemical staining was noted in all 19 cases studied. There were 8/38 sustained responses (1 complete and 7 partial). Of these, 5 had biology data: 3 had BRAF fusion, 1 had BRAFV600E mutation and 1 was negative for both. **Conclusions:** The RP2D of AZD6244 in children with recurrent LGG is 25 mg/m$^2$/dose BID, with the most common toxicity being rash. This study suggests promising activity in pediatric LGG. A Phase II study is currently ongoing. Clinical trial information: NCT01089101.

**10066 General Poster Session (Board #367), Mon, 8:00 AM-11:45 AM**

**Phase II trial of cixutumumab in combination with temsirolimus in pediatric patients with recurrent or refractory sarcoma: A report from the Children's Oncology Group.** *Presenting Author: Lars M. Wagner, University of Kentucky, Lexington, KY*

**Background:** The combined inhibition of insulin-growth factor type 1 receptor (IGF-1R) and the mammalian target of rapamycin (mTOR) has shown activity in preclinical models of pediatric sarcoma and in adult sarcoma patients. We evaluated the activity of the anti-IGF-1R antibody cixutumumab with the mTOR inhibitor temsirolimus in patients with relapsed Ewing sarcoma, osteosarcoma, rhabdomyosarcoma, and other soft tissue sarcoma. **Methods:** Cixutumumab 6 mg/kg and temsirolimus 8 mg/m$^2$ were administered intravenously once weekly in 4-week cycles to patients $<$ 30 years of age with recurrent or refractory sarcoma. Temsirolimus was escalated to 10 mg/m$^2$ for subsequent cycles in patients who did not experience unacceptable first-cycle toxicity. A two-stage enrollment design was used to identify a response rate of $<$ 10% or $>$ 35%, with expansion of a tumor-specific cohort only if 2 or more complete or partial responses were seen in the first 11 patients. Tumor tissue was analyzed by immunohistochemistry for potential biomarkers of response. **Results:** Forty-three evaluable patients (median age 17 years, range 1-27) received a median of 2 cycles (range, 1-7). No objective responses were observed; 7 (16%) patients were progression-free at 12 weeks. Dose-limiting toxicity occurred in 15 (16%) of 92 cycles. The most common toxicities were mucositis, electrolyte disturbances, and myelosuppression. The lack of objective responses precluded correlation with tissue biomarkers. **Conclusions:** Despite encouraging preclinical data, the combination of cixutumumab and temsirolimus did not result in objective responses in this Phase II trial of pediatric sarcoma patients with recurrent or refractory disease. Clinical trial information: NCT01614795.

**10067 General Poster Session (Board #368), Mon, 8:00 AM-11:45 AM**

**Characterization of *KIAA1549:BRAF* fusion in young pilocytic astrocytoma patients through fluorescence in situ hybridization.** *Presenting Author: Marileila Varella-Garcia, University of Colorado School of Medicine, Aurora, CO*

**Background:** Pilocytic astrocytoma (PA) often arises in young patients and may be related to type 1 neurofibromatosis (NF1). Although the 5-year survival is high, up to 10% of cases progress poorly. Alterations of *BRAF* mainly through gene fusions are key genetic events in this tumor type, and are reported to influence patient outcome. Our aim was to assess *BRAF* molecular changes in PAs for both p.V600E mutation and *KIAA1549:BRAF (K:B)* fusion and correlate with clinicopathological features in retrospective studies. **Methods:** Sanger sequencing was used to evaluate *BRAF* V600E mutation. *K:B* fusion was evaluated by a customized dual-target, dual-color fluorescence in situ hybridization (FISH) probe set in samples in tissue microarray format. The designed *K:B*FISH probe was validated in Agilent 8x60K aCGH and RT-PCR assays in 5 cases. **Results:** A total of 75 samples were evaluated from 69 patients (1.2 M/F), mean age of 11.6 years and long-term follow-up (7-196 months). Cerebellum was the main location (53.6%). Five patients had confirmed diagnosis of NF1 (7.2%) and 5 patients showed growing residual lesions in this series. There was only one *BRAF* mutated case. Complete concordance was seen between methodologies in the validation set, in which samples exhibiting gains at 7q34 were also positive for *K:B* by RT-PCR and FISH. Overall, we evaluated 69/75 samples by FISH, and observed that 38/64 (59.4%) of primary lesions displayed *K:B* fusion, with a strong positive correlation with cerebellar lesions ($p<0.001$) and negative with NF1 ($p=0.009$). No statistical difference was seen between age groups ($p=0.467$), and the Kaplan-Meier curve showed that presence of *K:B* fusion was significantly associated with better survival ($p=0.009$). Interestingly, in the subset of patients that recur, two specimens that demonstrated *K:B* fusion in the primary tumor, exhibited loss of the gene fusion in the recurrence. **Conclusions:** This study confirms the pivotal role of *K:B* fusion in PAs biology and its clinical impact, defining a subset of patients with better outcome. Moreover, we showed the feasibility of a custom FISH assay as a reliable method for detection of this alteration in routine-based neuropathology laboratory.

**10068 General Poster Session (Board #369), Mon, 8:00 AM-11:45 AM**

**The role of MEK inhibition in neuroblastoma tumor cells.** *Presenting Author: Peter E. Zage, Baylor College of Medicine, Houston, TX*

**Background:** Neuroblastoma is the most common extracranial solid tumor of childhood. High-risk cases of neuroblastoma have extremely poor long-term survival rates, and novel therapies are needed. The RAS/MAPK pathway has been shown to be involved in neuroblastoma tumorigenesis. We hypothesized that RAS/MAPK pathway inhibition via MEK inhibition with MEK162 would be effective against neuroblastoma tumor cells. **Methods:** We evaluated expression and activity of MEK and ERK in a panel of neuroblastoma tumor cells using Western blots and neuroblastoma tumor cell viability after treatment with MEK162 using MTT assays. Expression of NF1 protein was determined by Western blot. Analyses were performed for changes in RAS/MAPK pathway activity after MEK162 treatment. **Results:** Neuroblastoma tumor cell lines displayed differential responses to MEK162, with some cell lines being very sensitive and others being resistant. IC50 values for sensitive cell lines ranged from <10nM to 5mM, while resistant cells did not demonstrate any reduction in cell viability at doses exceeding 20mM. NF1 expression correlated with responses to MEK162. MEK162 treatment resulted in reduced ERK phosphorylation in sensitive neuroblastoma cells, while increased levels of MEK phosphorylation were seen in resistant cells. **Conclusions:** Treatment of neuroblastoma tumor cells with MEK162 inhibits RAS/MAPK pathway activity, resulting in cell death in sensitive cell lines. Resistant neuroblastoma tumor cell lines displayed increased MEK phosphorylation in response to MEK162, suggesting a possible feedback loop leading to treatment resistance. Inhibition of MEK represents a potential new therapeutic strategy for neuroblastoma, and further preclinical studies of MEK162 are warranted.

**10069 General Poster Session (Board #370), Mon, 8:00 AM-11:45 AM**

**Evaluation of resources used during care of children with high-risk neuroblastoma (HR NBL) via merging of cooperative group trial data and administrative data.** *Presenting Author: Rochelle Bagatell, The Children's Hospital of Philadelphia, Philadelphia, PA*

**Background:** Cooperative group trials have improved outcomes for children with HR NBL. Trial data provide reliable information regarding patient characteristics, treatment, and response but do not include information regarding resource utilization. Merging of trial and administrative data would facilitate comparative effectiveness studies. **Methods:** Data from the Children's Oncology Group (COG) and the Pediatric Health Information Systems (PHIS) were merged for patients (pts) enrolled on Phase 3 COG trials for HR NBL (A3973 and ANBL0032) at 43 PHIS centers. A3973 included induction chemotherapy, surgery, stem cell transplant, and radiation. Responders were eligible for ANBL0032, a randomized trial of chimeric antibody, cytokine and isotretinoin vs isotretinoin alone. Inpatient resource utilization summary statistics were tabulated based on PHIS data. **Results:** Of 323 enrollments on A3973 and/or ANBL0032 at PHIS centers, matching was successful and resource utilization data were available for 223 pts. The median age of newly diagnosed pts was 3.19 years (range 0.3-16.09) and 163 (88%) children had Stage 4 disease. Sixty-six (36%) had *MYCN* amplified tumors, 145 (87%) had unfavorable histology. Pts treated on A3973 for whom complete data were available (n=192) were hospitalized for a median of 100 days (d). Of these, 75 (39%) required intensive care resources; these services were delivered for a median of 4d per pt. Median cumulative duration of antibiotic use was 72d per pt. Ototoxic antibiotics were administered to 44% of pts; these were delivered for a median of 6d in total (range 1-93). **Conclusions:** Pts enrolled on cooperative group HR NBL studies can be successfully identified and resource utilization data can be collected across trials using an administrative dataset. Characteristics of pts in this cohort are consistent with those of pts on recent HR NBL studies. Information regarding length of stay and supportive care required for treatment of children with HR NBL will be used in comparative effectiveness studies and will aid in patient/family education. A larger cohort, created by adding pts from future trials, will permit additional analyses.

**10070 General Poster Session (Board #371), Mon, 8:00 AM-11:45 AM**

**Phase 1 trial of decitabine and CT antigen-specific vaccine in relapsed pediatric solid tumors.** *Presenting Author: Rani George, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The Cancer/Testis (CT) antigens MAGE-A1, MAGE-A3 and NY-ESO-1 are selectively expressed at varying levels on many pediatric solid tumor cells, including neuroblastoma (NB), and thus have the potential to be targeted for immune therapy by antigen-specific T cells. We have shown that the DNA methylating agent decitabine (DAC) upregulates CT antigen expression in a range of tumor types, leading us to evaluate the feasibility of combining DAC with a CT antigen-targeted dendritic cell (DC) vaccine in patients with relapsed solid tumors. **Methods:** In this two-institution trial, eligible patients had PBMCs collected by apheresis and transported to the lead center for vaccine preparation. The treatment regimen included 4 cycles of therapy: DAC 10mg/m$^2$/day for 5 days, followed by 2 weekly vaccinations of autologous DC pulsed with overlapping peptide mixes derived from full-length CT antigen sequences. The toll-like receptor agonist imiquimod was used at vaccination sites to facilitate immune response. Peripheral blood was collected weekly and analyzed for CT antigen-specific antibodies and CD137$^+$antigen-specific T cells by flow cytometry. **Results:** Fifteen patients have been enrolled (median age, 8.5 yrs); 10 with NB, 2 each with Ewing sarcoma and osteosarcoma, and 1 with rhabdomyosarcoma. DC vaccine preparation was successful for all 15 patients. Five patients did not receive vaccine due to disease progression. Of the 10 patients who received therapy, 3 completed all 4 cycles, and two, 3 cycles. Five patients received $\leq$ 2 cycles only, 4 due to disease progression and one due to a vaccine reaction. The major toxicity was neutropenia requiring growth factor support. Three of 7 NB patients in whom antigen-specific immune response was assessed had an increase in the number of CT antigen-specific CD8$^+$CD137$^+$ and/or CD4$^+$CD137$^+$T cells, while one had an antibody response to all three CT antigens. **Conclusions:** DAC followed by DC/CT antigen-targeted vaccine is well tolerated and highly feasible in heavily pretreated children with relapsed solid tumors, warranting further investigation in larger trials. Clinical trial information: NCT01241162.

**10071 General Poster Session (Board #372), Mon, 8:00 AM-11:45 AM**

**Fenretinide (4-HPR)/Lym-X-Sorb (LXS) oral powder plus ketoconazole in patients with high-risk (HR) recurrent or resistant neuroblastoma: A New Approach to Neuroblastoma Therapy (NANT) Consortium trial.** *Presenting Author: Barry James Maurer, Texas Tech University Health Sciences Center, Lubbock, TX*

**Background:** Fenretinide (4-HPR), a cytotoxic retinoid with preclinical activity in neuroblastoma (NB), formulated as 4-HPR/LXS oral powder increased plasma levels over a capsule formulation but exhibited a PK plateau at higher doses (Pediatr Blood Cancer 60:1801, 2013). Two expansion cohorts were undertaken to assess effects on 4-HPR plasma levels of: 1) removing dietary restrictions, 2) adding ketoconazole, an inhibitor of 4-HPR metabolism. **Methods:** Eligible patients had high-risk NB with recurrent or refractory disease, including in complete response (CR) after relapse (Cohort One-only). Treatment in Cohort One was 4-HPR at 1500 mg/m$^2$/day, divided TID, given on Days 1-7, every 3 weeks, with an unrestricted diet. In Cohort Two, concurrent oral ketoconazole (6 mg/kg/day) was given on Days 1-7. **Results:** Cohort One accrued 23 patients (3 not treated) with 15 eligible for PK analysis; Cohort Two accrued 22 patients, with 16 eligible for PK analysis (3 too early). There were no Course 1 DLT's. Grade 3 toxicities included rash, elevated triglycerides, lymphopenia, diarrhea, and transient transaminase elevation. Overall, patients received a median of 3 (range: <1-27) courses. In Courses 1 and 2, the mean (95% confidence interval) Day 7, 4-HPR peak plasma level ($\mu$M) at 4-6 hours post-morning dose for Cohort One was 11.7 (8.3, 15.1) and for Cohort 2 was 18.4 (14.6, 22.1). Ketoconazole significantly increased peak 4-HPR plasma levels ($p$=0.005, mixed effects ANOVA). Of 16 patients in Cohort One and 18 patients in Cohort Two with evaluable disease at study entry, there were 2 complete responses, 1 partial response, 1 mixed response (MIBG CR), 14 stable disease, and 12 progressive disease; 4 patients did not complete 1$^{st}$ course. For the 34 patients with evaluable disease, the median progression-free survival (PFS) is 4.1 (1.35-36.9+) months. **Conclusions:** 4-HPR/LXS + ketoconazole was tolerated and increased 4-HPR plasma levels. Objective responses and encouraging PFS in this heavily pre-treated patient population support evaluation of 4-HPR/LXS with ketoconazole in future trials of high-risk neuroblastoma. Clinical trial information: NCT00295919.

**10072 General Poster Session (Board #373), Mon, 8:00 AM-11:45 AM**

**Discrepancies in treatment of osteosarcoma according to insurance coverage: A review of the National Cancer Data Base.** *Presenting Author: Mimi Longo, Creighton University School of Medicine, Omaha, NE*

**Background:** Osteosarcoma is the most common primary bone malignancy in children and adolescents. It is an aggressive tumor with a tendency to metastasize to the lungs. It is believed that at the time of diagnosis, all patients have micrometastases. Therefore, neoadjuvant and adjuvant chemotherapy in addition to surgical removal of the tumors became the gold standard of care in the 1990s. The authors sought to learn if patients in the National Cancer Database from 2000-2011 received surgery and chemotherapy as their first course treatment. **Methods:** The National Cancer Data Base contains cases of cancer diagnoses from 1,404 American College of Surgeons-Accredited hospitals. There are 5,501 cases of osteosarcoma from 2000-2011 in the database, and these cases were used for analysis. **Results:** The authors found that 46.6% of patients with no insurance received surgery and chemotherapy, but 63.8% of patients with private/managed insurance received surgery and chemotherapy as their first course treatment (p-value $<0.01$). Only 21.20% of patients who had Medicare got surgery and chemotherapy as their first course treatment. Furthermore, a significant number of patients with no insurance received no therapy (14.8%) as compared to 3.7% of patients who had private/managed insurance ($p<0.001$). **Conclusions:** Patients with no insurance were less likely to receive chemotherapy and surgery for their disease, and they were much more likely to receive no treatment. Lack of insurance prevented patients from receiving life-saving treatments. Thirty-four percent of patients with no insurance were under age 20. Although only 21.20% of patients who had Medicare got surgery and chemotherapy as their first course treatment, 79% of the patients who had Medicare and got osteosarcoma were age 60 and older, so they may have had comorbidities that prevented them from getting surgery and chemotherapy. This is the largest review of osteosarcoma treatments according to insurance status to date.

**10073 General Poster Session (Board #374), Mon, 8:00 AM-11:45 AM**

**Preclinical evaluation of PARP inhibitors in combination with DNA-damaging agents in a Ewing sarcoma orthotopic xenograft model.** *Presenting Author: Elizabeth Stewart, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Ewing sarcoma (EWS) is an aggressive malignancy of childhood with a dismal prognosis in patients with metastatic or recurrent disease. Previous research demonstrated EWS cell lines with the EWS-FLI1 translocation be sensitive to Poly (ADP ribose) polymerase inhibitors (PARPi). Although phase 1 clinical trials have failed to demonstrate significant single agent efficacy for EWS, preclinical studies suggest increased efficacy with the addition of DNA damaging agents to PARPi. We examined the PARPi BMN 673, olaparib, and veliparib in combination with irinotecan and temozolomide (TMZ) in a clinically relevant EWS orthotopic xenograft model. **Methods:** EWS orthotopic xenografts were created by injecting EW-8 luciferase labeled cells into the femur of CD-1 nude mice. Mice were randomized to the following treatment groups (see Table.) Allometric doses were administered on a clinically relevant schedule for two cycles. Complete response (CR), stable disease (SD), and progressive disease (PD) were determined using bioluminescence. **Results:** The addition of TMZ and irinotecan to BMN 673 and olaparib (Groups 1, 2) showed significant disease response in comparison to irinotecan and TMZ alone (Group 4). Mice that received BMN 673 had the best response with 100% achieving CR. Mice that received olaparib (Group 2) had a 50% CR and 50% SD. Groups 3, 4, and 5 all had 80% PD and 20% SD. **Conclusions:** The addition of the PARP inhibitors BMN 673 and olaparib to irinotecan and TMZ provides significant disease response and stabilization in an orthotopic xenograft model of EWS. These drug combinations may be effective in the treatment of pediatric patients with EWS. Ongoing pharmacokinetic and preclinical studies will be performed to determine if efficacy is likely to be achieved within the therapeutic window of this patient population.

| **Group 5 (n = 5)** | Placebo |

**10074 General Poster Session (Board #375), Mon, 8:00 AM-11:45 AM**

**Postrecurrence survival for pediatric extracranial malignant germ cell tumors: A report from the Malignant Germ Cell Tumors International Collaborative (MaGIC) Group.** *Presenting Author: Furqan Shaikh, Hospital For Sick Children, Toronto, ON, Canada*

**Background:** Post-recurrence survival (PRS) of children and adolescents with malignant germ cell tumors (MGCTs) has not previously been described, due to the limited sample size of relapsed patients in clinical trials. **Methods:** Data from 7 pediatric extracranial GCT trials conducted by the Children's Oncology Group (COG, United States) or the Children's Cancer and Leukemia Group (CCLG, United Kingdom) between 1985-2009 were merged. The COG and CCLG trials differed mainly in the type of platinum agent used for upfront treatment (cisplatin or carboplatin, respectively), and event-free survival after either treatment were not significantly different, as previously reported. Kaplan-Meier survival curves and Cox regression were used to analyze the effects of potential predictor variables on PRS. **Results:** Among 1,107 children in the pooled dataset, 700 MGCT patients received treatment with platinum-based chemotherapy. 72 of these patients experienced a relapse or refractory disease. For these 72 patients, the 5-year PRS was 38% (95% confidence interval (CI) 26% - 49%). The 5-year PRS was significantly higher for 29 children who had been treated upfront with carboplatin regimens (51% , CI 31% - 67%) compared to 43 children treated upfront with cisplatin regimens (28%, CI 15% - 43%; log-rank $p=0.046$). PRS was not significantly associated with age at diagnosis, tumor site, stage, initial AFP, or time to relapse. In a multivariable model where the known prognostic factors for upfront pediatric GCT (age, stage, and site) were added, the effect of chemotherapy regimen remained significant (hazard ratio 2.06, CI 1.03 - 4.10; $p=0.041$). Data on post-recurrence treatment regimens were not available. **Conclusions:** Though limited by the lack of data on type of salvage therapy, we observed a significantly higher PRS after upfront carboplatin regimens compared to upfront cisplatin regimens. This observation should be explicitly tested in a prospective trial. This finding also suggests that overall survival, rather than relapse-free survival, should be utilized as the primary end-point in reduction-of-therapy trials for treatments with differences in PRS.

**10075 General Poster Session (Board #376), Mon, 8:00 AM-11:45 AM**

**Metastatic melanoma presenting during childhood: NCI Pediatric Oncology Branch experience.** *Presenting Author: Melinda S. Merchant, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

**Background:** Childhood melanoma is rare with an incidence of ~300 cases/yr in the United States. Stage IV disease is detected in 1-10% of reported pediatric melanomas. The treatment of this chemoresistant disease in pediatric patients can be quite challenging, even with access to recently approved therapies for melanoma. Limited numbers have made it difficult to determine if the presentation and characteristics of pediatric metastatic melanoma are similar to the disease seen in adults. **Methods:** In a retrospective chart review, we identified sixteen pediatric patients with metastatic melanoma who were referred to the Pediatric Oncology Branch. Molecular status of tumors was determined by CLIA certified tests. Patient overall survival data was collected while patients were treated with ongoing immunotherapy protocols or with treatment using approved agents. **Results:** A total of 16 patients aged 2-21yo were evaluated from January 2009 to January 2014. Fifteen patients had cutaneous melanoma and one teen had mucosal melanoma. Eleven patients (68%) had a head and neck primary, including 8 patients with the scalp identified as the primary site. One teenager presented with widely metastatic disease from an unknown primary. In addition to common sites of metastases in lymph node, liver, and lung, pediatric patients also developed brain metastases ($n=8$ patients) and ocular metastases ($n=1$ patient). Five of the 12 tumors (42%) tested at diagnosis were found to harbor the BRAF V600E mutation. An NRAS mutation was identified in two melanomas. No ckit mutations were identified. Despite multiple treatment strategies, all patients experienced progressive or relapsed disease. The median survival of this cohort was 6 months following diagnosis of metastatic melanoma. **Conclusions:** Metastatic melanoma in the pediatric population is an aggressive disease with widespread pattern of metastasis. Head and neck primaries had a higher incidence in this series than has been identified in pediatric or adult melanoma of all stages. It is unclear if this increase is due to delayed detection or differences in biology. Further advances in pediatric melanoma will be aided by in-depth genomic analysis and collaborative study of these rare cases.

**10076 General Poster Session (Board #377), Mon, 8:00 AM-11:45 AM**

**Proton radiation for treatment of infratentorial brain tumors in infants and very young children.** *Presenting Author: Christine E. Hill-Kayser, Hospital of the University of Pennsylvania, Philadelphia, PA*

**Background:** Radiation therapy (RT) has historically been delayed for infants with brain tumors due to data suggesting unacceptable toxicity after photon RT. Proton therapy allows definite sparing of normal brain, and may allow improved outcomes. **Methods:** 21 consecutive subjects age 3y or less with infratentorial brain tumors requiring RT were enrolled on a prospective registry from 6/2010 – 10/2013. All underwent maximal safe tumor resection. Eight received pre-radiation chemotherapy (ChT) based on diagnosis and tumor-specific treatment plan, but radiation was not delayed due to age. Focal RT was planned after CT simulation and fusion of pre and post-operative MRI scans. The tumor bed, clinical target volume (1 cm expansion), and organs at risk were contoured with Eclipse planning software. Doses are reported in radiobiologic-equivalent-weighted absorbed dose (cGyRBE). Brainstem planning constraints included maximum dose 6,000 and 95% ≤ 5,400. **Results:** The patient population at the time of RT ranged from 11 – 47m, and 13 (62%) were male. Diagnoses included ependymoma (13), medulloblastoma (5), ATRT (2), and Ewing sarcoma (1); the non-ependymoma patients received ChT pre RT. Median RT dose was 5,400 (R 5,040-5,940), and median days for RT course was 44 (R 40-50). RT was delivered using passive scattered proton beams for 20 patients, and pencil beam scanning for 1. All patients received daily general anesthesia. No patient experienced greater than grade 1 (CTCAEv4) acute toxicity. Grade 1 toxicities included fatigue (2), nausea (5), anorexia (4), constipation (2), dermatitis (15). With maximum follow-up of 35 months (range 1.4-35, mean 15 months), 19 patients are alive, no evidence of disease, 1 patient is LTFU, and one is dead of disease. No patient has experienced serious (grade 3-4) long-term toxicity related to radiation. **Conclusions:** With 3 years of follow-up, proton RT for infratentorial brain tumors appears to be well-tolerated by very young children, resulting in minimal acute toxicity and no serious long-term toxicity, with excellent disease control. Increasing use of RT for very young children supports more sophisticated toxicity evaluation prospectively, which is currently being performed at our center.

**10077 General Poster Session (Board #378), Mon, 8:00 AM-11:45 AM**

**Outcomes after proton radiotherapy for localized childhood ependymoma (EP).** *Presenting Author: Christine E. Hill-Kayser, Hospital of the University of Pennsylvania, Philadelphia, PA*

**Background:** Radiotherapy (RT) results in excellent local control and outcomes for resected EP. Proton RT may reduce acute and late RT-related toxicity by reduced exposure of normal brain and other organs at risk (OAR). **Methods:** From 2010-13, 23 subjects with newly diagnosed EP were enrolled on a prospective registry. All subjects underwent maximal safe resection; none had dissemination. Focal RT was planned after CT simulation and fusion of pre and post-operative MRI scans. The tumor bed, clinical target volume (1 cm expansion), and OAR were contoured using Eclipse treatment planning software. Doses are reported in radiobiologic-equivalent-weighted absorbed dose (cGyRBE). Brainstem planning constraints included maximum dose 6,000 and 95% less than 5,400. Neurocognitive (NC) testing was planned for all subjects prior to start of RT. **Results:** The median age at start of RT was 4yr (range 1-15) and 70% were male. Disease characteristics included infratentorial in 18, (78%), supratentorial in 5 (22%) [occipital (2), parietal (2), frontal (1)], and anaplastic histology in 11. Baseline NC testing was performed in 13 subjects, with overall pre-RT NC abilities ranging from low average to superior (median IQ=105, range 88-127). In subjects with non-anaplastic histology, average RT dose was 5,565 (range 5,400-5,940). For anaplastic disease, average dose was 5,900 (range 5,580-5,940). Median duration of RT was 44 days (range 37-50). RT was delivered using passive scattered proton beams for 20 subjects, and pencil beam scanning for 3. Toxicities during treatment (CTAEv4) included fatigue (G1, n = 3) headache (G1, n = 3), dermatitis (G1, n = 12; G2, n = 2), nausea (G1, n = 5), vomiting (G1, n = 2), anorexia (G1, n = 2), dysphagia (G1, n = 1). Post-RT chemotherapy was given to 2 subjects. With a maximum follow-up of 43 months (range 1-43, mean 17), 18 subjects are alive without disease, 2-dead of disease, 3-AWD. None have experienced grade 3 or 4 late RT-related toxicity. At 1 yr post-RT, overall IQ was 96-118 (n=5); at 2 years, 99-121 (n = 3). **Conclusions:** With over 3 years of follow-up, proton RT for pediatric EP appears well-tolerated, resulting in minimal acute toxicity and no serious late toxicity, with excellent disease control.

**10078 General Poster Session (Board #379), Mon, 8:00 AM-11:45 AM**

**A phase I study of cabozantinib (XL184) in children and adolescents with recurrent or refractory solid tumors, including CNS tumors: A Children's Oncology Group phase I consortium trial.** *Presenting Author: Meredith K. Chuk, Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD*

**Background**: Cabozantinib, an oral inhibitor of tyrosine kinases including MET, VEGFR2 and RET, is approved for adults with progressive, metastatic medullary thyroid carcinoma (MTC). We conducted a phase I and pharmacokinetic (PK) trial of cabozantinib in children with refractory solid tumors. **Methods**: Cabozantinib was administered daily (28 day cycles) using the rolling 6 design; 3 dose levels were evaluated. If a cohort was filled, patients (pts) with MTC could be enrolled at the previous lower dose. PK and pharmacodynamic (PD) studies were conducted in all patients, including an expanded cohort at the recommended phase 2 dose (RP2D). **Results**: 29 eligible (25 evaluable) pts, median age 14 yr (range, 4-18) [CNS tumor (n=6), MTC (n=3), hepatocellular carcinoma (HCC, n=2), Ewing sarcoma (EWS, n=2), other sarcomas (n=8), or other (n=8)] have received a median of 3 (range, 1-10) cycles, with 6 pts still on study. During the dose escalation phase dose-limiting toxicities (DLT) occurred in 0/6 pts at 30 and 40 mg/m$^2$ and 1/6 pts at 55 mg/m$^2$ [Gr3 fatigue and headache]. Other first cycle DLTs in expansion cohorts included: Gr 2 palmar plantar erythrodysesthesia (PPE) and oral mucositis (n=1; 40 mg/m$^2$); Gr3 proteinuria and Gr2 hypertension (HTN) (n=1; 55 mg/m$^2$); and Gr3 HTN and reversible posterior leukoencephalopathy syndrome (n=1; 55mg/m$^2$). Later cycle DLTs in 10 pts include: Gr3 weight loss (n=2), Gr3 PPE (n=2), Gr3 and 4 lipase increase (n=1 each), Gr4 neutropenia (n=1), Gr2 fatigue (n=1), Gr2 arthralgia (n=1) and Gr3 anorexia, dyspnea, skin ulcer (n=1). Cabozantinib exposure was not dose proportional. The mean ± SD steady state $AUC_{0\text{-}24h}$ at 30 mg/m$^2$ (n=6), 40 mg/m$^2$ (n=6) and 55 mg/m$^2$(n=6) was 31.9 ± 7.8, 33.3 ± 11.3 and 33.7 ± 15 $\mu$g·h/mL, respectively. The median accumulation index was 3.0 (0.5-8.7). Responses will be reported. **Conclusions**: Based on DLTs observed in later cycles, the recommended dose of cabozantinib in children with solid tumors is 40 mg/m$^2$ (adult fixed dose ≈72 mg). Enrollment is ongoing to further assess PK and PD at the RP2D. A phase II trial is planned. Clinical trial information: NCT01709435.

**10079 General Poster Session (Board #380), Mon, 8:00 AM-11:45 AM**

**Risk of subsequent malignant neoplasms in long-term retinoblastoma survivors following chemotherapy and radiotherapy.** *Presenting Author: Jeannette R Wong, National Cancer Institute, Rockville, MD*

**Background:** Hereditary retinoblastoma (Rb) survivors have increased risk for developing subsequent malignant neoplasms (SMN). Previous studies report elevated SMN risks related to radiotherapy (RT), but less is known about chemotherapy-related risks. Patients and **Methods:** In a long-term follow-up study of 906 five-year hereditary Rb survivors diagnosed 1914-1996 and followed through 2009, risks were quantified using cumulative incidence analyses and compared by type of Rb treatment using hazard ratios (HRs) and 95% confidence intervals (CIs) derived from multivariate Cox proportional hazards regression models. **Results:** Nearly 90% of Rb survivors were treated with RT and almost 40% received alkylating-agent (AA)-containing chemotherapy. Overall SMN risk was elevated among survivors receiving AA+RT compared to RT (without chemotherapy; HR 1.27, 95%CI 0.99-1.63). AA-related risks were significantly increased for subsequent bone (HR 1.30, 95%CI 1.03-2.49) and leiomyosarcoma (HR 2.67, 95%CI 1.22-5.85), but not melanoma (HR=0.74, 95%CI 0.36-1.55). Leiomyosarcoma risk was higher for survivors who received AAs at <1 year of age (HR 5.17, 95%CI 1.76-15.17) versus ≥1 (HR 1.75, 95%CI 0.68-4.51). Development of leiomyosarcoma was significantly more common among survivors who were treated with AA+RT versus RT (8.7% versus 6.3% at age 50 years, p=0.02). **Conclusions:** This first comprehensive quantification of SMN risk after chemotherapy and RT among hereditary Rb survivors demonstrates the contribution of AAs to SMN risk. This effect was driven by Rb survivors who were treated with triethylene melamine (64%). Although no longer prescribed, our findings warrant further follow-up to investigate potential SMN risks associated with current chemotherapies used for Rb.

**10080 General Poster Session (Board #381), Mon, 8:00 AM-11:45 AM**

**Individual risk prediction of major cardiovascular events after cancer: A Childhood Cancer Survivor Study report.** *Presenting Author: Eric Jessen Chow, Fred Hutchinson Cancer Research Center, Seattle Children's Hospital, Seattle, WA*

**Background:** Childhood cancer survivors are at increased risk of cardiovascular (CV) events. Models that combine information on cancer treatment exposures and conventional CV risk factors to estimate an individual's probability of developing major CV events would be clinically important. **Methods:** Cohort study of 10,521 five-year survivors of childhood cancer diagnosed 1970-86, free of CV disease at initial baseline survey, and who were followed with longitudinal surveys. Poisson regression models estimated the risk of the developing severe, life-threatening, or fatal CV events: 1) congestive heart failure (CHF), 2) coronary heart disease (CHD), 3) stroke, and 4) any CV-related death. Models accounted for sex, age at cancer diagnosis, and select chemo- and radiotherapy exposures. Secondary models accounted for late relapse and second cancers occurring beyond 5 years, and the effect of conventional CV risk factors (current smoking, alcohol use, physical activity, obesity, and any treatment for hypertension, dyslipidemia, or diabetes). Model prediction and discrimination were assessed via area under the curve (AUC) and the concordance (C) index. **Results:** After a median follow-up period of 25.8 years (range 7.4-39.2) since cancer diagnosis, the cohort experienced 182 (1.7%) CHF, 186 (1.8%) CHD, 159 (1.5%) stroke, and 66 (0.6%) deaths related to CV events. Models based on primary cancer treatment exposures predicted CHF, CHD, stroke, and CV death risk at/through age 40 with AUC and C-statistics ranging from 0.71-0.77. Adjusting for late relapse/second cancers and conventional CV risk factors further improved prediction (AUC/C-statistics 0.73-0.78; improvement in model prediction, $p=0.01$ to 0.07). The predictive weights assigned to hypertension and diabetes were similar to those assigned to high-level anthracycline or chest radiotherapy exposures. **Conclusions:** The predictive models we generated offer the potential for individual risk assessment of serious CV diseases at/through age 40. Once validated in other cohorts, these models may become important clinical tools in helping care for long-term childhood cancer survivors.

**10081 General Poster Session (Board #382), Mon, 8:00 AM-11:45 AM**

**Myocardial strain for detection of treatment-related cardiac dysfunction in adult survivors of childhood cancer: Results from the St. Jude lifetime cohort study.** *Presenting Author: Gregory T. Armstrong, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Ejection fraction (EF) by echocardiography (echo) is the recommended screening modality for treatment-related cardiac dysfunction in survivors of childhood cancer. Because decreased EF occurs late in its natural history more sensitive detection methods are needed. We hypothesized that myocardial strain would improve identification of survivors with reduced exercise capacity. **Methods:** Analysis included 1,107 >10 yr survivors of childhood cancer (median age 32 yrs, range 18-59; 593 anthracycline-no chest radiation [RT], 206 chest RT-no anthracycline, and 308 anthracycline + chest RT). Echo included systolic (3D EF, abnormal defined as <50%) and diastolic function (grades 1-3 abnormal), and global longitudinal (>-18.9) and circumferential (>-22.1) myocardial strain. Exercise capacity was assessed with a 6-minute walk (<490 meters abnormal). Associations between echo measures and exercise capacity were assessed using logistic regression adjusted for age, weight, height, pulmonary function, muscle strength, diastolic function, hypertension and diabetes to calculate odds ratios (ORs) and 95% confidence intervals (CI). **Results:** Systolic dysfunction was detected in 5%, diastolic dysfunction in 12%, and abnormal longitudinal and circumferential strain in 47% and 57%. Longitudinal strain was the only echo measure associated with reduced exercise capacity (OR 1.7, CI 1.1-2.6) with no association for 3D EF (OR 0.6, CI 0.2-1.8), diastolic function (OR 1.1, CI 0.6-1.9), or circumferential strain (OR 1.0, CI 0.7-1.6). Abnormal longitudinal strain was associated with older age, male sex and dose of chest RT. Among survivors with normal EF, abnormal longitudinal strain was significantly associated with detection of survivors with reduced exercise capacity (OR 1.7, CI 1.0-2.7). **Conclusions:** Among adult survivors of childhood cancer, abnormal global longitudinal strain is prevalent, associated with chest-directed RT exposure, and is the only echo measure independently associated with reduced exercise capacity. Longitudinal strain identifies at-risk survivors who should be targeted for potential clinical interventions.

**10082 General Poster Session (Board #383), Mon, 8:00 AM-11:45 AM**

**Breast cancer following spinal radiotherapy for a childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS).** *Presenting Author: Chaya S. Moskowitz, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Small dosimetry-based studies suggest females treated with spinal radiotherapy (RT) for a pediatric malignancy may have an increased risk of subsequent breast cancer (BC) due to scatter radiation to breast tissue. However, BC risk in this population has not been assessed in well-characterized survivor cohorts with long-term follow-up. **Methods:** In the CCSS cohort, we estimated BC incidence in 363 5-yr survivors of leukemia ($n=195$) and central nervous system (CNS) tumors ($n=168$) diagnosed 1970-86 prior to age 21 and treated with spinal RT. The median delivered dose of spinal RT for leukemia survivors was 1800 cGy (range 150-4175 cGy) and for CNS tumor survivors was 3453 cGy (range 475-6500 cGy). BC risk compared with the general population was evaluated with standardized incidence ratios (SIRs) estimated using the Surveillance, Epidemiology, and End Results (SEER) Program. Cumulative incidence was estimated treating death as a competing risk. **Results:** With a median follow-up time of 27.5 yrs (range 9-38) and a median attained age of 35 yrs (range 10-53), 3 women were diagnosed with BC at ages 31, 41 and 41 yrs. All were leukemia survivors with spinal RT doses of 1800, 2000, and 2588 cGy; none had a known family history of BC (1 was adopted). BC cumulative incidence by age 40 was 0.5% (95% confidence interval (CI) 0-2.5%). The SIR was 1.2 (95% CI 0.8-7.8) for all survivors treated with spinal RT, 3.9 (95% CI 1.3-12.1) for leukemia survivors, and 0 for CNS tumor survivors. **Conclusions:** We did not find convincing evidence that spinal RT for a childhood cancer is associated with an increased BC risk. The increased risk in leukemia survivors who were treated with lower doses of RT relative to CNS tumor survivors may be due to other factors including a genetic predisposition.

**10083 General Poster Session (Board #384), Mon, 8:00 AM-11:45 AM**

**Plasma microRNAs: Novel markers of cardiotoxicity in children undergoing anthracycline chemotherapy.** *Presenting Author: Kasey Joanne Leger, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Early detection of anthracycline cardiotoxicity may allow cardioprotective intervention(s) prior to irreversible damage. microRNA (miRNA) modulation in anthracycline cardiotoxicity has been identified in animal models, however there are no data regarding circulating miR expression following anthracycline-induced cardiac injury in humans. **Methods:** Plasma miRNA profiling was performed in 25 children before and after a cycle of anthracycline (AC, $n=18$) or non-cardiotoxic chemotherapy (CTRL, $n=7$). Samples were screened by qRT-PCR for 25 candidate miRNAs, including miRs -1, 133a/b, 145, 146, 195, 208a/b, 21, 210, 214, 215, 216, 23a, 29a/b/c, 30a, 34c, 423-3p/5p, 361, 367, 499, and let-7g. Candidates were selected based on their established roles in cardiovascular disease or pathways associated with cardiotoxicity. Relative quantification of each miRNA between the pre and post-cycle timepoints (6, 12, and 24 hours) was determined within each group. miRNAs with significant dysregulation from baseline were identified utilizing the paired t-test function within RealTime StatMiner (Integromics). Differences in miRNA regulation over time were compared between groups (AC vs. CTRL) using a mixed effects linear regression model. **Results:** Three miRNAs were upregulated post-anthracycline therapy, while unchanged after non-cardiotoxic chemotherapy. miR-1 was up by 7 and 5.6-fold at 6 and 12 hours post-anthracycline, respectively ($p<0.05$). Six hours post-anthracycline, miRs-29b and -499 were up by 10-fold ($p<0.01$) and 5.1-fold ($p=0.04$), respectively. In contrast, miRs-1, -29b, and -499 were unchanged at all timepoints after non-cardiotoxic chemotherapy. The difference in post-chemo miRNA dysregulation from baseline was significantly different between AC and CTRL groups at 6 hours for miRs-1, 29b, and 499 ($p<0.01$) and 12 and 24 hours for miR-499 ($p<0.01$); Thus it appears this miRNA upregulation is specifically anthracycline-induced. **Conclusions:** Plasma miR-1, -29b, and -499 are specifically upregulated following anthracycline chemotherapy and may herald acute cardiac injury. Further work is ongoing to evaluate these miRs as early markers of anthracycline-induced cardiotoxicity.

**10084 General Poster Session (Board #385), Mon, 8:00 AM-11:45 AM**

**Risk of second thyroid cancer (STC) among survivors of childhood cancer.** *Presenting Author: Rafaela Naves, Faculdade de Ciências Médicas da Santa Casa de São Paulo, Sao Paulo, Brazil*

**Background**: Thyroid carcinomas account for almost 10% of all second malignant neoplasms. The aim of our study was to assess the risk factors for second thyroid cancer (STC) among childhood cancer survivors (CCS), using population-based data. **Methods**: Using SEER-9 we identified 40,876 individuals with ages 0-19 diagnosed with any malignancy in the period 1973-2010. Standardized incidence ratios (SIR) and corresponding 95% confidence intervals (95% CI) for STC were calculated using SEERStat 8.1.2. **Results**: 131 STC were observed (SIR=5.10, 95% CI 4.26-6.05). The risk of STC was higher for males than females (SIR=8.93, 95% CI, 6.38-12.15, *vs.* SIR=4.29, 95% CI 3.45-5.27, respectively) and for blacks compared to whites (SIR= 10.96, 95% CI 5.26-20.15 *vs.* SIR=4.86, 95% CI 4.01-5.85). Patients < 10 years at diagnosis had a higher risk than patients diagnosed at an older age. (< 10 yrs SIR=8.73, 95% CI 6.50-11.48 vs.> 10 yrs SIR=4.03, 95% CI 3.20-5.02, respectively). Radiation therapy (RT) was associated with a higher risk of STC; risk associated with RT varied by race (blacks: SIR=15.85, 95% CI 5.15-37.00 vs. whites: SIR=7.21, 95% CI 5.54-9.22) and gender (males: SIR=15.23, 95% CI 9.95-22.31 vs. females: SIR=5.76, 95% CI 4.20-7.71). Black children <10 yrs who received RT had the highest risk of STC (SIR=42.67, 95% CI 11.63-109.24). However, an elevated risk was seen for STC even among children who did not receive RT [leukemia (No RT: SIR=6.57, 95% CI 3.59-11.03; RT: SIR=9.30, 95% CI 4.80-16.24) lymphoma (No RT: SIR=7.99, 95% CI 4.65-12.79; RT: SIR=9.71, 95% CI 6.68-13.64)]. The increased risk for CNS (SIR: 8.43; 95%CI, 4.66 – 14.31) and renal tumors (SIR: 8.54; 95% CI, 1.03 – 30.84) and for neuroblastoma (SIR: 21.83; 95%CI, 5.95 – 55.90) was only observed for individuals who had received RT. The increased risk of STC for bone tumors was not associated with RT (SIR=5.02, 95% CI 1.63-11.71). **Conclusions:** Risk for STC is higher for males and blacks, as compared to primary thyroid cancers that occur more commonly in whites and females. The risk of STC is elevated among those who received RT, but even CCS who did not receive RT are at risk. Surveillance of all CCS is recommended, particularly those treated at a younger age, and more exploration of non-RT risk factors is warranted.

**10085 General Poster Session (Board #386), Mon, 8:00 AM-11:45 AM**

**Extracting predictor variables for late effects of childhood cancer treatments from clinical notes.** *Presenting Author: Robert M Johnson, Innovation Center for Biomedical Informatics, Georgetown University, Washington, DC*

**Background:** Today almost 80% of children and adolescents diagnosed with cancer will be long term survivors. As a result of their treatment/cancer, research studies on childhood cancer survivors from the 1970s-1990s show that 75% of the survivors have at least one chronic health condition thirty years after diagnosis. Our goal was to develop a model that predicts late effects of cancer treatment given a set of drugs and diagnoses, which were extracted from clinical notes. Such late effects data could inform current treatments to minimize the incidence of late effects, and help clinicians monitor potential health outcomes for follow up care. **Methods:** We processed 27,533 clinical notes from 245 patients using cTAKES to extract disease/disorder, sign/symptom, and medication mentions. Patients were automatically diagnosed from clinical notes by filtering these extractions to a list of 26 known pediatric cancer diagnoses. Explicitly extracting drug mentions in text was not always reliable. Sometimes only protocols were mentioned (e.g. "COG protocol AALL0434") which infers a set of drugs. Machine learning was used to extract protocols from text and mapped to data from clinicaltrials.gov to obtain a list of drugs. **Results:** 1,785 unique sign/symptom, 1,866 unique disease/disorder, and 417 unique medication mentions were extracted by cTAKES for 245 pediatric cancer patients. Our protocol extraction algorithm performed with precision and recall of 0.86 and 0.83 respectively and inferred 54 drugs with 26 of them never being mentioned in text. Curated diagnoses for 237 patients revealed our diagnoses technique resulted in a precision of 0.68 and recall of 0.95. **Conclusions:** Our next steps are to automatically filter disease/disorder and sign/symptom mentions to extract legitimate late effects related to treatment for particular cancers, using a similar technique as how we diagnosed patients. Given the uncertainties associated with our extractions, we plan to use a Bayesian Network for our prediction model.

**10086 General Poster Session (Board #387), Mon, 8:00 AM-11:45 AM**

**Young and uninsured: Insurance patterns of recently diagnosed adolescent and young adult cancer survivors in the AYA HOPE study.** *Presenting Author: Helen M. Parsons, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

**Background:** Young adults have historically been the least likely to have health insurance in the United States. Previous studies of childhood cancer survivors found lower rates of insurance and less access to medical care compared to siblings; however, no studies have examined continuity of insurance after cancer diagnosis in adolescents and young adults (AYAs). **Methods:** Using the AYA Health Outcomes and Patient Experience study, a cohort of 465 15-39 year-olds from participating Surveillance, Epidemiology and End Results registries, we evaluated changes in and sponsors of health insurance coverage after diagnosis, coverage of doctor-recommended tests, and factors associated with lack of insurance post-diagnosis using chi-square tests and multivariable logistic regression. **Results:** Over 25% (n=118) of AYA cancer survivors experienced some period without insurance up to 35 months post-diagnosis. Insurance rates were high in the initial year after diagnosis (6-14 months; 93.3%) but decreased substantially at follow-up (15-35 months; 85.2%). The most common sponsor of health insurance was employer/school-coverage (43.7%). Multivariable analysis indicated that older survivors (25-39 vs. 15-19; Odds Ratio (OR): 3.35, p<0.01) and those with less education (high school or less vs. college graduate; OR: 2.80, p<0.01) were more likely to experience a period without insurance after diagnosis. Furthermore, >20% of survivors indicated there were doctor-recommended tests/treatments not covered by insurance, but >80% received them regardless of coverage. **Conclusions:** Insurance rates decrease with time since diagnosis in AYA cancer survivors. Future studies should examine how new policies under the Affordable Care Act extend access and insurance coverage beyond initial treatment.

**10087 General Poster Session (Board #388), Mon, 8:00 AM-11:45 AM**

**Investigating the effectiveness of the cognitive remediation and cognitive behavior therapy skills training program (CRCST).** *Presenting Author: Jun Zhao, Children's Blood and Cancer Center/ Dell Children's Hospital, Austin, TX*

**Background**: Improvements in cancer treatments over the past forty years have led to a significant increase in the number of pediatric oncology survivors. With this feat, also emerges the ongoing risk for the development of long-term cognitive impairments and corresponding emotional distress. In particular, neurocognitive late effects from treatment include deficits in attention, memory, and processing speed. Promising research has demonstrated cognitive remediation using a computerized exercise program can produce improvements in this area. Additionally, therapeutic skills from cognitive behavior therapy have shown to effectively reduce emotional vulnerability. The aim of this program was to improve difficulties with working memory, attention, and executive functioning as well as enhance emotional well being using a unique intervention program. **Methods**: Twenty-four patients, ages 8 to 18 years old, who have undergone radiation and/or chemotherapy treatment and displayed neurocognitive and/or psychological late effects indicated by neuropsychological testing participated. The program consisted of 9 group sessions in clinic and completion of 45 twenty-minute computer training sessions at home. Participants and parents completed self-report measures of the Behavior Rating Inventory of Executive Function and the Behavior Assessment System, 2nd Edition. **Results**: A paired sample t-test using the SPSS was conducted. A significant improvement was noted from pre-testing to post-testing for working memory [t(23)= 2.6., p<.05], attention [t(23) = 4.7, p<.05], executive functioning [t (23) = 2.1, p<.05], and emotional well being with improvement in internalization [t(23) = 2.6., p <.05]. **Conclusions:** These results suggest that a combined program with computerized cognitive exercises and cognitive strategies can effectively improve late-effects from treatment.

**10088 General Poster Session (Board #389), Mon, 8:00 AM-11:45 AM**

**Transitioning childhood cancer survivors to adult care: A survey of pediatric oncologists.** *Presenting Author: Lisa Brazzamano Kenney, Dana-Farber Boston Children's Cancer and Blood Disorders Center, Boston, MA*

**Background:** Pediatric oncologists are responsible for facilitating the transition of childhood cancer survivors to risk based adult focused care. This study describes transition practices, perceived barriers to transfer to adult care, and identifies areas for potential intervention. **Methods:** An electronic survey of U.S. members of the Children's Oncology Group; 492/1449 responded (34%) and 347/492 (71%) met eligibility (pediatric oncologist caring for outpatients > age 11 years). **Results:** Of the 347 respondents, 50% are male, median years in practice 10 (range 5-22), 82% are at an academic institution, 37% a free standing children's hospital, and 5% are board certified in adult medicine. Almost all continue to care for patients up to age 21 years (96%), 42% report continuing to take care of adult patients over age 25 years, 16% over age 30 years, and only 8% over 40 years. While 66% of oncologists report providing transition education to their patients, the majority report also having other staff provide this education (89%). Compared to the 147 (42%) who care for adult patients older than 25 years, those who do not were more likely to endorse specific criteria for transfer including survivors' age (p=0. 006), pregnancy (p=0.014), marriage (p=0.010), college graduation (p=0.006), and substance use (p=0.036). Most oncologists identified barriers to transfer to adult care including patients' attachment to provider (91%), parents' attachment to provider (90%), lack of knowledgeable adult providers (86%), cognitive delay (81%), and unstable social situation (80%). However, oncologists who continue to care for patients older than 25 years are more likely to perceive parents' attachment to provider (p=0.037) and patients' unstable social situation as barriers to transfer (p=0.044). **Conclusions:** Most pediatric oncologists report transferring adult childhood cancer survivors to adult care and providing transition education to their patients. Those who continue to care for survivors as adults are more likely to perceive psychosocial needs as barriers to transfer. Transition practices that address developmental and psychosocial challenges might facilitate successful transfer of childhood cancer survivors to adult care.

**10089 General Poster Session (Board #390), Mon, 8:00 AM-11:45 AM**

**Contraceptive recommendations for young women during cancer treatment: Examining contraceptive knowledge of pediatric oncology clinicians.** *Presenting Author: Sloane L. York, Rush University Medical Center, Chicago, IL*

**Background:** Adolescent and young adult women with cancer have specific reproductive health needs and may seek guidance from oncology clinicians. This study examined oncology clinicians' reported contraceptive recommendations and contraceptive knowledge. **Methods:** Oncology clinicians caring for women aged 13-45 completed an online survey. This secondary analysis reports on pediatric clinicians' contraceptive knowledge by identifying typical failure rates of 10 contraceptives and safety of 4 hormonal contraceptives using case scenarios. Knowledge score was determined by averaging the percent correct on safety and efficacy questions. **Results:** 518 respondents were included. Most were practicing pediatric oncologists (52.3%) or advanced practice clinicians (42.5%). Participants practiced a mean of 12.5 years and most (64.1%) saw 3-10 reproductive-aged female patients per month. Most (82.0%) reported regularly recommending a woman use contraception during treatment. Over half (53.2%) stated they were comfortable with contraceptive counseling, 69.9% provided contraception in the past year, and 67.1% wanted more information on contraception. Almost half (47.3%) stated they do not discuss pregnancy planning and 233 (45.0%) had cared for at least one pregnant cancer patient. Total knowledge score was 47.4% (95% CI: 45.8, 49.0). Participants identified 61.9% of contraceptives' safety (95% CI: 60.0, 64.2). 87.1% identified combined oral contraceptives as unsafe after pulmonary embolism. For a nulliparous woman with AML, 30.4% correctly identified the safety of the levonorgestrel intrauterine device (IUD) and 28.9% for the copper IUD. Participants identified 32.6% (95% CI: 31.0, 34.2) of 10 contraceptives' efficacy. 19.4% correctly identified condoms' efficacy, 12% for oral contraceptive pills, and 34.8% for depot-medroxyprogesterone acetate. Almost half correctly identified the failure rate of IUDs (46.1%). Most over-estimated the effectiveness of contraceptives. **Conclusions:** Pediatric oncology clinicians report recommending contraception during cancer treatment, but may lack comprehensive knowledge for counseling their patients.

**10090 General Poster Session (Board #391), Mon, 8:00 AM-11:45 AM**

**Knowledge, attitudes, and beliefs of parents toward whole-genome sequencing in pediatric cancer.** *Presenting Author: Jenny Ruiz, Columbia University College of Physicians and Surgeons, New York, NY*

**Background:** Introducing whole genome sequencing (WGS) in pediatric cancer patients at diagnosis poses a unique set of issues. We investigated parental knowledge, attitudes and beliefs about the role of genetics and WGS in the care of children with cancer and towards the return of secondary findings. **Methods:** Focus groups with parents/caretakers of children with cancer and semi-structured interviews with parents of healthy children were conducted. Participants were recruited from the outpatient pediatric oncology clinic and in-patient units, respectively, at Columbia University Medical Center. The topic guides included questions on genetic research, WGS, secondary findings, and timing of the consent process. All focus groups and interviews were audio recorded, transcribed and analyzed using thematic analysis. **Results:** 4 focus groups (16 participants (11 females, 5 males; 4 Hispanic, 4 African American, 1 Asian, 10 White)), and 8 semi structured interviews (7 females, 2 males; 4 Hispanic, 3 African American, and 3 White) ranging from high school to graduate school education were conducted. A wide range of knowledge about genetic testing existed among participants; few participants had prior knowledge about WGS. Participants expected that WGS research was more likely to benefit future children rather than their own child. Most participants said they would participate in WGS if there were no additional immediate risks to their child; they wanted to be told about secondary findings but worried about the potential psychosocial burden of those results. There was close to universal opinion that they would not be offering informed consent if asked to participate in WGS at diagnosis and preferred the idea of a two-step consent process. **Conclusions:** At baseline, parents have very limited knowledge about WGS, regardless of gender, ethnicity or attained education. Parents felt their current level of understanding and perceived level of stress at the time of a cancer diagnosis in their child would hamper the ability to give informed consent. Additional research is required to optimize patient education and timing of the informed consent discussion for WGS.

**Effect of topical clonidine on the duration and severity of radiation-induced oral mucositis (OM) in a translational hamster model.** *Presenting Author: Pierre Attali, BioAlliance Pharma, Paris, France*

**Background:** There is currently no effective mechanistically-targeted intervention for radiation-induced OM. Clonidine, a a2 adrenergic agonist, has been shown to impact NF-kappaB with consequent inhibition of the expression and the release of the pro-inflammatory cytokines thought to be involved in OM's pathogenesis. We assessed the efficacy of a topical formulation of clonidine to mitigate radiation-induced OM in an established translational hamster model. **Methods:** Two independent studies were performed in which 32 male Syrian Golden hamsters were randomly assigned to four equally-sized groups in each. OM in a saline-treated control was compared to three groups which received clonidine in different concentrations and/or dosing frequency. Study drug was administered topically from the day before radiation (Day -1) until day 20. On study day 0, hamsters were irradiated with a single 40 Gy dose directed to the left buccal cheek pouch. Beginning on day 6 images of the left cheek pouch mucosa were obtained every other day and blindly scored for OM severity using a validated 6-point scale. The number of days of ulcerative OM with scores of $\geq 3$ was assessed (Chi-2 test). The individual daily group scores were evaluated (rank sum test). In Study 1 (S1), clonidine was given topically once daily at doses of 30, 100 and 300 $\mu$g/kg. In Study 2 (S2), clonidine was given QD at 100 $\mu$g/kg and QID at 12.5 and 25 $\mu$g/kg. **Results:** Clonidine consistently reduced the duration and severity of OM. In S1, clonidine dose dependently reduced the % days of score $\geq 3$ from 46.9% in controls to 41.7%, (p=0.35), 29.2% (p<0.001) and 30.2% (p<0.001) in clonidine 30, 100 and 300 $\mu$g/kg treated animals. In S2, % days was reduced from 35.4% in controls to 21.9% (100 $\mu$g/kg, p=0.003), 28.1% (12.5 $\mu$g/kg, p=0.12) and 26% (25 $\mu$g/kg, p=0.04). OM severity was significantly reduced compared to controls in the clonidine 100 and 300 $\mu$g/kg QD groups in S1, and in the clonidine 100 $\mu$g/kg QD, 12.5 and 25 $\mu$g/kg qid in S2. Clonidine was not shown toxic. **Conclusions:** Topically administered clonidine mitigated radiation-induced OM in hamsters in a dose-dependent manner. QD administration was as effective as QID dosing. The optimal dose in this model was 100 $\mu$g/kg QD.

**10092 General Poster Session (Board #393), Mon, 8:00 AM-11:45 AM**

**Mediating role of emotional symptoms on assessment of health-related quality of life of adult survivors of childhood cancer: A report from the Childhood Cancer Survivor Study.** *Presenting Author: I-Chan Huang, University of Florida College of Medicine, Gainesville, FL*

**Background:** Factors that may mediate or influence how cancer survivors endorse health-related quality of life (HRQOL) items are not well studied. This study compared HRQOL between adult survivors of childhood cancer and siblings by accounting for the mediating effect and measurement non-invariance related to emotional symptoms. **Methods:** 7,103 cancer survivors and 390 siblings in the Childhood Cancer Survivor Study completed the SF-36 measuring eight domains of HRQOL. Symptoms of anxiety, depression and somatization were measured using the Brief Symptom Inventory-18. Multiple Indicators & Multiple Causes model was used to identify measurement non-invariance related to emotional symptoms in the SF-36 items. Structural equation modeling was performed to test direct and indirect effects of cancer experience on HRQOL accounting for the mediating role of emotional symptoms. **Results:** 10, 12, and 14 items of the SF-36 were identified with measurement non-invariance related to anxiety, somatization and depression, respectively. Survivors reported poorer HRQOL in all domains than siblings did (all p's$<$0.05), except for pain (p$>$0.05). Poorer physical functioning was significantly explained by direct effect of cancer experience (p$<$0.05) and indirect effect of cancer experience through emotional symptoms (p$<$0.05). However, poorer HRQOL in other domains was greatly explained by the mediating role of emotional symptoms, indicating indirect effect (p$<$0.05) rather than direct effect (p$>$0.05). Indirect effects explained 40-70% of total effects in the association of cancer experience and HRQOL. Adjusting for measurement non-invariance for the SF-36 items did not change the association of cancer experience with HRQOL compared to not adjusting for non-invariance. **Conclusions:** Childhood cancer survivors reported poorer HRQOL than siblings. The differences appear due, in part, to measurement non-invariance related to emotional symptoms that influence perceptions of HRQOL, and the mediating effect of emotional symptoms on HRQOL. Evaluating emotional health is an important component in survivorship care toward improving their HRQOL.

**10093 General Poster Session (Board #394), Mon, 8:00 AM-11:45 AM**

**Cardiotoxicity and second malignant neoplasms associated with dexrazoxane in children and adolescents: A systematic review of randomized trials and nonrandomized studies.** *Presenting Author: Furqan Shaikh, Hospital For Sick Children, Toronto, ON, Canada*

**Background:** Several randomized controlled trials (RCTs) in breast cancer have demonstrated the efficacy of dexrazoxane (DRZ) in reducing anthracycline cardiotoxicity. However, research on DRZ in pediatric patients has been stalled by a recent report of increased second malignant neoplasms (SMN). The objective of this study was to systematically review the evidence for and against the use of DRZ in children. **Methods:** We searched Medline, Embase, Cochrane, and abstracts for all RCTs and non-randomized studies (NRSs) that compared DRZ to no cardioprotection among cancer patients $<$18 years of age receiving anthracyclines. **Results:** 23 articles reporting 5 RCTs (1,254 patients) and 11 NRSs (3,329 patients) were identified. Among 5 RCTs, there were 16/625 (2.5%) SMN with DRZ vs 6/619 (1.0%) SMN without DRZ (risk ratio (RR) 2.52, p=0.06, number needed to harm = 63). The types of SMN varied: two RCTs that used concurrent etoposide reported an increased risk of AML, while one RCT that used cranial radiation reported an increased risk of brain tumors. There was no significant difference in EFS (5 RCTs, p=0.93). Among 2 RCTs, DRZ was associated with an improved shortening fraction Z-score (mean difference (MD) 0.61, p=0.002) and thickness: dimension Z-score (MD 0.66, p$<$0.001). A significant effect on clinical cardiotoxicity could not be shown due to a very low cardiotoxic event rate (3 events among all RCT patients). Among NRSs, there were 6/860 (0.7%) SMN with DRZ vs 18/1,825 (1.0%) SMN without DRZ (p=0.58). DRZ was associated with a reduction in clinical cardiotoxicity (RR 0.29, p=0.001, NNT=14) and clinical+subclinical cardiotoxicity (RR 0.43, P$<$0.001, NNT=4). However, NRSs were subject to time-related bias, with control arms generally having longer follow-up. **Conclusions:** DRZ is associated with a significant reduction in cardiotoxicity in pediatric NRSs. Evidence of benefit from pediatric RCTs currently relates only to surrogate outcomes and is limited by a low clinical event rate. DRZ is associated with a statistically borderline increase in SMN, although an interaction with other carcinogenic treatments (radiation, etoposide) may be responsible.

**TPS10094 General Poster Session (Board #395A), Mon, 8:00 AM-11:45 AM**

**SIOPEL 6: A multicenter open-label randomized phase III trial of the efficacy of sodium thiosulphate (STS) in reducing ototoxicity in patients receiving cisplatin (Cis) monotherapy for standard-risk hepatoblastoma (SR-HB).** *Presenting Author: Rudolf Maibach, IBCSG Coordinating Center, Bern, Switzerland*

**Background:** The SIOPEL 3 trial of Cis monotherapy and surgery in SR-HB showed a 3yr OS of 95% at 5 years. SR-HB is defined as tumor extension limited to PRETEXT I, II or III, no involvement of portal or hepatic veins, no intra-abdominal extrahepatic disease, AFP $>$100ng/ml and no metastases. At commonly used doses and schedules, Cis can cause permanent bilateral high-frequency hearing loss. Several pre-clinical and clinical studies in adults and children (particularly from the Oregon group) suggest that STS may reduce the risk of ototoxicity. There are however concerns that STS could reduce the anti-tumor efficacy of Cis, hence the time separation of Cis and STS and the close monitoring of the trial. **Methods:** Newly diagnosed patients with SR-HB are treated with 4 chemotherapy courses every 2 weeks before surgery and 2 courses after surgery. Patients are randomly assigned to receive Cis alone or Cis followed by STS. Cis 80mg/m$^2$ is administered i.v. over 6 hrs. STS is administered i.v. exactly 6 hrs after stop of Cis over 15 minutes at 20g/m$^2$. Serum sodium is monitored 1 hr, 6 hrs and 18 hrs post STS. Tumor response is assessed after 2 and 4 cycles preoperatively with serum AFP and liver imaging. In case of lack of response after 2 cycles, STS is stopped and chemotherapy is changed to combination therapy with Cis and doxorubicin 60mg/m$^2$ continuous infusion over 48 hrs. A DNA sample for central analysis of ototoxicity predisposition factors and a tumor sample are requested. The primary endpoint of the trial is centrally reviewed absolute hearing threshold, at the age of $\geq$3.5 yrs, by pure tone audiometry. With a sample size of 102, the trial has 80% power to detect a reduction of the rate of hearing loss defined as Brock grade $\geq$ 1 from 60% under Cis alone to 35% under Cis and STS. In case of concerns of an adverse effect of STS on the efficacy of the Cis chemotherapy, the trial may be stopped early. Interim efficacy results on response to chemotherapy are evaluated after every 20 patients and submitted immediately to the IDMC. The IDMC has recommended continuing the trial after review of the results on 20, 40 and 60 pts. Clinical trial information: NCT00652132.

**TPS10095 General Poster Session (Board #395B), Mon, 8:00 AM-11:45 AM**

**Phase I/IIa multicenter trial for high-risk and recurrent neuroblastoma: Anti-GD2 antibody (ch14.18) immunotherapies using M-CSF or G-CSF.** *Presenting Author: Hiroshi Kawamoto, National Cancer Center Hospital, Tokyo, Japan*

**Background:** Anti-GD2 antibody, ch14.18, with GM-CSF or IL2, has significantly improved disease free survival in high-risk neuroblastoma. ch14.18 generally induces cell lysis through the process of antibody-dependent Cellular Cytotoxicity (ADCC) through PBMC (NK cell etc.) as effector cell. Concurrent use of GM-CSF with ch14.18 enhances the effect of both neutrophils and PBMC mediated ADCC. To maximize ADCC, this phase I/IIa study was planned to optimize dosing and feasibility, and to evaluate ADCC in using M-CSF (R1) and G-CSF (R2). **Methods:** Eligibility: Patients (pts) aged between 2 and 45 years with refractory or relapsed (phase I and phase IIa) and high risk (phase IIa) neuroblastoma. Other important requirements were as follows: good PS; normal organ function; appropriate interval from prior antitumor therapies; no history of allogeneic hematopoietic stem cell transplantation; No intracranial hemorrhagic episode within one month if central nervous system metastasis exits. Treatment plan: In R1, CSF regimen (ch14.18 10-20h div d4-7, M-CSF 2h div d1-14) and IL2 regimen (ch14.18 10-20h div d8-11, IL2 24h div d1-4, d8-11) are alternately performed every one month, up to 5 courses with starting from CSF regimen. In R2, G-CSF s.c. is replaced with M-CSF in CSF regimen. Endpoints: Primary endpoint is DLT of ch14.18, IL2, M-CSF, G-CSF (phase I) and proportion of completing 5 courses of R1 and R2 (phase IIa). Secondary endpoints include pharmacokinetics and dose-response for ch14.18 and IL2, ADCC activity and anti-chimera antibody response proportion. Study design: Multi-center, phase I/IIa design. In phase I, ch14.18, M-CSF, G-CSF, IL2 are all object for dose finding by 3+3 design, with starting dose 17.5mg/m2 (level1), 6 million IU/m2 (level1), 5 ug/kg (level1), 0.75 million IU/m2(1 week) and 1 million IU/m2(2 week) (level0). In phase IIa, sixteen pts are required to confirm feasibility of optimized R1 and R2 regimens in phase I with a threshold for five month PFS of 31% and one-sided alpha level 5%. Clinical trial information: UMIN000012001.

**10500 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Prognostic/predictive biomarkers in advanced soft tissue sarcomas (STS): Translational research associated to randomized phase II trial comparing trabectedin-doxorubicin versus doxorubicin—A GEIS study.** *Presenting Author: Javier Martin Broto, Hospital Son Espases, Palma de Mallorca, Spain*

**Background:** Nucleotide excision and homologous recombination DNA repair pathways are the most recognized antitumor mechanism of action of trabectedin in STS. Additionally, our group has shown the relevance of FAS and calcium signaling pathways in the efficacy of trabectedin in preclinical experiments with sarcoma cell lines. Thus, in vein with that, a prospective translational research focusing on DNA repair genes, calcium and FAS signaling pathways was designed accompanying a randomized phase II trial in STS. The trial comparing trabectedin-doxorubicin (TD) vs doxorubicin (D) as first line of advanced or metastatic STS patients was stopped for futility after enrolling 115 patients. **Methods:** Immunohistochemistry studies were performed for FASR, Bcl2, p53, PKC-$\alpha$ and PKC-$\beta$ and for RNA expression *FASR*, *FASL*, *CUL4A*, *ERCC1* and *ERCC5* were analyzed. Kaplan–Meier estimations were used for time-to-event variables and the log-rank test was used to compare groups. **Results:** With a median follow-up of 11 months, there were 95 events of recurrences and 63 of deaths. Regarding the entire series, p53+ had significant lower PFS (1.33m vs 6.53m, p= 0.002) and FASR+ showed a significant better OS (21.07m vs 8.33m, p= 0.002). Remarkably, combining FASR/p53 showed to be a strong prognostic factor for PFS (7.03m if FASR+ and p53-, 2.93m if FASR+ or p53 – and 0.50m if FASR- and p53 +; p < 0.001) and OS (26.9m if FASR+ and p53-, 13.5m if FASR+ or p53- and 4.5m if FASR- and p53 +; p=0.001). In TD arm, the following biomarkers showed significant better PFS: FASR+ (6.5m vs 2.9m; p= 0.033); p53- (6.53 m vs 1.33 m; p=0.02); CUL4A above median (8.1 m vs 1.7m; p= 0.015) and ERCC1 above median (8.23 m vs 2.93, p= 0.031). Those with a significant better OS were: FASR+ (21.07m vs 5.9 m; p=0.033) and CUL4A above median (21.83m vs 9.43m; p=0.041). In D arm no significant association was seen **Conclusions:** FASR and p53 have shown to be strong prognostic factors in advanced/metastatic STS while CUL4A seemed highly predictive to trabectedin. These biomarkers should be taken into account in future trials design focusing on this population of STS. Clinical trial information: NCT01104298.

**10501 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**ANGIOTAX-PLUS trial: A randomized phase II trial assessing the activity of weekly paclitaxel (WP) plus or minus bevacizumab (B) in advanced angiosarcoma (AS).** *Presenting Author: Nicolas Penel, Centre Oscar Lambret, Lille, France*

**Background:** Paclitaxel is an active agent in advanced AS. The objective of this study was to explore the activity and safety of adding B to WP in treatment of AS. **Methods:** We conducted a multicenter randomized (1/1) phase II trial for assessing both regimens. WP: 90 mg/m$^2$ d1,8 and 15 in 4-wks cycle for 6 cycles, +/- B 10 mg/kg d1,8 and 15 followed by maintenance therapy 15 mg/kg/3 wks until intolerance/progression. Stratification factors were: superficial vs visceral AS, de novo vs radiation-induced (RI) AS. Primary endpoint was 6-month progression-free rate (RECIST 1.1). Statistical assumptions were: P0=20%; P1=40%, $\alpha$=10% and $\beta$=20%. **Results:** From 09/2010 to 09/2013, 50 pts (26 in WP and 26 in WP-B arm) have been enrolled in 14 centers. There were 12 men and 38 women (median age 66, 24-82). Most common primaries were: breast (24, 49%) and skin (6, 12%). There was 17 (34%) visceral and 24 (49%) RI AS. PS was 0 in 24 (50%) and 1 in 23 (48%). 16 pts have previously received anthracyclines (32%); 32 pts (64%) were chemo-naive. 8/24 (33%) pts enrolled in WP-B arm have received B as maintenance therapy. Median follow-up was 14.5 months. Both regimens were considered active with a 6-mPFR of 57% (15/26) in WP arm and 57% (14/24) in WP+B arm. Median PFS was 6.8 vs 6.9 months. 1-year OS was 55 vs 58%. 4 pts experienced Gr5-AE: 1 in WP arm (hemorrhage) and 3 in WP-B arm (suicide, intestinal occlusion, general condition deterioration). We had observed arterial hypertension in both arms: WP (1 Gr2) and WP-B (1 Gr2/1 Gr3), hemorrhage in both arms: WP (2 Gr1/1 Gr5) and WP-B (2 Gr1/1 Gr2), thrombosis in both arms: WP (1 Gr1) and WP-B (1 Gr2/ 1 Gr4) and 1 case of Gr1 proteinuria in WP-B arm. There was no reported wound dehiscence and gastro-intestinal perforation. Hematological toxicity profile was similar in both arms. **Conclusions:** WP and WP-B are both active regimens of AS. B did not improve the outcome of AS pts. This study illustrates the importance of randomization in phase II trial. In the present trial, WP provides PFS (6.8 vs 4.0 months) and OS (>12 vs 8 months) significantly higher than previously reported in the AngioTax Study (Penel JCO 2008). Clinical trial information: 2009-017020-59.

**10502 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Randomized phase 2b trial comparing first-line treatment with aldoxorubicin versus doxorubicin in patients with advanced soft tissue sarcomas.** *Presenting Author: Sant P. Chawla, Sarcoma Oncology Center, Santa Monica, CA*

**Background:** Doxorubicin (D) is the only approved first line therapy for most advanced soft tissue sarcomas (STS). Aldoxorubicin (A) consists of doxorubicin attached to an acid-sensitive linker that binds covalently to serum albumin. We compared the efficacy and safety of A to D as first line treatment for patients with advanced STS. **Methods:** 31 site international trial; 123 patients ages 18-78 years with histologically confirmed metastatic, locally advanced or unresectable STS randomized 2:1 to receive either 350 mg/m$^2$ A (260 mg/m$^2$ D equivalents) or 75 mg/m$^2$D, every 3 weeks for a maximum of 6 cycles. Tumor response by CT was monitored every 6 weeks until completion of treatment, 2 months post treatment, then every 3 months to progression or withdrawal from study. Primary endpoint: progression-free survival (PFS). Secondary endpoints: overall response rate (ORR), PFS at 6 months and overall survival (OS). Both a blinded, independent review and an investigator site review were performed for each scan. **Results:** 83 patients were randomized to A and 40 to D. Groups were well-balanced for age, sex, race, performance status, and sarcoma pathology. Median (range) # of completed cycles: A = 6 (1-6); D = 4 (1-6). 30% of patients were from the U.S., 47% from Europe and 23% from Asia Pacific. Efficacy results are shown in the Table. Grade 3 or 4 adverse events that were increased in patients treated with A were neutropenia (28% vs 15%), nausea/vomiting (10% vs 0%), mucositis (12% vs 2 %), fatigue (5% vs 0%) and anorexia (4% vs 0%). LVEF < 50%: A = 0, D = 9.5%. Grade 3/4 pain was increased in the D arm (2% vs 8%). Grade 3/4 febrile neutropenia (17% vs 18%), anemia (17% vs 20%) thrombocytopenia (7% vs 5%) were similar for patients receiving A or D. **Conclusions:** Aldoxorubin is more efficacious than doxorubicin in the treatment of advanced STS with an acceptable safety profile. Clinical trial information: NCT01514188.

**10503^ Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**A pilot study of PLX3397, a selective colony-stimulating factor 1 receptor (CSF1R) kinase inhibitor, in pigmented villonodular synovitis (PVNS).** *Presenting Author: William D. Tap, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** PLX3397 is a novel, oral small molecule that potently and selectively inhibits CSF1R, Kit, and Flt3 kinases. CSF1R and Kit regulate key components of both the tumor and its microenvironment (macrophages, osteoclasts, mast cells). PVNS is a rare proliferative neoplasm involving the synovium of joints or tendon sheaths. Tumors contain CSF1R-bearing macrophages recruited by local overexpression of CSF-1 due to a gene translocation. **Methods:** Patients (pts) with advanced PVNS were enrolled onto an expansion cohort of an ongoing single-arm, multicenter, clinical study. PLX3397 was given orally, 1000 mg daily (600 mg AM, 400 mg PM – 28 day cycles). MRI assessment by a central musculoskeletal radiologist blinded to chronology was performed every 2 cycles using a novel Tumor Volume Score (TVS) developed specifically for PVNS. Partial response (PR) was defined as ≥50% decrease in TVS compared to screening and progressive disease was ≥30% increase relative to lowest score. Patients remained on treatment until disease progression or intolerability. **Results:** 17 PVNS pts have been enrolled to date. Median exposure 166 days (range 23- 264). 59% pts were women; median age 46 yrs (range 22-80). Tumor locations: knees (12), ankles (2), feet (2), elbow (1). Of the 11 pts with evaluable MRI scans at this interim analysis, 7 pts (64%) achieved a PR and 4 pts (36%) had stable disease (SD). Mean tumor size reduction was 51% (range: -10% to -88%). Clinical improvements were seen in pain, stiffness, and overall function. Common AEs (>10%): fatigue, nausea, hair color changes, and diarrhea. Treatment-related AEs ≥Grade 3: anemia (1), hyponatremia (2), elevated ALT and AST (1), fatigue (1) and diarrhea (1). **Conclusions:** PLX3397 was well tolerated and demonstrated profound activity as measured by a novel response criterion in pts with advanced PVNS. PLX3397 warrants further study in a larger clinical trial. Clinical trial information: NCT01004861.

**Percent change in TVS compared to screening.**

**Phase 1 study of RG7155, a novel anti-CSF1R antibody, in patients with locally advanced pigmented villonodular synovitis (PVNS).** *Presenting Author: Philippe Alexandre Cassier, Centre Léon Bérard, Lyon, France*

**Background:** PVNS, also known as tenosynovial giant cell tumor (TGCT), is a rare disease mainly affecting young adults. This neoplastic disease is driven in most cases by a t(1;2) translocation resulting in fusion of COL6A3 and M-CSF genes encoding for colony-stimulating factor 1 (CSF1). The bulk tumor mass consists of CSF1 receptor (CSF1R) positive cells. RG7155 is a monoclonal antibody that potently inhibits the dimerization of CSF1R. **Methods:** In this dose-escalation and −extension phase I study, we treated patients with locally advanced PVNS, who were not amenable to surgical treatment. Primary objectives were to assess safety, tolerability, pharmaco-kinetics and -dynamics. Clinical activity was evaluated using FDG-PET (at 4 weeks after treatment start; EORTC criteria) and MRI (at 6 weeks; RECIST 1.1). Pre- and on-treatment biopsies of tumor and surrogate skin tissue as well as peripheral blood PD markers were analyzed. **Results:** Between September 2012 and October 2013, 11 PVNS patients (median age 38 (range 18-64)) were treated at three French institutions at four different dose levels (q2w). Three patients had previously been treated with nilotinib and imatinib, respectively. Seven patients had undergone previous surgeries. RG7155 induced a sustained increase of CSF1 associated with a decrease of $CD14^{+}CD16^{+}$ monocytes in peripheral blood in all 10 evaluable patients. RG7155 led to striking reductions of $CSF1R^{+}$ and $CD163^{+}$ macrophages in tumor tissue associated with rapid onset of objective clinical responses in 7/9 patients (78%; partial metabolic response at 4 weeks; FDG-PET) and 7/10 patients (70%; PR at 6 weeks; MRI). All patients showed tumor shrinkage associated with symptomatic improvement. 9/10 patients remained clinically progression-free with a longest follow-up of 17 months. RG7155 was well tolerated with only two patients experiencing grade 3 adverse events (periorbital edema; mucositis). **Conclusions:** RG7155 treatment induced rapid clinical responses in the vast majority of PVNS patients associated with profound reduction of $CSF1R^{+}$ and $CD163^{+}$ macrophages in tumor tissue. Clinical trial information: NCT01494688. Clinical trial information: NCT01494688.

**10505 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Response to treatment with denosumab in patients with giant cell tumor of bone (GCTB): FDG PET results from two phase 2 trials.** *Presenting Author: Keith M. Skubitz, University of Minnesota, Minneapolis, MN*

**Background:** GCTB is a primary osteolytic tumor characterized by local invasiveness and limited non-surgical treatment options. Osteoclast-like giant cells expressing surface RANK, and stromal cells expressing RANK ligand (RANKL), are features of GCTB. Denosumab, a monoclonal antibody against RANKL, is approved in the US for treatment of GCTB that is unresectable or where surgery would be associated with severe morbidity. Here, we report sequential FDG-PET as a sensitive early indicator of GCTB response to denosumab from 2 phase 2 trials. **Methods:** Adult or skeletally mature patients with GCTB (N=360) received subcutaneous (SC) denosumab 120 mg on days 1, 8, and 15, and every 4 weeks thereafter. In some centers, combination FDG-PET and CT images were obtained sequentially as part of routine care. All evaluable scans were reviewed by central independent treatment-blinded reviewers. **Results:** Paired pre- and post-treatment FDG PET scans from 26 patients (144 scans) showed marked reductions in FDG-PET avidity and reductions in standardized uptake values (SUV) early in response to denosumab at the first post-treatment scan (median [Q1, Q3] 68.5 [50, 84] days from first dose). All paired samples showed a best EORTC response of >25% reduction in SUV uptake following initiation of denosumab treatment. Sequential PET imaging studies revealed a sustained and progressive SUVmax reduction in GCTB lesions with continued denosumab treatment. **Conclusions:** This study represents the largest GCTB FDG-PET imaging data set from an interventional clinical trial reported to date. It shows that FDG-PET is a sensitive early indicator of tumor response to denosumab, preceding both cytoreduction (RECIST) and new bone formation/calcification (HU density), and that this response is sustained in denosumab-treated GCTB. Clinical trial information: NCT00396279, NCT00680992.

**10506 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**A phase 2 study of ponatinib in patients (pts) with advanced gastrointestinal stromal tumors (GIST) after failure of tyrosine kinase inhibitor (TKI) therapy: Initial report.** *Presenting Author: Michael C. Heinrich, OHSU Knight Cancer Institute and Portland VA Medical Center, Portland, OR*

**Background:** Ponatinib is an oral TKI that has potent preclinical activity against several mutant isoforms of KIT, including secondary exon 17 resistance mutants, and PDGFRA. Its preclinical activity against a broad spectrum of clinically-relevant resistance mutations suggests it may provide clinical benefit in pts with GIST resistant to standard approved TKI therapies. **Methods:** This phase 2 single arm trial evaluates efficacy and safety of ponatinib at 45 mg QD in advanced GIST pts after TKI failure. Cohorts are enrolled based on the presence (A) or absence (B) of primary mutations in *KIT* exon 11. Primary end point: clinical benefit rate (CBR=CR+PR+SD ≥16 wks) by modified RECIST 1.1 in Cohort A. Secondary end points include CBR in Cohort B, ORR, safety/tolerability. Enrollment of new pts is on hold due to safety observations in other ponatinib trials; enrollment criteria are being revised to include only pts with failure of all 3 TKIs approved for GIST. NCT01874665. **Results:** From June to Oct 2013, 35 of a planned 45 pts have been enrolled (24 in Cohort A). Baseline characteristics: median age 58 yrs; 46% 2 prior approved TKIs, 46% 3 prior approved TKIs. 74% of pts had ≥4 prior cancer regimens. The median time since diagnosis was 6 yrs. 17 pts discontinued (8 PD, 5 AE, 4 other). As of 6 Jan 2014, median follow-up: Cohort A 4 mos, Cohort B 3 mos. Cohort A CBR at ≥16 wks: 55% (11/20 pts) 1 PR and 10 SD. Cohort A ORR: 8% (2/24). All 5 Cohort A pts with matched PET scans (BL v. C1) had decreased FDG uptake in active lesions and remain on study with SD or better. Cohort B CBR: 22% (2/9); Cohort B ORR: 0%. Most common (≥30%) treatment-emergent AEs of any grade are: rash (54%), fatigue (46%), myalgia (46%), dry skin (40%), headache (40%), abdominal pain (34%), constipation (34%). Treatment-emergent serious AEs (SAEs) occurring in ≥2 pts are: abdominal pain (11%), nausea (6%), vomiting (6%), fatigue (6%). One pt had myocardial ischemia. There was 1 death (pneumonia) possibly ponatinib-related. **Conclusions:** Initial analysis of this ongoing trial suggests that ponatinib has activity in pts with advanced GIST after failure of prior TKI therapy. Clinical trial information: NCT01874665.

**10507 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Results of SARC 022, a phase II multicenter study of linsitinib in pediatric and adult wild-type (WT) gastrointestinal stromal tumors (GIST).** *Presenting Author: Margaret von Mehren, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Most GISTs have activating mutations of KIT/PDGFRA, with rare cases of B-RAF/RAS mutations. 15% of GIST in adults and 85% in children are WT and commonly have high expression of IGF1R likely due to loss of succinate dehydrogenase (SDH) function. We tested the clnical benefit of linsitinib (L), an oral TKI with in vitro efficacy against IGF1R in WT GIST patients (pts). **Methods:** A multi-center phase II trial of L using Clopper-Pearson two-stage design was conducted by SARC. All eligible pts signed consent, were >18 yo, had KIT/ PDGFRA WT GIST, RECIST1.1 measurable disease, ECOG PS of 0-2, and adequate organ function including: fasting glucose of < 150 mg/dL, hemoglobin A1c < 7%, and a QTcF interval of < 450 msec. The trial's primary endpoint was objective response rate (ORR) and secondary endpoints were clinical benefit rate (CBR): CR, PR and SD≥9 mos, and qualitative and quantitative FDG metabolic response (MR) at 8 weeks. **Results:** 20 pts were accrued to stage I of the study from 11/12-4/13 (Table). Treatment with L was well tolerated. Of the toxicities reported, 8.5% were grade 3/4. 36% were possibly related to L with nausea/vomiting (7.3%), fatigue (3.6%), and elevated LFTs (3.2%) being the most common. No objective responses were seen. Qualitative partial and stable MR were seen in 6/17 (35%) respectively. As of 1/5/2014, the average days on study was 231 (range 49-318+) with 5 patients remaining on L. CBR at 9 mos was 45% and MR was seen in 2/13 (15%); PFS and OS Kaplan Meier estimates at 9 months were 52% and 80% respectively. Correlative studies of SDHB immunohistochemistry and mutational testing, serum levels of insulin, IGF1R, its ligands and inhibitors at baseline, week 2, 4 and 8 on therapy will be presented. **Conclusions:** L is well tolerated in patients with WT GIST. While the CBR with L was 45% and PFS at 9 mos was 52%, no objective responses have been observed. Rapid accrual to this study demonstrates clinical studies in selected subtypes of GIST are feasible. Clinical trial information: NCT01560260.

**Long-term disease control of advanced gastrointestinal stromal tumors (GIST) with imatinib (IM): 10-year outcomes from SWOG phase III intergroup trial S0033.** *Presenting Author: George D. Demetri, Dana-Farber Cancer Institute, Boston, MA*

**Background:** S0033 was designed to study the impact of IM, randomized between two doses, in patients (pts) with incurable GIST. **Methods:** Full accrual to this phase III trial occurred over 8 months, ending 01SEP2001. A study amendment allowed collection of additional clinical information on long-term survival outcomes and annotation of any therapies subsequent to IM. **Results:** Of 695 eligible patients, 180 (26%) survived 8 years or longer [94 on IM 400 mg/day arm and 86 on IM 800 mg/d arm). The 10-year estimate of overall survival (OS) across both study arms combined is 22% (95% confidence interval (CI)=19-26%). Additional therapy information was obtained for 137 long-term survivors: IM was the sole therapy, administered continuously, in 49%; fifty-four (39%) received subsequent systemic agents, including sunitinib (41) and sorafenib (16). Local therapies, includingsurgical resection of metastases, radiofrequency ablation, and radiation therapy were also utilized in subsets. Univariate analyses with long-term survival data show that pts whose tumors harbored a *KIT* exon 9 mutation had a significantly shorter OS than those with *KIT* exon 11 mutations (p=0.0013) or *KIT/PDGFRA*wild-type (WT) genotypes (0.047). **Conclusions:** A significant subset of pts with metastatic GIST achieved durable long-term overall survival with single-agent IM. Further investigation of what enables pts to live progression-free for more than a decade is warranted to optimize treatment approaches in this oncogene-driven disease, as well as to improve outcomes for more challenging molecular subsets, including *KIT* exon 9 or SDH-deficient (*KIT/PDGFRA* WT) GIST. Clinical trial information: NCT00009906.

**10509 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM**

**Predictive biomarker profiling of > 1,900 sarcomas: Identification of potential novel treatment modalities.** *Presenting Author: Sujana Movva, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Sarcomas are a heterogeneous group of tumors with > 50 subtypes. First line chemotherapy such as doxorubicin and ifosfamide yields limited survival benefit. New therapeutic options for sarcomas are needed; multiplatform profiling may provide potential targeted therapies. **Methods:** 1922 sarcomas were profiled using multiplatform biomarker assessment (Caris Life Sciences, Phoenix, AZ), including DNA sequencing (Sanger and next generation (NGS), Illumina MiSeq), gene copy variations and protein expression by immunohistochemistry. **Results:** Overexpression of TOPO2 and TOPO1 were observed in > 50% of sarcomas of various histopathologic types. Low MGMT expression was observed in 75% of osteosarcomas. Absence or low thymidine synthase (TS) expression was seen in Kaposi sarcoma, leiomyosarcomas (LMS), hemangiopericytomas and liposarcoma. PTEN loss was observed in up to 80% of subtypes including angiosarcoma, Kaposi sarcoma, LMS, liposarcoma, rhabdomyosarcoma, Ewing sarcoma, osteosarcoma, chondrosarcoma and others. cMET was amplified in 17 % of LMS; increased EGFR gene copies were detected in > 30% of malignant fibrous histiocytomas and malignant peripheral nerve sheath tumors. Of 281 patients tested using NGS, 137 mutations were detected in 24 genes (37%). TP53 was the most common (40%) followed by PIK3CA, PTEN, APC, KRAS, RB and ATM. TP53 mutations were associated with TOPO2 overexpression in 80% ($p$=0.0003), with PTEN loss in 20% of patients ($p$=0.17) and with PIK3CA mutations in 2 patients (liposarcoma, LPS). **Conclusions:** Profiling of protein expression, gene copy variations and mutations identified clinically relevant alterations in 99% of sarcomas. Given the overexpression of TOPO2 in approximately 50% of sarcomas, its utility as a biomarker of sensitivity to anthracyclines should be studied, especially in relation to TP53 status in a tumor. Trials of agents like mTOR and PI3K inhibitors could benefit from designs in which patient selection is based on PTEN loss or PIK3CA mutations instead of sarcoma histology. The prognostic implications of the co-existence of TP53 mutations and PTEN loss in sarcomas is yet to be elucidated.

**10510 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM**

**Preliminary analysis of the mutational landscape of non-rhabdomyosarcoma soft tissue sarcoma: A Children's Oncology Group study.** *Presenting Author: Raphael Asher Wilson, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Pediatric non-rhabdomyosarcoma soft tissue sarcomas (NRSTS) represent a histologically diverse group of more than 20 tumor subtypes, including synovial sarcoma, liposarcoma, and malignant peripheral nerve sheath tumors. Unlike children with rhabdomyosarcoma, systemic chemotherapy has failed to improve survival for those with NRSTS. Of the nearly 50% with intermediate or high-risk disease, only 50% and 15%, respectively, are expected to survive. **Methods:** To determine more effective, targeted therapies, we analyzed 55 archived formalin-fixed paraffin-embedded (FFPE) cases of NRSTS using Sequenom's MassARRAY system to interrogate 296 unique "actionable" mutations (mutations that can be targeted by currently available drugs) in 33 oncogenes and tumor suppressor genes. We also analyzed 15 of the samples for copy-number variation and 74 additional "actionable" mutations in 9 cancer-associated genes using the Affymetrix OncoScan platform. **Results:** Using MassARRAY, we found 11 mutations in 8 NRSTS subtypes. Interestingly, about half of these mutations are in genes involved in the Ras signaling pathway. We found an additional 33 potential mutations in 15 NRSTS subtypes, 28 of which are involved in Ras signaling; these mutations were detected at around 10% of the alleles present in a sample, the detection limit for MassARRAY, so they cannot be distinguished from background with certainty. Using OncoScan, we found that 67% and 73% of the samples contained mutations in EGFR and TP53, respectively, and 53% contained mutations in NRAS. 6 of the 15 samples contained between 1 and 5 large chromosomal gains or losses, while 2 of the samples had more than 10 large gains or losses. 3 recurrent gains were found in several of the samples, while 10 of the samples contained gains or losses in at least one gene. **Conclusions:** The rarity of the individual NRSTS subtypes has made it nearly impossible to determine the mutational profiles and optimal treatment for this group of tumors. With the ability to extract information from FFPE material using new genomic platforms, we have successfully grouped tumor subtypes and have identified actionable mutations guiding future directions.

**10511 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM**

**The driver landscape of angiosarcoma.** *Presenting Author: Sam Behjati, Wellcome Trust Sanger Institute, Cambridge, United Kingdom*

**Background:** Angiosarcoma is an aggressive tumour of presumed vascular endothelial origin that is commonly thought to be driven by aberrant angiogenesis. The somatic alterations underpinning angiosarcoma are largely unknown and have not previously been investigated by unbiased next generation sequencing. **Methods:** Thirty nine primary and secondary angiosarcomas were screened by whole genome (n=3), exome (n=8), or targeted re-sequencing of 33 angiogenesis genes (n=28). Somatic alterations were identified using the analysis pipeline of the *Cancer Genome Project*. **Results:** We identified novel driver mutations in two genes, *PTPRB* and *PLCG1*, both of which function to regulate angiogenesis signalling. *PTPRB* mutations were identified in 10/39 (26%) tumours, comprising 11 truncating and 3 missense variants. Four cases harboured 2 different *PTPRB* mutations each. A single recurrent missense variant, R707Q was identified in the *PLCG1* gene in (3/34) 9% of tumours. The enrichment of *PTPRB* and *PLCG1* mutations was highly significant ($q=10^{-9}$; $q=2x10^{-6}$). **Conclusions:** The mutational profile, comprising predominantly truncating mutations, suggests that *PTPRB* operates as a recessive cancer gene in angiosarcoma. This proposition is consistent with the function of PTPRB as a negative regulator of vascular growth factor tyrosine kinase receptors. In contrast, *PLCG1*, which transduces signalling of these receptors, likely operates as a dominant cancer gene with a single recurrent missense mutation found in three cases. Molecular modelling revealed that the R707Q *PLCG1*mutation is predicted to lead to constitutive activation of the PLCG1 enzyme and may therefore represent an attractive therapeutic target. Combining the *PTPRB* and *PLCG1* mutations with other driver mutations we found, shows that 15/39 (40%) tumours harbour at least 1 canonical driver mutation in angiogenesis genes, including in *H/N/K-RAS* (13%), *PIK3CA* (3%), and *FLT4* (3%). Driver mutations in angiogenesis genes were not mutually exclusive and co-occurred in a single dominant tumour clone. A pertinent question that arises from our study is whether the largely disappointing results from clinical trials of anti-angiogenesis drugs in angiosarcoma are confounded by the apparent redundancy of angiogenesis driver mutations.

**10512 Clinical Science Symposium, Mon, 1:15 PM-2:45 PM**

**Whole-exome and targeted sequencing of angiosarcomas: Target identification and treatment implications.** *Presenting Author: Vinod Ravi, Department of Sarcoma Medical Oncology. The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Angiosarcoma (AS) is a rare, aggressive tumor with vascular differentiation. Mutational landscape of AS is largely unknown. Utility of inhibition of targets/pathways identified by sequencing has not been investigated in AS. **Methods:** Study population included 20 patients with AS with tissue available for sequencing. 6 patients with fresh frozen paired normal and tumor samples underwent whole exome sequencing (WES) to identify somatic mutations. 14 patients with formalin fixed paraffin embedded (FFPE) tumor tissue underwent targeted sequencing of select cancer associated genes at high coverage. These data were filtered for germline SNPs utilizing publicly available databases and the remaining variants were classified on the basis of their being previously reported in the COSMIC database. Retrospective chart review was used to determine utilization of targeted therapies and clinical outcomes. **Results:** Study population (N=20) was predominantly Caucasian (80%), median age 64 years, with localized AS in 15%, nodal involvement in 40%, distant metastases in 45%. 60% of patients had cutaneous AS and 65% had previous history of radiation exposure prior to diagnosis. 65% of patients were alive at last follow-up. WES of patients with normal/tumor paired samples (n=6) showed a total of 485 alterations in 371 genes (range: 4-189 alterations/patient). Alterations were observed in the angiogenesis associated genes *PTPRB* (2/6 patients) *PLCG1* (2/6) as well as *TP53 (*1/6) in addition to other alterations. Targeted sequencing of FFPE samples (n=14) showed 27 alterations in 10/14 patients that were either mutations described in COSMIC or structural variants. These included *MYC & KDR* amplifications and mutations in *TP53, MDM2, KDR, FLT4 & PIK3CA*. 9 patients received 1 or more targeted agents creating 18 episodes of treatment. Clinical benefit rate was 45% when target was absent compared to 71% when target was present. **Conclusions:** Identification of genetic alterations specific to AS using WES should be utilized to construct targeted sequencing panels of select genes that help identify actionable targets and potential prognostic and predictive markers in patients with AS.

**10513 Poster Highlights Session (Board #1), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Integrate whole genomic study of KIT/PDGFRA wild-type (WT) GIST.** *Presenting Author: Margherita Nannini, Department of Specialized, Experimental and Diagnostic Medicine, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy*

**Background:** KIT/PDGFRA wild-type (WT) GIST comprise different subgroups with distinct molecular hallmarks, including defects in the succinate dehydrogenase (SDH) complex and mutations of neurofibromatosis type 1 (NF1), BRAF, or KRAS genes. We investigate the genomic profile of WT GIST for each of known mutations, referred as *quadruple* WT GIST, by using a massively parallel sequencing and microarray approach, and compare it with the genomic profile of other GIST subtypes. **Methods:** whole-Transcriptome Paired-End RNA Sequencing was performed on 16 GIST, including 2 KIT/PDGFRA WT GIST patients without SDH-inactivating mutations (GIST_133 and GIST_127), 2 KIT/PDGFRA WT GIST patients harbouring SDHA-mutations (GIST_7 and GIST_10), and 12 KIT or PDGFRA mutated GIST patients (7 harboured exon 11 KIT mutations and 5 harboured exon 18 PDGFRA mutations). Whole-genome gene expression analysis was performed on 9 of the above 16 GIST and extended to include an additional 20 GIST: 1 KIT/PDGFRA WT/SDHA-mutated GIST and 19 KIT or PDGFRA mutated GIST, of which 13 harboured KIT mutations (12 in exon 11 and 2 in exon 9), and 5 harboured PDGFRA mutations (2 in exon 12, 1 in exon 14 and 2 in exon 18). **Results:** the principal component analysis showed that both GIST_133 and GIST_127 are characterized by a gene expression profile profoundly different from both GIST_7 and GIST_10. No private or cryptic mutations of KIT and PDGFRA, as well as no NF-1, BRAF, RAS mutations were found. The supervised gene expression analysis revealed that GIST_133 and GIST_127 were characterized by an overexpression of molecular markers (CALCRL and COL22A1) and of specific oncogenes including tyrosine and cyclin-dependent kinases (NTRK2 and CDK6) and ERG. Overexpression of NTRK2 (TrkB) and of ERG was confirmed also by quantitative PCR. No mutations were identified in NTRK2, and there were no ERG fusions. **Conclusions:** The integrated genomic picture of WT GIST, using massively parallel sequencing and gene expression analyses, showed that *quadruple* WT GIST have an expression signature that is distinct from SDH-mutant GIST as well as GIST harbouring mutations in KIT or PDGFRA, suggesting that they represent another unique group within the family of gastrointestinal stromal tumors.

**10514 Poster Highlights Session (Board #2), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Disregulation of *mir-550* and *let-7e* in intestinal high-risk localized GIST: A GEIS study.** *Presenting Author: Jose Antonio Lopez-Guerrero, Laboratory of Molecular Biology, Instituto Valenciano de Oncologia, Valencia, Spain*

**Background:** Risk classification of gastrointestinal stromal tumors (GISTs) is critical owing to adjuvant systemic treatments with tyrosine kinase inhibitors (TKI). Tumor size, mitotic count, location or tumor rupture are used to assess patient prognosis after surgical resection and have been validated for GIST risk stratification. miRNAs have been involved in the pathogenesis and progression of most tumors. The purpose of this study is to characterize and to validate differentially expressed miRNAs from a series of recurrent and non-recurrent intestinal hig-risk GIST patients. **Methods:** RNA from 14 formalin-fixed and paraffin-embedded (FFPE) intestinal high-risk GIST was extracted and analyzed using the GeneChip miRNA 3.0 Array (Affymetrix). The median of tumor size and mitotic count was 11cm (range: 5-25) and 12.5 (range: 0-113 x50 HPF) respectively. Recurrence [median follow-up: 84 months (1-180)] was reported in 8 patients. Normalization and statistical analysis were performed with Partek Genomic Suite 6.6 software and technical validation was conducted using qRT-PCR. **Results:** A set of 33 miRNAs was significantly deregulated ($p=0.05$; FC=2) comparing relapsed and non-relapsed patients. Principal Components Analysis divided the patients into two groups: one that comprised the three largest GIST from relapsed patients, and another group with the other cases. We identified 134 miRNAs as differentially expressed between these two groups ($p<0.0001$; FC=20). The most significantly downregulated miRNAs were let-7e (FC=-1163,99, $p<0.0001$), miR-17 (FC= -861,879, $p<0.0001$), miR-195 (FC= -785,334, $p<0.0001$), miR-143 (FC= -627,526, $p<0.0001$) and up regulated miR-550 (FC= 204.173, $p<0.0001$) and miR-1184 (FC= 184.493, $p<0.0001$). miR-550 and let-7e were selected for technical validation by qRT-PCR confirming the up- (FC=18.0421) and down-regulation respectively (FC=0.6294). **Conclusions:** Most of the identified miRNAs are involved in cell cycle control and proliferation. We validated the deregulation of *miR-550* and *let-7e* in large intestinal high-risk GISTs. Further studies in independent series of localized GIST with long follow-up are needed in order to demonstrate the prognostic potential of these miRNAs.

**10515 Poster Highlights Session (Board #3), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Second-line treatment in exon 11-mutated GIST patients: Imatinib dose escalation or sunitinib? Retrospective analysis of a multi-institutional experience.** *Presenting Author: Bruno Vincenzi, Department of Medical Oncology, Campus Bio-Medico University of Rome, Rome, Italy*

**Background:** Data from metastatic GIST patients harbouring exon 11 mutation who received a second line treatment with sunitinib or imatinib dose escalation were retrospectively analysed to compare survival. **Methods:** 123 exon 11 mutated advanced GIST patients were included. All patients progressed on imatinib 400 mg/die and received, on discretion of physician, a second line treatment with either imatinib (800 mg/die) or sunitinib (50 mg/die 4 weeks on/2 weeks of or 37.5 mg/day continuous daily dose). The type of exon 11 mutation was recorded (deletion versus others) and correlated with survival and response according to RECIST or CHOI criteria **Results:** 79 patients (64%) received a second line treatment with imatinib, 44 (36%) sunitinib. For 94 patients the exact mutation was available: exon 11 mutation was represented by a deletion in 42 cases (45%), by other gene aberrations in 52 (55%). Median follow-up was 61 months. The median time to progression (TTP) in patients receiving sunitinib and imatinib was 10 (95% CI 9.7-10.9) and 5 months (95% CI 3.6-6.7) respectively (P=0.012). No significant difference was found in overall survival (OS) (58 versus 62 respectively, P=0.883). Interestingly, the impact of deletion in exon 11 was statistically significant longer in patients treated with imatinib (TTP 24 versus 6 months, P=0.02), while it was irrelevant in patients treated with sunitinb (P=0.683). A border line statistically significant difference was identified also in terms of OS in the group of patients treated with imatinib as second line (71 months in not deletes exon 11 patients vs 54 months in deleted ones, P=0.063). No difference was detected in the group of patients treated with sunitinb according to the mutation status in the exon 11 (P=0.370). **Conclusions:** In exon 11 mutated GIST patients progressing on a first line treatment with imatinib 400 mg/die, a second line treatment with sunitinib is associated with an improvement in TTP without any impact on survival. Deletion in exon 11 seems to be relevant for sensitivity to imatinib-based therapy as second line in terms of TTP, while the impact of mutation was not identified in patients treated with sunitinib.

**10516 Poster Highlights Session (Board #4), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Metabolomic profiling of gastrointestinal stromal tumor (GIST) in human tissue samples and xenografts.** *Presenting Author: Danny Yakoub, Sylvester Comprehensive Cancer Center, University of Miami, Miller School of Medicine and Jackson Memorial Hospital, Miami, FL*

**Background:** There is a growing need for novel agents to treat resistant GIST. The goal of this study was to characterize and identify potential therapeutic targets in the metabolic profile of GIST. **Methods:** Tumor, adjacent control tissue samples from 7 patients (five exposed to imatinib) and two tumor samples from xenografts in nude mice models (non-exposed) were extracted for analysis. $^{1}$H-NMR spectra, using a 500MHz spectrometer equipped with a cryoprobe head, were acquired and processed. Energy state, glucose (cytosolic glycolysis versus mitochondrial Krebs cycle), protein and lipid metabolism (indicators of proliferation and invasiveness) metabolomic profiles were assessed globally in correlation with clinical and histopathologic findings. **Results:** Findings suggest shift from cytosolic glycolysis (glucose decrease and increased lactate with minimal changes in pyruvate) towards the mitochondrial Krebs cycle (elevated glutamine and glutamate synthesis) in all tumor samples. Aspartate, myoinositol, and cell membrane phospholipids such as phosphocholine/glycerophosphocholine were greater in untreated GIST xenografts compared to treated tumors. Alanine, taurine, proline, ADP and phosphocholine were significantly higher in tumor tissue extracts compared to control (imatinib treated) ($p<0.05$). Tumor stage, mitotic index or mutation type did not correlate with metabolomic profile. Differences were accentuated among untreated patients. Partial Least Squares-Discriminant Analysis (PLS-DA) model successfully separated tumor tissues from controls (R2Y=0.56, Q2Y=0.22). **Conclusions:** Metabolomic profiling of patient and xenograft GIST samples exposed to KIT inhibitors suggest that cytosolic glycolysis and phospholipid biology may be important not only in the GIST phenotype but may be ameliorated with KIT inhibition by imatinib. Further understanding of GIST metabolomics may lead to the identification of new therapeutic targets.

**10517 Poster Highlights Session (Board #5), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Improvement of existing risk classifications in primary gastrointestinal stromal tumors (GIST).** *Presenting Author: Piotr Rutkowski, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland*

**Background:** The reliable risk assessment of relapse and survival after initial resection are needed for a proper selection of GIST patients for adjuvant therapy. **Methods:** We analyzed group of registered prospectively 692 primary GISTs CD117(+) treated surgically with curative intention between 1999-2009, with no adjuvant imatinib. Median follow-up time was 34 months. We analyzed the factors influencing on 1-year and 5-year disease-free survival time (DFS; calculated from the date radical operation) and 5-year overall survival (OS). We also compared the reliability of existing risk classification (NIH, NCCN-AFIP according to Miettinen-Lasota, TNM-AJCC, revised NIH according to Joensuu, nomograms according to Gold et al and according to Rossi et al) using Receiver Operating Characteristic (ROC) curves tests. **Results:** With univariate analysis the following negative prognostic factors for DFS have been identified: male sex, mitotic index 5-10/50 and >10/50 HPF ($p<0.001$), primary tumor size 5-10 cm and >10 cm ($p<0.001$), non-gastric location ($p<0.001$), R1 surgery or tumor rupture ($p<0.001$), presence of exon 11 *KIT* 557_558 del or exon 9 KIT mutations ($p=0.009$). The negative prognostic factors for OS were: age <40 ($p=0.045$), mitotic index 5-10/50 and >10/50 HPF ($p<0.001$), primary tumor size 5-10 cm and >10 cm($p<0.001$), R1 surgery or tumor rupture ($p<0.001$). These factors were found also statistically significant in multivariate analyses. All existing risk classification demonstrated prognostic value for assessment of differences in DFS and OS, and we have not found significant differences between them when compared with ROC tests. In addition, the reliability of all these classifications was improved when gender/age and mutational status were added. The additive value of mutational status for better risk assessment was the most significant when used in intermediate risk groups according to different classifications ($p<0.01$). **Conclusions:** The reliability of existing classifications for the risk assessment of disease recurrence and death after resection of primary GIST can be improved by adding mutational status, with the mostly significant refinement of better stratifications in intermediate risk groups.

**10518 Poster Highlights Session (Board #6), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Interrelationship of primary and secondary mutations in gastrointestinal stromal tumors during TKI therapy.** *Presenting Author: Peter Hohenberger, University Medical Center Mannheim, Department of Surgery, Mannheim, Germany*

**Background:** Gastrointestinal stromal tumors (GISTs) show *KIT* or *PDGFR*$\alpha$ gain-of-function mutations in 85% as the primary oncogenic drivers. Although the use of tyrosine kinase inhibitors (TKI) like imatinib has greatly improved therapy, the occurrence of secondary resistance to TKIs is a challenging problem. Secondary mutations in *KIT/PDGFR*$\alpha$ are believed to be the most important mechanism of drug resistance. We analyzed whether this might be a random process or whether these effects could be correlated to primary tumor characteristics and primary drug therapy. **Methods:** 58 patients undergoing surgery or CT-guided biopsy of progressive GIST lesions while being on TKI therapy and with known mutations from their primary tumor formed the basis of our study. Paraffin-embedded specimens were used to examine the primary and secondary mutations in exons 8, 9, 11, 13, 14, 17 of *KIT* and exons 12, 14 18 of the *PDGFR*$\alpha$by macrodissection, genomic DNA extraction, PCR amplification, designed primers for exons, Sanger-sequenced twice. **Results:** Point mutation was the most common type of 2ndary mutation (52/58, 89.7%). Codon 654 of *KIT* exon 13 (n=20) and codons 820 to 822 of *KIT* exon 17 (n=28) were the predominant regions of 2ndary mutations. Secondary mutations in KIT exon13 were exclusively found in tumors with primary mutations in *KIT* exon11. GISTs of non-gastric origin had a higher frequency to develop secondary mutation in activation-loop (AL, exon 17) of *KIT* than those with gastric origin (67.7% vs. 35.7%, $P=0.047$). Mean duration of TKI treatment did not influence significantly AL vs non-AL mutations. With respect to the TKIs used, secondary mutations in the activation-loop were more often found after multiple TKIs (imatinib, sunitinib, nilotinib, sorafenib) than after just imatinib, but the difference was not quite statistically significant (85.7% vs. 50.0%, $P=0.066$). **Conclusions:** The development of secondary tyrosine kinase mutations in advanced GISTs during treatment with TKIs is not a random effect. Correlations between primary vs. secondary mutations and initial tumor site can be demonstarted. Besides, it seems possible that the use of different TKIs itself may impact on the development as well as type of secondary mutations.

**10519 Poster Highlights Session (Board #7), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Neoadjuvant administration of radiation therapy and intratumoral autologous dendritic cells in patients with localized high-risk soft tissue sarcomas.** *Presenting Author: Shailaja KS Raj, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background**: Patients with high grade, large (<5 cm) soft tissue sarcomas (STS) can develop metastases after surgical therapy with no proven benefit to adjuvant chemotherapy. Our in vivo murine model demonstrated that standard external bean radiation therapy with experimental intratumoral injection of dendritic cells (DC) produces tumor-directed immunity. Our protocol, established that preoperative RT +DC regimens safe in patients with large high grade STS with a significant anti autologous tumor cell immune response. We hypothesize that release of tumor antigens to the intratumoral dendritic cells results in the cross priming of an effector anti tumor cell response. **Methods:** 32 patients were enrolled in two (phase I & II) trials given radiation neoadjuvantly, up to 50Gy,5days a week, combined with intratumoral injection of dendritic cells, followed by surgery and compared to 54 historic controls treated at Moffitt Cancer Center during the same period with radiation. Dendritic cells were prepared using culture of mononuclear cells with granulocyte-macrophage colony stimulating factor GM-CSF and interleukin-4. **Results:** 9/17 patients on the phase I developed tumor-specific immune responses, which lasted from 11 to 42 weeks. The remaining immunological results will be presented at the meeting. In multivariate analysis using Cox-proportional hazards model, tumor size (>=10cm) was associated with poorer OS ($p=0.028$; HR=3.6 with 95%CI=1.1-11.4) and with DFS ($p=0.021$; HR=2.8 with 95%CI=1.2-6.9). A trend to better overall survival (OS) and progression free survival (DFS) of the patients, in the dendritic cell vaccine arm was seen, when compared to the historic controls but this was not statistically significant by univariate analysis (OS: $p=0.29$; DFS: $p=0.24$). **Conclusions**: Neoadjuvant therapy with radiation and intratumoral autologous dendritic cells in high risk soft tissue sarcoma patients is safe. Tumor specific immune responses were seen with CD4 positive T cells in the earlier group of patients. Clinical trial information: 16441.

**10520 Poster Highlights Session (Board #8), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Trivalent ganglioside vaccine and immunologic adjuvant versus adjuvant alone in metastatic sarcoma patients rendered disease-free by surgery: A randomized phase 2 trial.** *Presenting Author: Richard D. Carvajal, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Recurrence after resection of metastatic sarcoma is common. The gangliosides GM2, GD2 and GD3 are strongly expressed on many sarcomas. The generation of anti-ganglioside antibodies might control micrometastases and improve outcomes. **Methods:** We conducted a randomized phase 2 study of the immunological adjuvant OPT821 with a KLH conjugated ganglioside vaccine targeting GM2, GD2 and GD3 (vaccine) or placebo (control) in patients (pts) with metastatic sarcoma following complete metastastectomy. Randomization was stratified by disease state (relapsed disease vs metastasis at diagnosis) and for those with relapse by disease-free interval ($<12$ vs $\geq 12$ months) and number of relapses (1 vs $>1$). Pts received 10 injections at weeks (wks) 1, 2, 3, 8, 16, 28, 40, 52, 68 and 84. Imaging was performed at wk 16 and every 12 wks subsequently. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS) and serologic response. **Results:** We randomized 136 pts: median age 51 (range 17-84); 52% male; 77% ECOG PS 0 (range 0-1); 90% with relapsed disease; 14% had $\geq 4$ metastases resected. Histology included leiomyosarcoma (n=48), spindle cell (n=19), undifferentiated/pleomorphic (n=18), osteosarcoma (n=14), synovial (n=12), liposarcoma (n=12) and others (n=13). Toxicities included grade 1/2 injection site reactions (79%), fatigue (32%), fever (15%) and flu-like symptoms (10%) and were more frequent with complete vaccine. With 89 PFS events observed, median PFS and 1-year PFS rate were 6.4 months (mos) and 35%, respectively, with no difference between arms. With a median follow-up of 18 mos and 22 pts deceased, the 1-year OS rate was >90%. Serologic responses (IgM and/or IgG) to GM2 and GD2 were observed in 98% and 21% of pts treated with complete vaccine and control, respectively. At wks 40-68, induction of high (>160) IgM and IgG titers was observed in 52% and 24% of pts receiving vaccine and 0% and 2% of pts receiving control. **Conclusions:** A sustained serologic response to vaccination was induced with the complete vaccine. No difference in PFS was observed between arms. Follow-up for OS is ongoing. Clinical trial information: NCT01141491.

**10521 Poster Highlights Session (Board #9), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Combined KIT and CTLA-4 blockade in patients with refractory GIST and other advanced sarcomas.** *Presenting Author: Alexander Noor Shoushtari, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Few effective treatments (tx) exist for patients (pts) with tyrosine kinase inhibitor (TKI)-resistant gastrointestinal stromal tumors (GIST) and other advanced soft tissue sarcomas (STS). In a murine GIST model, we showed that the efficacy of KIT inhibition is immune-mediated via decreases in indoleamine 2,3-dioxygenase (IDO), with improved antitumor effects using combined KIT and CTLA-4 blockade (Balachandran, Nat Med 2011). **Methods:** This Phase Ib trial used a standard 3+3 design of ipi 10 mg/kg (q3 week [wk] x4 induction + q12 wk maintenance) plus escalating doses of dasatinib (das; 70 mg QD, 100 mg QD, 70 mg BID). Pts with refractory GIST or advanced STS and $\geq 1$ prior tx were eligible. Primary objective was to estimate the maximum tolerated dose (MTD). Secondary objectives included response assessed by RECIST1.1, Choi, and immune-related response criteria (irRC) at week 12 and q6 wks afterward. **Results:** 13 pts were treated: median (range) age 56 (40-72), 7 male, prior tx = 4 (1-8). Histologies: 8 GIST, 2 leiomyosarcomas, 3 other. All GIST pts progressed on imatinib and sunitinib; 7 had prior sorafenib. Potential immune-mediated toxicities included grade (G) 1/2 rash (n=6), diarrhea (n=4), pruritus (n=2). Other common G1/2 toxicities included fatigue (n=8), anemia (n=6), edema (n=5), nausea (n=5) and pleural effusion (n=3). At das 70 mg QD, one dose-limiting toxicity (DLT) was seen: G3 upper GI hemorrhage. Two DLTs were observed at das 100 mg QD: G3 ALT elevation and G3 upper GI hemorrhage. 3/8 GIST pts achieved a durable Choi response (24, 25, 59+ wk). No irRC or RECIST responses were observed. Durable irRC SD was achieved in 1 pt with GIST (59+ wk) after 4 prior TKIs and 1 pt with high-grade sarcoma (34+ wk) after 5 prior tx. 4/5 pts completing ipi induction had radiologic SD vs wk 12 scans (24, 24, 33+, 59+ wk). Median ALC increased from b/l to wk 7 (1100 to 1550, p=0.04) with no association with clinical benefit. **Conclusions:** In this completed Phase Ib trial, the recommended phase 2 dose is das 70 mg QD + ipi 10 mg/kg. Disease stability was seen post-ipi induction, suggesting an immune-mediated effect. Analysis of tumor IDO expression and other immune correlates from serial biopsies obtained from a follow-up GIST cohort is ongoing. Clinical trial information: NCT01643278.

**10522 Poster Highlights Session (Board #10), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**PD-L1 expression and immune infiltrates in sarcoma.** *Presenting Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background**: Programmed death-1 (PD-1) is a member of the CD28 family of T-cell costimulatory receptors that attenuates immune responses by negatively regulating T-cell proliferation and function. The prognostic and predictive implications of programmed death-ligand 1 (PD-L1) has been described in multiple malignancies but are unknown in sarcoma. We previously demonstrated PD-L1 expression by western blot and flow cytometry in 65% of sarcoma cell lines. We now examined PD-L1 expression by IHC in sarcoma specimens and tumor-associated immune cells and correlated expression with clinical parameters and outcomes. **Methods**: 50 sarcoma patients treated at Memorial Sloan Kettering Cancer Center who were consented to our IRB approved tissue procurement protocol were selected. Correlative clinical information was collected.Using the DAKO PD-L1 IHC assay and archival formalin-fixed paraffin embedded tissue specimens; PD-L1 expression was examined. Positive was defined as >1% of tumor cells (minimum of 100 evaluable cells) with plasma membrane staining. Staining intensity was not used to define positivity. Macrophage (M) and lymphocyte (L) PD-L1 status was determined qualitatively. Associations between PD-L1 expression in tumor, M and L and clinical-pathological characteristics were performed. **Results**: Median age 46 years (range, 22 - 76), 66% male. Disease status: 70% primary disease/locally recurrent, 26% metastatic and 4% unknown. Tumor, L and M PD-L1 expression was noted in 12%, 30% and 58%, respectively. L and M infiltration was present in 98% and 90%, respectively. There was no association between clinical features, overall survival and PD-L1 expression in tumor or immune infiltrates. **Conclusions**: L/M infiltration is common in sarcoma. PD-L1 tumor expression is uncommon with the highest frequency observed in GIST. There was no association between PD-L1 expression and OS. Forthcoming studies include a characterization of the immune infiltrates and expansion to additional tumor specimens.

**10523 Poster Highlights Session (Board #11), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Results of the prospective T-DIS randomized phase II trial comparing interruption versus continuation of trabectedin after six cycles of treatment in patients (pts) with advanced soft tissue sarcoma (ASTS).** *Presenting Author: Axel Le Cesne, Institut Gustave Roussy, Villejuif, France*

**Background:** Trabectedin (T) maintenance beyond 6 cycles (cy) of treatment in responding pts with ASTS is associated with improved outcomes (Retrospective on database analysis; ASCO 2013). Herein, the impact of T discontinuation on progression-free survival (PFS) and overall survival (OS) was prospectively analyzed by the French Sarcoma Group in a national non-comparative randomized phase II trial. **Methods:** After the initial 6 cy of T (1.5 mg/m$^2$ as 24-h infusion every 3 weeks), pts free from progressive disease (PD) were randomly assigned either to continuous treatment (C arm) or therapy interruption (I arm) with T. Pts who declined randomization could continue with T. Pts allocated to the I arm could restart T in case of PD. Primary endpoint was PFS rate at 6 months (m) weeks after randomization. **Results:** FromFebruary 2011 to March 2013, 178 pretreated pts have been enrolled. At inclusion, the pts had a median age of 57.5 years (range19-82) and a median performance status of 1 (range 0-3) and most had leiomyosarcoma (30%), liposarcoma (18%) or synovial sarcoma (12%). Among evaluable pts (n=178), the rate of non-progression after the initial 6 cycles of T was higher than expected (29.7%). After 6 cy of T, 27 and 26 non progressive pts were randomized to C and I arm, respectively (30% of included pts). After randomization, a median number of T cy were similar in both arms: 5 (range 2-17) for C arm and 5 (range 1-12) for I arm. In December 2013, the median PFS after randomization was 7.2 m in C and 3.7 m in I arm ($p$=0.05), respectively, with the 6-m PFS of 50% and 16% for C and I arm. The 12-m OS rate after randomization was 86% (62.4-95.3) and 74% (44.1-89.2) for C and I arm, respectively. T has been reintroduced in 19/21 pts who progressed in I arm. **Conclusions:** The rate of non-progression after 6 cycles of T was higher than previously reported, probably due to a better selection of ASTS pts in referral centers and a better management of T. Interruption of T resulted in a rapid PD in the vast majority of pts, independently of the response achieved after initial 6 cy of T. Therefore, T treatment has to be given until PD, intolerance or patient refusal. Clinical trial information: 2010-022613-26.

**10524 Poster Highlights Session (Board #12), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A randomized phase II study comparing trabectedin (T) and best supportive care (BSC) in patients (pts) with translocation-related sarcomas (TRS).** *Presenting Author: Shunji Takahashi, Department of Medical Oncology, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

**Background:** T binds to the minor groove of DNA and blocks DNA repair machinery following the inhibition of cell cycle and proliferation. In addition, T inhibits interactions of transcription factors including TRS-related transcription factors with the DNA in a competitive manner. This is the first time that the progression-free survival (PFS) of T is compared with BSC as a second or later line treatment in pts with TRS in a multi-center, open, phase II trial. **Methods:** Main inclusion criteria were the following: histologically proven TRS; unresponsiveness or intolerability to standard chemotherapy regimens (pts with extraskeletal Ewing sarcoma (EES), myxoid liposarcoma (ML), or synovial sarcoma (SS) should have received anthracyclines); at least 1 measurable baseline lesion (RECIST v1.1); confirmed disease progression (per RECIST) compared with the image assessment performed during the previous 6 months(m). Pts stratified by subtype (alveolar rhabdomyosarcoma, ESS, ML, SS vs other TRS) were randomly assigned 1:1 to T (1.2 mg/m$^2$ in 24h continuous infusion every 21 days) or BSC. The primary endpoint was PFS by independent review assessment (IR). This study had 80% power for a one-sided 5% significance level test given a hazard ratio (HR) (T relative to BSC) of 0.50. Sample size goal was 74 pts with an event goal of 52 events by IR requiring a total of 60 events by investigator's assessment (IA). PFS and overall survival (OS) were analyzed using a stratified log-rank test. **Results:** Data cut-off date was 8$^{th}$ February 2014. Total of 76 pts were enrolled. Number of pts for efficacy analysis was 73 (T: 37 pts and BSC: 36 pts). Median PFS (90% confidence interval(CI))for T and BSC were 5.6 m (4.2-7.5) and 0.9 m (0.9-1.0), respectively ($p<0.0001$; HR=0.07, 90% CI: 0.03-0.14). Median OS (95% CI) for T and BSC were not reached (NR) (12.8-NR) and 8.0 m (7.0-NR), respectively ($p=0.025$; HR=0.38, 95% CI: 0.16-0.91) under permission of crossover. **Conclusions:** T is an active drug in TRS pts pretreated by available chemotherapies with a significant increase in PFS and OS. Clinical trial information: JapicCTI-121850.

**10525 Poster Highlights Session (Board #13), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A four-arm randomized phase II trial with NGR-hTNF given at low or high dose with or without doxorubicin in soft tissue sarcomas (STS).** *Presenting Author: Stefano Ferrari, Istituto Ortopedico Rizzoli, Bologna, Italy*

**Background:** NGR-hTNF, a tumor targeted antivascular agent, exhibits a biphasic dose-response curve with activity shown at low dose (LD) or high dose (HD). Vascular effects at LD are driven by early vessel normalization that enhances intratumoral doxorubicin (D) uptake and late vessel damage, while at HD by rapid vessel disruption. **Methods:** Advanced STS patients (pts), stratified by prior D dose ($>$ or $\leq$ 300 mg/m$^2$), were randomly assigned to receive NGR-hTNF alone at LD (0.8 $\mu$g/m$^2$/d1/q1w) in arm A or at HD (45 $\mu$g/m$^2$/d1/q1w) in arm B, or with D (60 mg/m$^2$/d1/q3w) at LD in arm C and at HD in arm D. Progression free survival (PFS) was primary endpoint with tumor assessment done q6w until progressive disease (PD). Using a 2-stage design, each regimen was rejected if $\leq$2/14 and $\leq$7/24 pts were PD free at 3 months after 1st and 2nd stage, respectively ($\beta$=20%; $\alpha$=10%; n=96). Secondary aims: adverse events (AEs), tumor response by RECIST criteria and early metabolic response (MR), quantified by fractional changes in SUV using FDG-PET according to EORTC criteria **Results:** In all, 69 pts (median age 55 years; men 38; PS $\geq$ 1 31; median prior lines 2, range 0-7) received 767 weekly cycles (mean 11; range 1-51). Main grade 3/4 AEs were neutropenia (23%) and chills (7%). Primary endpoint was met only for arm C (LD NGR-hTNF plus D), with 7/14 and 15/28 pts PD free at 3 months after 1st and 2nd stage, respectively. Median PFS was 1.3 months (95% CI, 1.1-1.5) for arm A, 1.5 (1.1-1.9) for B, 3.6 (2.3-4.9) for C and 1.4 (0.9-1.9) for D ($p=0.005$ for trend). As best response per RECIST, 28 (45%) of 62 evaluable pts had stable disease (SD): 1/12 in arm A, 6/12 in B, 17/26 in C (median length 4.3 months; range 2.9-23.2) and 4/12 in D. In arm C, median PFS was 2.9 and 4.3 months for naive and pretreated pts, respectively, while median OS was 9.8 months (HR=0.46 vs other pooled arms; $p=0.01$). By PET imaging done at 3 weeks, 10 (23%) of 43 assessable pts had partial MR (5 SD/5 PD per RECIST), with mean change in SUV of -37% ($\pm$12), 25 pts stable MD (8 SD/17 PD) and 8 progressive MD (5 SD/3 PD). PET sensitivity in predicting PD or non-PD per RECIST was 12% and 72%, respectively. **Conclusions:** LD NGR-hTNF plus D shows safe and favourable clinical activity particularly in pretreated STS. Clinical trial information: NCT00484341.

**10526 Poster Highlights Session (Board #14), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**NCI #8412: A randomized phase II trial of AZD6244 alone and AZD6244 plus temsirolimus for soft-tissue sarcomas.** *Presenting Author: Zeynep Eroglu, City of Hope, Duarte, CA*

**Background**: Outcomes for advanced soft-tissue sarcomas (STS) are poor given their relative insensitivity to chemotherapy. AZD6244 (AZD) is a MEK1/2 inhibitor that suppresses STS proliferation in vitro. mTOR inhibitors (mTORi) possess modest activity against STS, and resistance rapidly develops via MAPK pathway feedback activation. The combination of AZD and the mTOR inhibitor temsirolimus (Tem) synergistically inhibits STS cell line growth. Therefore, a randomized, phase II trial of AZD vs. AZD plus Tem in advanced STS was conducted. **Methods**: Adults with advanced STS who received $\leq$2 prior chemotherapeutics were eligible; pediatric-type sarcomas and brain metastases were excluded. 69 subjects were randomized to AZD 75 mg PO bid (n=34) and allowed to crossover upon progression, or to AZD 50 mg PO bid plus Tem 20 mg IV weekly (n=35), with 28 day cycles. Primary endpoint was progression-free survival (PFS). Secondary objectives were to compare: response rate, 4-month PFS rates, and toxicities; and changes in ERK-phosphorylation in stimulated PBMCs pre- and post-treatment. **Results**: While there was no difference in PFS between the single agent vs. combination arm for the overall cohort (median 1.9 vs. 2.1 months), an improved median PFS was observed in the combination arm (N=11) over single agent (N=10) in the pre-specified leiomyosarcoma stratum (median 3.7 vs. 1.8 months; $p=0.01$). 4-month PFS rate was 24% for both arms in the overall cohort, but 50% (95% CI 0.19-0.81) with the combination vs. 0% with AZD alone in the leiomyosarcoma cohort. One PR and 4 SD were seen with the combination arm in leiomyosarcoma patients, and 2 SD in AZD alone. 18 of 34 AZD6244 patients crossed over, with 5 patients receiving $\geq$ 6 cycles after crossover. Most common grade 3/4 adverse events in the combination arm were mucositis (29%), lymphopenia (26%), neutropenia and anemia (20% each); hypertension (12%) was observed with AZD alone. Correlative studies showed that AZD significantly inhibited ERK phosphorylation. **Conclusions**: The combination of AZD and Tem appears to be an active regimen in the leiomyosarcoma subset. Emerging preclinical data revealing activation of the mTOR pathway in leiomyosarcoma development may explain this result. Clinical trial information: NCT01206140.

**10527 Poster Highlights Session (Board #15), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Alliance A091102: Phase II study of MLN8237 (Alisertib) in advanced/metastatic sarcoma.** *Presenting Author: Mark Andrew Dickson, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** About 13,000 cases of soft tissue and bone sarcoma are diagnosed annually in the US. Despite surgery many patients (pts) develop recurrent disease. Response rates (RR) to chemotherapy are low; new agents are needed. In gene array studies Aurora Kinase A (AURKA) is commonly overexpressed. Inhibition of AURKA by shRNA or by a specific AURKA inhibitor blocks in vitro proliferation of multiple sarcoma subtypes. MLN8237 (alisertib) is a novel, oral, ATP-competitive, selective small-molecule inhibitor of AURKA. **Methods:** This multi-center phase II study of alisertib in pts with advanced/metastatic sarcoma was conducted through the Alliance for Clinical Trials in Oncology (A091102). Adequate performance status, organ function, and measurable disease (RECIST v1.1) were required. Pts enrolled into histology-defined cohorts: 1) liposarcoma (LPS), 2) leiomyosarcoma (LMS), 3) undifferentiated sarcoma (US), 4) malignant peripheral nerve sheath tumor (MPNST), or 5) other. Alisertib 50mg PO BID d1-d7 was given every 21 days until progressive disease (PD) or unacceptable toxicity. The primary endpoint was confirmed RR in each of 5 cohorts. Progression-free survival (PFS) was a secondary endpoint. 1 confirmed response in the first 9 pts expanded enrollment in a cohort to 24 using a Simon 2-stage design. **Results:** 72 pts were enrolled at 24 sites (12 LPS, 10 LMS, 13 US, 10 MPNST, and 27 Other). Median age was 55 (range 20-84); 54% were male; 58/38/4% were ECOG PS 0/1/2. 1 confirmed PR in the Other cohort (angiosarcoma) expanded to 2nd stage accrual. The histology-specific cohorts ceased at the 1st stage. Overall, 76% have PD; 25% have died, with median follow-up of 4.4 months (0.4-11.9). 12-week PFS was 73% (LPS), 44% (LMS), 23% (US), 57% (MPNST), and 39% (Other). Common grade 3-4 adverse events included (%): mucositis (13), anemia (14), leukopenia (22), and neutropenia (40). **Conclusions:** Alisertib was well-tolerated in this study of multiple sarcoma histologic subtypes. Rare responses, yet prolonged stable disease, were observed. Although failing to meet the primary RR endpoint, PFS was promising. Alisertib warrants further study in sarcoma. Clinicaltrials.gov: NCT01653028. Funded by the Alliance for Clinical Trials in Oncology Clinical trial information: NCT01653028.

**10528 Poster Highlights Session (Board #16), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II study of oral ENMD-2076 administered to patients (pts) with advanced soft tissue sarcoma (STS).** *Presenting Author: Herbert H. F. Loong, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

**Background:** The use of angiogenic and Aurora kinase inhibitors has been shown to abrogate tumor growth in STS. ENMD-2076 is an oral Aurora A and angiogenic kinase inhibitor that has demonstrated single-agent activity in STS cell lines and inhibition of sarcoma growth for a patient in a phase 1 clinical trial setting. **Methods:** This is a single-center, open-labeled phase II study of ENMD-2076 in advanced STS pts treated with ≤1 line of prior therapy in the advanced/metastatic setting. Pts were commenced on 275mg daily dose (on a 28-day cycle. Treatment-emergent adverse events were assessed by CTCAE (4.0). Radiographic or clinical tumor measurements occurred every 2 cycles (RECIST 1.1). **Results:** 10 pts were enrolled from 2/2013 – 11/2013 and evaluable for efficacy. Median age is 58 yrs (41 – 72). Male: Female 1:9. Histology: Leiomyosarcoma / pleomorphic sarcoma / angiosarcoma: 7/2/1. Pts received the following prior systemic therapies: doxorubicin/gemcitabine/others: 2/3/5. At time of abstract submission, median follow-up is at 7 months (2-12). 3 pts continue on study. Median number of cycles administered per pt = 2 (1-8). 2 pts had confirmed partial response (PR) and 1 pt with confirmed stable disease (SD) of > 6 months. Clinical benefit rate (PR+SD >6 months) was 30%. Median OS has not been reached. Median PFS at 1.8 months (95% CI: 1.2 – not reached). ENMD-2076 has generally been well tolerated with primarily grade 1 and 2 adverse events (AEs). Specifically, drug-induced hypertension occurred in 6 pts (grade 1-2: 4 pts, grade 3: 2 pts). Proteinuria, all grade 1-2, occurred in 6 pts. Other drug related grade 3 or 4 AEs include (pts): elevated transaminases (1), leukopenia (1), and diarrhea (1). 1 pt developed Posterior Reversible Encephalopathy Syndrome (PRES) presenting as grade 4 loss of consciousness at Cycle 1 Day 15 required ICU admission. Full neurological recovery was attained after cessation of treatment. **Conclusions:** ENMD-2076 has shown activity in patients with advanced STS, with meaningful clinical benefits and a side effects profile typical of this class of agent. PRES is a rare but fully reversible side effect of ENMD-2076. Clinical trial information: NCT01719744.

**10529 Poster Highlights Session (Board #17), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Long-term follow-up of the CESS 81 and CESS 86 Ewing sarcoma trials.** *Presenting Author: Herbert Juergens, University Hospital of Muenster, Muenster, Germany*

**Background:** Since 1980 patients with Ewing sarcoma have been treated according to consecutive protocols (CESS) of the German Society of Pediatric Oncology and Hematology (GPOH)(supported by Deutsche Krebshilfe). Post treatment surveillance also includes long term follow-up (supported by BMBF/DLR 01ER0807). The observation time now covers a period of more than 30 years. **Methods:** 673 patients (pts) entered into the CESS 81 (n=183) (1980-1985) and CESS 86 (n=490) (1985-1992) Ewing sarcoma trials were analyzed. 375 pts (59%) were male, 278 (41%) female. 549 pts (82 %) had localized, 124 (18%) metastatic disease. Primary tumor location was lower extremity in 37%, pelvis in 26%, other axial sites in 29%, and upper extremity in 8%. The median age at diagnosis was 14.8 years (range 0.7 - 41.4). The median age of survivors at last time of observation was 28.9 years (range 8.8 - 63.3). Median follow-up time of survivors was 15.5 years (range 0.3 - 30.6). Data were retrospectively analyzed with descriptive statistics and survival analyses, and complemented by questionnaire information. **Results:** 315 pts (47%) were alive at last follow-up, 358 pts (53%) have died. The cause of death was DOD in 318 pts (89%), DOC in 31 pts (9%), and death of other cause in 9 pts (2%). Events were observed in 361 pts: local relapse in 19%, distant relapse in 64%, combined relapse in 13%, and secondary malignancies in 4%. Self-reported late morbidity was available from 128 of 315 survivors: 19.5% cardiac and 6.2% renal abnormalities. In 5 pts (3.9%) secondary amputation was reported. The analysis of late functional outcome is ongoing. 10-year event-free survival (EFS) was 0.49 (SE=0.02) in localized, and 0.21 (SE=0.04) in metastatic disease. 10-year overall survival (OS) was 0.54 (SE=0.02) in localized, and 0.23 (SE=0.04) in metastatic disease. **Conclusions:** Long-term observation is crucial in pediatric cancer survivors. Nearly half of patients of the earliest phase III Ewing sarcoma trials are long-term survivors. Approx. 90% of patients with recurrence died from disease. Patient-related outcome scores are currently investigated in a long-term observation study for inclusion into long-term follow-up guidelines and to better predict the long-term quality of survivorness.

**10530 Poster Highlights Session (Board #18), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Survival of adolescents and young adults (AYAs) with skeletal Ewing sarcoma: A Dutch population-based study.** *Presenting Author: S.E.J. Kaal, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** Ewing sarcoma is most prevalent among children and adolescents. Although increasing age in general is associated with poorer survival, little is known about survival in adolescents and young adults (AYA: 15-39 years) compared to children (0-14 yrs). **Methods:** In this cohort study data from all patients diagnosed with skeletal Ewing sarcoma between 1989 and 2011 were obtained from the Netherlands Cancer Registry. Patients were divided in three age groups: children (age 0-14), AYAs (age 15-39) and older adults (age 40+). One, 3 and 5 year overall survival (OS) estimates by age group were determined and sex, period (1989-1994 vs 1995-2000, 2001-2006, 2007-2011), site (axial vs extremity) and stage (with or without metastases) adjusted Hazard Ratios (HR) and 95% Confidence Intervals (95%CI) were calculated using a Cox Proportional Hazard Regression model. **Results:** In total 180 children, 247 AYAs, and 29 older adults with skeletal Ewing sarcoma were identified. AYAs appear to be more often male compared to children (64% and 53% respectively, $Chi^2$ p-value=0.02) and were more often diagnosed with metastatic disease (31% and 22% respectively, $Chi^2$p-value=0.05). Five-year OS for AYAs was 46% (95%CI: 39-52%) compared to 68% (95%CI: 60-74%) in children and 33% in older adults (95%CI: 16-50%). Table shows 1, 3 and 5 year OS survival data. AYAs have an almost twofold increased risk of death compared to children; the gender, site, stage, and period adjusted HR was 1.9 (95%CI 1.4-2.6) for AYAs compared to children. **Conclusions:** As compared to children AYAs with skeletal Ewing sarcoma more often are male, present with metastatic disease at diagnosis and have a worse survival even after adjustment for tumor stage, site, gender and treatment period. Since detailed data about treatment were not available, no conclusion can be drawn about the effect of treatment on survival. Furthermore, differences in tumor biology should be considered.

**1, 3, and 5 years OS percentages (with 95% confidence intervals) in patients with skeletal Ewing sarcoma.**

| Age group | 1 yr OS | 3 yr OS | 5 yr OS |
|---|---|---|---|
| Children | 94 % (90-97) | 73% (66-79) | 68% (60-74) |
| AYAs | 87% (82-91) | 50% (44-57) | 46% (39-52) |
| 40 + | 66% (45-80) | 38% (20-55) | 33% (16-50) |

**10531 Poster Highlights Session (Board #19), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Eliciting early-response signals from first-in-human clinical trials and validation of prognostic scores in aggressive biology bone cancers: The MD Anderson experience.** *Presenting Author: John Andrew Livingston, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** There have been no new US FDA approved therapies for bone sarcomas (osteosarcoma, Ewing's sarcoma, and chondrosarcoma) in the last three decades. Current treatment options are limited and the prognosis of aggressive bone cancers remains extremely poor. Rarity poses an additional challenge in developmental therapeutics for bone sarcoma. Advanced relapsed/ refractory bone cancer patients may be enrolled in targeted therapy phase 1 trials which may provide unique insight and an opportunity to elicit early response signals. **Methods:** We systematically analyzed the characteristics and outcomes for advanced bone sarcoma patients referred for treatment on phase I trials at MD Anderson Cancer Center (MDACC) from 7/2005 to 11/2013 with an emphasis on targeted agents. In addition we sought to validate the Royal Marsden Hospital (RMH) score and the MDACC score as survival stratification tools within this population. **Results:** Among the 92 patients analyzed [Ewing's sarcoma N=47, osteosarcoma N=22, chondrosarcoma N=16, chordoma N=5, Other N= 2] median age at phase I trial referral was 24 (range 11 to 79), 58 (63%) were males; ECOG PS was zero in 25 pts (27 %), the number of metastatic sites were > 2 in 26 pts (28 %). The median number of prior chemotherapy regimens was 3 (range 0 to 11) and 57 pts (62 %) had prior radiation. Both RMH score (HR = 5.8 (2.9, 11), $p < 0.0001$) and MDACC score (HR = 3.2 (1.9, 5.6), $p < 0.0001$) were successfully validated. Responses were seen in IGF1R +/-mTOR therapy in Ewing's sarcoma and Apo2L/TRAIL in chondrosarcoma. No responses were seen in osteosarcoma. Ten pts (11%) had stable disease. Clinical benefit rate (CR+ PR+SD > 6 mo) was 18% (17 pts). **Conclusions:** Both the RMH and MDACC prognostic scores were validated for predicting overall survival in patients with bone cancers who were referred for phase 1 trials. Responses were seen with targeted therapies in Ewing's sarcoma and chondrosarcoma, however prognosis remains poor. Novel approaches are urgently needed for bone sarcomas.

**10532 Poster Highlights Session (Board #20), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Results of a randomized prospective clinical trial evaluating maintenance chemotherapy in patients with high-grade, operable osteosarcoma: A report from the Latin American Group of Osteosarcoma Treatment.** *Presenting Author: Antonio Sergio Petrilli, Instituto de Oncologia Pediatrica IOP/ GRAACC - UNIFESP, Sao Paulo, Brazil*

**Background:** Preclinical models show that a daily antiangiogenic regimen at low-dose may be effective against chemotherapy-resistant tumors. In patients (pts) with high grade, operable osteosarcoma (OST) of the extremities, efficacy of maintenance therapy with continuous oral cyclophosphamide and methotrexate was investigated. **Methods:** Pts ≤30yrs with high-grade OST were eligible for registration at diagnosis. Eligibility for randomization included: 1. Non-metastatic pts 2. high-grade extremity OST 3. receipt of two cycles pre-operative methotrexate, doxorubicin, cisplatin (MAP); 4. complete macroscopic resection of primary tumor. The study design includes a backbone of 10 weeks of preoperative therapy using MAP. Following surgery, non-metastatic pts were randomized by blocks to complete 31 weeks of MAP or to receive 73 weeks of maintenance therapy following MAP; while metastatic pts received maintenance therapy in combination with MAP since the beginning of treatment. The primary end point was event-free survival (EFS) from randomization. **Results:** Of the 682 pts registered (April, 06 to July, 13) from 3 countries (27 sites), 535 were evaluable, mean age at enrollment of 13.5 years, mean time to diagnosis of 3.8 months and metastatic disease in 38% of the pts. The multivariate analysis showed that metastases at diagnosis ($p<0.001$), necrosis grades 1 and 2 ($p=0.001$) and amputation ($p=0.02$) were associated with a shorter EFS. In the whole cohort of pts, overall survival (OS) was 62% at 5 years and event free survival (EFS) was 50%. For non-metastatic pts, OS was 72% and EFS was 60%. There was *no significant* difference in *EFS*between pts who received MAP+maintenance chemotherapy *compared*with *MAP alone* (61% vs 64%, log-rank test $p=0.3$). **Conclusions:** OST survival rates were improved by the use of this regimen compared with previously reported results by the group. However, with current follow-up, EFS for MAP+maintenance chemotherapy is not statistically superior to MAP alone in pts with high-grade resectable OST of the extremities. Further follow-up for events and survival continues.

**10533^ Poster Highlights Session (Board #21), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A nonrandomized phase II trial of sorafenib (S) and everolimus (E) in unresectable metastatic osteosarcoma (OST) patients (pts) relapsed after standard chemotherapy.** *Presenting Author: Giovanni Grignani, Sarcoma Unit, Division of Medical Oncology, IRCCS Istituto di Candiolo, Candiolo, Italy*

**Background:** After standard therapy OST relapse is an ominous event almost uniformly fatal in non resectable cases. Our group explored the activity of the multikinase inhibitor S demonstrating a short-lasting tumor growth arrest and 8% objective responses (OR). We hypothesized that other pathways might be responsible for S failure and we showed mTOR as a reasonable co-target to hit by means of E. **Methods:** Pts>17 years with relapsed unresectable OST, progressing after standard treatment, were eligible to receive S 400 mg b.i.d + E 5 mg once daily until progression (PD) or unacceptable toxicity. We designed a Simon two-stage study with progression-free survival rate at 6 months (PFS@6m) as the primary endpoint. With $\alpha=5\%$, $\beta=10\%$, 37 pts were needed to test if PFS@6m was ≤25%=P0 (9 pts) or ≥50%=P1 (19 pts). Secondary endpoints were PFS, overall survival (OS), RECIST 1.1 OR, safety and their correlations with molecular markers of targeted pathways. We estimated PFS and OS by Kaplan-Meier method with their 95% confidence intervals (95% CI). All tests were two sided. **Results:** We enrolled 38 pts (15 females) from June 2011 to June 2013. PFS@6m was 45% (95%CI 28-61%, 17 pts). Median PFS and OS were 5 (95%CI 2-7) and 11 (95%CI 9-14) months, respectively. We observed 2 (5%) partial responses (PR), 2 minor responses (5%), 20 (53%) stable diseases (SD) for an OR of 10%. PR/SD lasted ≥ 6 months in 8 (21%) pts (6, 6, 7, 8, 8, 8, 10, 11). 1 pt interrupted the study because of lung metastasectomy after 10 months of disease control. Treatment was feasible but demanded both dose reductions and short interruptions for both drugs in 25 (66%) pts due to toxicity Treatment was permanently discontinued in 2 (5%) pts due to toxicity. Results of the correlation of ERK1 and pS6 expression with primary and secondary endpoints will be presented at the meeting. **Conclusions:** S + E showed activity in terms of PFS@6m as second- or further-line treatment in advanced unresectable OST with some long-lasting responses. Toxicity was manageable but required short interruptions, dose reductions and few permanent discontinuations. Despite some hints of activity, S + E failed to reach the prespecified target of PFS@6m. Clinical trial information: NCT01804374.

**10534 General Poster Session (Board #241), Mon, 8:00 AM-11:45 AM**

**Efficacy of novel proteasome inhibitory platinum complex against osteosarcoma.** *Presenting Author: Kentaro Igarashi, Department of Orthopaedic Surgery, Kanazawa University, Kanazawa, Japan*

**Background:** We have developed novel proteasome inhibitory mononuclear platinum compound; 1Pt. We have already reported in vivo study of this compound against osteosarcoma cell lines. Now, we performed comparative studies of our novel proteasome inhibitory platinum compounds against cisplatin resistant osteosarcoma cell lines. And we performed in vitro study using orthotopic mouse model. Then, we also accessed expression of apoptosis related protein after drug exposure. **Methods:** The novel proteasome inhibitory platinum complex was synthesized by Prof. Odani. Cisplatin and proteasome inhibitory platinum were used in this study. Three cell lines (MG63, 143B, and LM8) and three cisplatin resistant cell lines (MG63cis-R, 143BcisR, LM8-cisR) were used. Cell survival after a 72 hrs exposure to these compounds was assessed by WST-8 assay, and IC50 value was calculated for each compound. Apoptosis was assessed by DNA fragmentation and Annexin V / PI assay. DNA double-strand breaks were assessed by acetylation of histon H2AX. Proteasome inhibitory activity was assessed by 20S proteasome assay kit. Expression of apoptotic related protein was accessed by western blotting. In vivo, 143B was transplanted to the tibia of nude mice, and treated with each drugs. **Results:** Both compound strongly caused concentration-dependent cytocidal effect. IC50 value of 1Pt was relatively high. 1Pt does not show cross resistance to cisplatin. Apoptosis induction and acetylation of histon H2AX were observed. Proteasome activity was surpressed after 1Pt administration. Expression of apoptotic related protein was up-regulated after 1Pt exposure. In orthotopic mouse model, 1Pt showed stronger anti-tumor effect, in dose escalation model, compared to cisplatin. **Conclusions:** 1Pt showed moderate anti-tumor activity against osteosarcoma cell line in vitro and showed suppression of proteasome activity. 1Pt had no cross resistance to cisplatin. In ortotopic mouse model, 1Pt showed stronger anti-tumor activity compared to cisplatin.

**10535 General Poster Session (Board #242), Mon, 8:00 AM-11:45 AM**

**Impact of excision repair cross-complementation group 1 (ERCC1) protein on survival of patients with osteosarcoma treated with cisplatin-based chemotherapy.** *Presenting Author: Kentaro Igarashi, Department of Orthopaedic Surgery, Kanazawa University, Kanazawa, Japan*

**Background:** Excision repair cross-complementation (ERCC) genes encode proteins that participate in nucleotide excision repair, and these proteins are crucial for preventing DNA damage caused by cisplatin and its low expression correlates with better survival after cisplatin-based chemotherapy in several cancers. We retrospectively evaluated the relationship between expression of the excision repair cross-complementation 1 (ERCC1) protein and outcome in patients with osteosarcoma treated with cisplatin-based chemotherapy. **Methods:** Medical records and tissue samples from 105 patients with a histologically confirmed diagnosis of high-grade osteosarcoma previously treated with cisplatin-based chemotherapy (K2 protocol) were retrospectively analyzed. They were 61 males and 44 females with the mean age of 23.3 years (range 5–76). A Immunohistochemical staining of biopsy specimen was used to assess the expression of ERCC1. **Results:** Thirty-two (30%) samples were ERCC1-positive. Metastasis at diagnosis, chondroblastic subtype, poor response to chemotherapy, and positive ERCC1 expression were associated with poor event free survival ($P = 0.044$, $P = 0.039$, $P = 0.003$, and $P = 0.001$ respectively). Trunk location, metastasis at diagnosis, chondroblastic subtype, poor response to chemotherapy, and positive ERCC1 expression were associated with poor overall survival ($P = 0.006$, $P < 0.001$, $P = 0.012$, $P = 0.018$ and $P < 0.001$ respectively). Patients with an ERCC1-negative tumor had a significantly longer event-free survival (113.7 versus 55.5 months; $P = 0.001$) and overall survival (198.9 versus 99.6 months; $P < 0.001$) compared with the group positive for ERCC1. Multivariate analysis for event-free survival and overall survival confirmed that the absence of ERCC1 expression correlated with longer event-free survival (HR 2.297, 95% CI 1.284–4.106, $P = 0.005$) and longer overall survival (HR 3.220, 95% CI 1.329–7.800, $P = 0.010$). **Conclusions:** We confirmed that ERCC1 expression is predictive of outcome in osteosarcoma patients treated with cisplatin-based chemotherapy. Patients with ERCC1-negative tumors showed an increased survival rate.

**10536 General Poster Session (Board #243), Mon, 8:00 AM-11:45 AM**

**Molecular targeted therapy for osteosarcoma using glycogen synthase kinase-3 beta (GSK-3$\beta$) inhibitors.** *Presenting Author: Shingo Shimozaki, Department of Orthopedic Surgery, Kanazawa University, Kanazawa, Japan*

**Background:** Chemotherapy for osteosarcoma has improved the 5-year survival rate in osteosarcoma patients to 70%. However, development of new therapies for osteosarcoma is warranted, as chemotherapy is associated with several disadvantages such as toxicity and drug resistance. Although use of molecular targeted therapies has been reported for many types of cancer, their use in osteosarcoma treatment has not been reported yet. Glycogen synthase kinase-3 beta (GSK-3$\beta$) has been reported to sustain tumor cell survival, proliferation, and invasion in some types of cancer. Accordingly, GSK-3$\beta$ has emerged as a potential therapeutic target for the treatment of cancer. **Methods:** Four osteosarcoma cell lines and 1 osteoblast cell line were used for this study. Each cell line was treated with the GSK-3$\beta$ inhibitors, AR-A014418 and SB-216763. GSK-3$\beta$ activity was analyzed for all cell lines using western blotting analysis. Cell viability and proliferation were analyzed using the WST-8 assay kit and the BrdU ELISA kit, respectively. Apoptosis that occurred after treatment with GSK-3$\beta$ inhibitors was analyzed using the TUNEL imaging assay kit. **Results:** The expression of the active form of GSK-3$\beta$ was high in all osteosarcoma cell lines as determined by western blotting analysis. Cell proliferation was suppressed in the 4 osteosarcoma cell lines 48 hours after the administration of GSK-3$\beta$ inhibitors, but not in the osteoblast cell line. The $IC_{50}$ of the GSK-3$\beta$ inhibitors for each osteosarcoma cell line was below 20 $\mu$M. The t-test analysis showed a significant difference in cell proliferation in the osteosarcoma cell lines between the AR-A014418-treated group and the control group. Apoptosis was seen in all osteosarcoma cell lines but not in the osteoblast cell line. **Conclusions:** It was suspected that the activity of GSK-3$\beta$ was strongly associated with cell proliferation in osteosarcoma. Our findings indicate that GSK-3$\beta$ inhibitors could have a therapeutic effect on osteosarcomas in vivo. In the future, we aim to investigate the role of GSK-3$\beta$ in osteosarcoma and to perform in vivo studies in mice transplanted with osteosarcoma cells to understand the mechanism underlying the therapeutic effect of GSK-3$\beta$ inhibitors in this tumor.

**10537 General Poster Session (Board #244), Mon, 8:00 AM-11:45 AM**

**Is non-HD–MTX based, dose-dense, combination chemotherapy a valid choice in osteosarcoma in developing world?** *Presenting Author: Jyoti Bajpai, Tata Memorial Hospital, Mumbai, India*

**Background:** Recent meta-analysis in osteosarcoma (OGS) revealed superiority of high-dose-methotrexate (HD-MTX) containing 3-drug combination chemotherapy (CTh) compared to 2-drug regimens with 5y-EFS of 54% and 46%, respectively ($p = 0.03$). The use of HD-MTX requires in-patient treatment with stringent monitoring. Non HD-MTX based CTh regimens merit evaluation especially in resource constrained scenarios. **Methods:** This prospective study evaluated the efficacy & toxicity of dose-dense CTh regimen comprising doxorubicin, ifosfamide, and cisplatin. Response to CTh was graded based on histological necrosis (HN). Good responders (GR) were defined as those with $\geq$ 90% HN. Survival analysis was performed using the Kaplan-Meier method and compared the log-rank test. Baseline disease status and nutritional parameters were correlated with outcomes. **Results:** Majority were males (61%) with a median age of 18 yrs. Thirteen (36 %) had metastatic disease. The mean lesion size was 11.5cm. Seventeen (47%) were malnourished, 9 (25%) anemic, 12 (33%) iron deficient and 15 (41%) were B12 deficient at presentation. Post CTh 21(91%) with non-metastatic and 6 (46%) with metastatic disease underwent surgery. For either group GR was 67%. At the median follow-up of 2.2yrs, 30 (84%) were surviving and 21 (59%) remained progression free. Patients with non-metastatic disease had an OS and PFS of 95% and 70% while patients with metastatic disease have an OS & PFS of 61% and 40% respectively. Survival difference between the two groups was statistically significant. Other prognostic factors like ECOG score of $\geq$ 2 & Hb levels $\leq$ 10.6 gm% had a significant impact on PFS (p=0.01 & 0.03) and OS (p =0.01& 0.05). On multivariate analysis presence of metastasis was an independent prognostic factor. During CTh 41% patients had febrile neutropenia after the first cycle and were managed successfully. **Conclusions:** Non-HD-MTX based dose-dense CTh results in acceptable disease control and toxicity in patients with non-metastatic OGS. Patients with metastatic disease probably warrant more aggressive regimens.

**10538 General Poster Session (Board #245), Mon, 8:00 AM-11:45 AM**

**A controlled, nonrandomized clinical research on chemotherapy combined with re-endostatin for stage IIB ostosarcoma.** *Presenting Author: Hairong Xu, Department of Orthopedic Oncology Surgery, Beijing Ji Shui Tan Hospital, Peking University, Beijing, China*

**Background:** The aim of this study was to investigate the efficacy and safety of chemotherapy combined with re-endostatin (endostar) against stage IIB ostosarcoma. **Methods:** Patient of stage IIB ostosarcoma enrolled in Beijing Jishuitan Hospital from January 2008 to April 2012 were divided into combined group and control group. The chemotherapy regimen was as follows: methotrexate 10 g/m$^2$ iv $d_1$, ifosfamide 3 g/m$^2$ iv $d_1$-$d_5$, cisplatin 120 mg/m$^2$ iv $d_1$, doxorubicin 30 mg/m$^2$ iv $d_1$-$d_3$. Based on the same chemotherapy, endostar was added in combined group (15 mg/m$^2$ iv $d_1$-$d_{14}$, 21 days was a cycle, for 4 cycles). **Results:** A total of 388 patients were enrolled in this study, and 58 cases were excluded in the final analysis. A total of 330 patients could be evaluated, in which 272 cases were in control group and 58 in combined group. Patients were followed up 6-59 months with a median period of 20.2 months. In the control group, 1-, 2- and 3-year distant metastasis-free survival rates were 79%, 70% and 65%, respectively, while those of combined group were 93%, 86% and 77% ($p = 0.045$). In the control group, 1-, 2- and 3-years of progression-free survival rates were 76%, 66% and 60%, respectively, while those of combined group were 90%, 83% and 74% ($p = 0.025$). In the control group, 1-, 2- and 3-year overall survival rates were 94%, 84% and 79%, while those of combined group were 98%, 94% and 85% ($p = 0.220$). The side effects in two groups were mainly in grade 1-2, and the common grade 3-4 side effects were leucopenia, anemia, hepatic dysfunction, nausea and vomiting. There was no difference in side effects of the two groups. **Conclusions:** The combination of chemotherapy and endostar can significantly improve the distant metastasis-free survival and progression-free survival in osteosarcoma patients, with tolerable side effects, worthy of further study.

**10539 General Poster Session (Board #246), Mon, 8:00 AM-11:45 AM**

**Dendritic cells immunotherapy for patients with malignant bone and soft tissue tumors.** *Presenting Author: Hideji Nishida, Department of Orthopedic Surgery, Kanazawa University, Kanazawa, Japan*

**Background:** We evaluated the safety and feasibility of autologous dendritic cell (DC) immunotherapy for patients with malignant bone and soft tissue tumors. **Methods:** Forty one patients were enrolled and immunized with DCs. Patient tumors comprised twenty one malignant bone tumors, seventeen malignant soft tissue tumors, and three metastases. 1st generation of DC immunotherapy was started in 2008. Autologous DCs were generated ex vivo and pulsed with original tumor lysate and OK-432. For the 2nd generation, we added TNF-$\alpha$- pulsed with tumor lysate. 3rd generation was DC immunotherapy incorporated low dose cyclophosphamide. Each patient received 2-5 x $10^6$cells one time a week for 6 weeks. **Results:** Immunizations were well tolerated by patients with only local redness at the injection site in 9 cases. Levels of interferon-gamma and interleukin-12 cytokines were increased after DC immunotherapy in twenty six patients (65%), eighteen of whom (44%) subsequently developed delayed-type hypersensitivity. At the final follow-up, one patient had partial response, eight patients had stable disease and thirty two patients had progressive disease. **Conclusions:** Although improvement of clinical efficacy requires further research, toxicity-free immunization by tumor lysate- and OK-432-pulsed DCs is safe and feasible in patients with malignant bone and soft tissue tumors.

**10540 General Poster Session (Board #247), Mon, 8:00 AM-11:45 AM**

**Outcome and prognostic factors in localized osteosarcoma with uniform chemotherapy protocol: A single-center experience of 234 cases.** *Presenting Author: Vijaya Murugan, DR BRA IRCH, All India Institute of Medical Sciences, New Delhi, India*

**Background:** Data on outcome of localized Osteosarcoma (OS) treated with uniform protocol is limited from Asia. **Methods:** This is a single institutional review of patients treated between Jan 2004-Dec 2012, and evaluated on per protocol analysis. All patients received uniform chemotherapy protocol with cisplatin, doxorubicin as neo-adjuvant chemotherapy (NACT), followed by surgery and adjuvant chemotherapy (ACT) based on risk stratification. **Results:** 234 OS patients were treated with median age 17 years (range: 2–66), Male: Female: 2:1, tumor diameter 9 cm (range: 1-25) and symptom duration 4 months (range: 1-36). Sites of disease were extremities 93%, pelvis 2 % and head & neck 5%. Of them 218 (93.2%) received NACT and 16 (6.8%) underwent upfront surgery. Post-NACT, 4(1.7%) were in CR; 152(66%) in PR with ORR 67.7%. Of the 218 patients who received NACT, 198 (90.8%) underwent surgery (70.2%- Limb salvage, 29.8%-Amputation). On histological examination, 47(28.4%) achieved >90% tumor necrosis while 118(71.6%) achieved <90% tumor necrosis. Adjuvant chemotherapy was given to 198 (84.6%) patients with median of 5 cycles. At median follow-up of 68 months (range: 2–119), 5-year EFS, overall survival were 39.5%, 51.5% respectively. Multivariate analysis showed tumor site and tumor necrosis as significant risk factors for EFS and OS respectively. **Conclusions:** This is largest single institutional study of localized osteosarcoma from Asia which constituted 70% of entire cohort with delayed presentation. More than 2/3$^{rd}$of patients had successful limb salvage chemotherapy after NACT. Extremities OS with post NACT tumor necrosis >90% had best outcome.

**Gemcitibine (G) and docetaxel (D) in relapsed and unresectable high-grade osteosarcoma after failure of standard multimodal therapy.** *Presenting Author: Emanuela Palmerini, Istituto Ortopedico Rizzoli, Bologna, Italy*

**Background:** The prognosis of relapsed and unresectable high-grade osteosarcoma is poor and has remained unchanged for decades. Increased survival for metastatic soft tissue sarcomas was previously shown with the combination G+D compared to G alone (Maki R, JCO 2007). Thus, we explored G+D activity in patients (pts) with relapsed and unresectable osteosarcoma / spindle cell pleomorphic sarcoma. **Methods:** Pts progressing after standard treatment were eligible to receive G 900 mg/m$^2$day 1, 8 + D 75 mg/m2 day 8, every 21 days, until progression or unacceptable toxicity. The primary end point was progression-free survival (PFS) at 4 months (mo). Secondary objectives were overall survival (OS) and disease control rate (DC), defined as complete response (CR), partial response (PR) or stable disease (SD) lasting at least 6 months. **Results:** We enrolled 46 pts. Median age was 18 (8-71): 26 pts pediatric pts, 20 adult. Line of treatment: 14 pts in 1$^{st}$line; 32 pts were in ≥ 2nd line (up to 5). Pattern of metastases: 26 pts lung only, 20 multiple sites. Histology: 35 pts classic osteosarcoma, 11 high grade spindle cell sarcoma (HGS). ECOG: 31 pts 0, 11 pts 1, 4 pts 2. 41 pts were evaluable for RECIST response (2 pts off study for D allergic reaction, 1 pt for G4 skin toxicity, 2 pts with no measurable lesions). 4-mo PFS rate was 47%. 4-mo PFS was significantly better for ECOG 0 pts (ECOG0: 57% vs ECOG 1: 37% vs ECOG 2: 0%; p= 0.01), with a trend to superiority in pts with lung only metastases (lung only: 58%; multiple sites: 35%; p=0.09), and classic osteosarcoma (classic osteosarcoma 50% vs. HGS 22%; p=0.2), while there was no difference according to age or line of treatment. PFS and OS at 6 mo were 23% and 71%, respectively. Tumor responses: CR: 0/41, PR: 5/41 (12%), SD 18/41 (44%), progressive disease (PD) 18/41 (44%); DC: 8/41 (20%). **Conclusions:** G+D demonstrated activity in pre-treated relapsed high grade classic osteosarcoma pts, especially in pts with ECOG 0 and lung only disease. This combination should be included in the therapeutic armamentarium of metastatic osteosarcoma as an active line of therapy.

**10542 General Poster Session (Board #249), Mon, 8:00 AM-11:45 AM**

**Osteosarcoma of the head and neck (OHN): A multicenter case series of 79 adult patients in the Netherlands.** *Presenting Author: Eline Boon, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** OHN is rare and behaves differently from osteosarcoma in the extremities. There is an ongoing debate about the value of (neo-) adjuvant chemotherapy in OHN. In this study we describe the general practice and outcome of patients (pts) treated for OHN in the Netherlands, with special attention to the efficacy of chemotherapy on overall survival (OS). **Methods:** A retrospective cohort study was conducted within the Dutch Head and Neck Society. All pts >16 years of age treated for OHN between 1993-2013 were included in this analysis. Review of pathology for tumors with uncertain grading was performed. Kaplan-Meier survival analysis and log rank testing were performed. **Results:** Seventy-nine pts with OHN were included, 42 (53%) female, median age 46 years (range 16-95). Twenty-five (32%) pts had a prior malignancy, 19 (24%) pts received previous radiotherapy to the head and neck region. Most common tumor location was the jaw, with 32 (40%) mandibular and 26 (33%) maxillary tumors. A total of 17 (22%) pts received (postoperative) radiotherapy. All 12 (15%) low grade OHN pts underwent a resection, without chemotherapy and had a 5 year OS of 90%. Fifty-six (71%) pts had a high grade OHN; 50/56 (89%) were operated and 25/50 (50%) received (neo-) adjuvant chemotherapy. In the 50 resected high grade OHN pts, 5 year OS was 73% versus 36% for pts treated with or without (neo-) adjuvant chemotherapy, respectively (p = 0.004). The 5 years local recurrence rate in high grade resected OHN pts was 15% versus 63% in pts treated with and without (neo-) adjuvant chemotherapy, respectively (p = 0.006), whereas the risk of distant metastases was not significantly different (13% versus 39%, respectively p = 0.08). The 5 year OS of the 56 high grade OHN was 30% versus 56% in pts with or without a prior malignancy, respectively (p = 0.08). **Conclusions:** Pts with high grade resected OHN have a better OS when treated with (neo-) adjuvant chemotherapy. Remarkably, local recurrence rate is significantly lower in resected OHN pts treated with (neo-) adjuvant chemotherapy, whereas no significant difference in distant metastases rate was shown.

**10543 General Poster Session (Board #250), Mon, 8:00 AM-11:45 AM**

**Mouse models to study cancer stem cells in osteosarcoma.** *Presenting Author: Nino Carlo Rainusso, Texas Children's Hospital, Baylor College of Medicine, Houston, TX*

**Background:** Osteosarcoma (OS) is the most common malignant bone tumor in children and young adults. Many patients suffer disease recurrence and eventually die from metastatic disease that has spread to the lungs. Clearly, more research is needed to understand the biology and molecular mechanisms driving OS metastasis and chemoresistance. The identification of cancer stem cells (CSCs) in solid tumor malignancies, mainly carcinomas and brain tumors, has expanded our knowledge about tumor heterogeneity and its role in tumorigenesis, metastasis and therapy resistance. However, similar research accomplishments have not been established in sarcomas. **Methods:** We performed our experiments aimed to identify OS stem cells using two distinct mouse models: a genetically engineered mouse model that carries an osteoblast-specific p53 mutation and a syngenic (DLM8 tumor cells orthotopically injected in C3H mice) mouse model. **Results:** We observed that murine tumor cells obtained from freshly isolated tumors developed sphere-like structures (sarcospheres). Sarcophere forming capacity was significantly increased in tumor cells obtained from metastatic lesions. We found that both OS models contain ALDH Hi (stem-like) cells. The high expression of ALDH ranged from 0.7 to 17%. Further analysis showed that distal metastases contained up to 10 times more ALDH Hi cells than the primary bone tumors. Moreover, we performed microarray analysis of primary bone tumors, pulmonary nodules and CSCs in both primary and metastatic sites, and found that 159 genes were differently expressed between bone and metastatic lung OS tumors. Our preliminary data showed that genes involved in the biologic processes of bone development, mesenchymal differentiation and skeletal morphogenesis were enriched in ALDH Hi cells in primary bone tumors, and genes involved in immune response, inflammatory response and cytokines/chemotaxis were up-regulated in ALDH Hi cells in metastatic tumors. **Conclusions:** We have identified putative OS stem cells in two immunocompetent mouse models of metastatic OS. Our preliminary data have shown that CSC content seems to be increased in metastases.

**10544 General Poster Session (Board #251), Mon, 8:00 AM-11:45 AM**

**Association of ABCG2 polymorphism with clinical efficacy of imatinib in patients with gastrointestinal stromal tumor.** *Presenting Author: Dong Hoe Koo, Division of Hematology/Oncology, Department of Internal Medicine, Kangbuk Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** Imatinib is a substrate of drug metabolizing enzymes, including those of the cytochrome P450 (CYP) system, and of several drug transporters. Differences in imatinib pharmacokinetics among individual patients may be influenced by genetic polymorphisms and be associated with clinical imatinib efficacy. This study evaluated the correlation of genetic polymorphisms with trough imatinib levels and clinical efficacy in GIST patients. **Methods:** A total of 209 patients with GIST who had received imatinib (400 mg daily) were genotyped for 6 single-nucleotide polymorphisms in 3 genes (CYP3A5 6986A>G; ABCB1 1236C>T, 2677G>A/T, and 3435C>T; and ABCG2 34G>A and 421C>A) via blood samples. Imatinib plasma trough levels and progression-free survival (PFS) were analyzed for association with each genotype. **Results:** With a median follow-up of 39.6 months (range, 16.7-97.5 months), the estimated 5-year PFS rate was 67.5% (95% CI, 59.9-75.1). Among the CYP3A5, ABCB1, and ABCG2 genotypes, there were no significant differences in imatinib plasma trough levels or PFS, while ABCG2 421C>A was associated with PFS. The 5-year PFS rate in patients with the AA variant of ABCG2 421C>A (92.3%; 95% CI, 77.8-100.0) was significantly superior to that of patients with CC/CA genotypes (65.0%; 95% CI, 56.9-73.1) (P = 0.047). **Conclusions:** The ABCG2 421C>A genetic variation could influence clinical efficacy in terms of PFS in patients with advanced GIST undergoing imatinib treatment.

**10545 General Poster Session (Board #252), Mon, 8:00 AM-11:45 AM**

**Impact of underestimation of risk on treatment duration and recurrence in GIST patients.** *Presenting Author: Annie Guérin, Analysis Group, Inc., Montréal, QC, Canada*

**Background:** Adjuvant imatinib therapy has been shown to reduce risk of recurrence and improve survival in gastrointestinal stromal tumor (GIST) patients (pts) who had complete tumor resection. Though different tools are available, the revised NIH criteria are most widely used to assess recurrence risk and help determine treatment duration. This study analyzed the impact of risk under-estimation on under-treatment and recurrence in GIST pts. **Methods:** An online questionnaire was used to collect chart data on 506 pts with primary resectable KIT+ GIST from 109 US oncologists. By comparing the risk of recurrence evaluated by NIH criteria based on primary tumor characteristics vs. physicians' assessment noted in pts' charts, pts' recurrence risks were categorized as underestimated, consistent, or overestimated. Under-treatment was defined for high risk pts as <36 months of planned adjuvant imatinib therapy (NCCN Guidelines). The impact of underestimated risk on under-treatment and recurrence were analyzed using GEE logistic and Cox proportional hazard regression models, adjusting for potential confounding factors. **Results:** Risk of recurrence was underestimated in 37.5% of pts (53.4% consistent; 9.1% over-estimated). Among the 65.8% of pts who were at high risk (NIH criteria), 50.8% had their risk underestimated. Pts with intermediate tumor size, intermediate mitotic count, and non-gastric primary tumor were the most likely to have their risk underestimated; 46.8% of underestimated pts had a tumor >5-10cm, 64.7% had a mitotic count 6-10/50 HPF, and 70.0% had non-gastric tumor. High risk pts who had their risk underestimated (vs. not underestimated) were more likely to be under-treated (OR=2.26, $p$=.001). Among all GIST pts, those with underestimated risk (vs. not underestimated) had a significantly higher hazard of recurrence (hazard ratio=1.81, $p$=.028). **Conclusions:** Underestimation was found to lead to under-treatment in high risk pts and an overall higher risk of recurrence. Given the high proportion of pts with underestimated risk, these findings suggest that with more consistent and systematic approaches to assess risk, overall recurrence-free survival could be improved in GIST patients.

**10546 General Poster Session (Board #253), Mon, 8:00 AM-11:45 AM**

**Correlation of PET/CT and CT RECIST response in GIST patients with PDGFRA D842V gene mutations treated with crenolanib.** *Presenting Author: Jennifer Madeline Matro, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Crenolanib (CP-868,596) is an orally bioavailable, selective inhibitor of platelet derived growth factor receptor (PDGFR) tyrosine kinase, with in vitro studies demonstrating activity against PDGFRA D842V mutant cell lines. A phase II study evaluated antitumor efficacy of crenolanib in patients (pts) with advanced gastrointestinal stromal tumor (GIST) with PDGFRA D842 related mutations and deletions. An exploratory objective evaluated metabolic response after 1 cycle of therapy as a predictor of RECIST response, so positron emission tomography/computerized tomography (PET/CT) data was available for a majority of pts. We present the results of this exploratory objective. **Methods:** Pts with advanced GIST with PDGFRA D842 related mutations and deletions, including D842V, with residual measurable disease were eligible for enrollment at 1 of 2 study sites. Pts with a baseline PET/CT and a follow-up PET/CT after 1 cycle were included in this analysis. One nuclear medicine specialist interpreted the scans and provided SUV estimates for index lesions at baseline and after 1 treatment cycle. RECIST measurements were provided by the local interpreting radiologist. **Results:** 12 pts treated with crenolanib had both a baseline and follow-up PET/CT after 1 cycle. Baseline FDG avidity was lower than expected for GIST based on published reports, with the exception of 1 pt who had average initial standardized uptake value (SUV) of 33. Average SUV excluding this pt was 4.6. The table shows PET metabolic response after 1 cycle and CT RECIST best response. 7 of 12 (58%) pts had non-concordant PET and CT responses, including one with partial response (PR) on PET but progressive disease (PD) on CT. **Conclusions:** In this small exploratory analysis, pts with PDGFRA D842 related mutations had lower than expected SUV activity on PET, and metabolic response did not predict response by RECIST. These results suggest that PET/CT may not be an optimal method for predicting, evaluating and following response among GIST pts with PDGFRA D842 related mutations. Clinical trial information: NCT01243346.

**MDCT and clinicopathologic characteristics of small bowel gastrointestinal stromal tumors (GISTs) in 102 patients: A single-institute experience.** *Presenting Author: Akshay D Baheti, Department of Imaging, Dana-Farber Cancer Institute, Boston, MA*

**Background:** SB is the 2nd most common site of GISTs and has worse prognosis than gastric GIST. We evaluated clinical presentation, pathology and imaging features of SB GIST. **Methods:** Imaging and clinicopathologic data of 102 pts (53M, 49F; mean age: 55 yrs; range: 19-83 yrs) with jejunal/ ileal GIST treated at our institute between 2002 and 2013 was reviewed. 2 radiologists in consensus reviewed imaging of treatment-naive primary in 41 pts and follow-up imaging in all pts. **Results:** 90/102 pts weresymptomatic at presentation (abdominal pain= 50, GI bleed= 40). Site of origin: jejunum= 64, ileum= 38. Risk stratification: low= 21; intermediate= 17; high= 64. Mean tumor size= 8.5 cm (range: 1-28 cm). On baseline CT (n= 41), tumors were predominantly well circumscribed and smooth/ mildly lobulated in contour. 22/41 tumors were exophytic, 16 had both exophytic and intraluminal components and 3 were intraluminal. 16/41 tumors were homogenous; 25 were heterogenous. Cystic/ necrotic areas (HU<20) were seen in 16/41 and calcification in 9. 14 homogenous (87%) and 16 heterogenous (64%) tumors had mitotic index $^{2}$5. CT demonstrated tumor-bowel fistula in 7/41, intraperitoneal rupture in 2 and bowel obstruction in 4. Amongst 102 total pts, metastases developed in 51 (27 at presentation), predominantly involving peritoneum and liver (refer table). 7/8 (87%) pts presenting with intraperitoneal rupture developed metastases. Metastases elsewhere were always associated with hepatic/ peritoneal metastases. At last follow-up, 28 pts were deceased (median survival 65 months, range: 22-179 months). **Conclusions:** SB GISTs were often symptomatic at presentation, high risk on pathology and had greater propensity for peritoneal metastases. On CT, they were predominantly large, well-circumscribed, exophytic tumors with or without cystic/ necrotic areas. Complications like rupture and bowel obstruction must be looked for.

**Do CT features predict the behavior of treatment-naive gastric GIST?** *Presenting Author: Ailbhe C O'Neill, Dana-Farber Cancer Center Institute, Boston, MA*

**Background:** Risk stratification of gastric GIST is currently based on size and mitotic count. Patients with large primary tumors often undergo neoadjuvant treatment with imatinib which limits the assessment of mitotic count in the final resection specimen. Since most patients with gastric GIST undergo pretreatment CT, risk-assessment based on the CT features would be helpful. Therefore, we aimed to assess if pre-treatment CT features can predict the metastatic potential and overall survival (OS) of gastric GIST. **Methods:** In this IRB approved retrospective study, CT images of 164 patients with pathologically confirmed treatment-naive gastric GIST (88 men; mean age 60 years, SD 13.8) were reviewed in consensus by two radiologists blinded to clinicopathologic features and outcome. The metastatic spread and OS was then recorded using available imaging studies and electronic medical records (median follow up 33 months, IQR 18-56). Predictors of metastatic disease were analyzed using univariate and multivariate (logistic regression) analysis. Effect of the identified predictors on OS was assessed using Log-Rank test. **Results:** Metastatic disease developed in 51 patients (31%) and 25 (15%) patients died. Tumor size ≥10cm (p=0.02, OR 5.27), irregular/lobulated margin (p=0.009, OR 3.45) and hyperenhancing solid component (p=0.0015, OR 6.68) were independent predictors of metastatic spread. Presence of two or more of these three features predicted a worse OS (p=0.002). **Conclusions:** Irregular/ lobulated margin, presence of hyperenhancing solid component and tumor size ≥10 cm on pretreatment CT predict worse outcome of gastric GIST.

**Correlation of *KIT* and *PDGFRA* mutational status with clinical benefit in patients (pts) with gastrointestinal stromal tumor (GIST) treated with sunitinib (SU) in a worldwide treatment-use (TU) trial.** *Presenting Author: Peter Reichardt, HELIOS Klinikum Bad Saarow, Bad Saarow, Germany*

**Background:** This study retrospectively explored the role of *KIT* and *PDGFRA* mutations in response to SU therapy in pts with imatinib (IM)-resistant/intolerant GIST in a worldwide TU trial. **Methods:** SU was administered at a starting dose of 50 mg/day on a 4-week-on, 2-week-off schedule in the TU study. Clinical outcome data (PFS and ORR, both investigator-assessed per RECIST 1.0, and OS) from the TU study were correlated with *KIT/PDGFRA* mutational data obtained with IRB approval in the present correlative study. Tumor tissue utilized for molecular status determination was obtained pre-IM, post-IM−pre-SU, or post-SU treatment. All available data were used in all analyses regardless of time of collection. Mutational status was provided by investigators following local laboratory analyses. The primary analysis compared median PFS in pts with primary *KIT* exon 11 vs. exon 9 mutations using a 2-sided log-rank test. Similar methods were used for OS; ORRs were compared using a 2-sided Pearson $\chi^2$ test. **Results:** Of 1124 pts in the TU study, genotyping data were available or generated for 230 (20%), all of which were included in the present study. Study population and clinical outcomes were representative of the full TU study population. Prior IM therapy was discontinued due to resistance in 92% of pts and intolerance in 8%. 197 pts (86%) had primary *KIT* mutations, mainly in exon 11 (62%) or exon 9 (18%). Of 101 pts with additional *KIT* mutation data (44%), 26 (26%) had another *KIT* mutation (12% in exon 13, 12% in exon 17, 1% in exon 11, and 1% classified as "other"). 12 pts (5%) had a primary *PDGFRA* mutation, including 5 (2%) in exon 18. Pts with primary *KIT* exon 9 mutations had better outcomes vs. those with exon 11 mutations: median PFS, 12.3 vs. 7.0 months (HR, 0.59; P=0.011); median OS, 26.3 vs. 16.3 months (HR, 0.55; P=0.002); ORR, 19.0% vs. 6.3% (P=0.012). There were insufficient data to analyze the effects of *PDGFRA* or additional *KIT*mutations. **Conclusions:** The distribution of *KIT*/*PDGFRA* mutations in IM-resistant/intolerant pts with GIST and clinical outcomes observed with SU treatment were consistent with previous reports. Clinical trial information: NCT01459757.

**10550 General Poster Session (Board #257), Mon, 8:00 AM-11:45 AM**

**Analysis of serum protein biomarkers and circulating tumor (ct) DNA for activity of dovitinib in patients (pts) with tyrosine kinase inhibitor (TKI)-refractory gastrointestinal stromal tumors (GIST).** *Presenting Author: Changhoon Yoo, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

**Background:** Dovitinib is a multikinase inhibitor targeting VEGFR, FGFR, PDGFR beta, and KIT. Serum protein biomarkers and ctDNA were analyzed for the correlation with the outcomes of dovitinib in a phase II study for TKI-refractory GIST (Br J Cancer 2013;109:2309). **Methods:** In total of 30 pts, predose serum samples were collected at day 1 of cycle 1 (n=30) and cycle 2 (28). Eight serum proteins were assessed by ELISA (Table 1). Mutation analysis was performed via BEAMing from ctDNA, isolated from baseline samples. Pts were classified by quartiles (Q) of biomarker levels and grouped as appropriate for the analyses. **Results:** With dovitinib treatment, FGF23, VEGF, VEGF-A, PIGF, and IL-8 increased by 1.5 fold (p=0.02), 1.3 (p=0.006), 1.3 (p=0.004), 6.0 (p=0.002), and 1.8 (p=0.04), respectively, and sVEGFR2 decreased by 0.8 fold (p=0.001) from baseline. Although baseline serum proteins were not associated with efficacy outcomes, pts whose sVEGFR2 decreased more (Q1-Q3) with dovitinib treatment showed better progression-free survival (PFS) than those with a smaller decrease (Q4; median 4.2 months [mo] vs 2.7 mo; p=0.02). Primary KIT mutations were identified via serum in 5 pts (2 for exon 11, and 3 for exon 9), and 100% concordant with results via tissue. Secondary KIT mutations were detected in 11 pts (37%) via serum: 10 had mutations on exon 17/18 and one on both exon 13 and 17. The presence of secondary mutations showed a tendency for shorter PFS (median 3.4 mo vs 4.2 mo; p=0.11) and significantly associated with shorter overall survival (median 5.5 mo vs 9.8 mo; p=0.02). **Conclusions:** Dovitinib modulates serum levels of circulating proteins involved in VEGF and FGF signaling. The change of sVEGFR2 might predict the outcomes of dovitinib. Secondary KIT mutations could be successfully detected from ctDNA and was associated with poor prognosis.

**Regorafenib treatment for advanced, refractory gastrointestinal stromal tumor: A report of the U.K. Managed Access Program.** *Presenting Author: Marco Maruzzo, Sarcoma Unit, Royal Marsden Hospital, London, United Kingdom*

**Background:** Tyrosine kinase inhibitors (TKI) have revolutionized the treatment of gastrointestinal stromal tumours (GIST) although most patients develop resistance to first and second-line therapies. Regorafenib, an oral multi-targeted TKI, has demonstrated benefit in previously treated GIST patients. **Methods:** We assessed safety and preliminary activity of regorafenib in patients treated within the Managed Access Programme (MAP). All consecutive patients with advanced GIST who had progressed on or were intolerant of imatinib and sunitinib were recruited from the Royal Marsden Hospital and University College Hospital. We retrospectively reviewed the data for response, toxicity and treatment duration. Response was assessed by RECIST and Choi criteria. Toxicity was graded according to CTCAE v4.0 criteria. **Results:** 20 patients were included in the MAP in the UK between 3/2013 and 9/2013. Median age was 68 (range 45-87), 65% of patients were male. Performance Status was 0-1 for 18 patients (90%), 2 for 2 patients (10%). The median treatment duration was 29 weeks (range 1-50). 18 patients were assessable for response and all patients attained a best response of at least stable disease. At a median follow-up of 6.7 months, there were 2 partial responses (11%) by RECIST and 7 partial responses (39%) according to Choi's criteria. One patient who had a PR on regorafenib had not benefited from previous sunitinib. 3 patients had disease progression and 3 patients discontinued treatment due to unacceptable toxicities; fistulation, myalgia and fatigue. 10 (50%) patients had grade 3 toxicities and 11 (55%) patients required a dose reduction. 5 patients started at reduced dose due to previous significant TKI toxicity, however 2 patients were able to be dose escalated. Median PFS and OS have not yet been reached but notably, prolonged stable disease was seen in 1 patient with exon 9 mutation and 1 patient with PDGFR D842V mutation. **Conclusions:** These data demonstrate encouraging activity of regorafenib in routine clinical practice. The documented adverse events are in line with previous trial data. Updated survival data and the role of RECIST/Choi response criteria in predicting survival will be presented.

**10552 General Poster Session (Board #259), Mon, 8:00 AM-11:45 AM**

**Second primary malignances (SPMs) in patients with gastrointestinal stromal tumors (GIST): The potential influence of imatinib treatment.** *Presenting Author: Anna Estival, Institut Català d'Oncologia Badalona- HU Germans Trias i Pujol, Barcelona, Spain*

**Background:** GISTs are relatively uncommon and predominantly sporadic tumors of the gastrointestinal tract. The high incidence of SPMs observed in patients (p) with GIST (13-20 %), has suggested a possible cause-and-effect relationship between treatment with imatinib and SPMs. Whether this concomitant occurrence is a causal association or a coincidence is not yet resolved. **Methods:** We have retrospectively analyzed the incidence of synchronous and metachronous SPMs, in all p diagnosed with GIST and treated at a single institution between 1997 and 2012. **Results:** A total of 95p were diagnosed with GIST, 18 (19%) of whom developed SPMs. For these 18p, the median age at GIST diagnosis was 61.7 years (range, 27-75). The GIST was located in the stomach in 10p (52.6%) and in the small bowel in 8 (47.4%). The SPMs were more frequent in the colon (4p), breast (4), kidney (3), esophagus (2), lymphoproliferative disease (2), bladder (2), adrenal gland (1), prostate (1), pancreas (1), vocal cord (1) and oligodendroglioma (1). 3p had more than one SPM and only one p had the diagnosis of Neurofibromatosis as a genetic sydrome. Of 14p with metachronous SPMs, GIST was the first tumor in 8p, with a median time of 53.9m (range, 4-169) between tumors. GIST was the second tumor in the remaining 6p, with a median time to diagnosis of 34.3m (range, 5-98). Only 4 of our 18p (22.2 %) received imatinib, two of whom were diagnosed with SPMs after having been treated with Imatinib. **Conclusions:** We have observed SPMs in 19% of p with GIST. The cause of this association is difficult to determine but it seems unrelated to imatinib treatment. The potential non-random association between GIST and other malignances merits further investigation.

**10553 General Poster Session (Board #260), Mon, 8:00 AM-11:45 AM**

**Prognostic value of miR-196, IDO, and AXL in patients (p) with localized gastrointestinal stromal tumors (GIST).** *Presenting Author: Jose Luis Cuadra-Urteaga, Institut Català d'Oncologia Badalona- HU Germans Trias i Pujol, Universitat Autònoma de Barcelona, Badalona, Spain*

**Background:** GIST is the most common gastrointestinal sarcoma. Miettinen criteria (Mc) define the risk of recurrence. Overexpression of miR-196 has been associated with high risk of relapse, metastasis and poor survival. Overexpression of AXL and IDO have been related to resistance to imatinib mesilate (IM). To date, the prognostic value of these molecular markers has not been examined. **Methods:** We retrospectively reviewed 40 p with localized GIST diagnosed between 2003 and 2012 in a single institution. Clinical and pathological variables and the expression levels of miR-196, AXL and IDO were correlated with outcome. **Results:** 52.5% of p were female; mean age was 59.3 years. GISTs were located mainly in the stomach (50%) and small intestine (42.5%). 67.5% were spindle cell tumors; 70% had $<5$ mitoses per 50 high-power fields. Risk of relapse was high for 45% of p. The capsule was broken in 5 p, and resection was incomplete in 2. cKIT mutations were present in exon 9 in 17.5% of p and in exon 11 in 62.5%. Adjuvant IM was administered in 5 p. 22.5% of p relapsed. Median progression-free survival (PFS) was 39.5 months (m) (95% CI, 7-201 m). A negative effect on PFS was observed for Mc high risk ($P=0.001$), cKIT mutation at exon 9 ($P=0.013$), and a broken capsule ($P=0.034$). Overexpression of miR-196 was associated with shorter PFS in all patients ($P=0.001$) and in the subgroups of p with Mc high risk ($P=0.023$) or with cKIT exon 9 mutations ($P=0.012$). No correlation was observed between expression of AXL or IDO and PFS. Median overall survival was not reached. **Conclusions:** Among p with localized GIST, those with Mc high risk, a broken capsule, or cKIT mutations in exon 9 had shorter PFS. Overexpression of miR-196 has emerged as a potential molecular marker of high risk of recurrence in GiST p which merits further investigation.

**10554 General Poster Session (Board #261), Mon, 8:00 AM-11:45 AM**

**Metastatic pattern of late metastases of gastrointestinal stromal tumors and the contribution radiation therapy for disease control.** *Presenting Author: Peter Hohenberger, University Medical Center Mannheim, Department of Surgery, Mannheim, Germany*

**Background:** Metastases to the liver and the peritoneum are the typical locations of tumor spread in GIST. Effective 2nd and 3rd line therapies beyond imatinib lead to advanced GIST as a chronic disease. Newly arising metastases after 4 years of being stable on TKIs is a rare event. We were interested to analyze the pattern of late metastases and evaluated the effects of radiation therapy to control bone and soft tissue lesions. **Methods:** 731 pts with biopsy proven GIST were treated and followed-up since 2004 with a median follow-up 43.6 months (range, 1-274 mos); data were prospectively documented. There were 394 females (53.9%). 101 (13.8%) pts. presented with M1 disease initially. Of the remaining 630 pts, 358 pts (56.8%) developed tumor recurrence. **Results:** Median time to disease recurrence was 22 months, (range, 2-144) and 312/358 pts (87%) developed metastases within the abdomen: liver n=96, peritoneal n=97, liver+peritoneal n=78, locoregional n=10, locoreg.+hep/per n=21. In 35 pts, extraabdominal sites were found (biopsy 29 pts): bone n=19, multiple sites n=12; soft tissue (STS) n=9, lung/pleura n=7, spleen n=1, brain n=1. All of these locations occurred after at least liver or peritoneal metastases with a median RFS of 58 months (range, 27-105 months). 26 pts had at least two lines of therapy prior to 'atypical' metastases. The median OS of this cohort is 118 months (range, 40-264 months) and 11 pts are still alive. 4/9 pts with STS and 21 sites of pts with bone metastases underwent radiation therapy of 45- 56 Gy, all in parallel to continued TKI therapy. Only one patient showed PD after RT at 6 months. The average duration of local control is 22 months. No unusual mutational pattern was detected in the primary tumors. Interestingly, in 7 pts a 2ndary exon 13 V654A mutation could be found. **Conclusions:** Extraabdominal metasteses of GIST are a rare and late event in the course of disease and occurs only after long-lasting therapy with TKIs. These 'atypical' metastases do not indicate rapid disease progression and may be controlled by radiation therapy if located in the bones or soft tissues. Whether continued TKI therapy contributes to the effective use of RT warrants further exploration.

**10555 General Poster Session (Board #262), Mon, 8:00 AM-11:45 AM**

**Effect of secondary KIT mutations on growth of GIST cells in the absence of selective pressure by imatinib in isogenic models of imatinib resistance.** *Presenting Author: Susanne Grunewald, Department of Medical Oncology, West German Cancer Center, University Hospital Essen, University Duisburg-Essen, Essen, Germany*

**Background:** Secondary mutations of KIT are commonly found in progressing lesions of imatinib (IM)-resistant GIST and represent a major factor of drug resistance. Development of salvage treatments is complicated by the genomic heterogeneity of secondary mutations. We hypothesize that resistant clones require selective pressure to overgrow sensitive GIST and that mixed sensitive/resistant populations may still display drug sensitivity. **Methods:** Based on parental IM-sensitive GIST-T1 (KIT Ex11 57bp del) we have developed IM-resistant isogenic sublines harbouring critical secondary mutations (T670I, D816E, D820A, A829P). Each subline was transduced with specific marker proteins allowing detection of resistant subclones by FACS or IHC. Proliferation and cell viability for individual cell lines and mixed cell populations (+/- IM) were evaluated in vitro and in vivo. **Results:** IM-resistant cell-lines grew faster in the presence of IM compared to no treatment. Resistant sublines were xenogenic in nude mice but were overgrown by parental GIST-T1 in mixed populations in the absence of IM. Tumors derived from mixed GIST populations contained high levels of resistant clones in IM-treated mice. To estimate the proportion of resistant cells within a population necessary to display resistance, we mixed resistant sublines with sensitive cells at known percentages. Sensitivity to IM was lost when the fraction of resistant cells was $>50\%$ compared to parental cells (3- and 6 day time point). **Conclusions:** GIST with acquired resistance likely harbor mixed populations of drug-sensitive and resistant cells which exhibit differential growth rates. Our studies show that tumor populations with low levels of resistant clones may still respond to treatment. Secondary KIT mutations confer a growth disadvantage in the absence of IM. Selective pressure by IM results in partial KIT inhibition which may reduce the oncogenic stress of kinase hyperactivation in GIST harbouring secondary mutations. Altering the selective pressure could therefore delay the emergence of resistant clones and our models could be applied toward optimization of drug selection and dosing strategies.

**10556 General Poster Session (Board #263), Mon, 8:00 AM-11:45 AM**

**Predictive ability of blood neutrophil-to-lymphocyte and platelet-to-lymphocyte ratio in gastrointestinal stromal tumors (GIST).** *Presenting Author: Jennifer M. Racz, Department of Surgical Oncology, University of Toronto, Toronto, ON, Canada*

**Background:** The immune response, specifically the neutrophil-to-lymphocyte ratio (NLR), has recently been shown to be prognostic in untreated, primary GIST. Moreover, the platelet-to-lymphocyte ratio (PLR) has been shown to predict outcome in several gastrointestinal tumors; however, no studies have examined its predictive ability in GIST. This study serves to evaluate the prognostic utility of NLR and PLR in patients undergoing surgical resection for GIST. **Methods:** All patients who underwent surgical resection for primary, localized GIST from 2001 to 2011 were identified from a prospectively maintained database. Demographic profile, clinicopathologic variables, laboratory values and recurrence rates were analyzed. NLR and PLR were both assessed pre-operatively. Survival curves were calculated by the Kaplan-Meier product limit method and compared by the log-rank test. Univariate and multivariate Cox proportional hazard regression models were used to identify associations with outcome variables. High/low NLR and PLR were determined using optimization techniques, and defined as $\geq$2.04/$<$2.04 and $\geq$245/$<$245, respectively. **Results:** 93 patients were included. On univariate analysis, PLR was associated with recurrence-free survival (RFS) (HR .271, 95% CI .078 – .938, p = .039). PLR was also associated with RFS on multivariate analysis (HR .048, 95% CI .003 – .884, p = .041). Patients with low PLR had 2- and 5-year RFS of 94 and 84%, compared with 57 and 57% in those with high PLR. RFS in patients with mitotic rate $\leq$5/50 HPF with low PLR was significantly longer than in those with high PLR (p = .007). Similarly, RFS in patients with tumor size $<$5 cm with low PLR was significantly longer than in those with high PLR (p = .004). NLR was not associated with either RFS (p = .226) or overall survival (p = .994). **Conclusions:** Although there was no association between NLR and survival, a low PLR was associated with improved RFS, especially in tumors with mitotic rate $\leq$5/50 HPF or $<$5 cm. The independent prognostic ability of PLR to predict disease recurrence in these patients suggests that it may play a role in risk stratification schemes when deciding which patents will benefit from adjuvant therapy.

**10557 General Poster Session (Board #264), Mon, 8:00 AM-11:45 AM**

**The relationship between overall survival (OS) and progression-free survival (PFS) in gastrointestinal stromal tumor (GIST).** *Presenting Author: Ipek Özer Stillman, Evidera, Lexington, MA*

**Background:** OS is the gold-standard measure of treatment efficacy in cancer. However, PFS is often used as primary endpoint when OS follow-up is long and/or post-progression therapy is common. In unresectable and/ or metastatic GIST, a previous study showed a moderately strong linear relationship between median PFS (mPFS) and median OS (mOS). This study presents an updated analysis. **Methods:** A systematic literature review identified fourteen clinical trials and five observational studies of sufficient quality from Jan 1995 to Dec 2013 (29 total treatment arms; 2,189 patients). These studies encompassed first and later lines of treatment with targeted therapies. Scatter plots and linear regressions (weighted by the number of patients) were used to evaluate the relation between mOS and mPFS for all arms combined. Sensitivity analyses investigated the impact of treatment line, treatments, and study quality score. **Results:** mOS and mPFS (in months) were positively related with an overall correlation of 0.912 in linear regression (slope = 2.083, standard error [SE] = 0.178; intercept = 5.618, SE = 2.436; adjusted $R^2$= 0.830). Eliminating four influential datapoints using the Difference in Beta Scaled, reduced the estimates for association, though the association was still strong (overall correlation = 0.724). The correlation was greater in later lines of therapy (first line = 0.518; second line = 0.797; third- and later-line = 0.702). **Conclusions:** This study showed a strong relationship between mPFS and mOS in GIST, especially in later lines of therapy. The number of studies included is relatively small and some treatment arms have $<$50 patients, which is not unexpected in a rare disease like GIST. While these findings provide some insight into PFS as a surrogate marker for OS, analyses of patient level data are needed to fully establish its validity in GIST.

**10558 General Poster Session (Board #265), Mon, 8:00 AM-11:45 AM**

**Extra-gastrointestinal stromal tumors (eGISTs): Experience of a cooperative group.** *Presenting Author: Matias Chacon, GATE-D, Buenos Aires, Argentina*

**Background:** eGIST occurs in regions such as omentum, mesentery, retroperitoneum and undefined abdominal and pelvis locations. Some authors hypothesized that the origin are Cajal interstitial cells from the abdominal cavity or the tumors are mural GISTs with extramural growth. Clinical, pathology and molecular profile of eGIST is similar to GISTs. Some publications show higher size and mitotic index than GIST. eGISTs are not consider in risk stratification consensus. Differential diagnosis of abdominal or pelvis mass with other tumors requires expert pathologist. The aim of the study is to evaluate clinical characteristics and mutation profile of consecutive eGISTs from a prospective database. **Methods:** Data from patients (pts) with histologic diagnosis of GIST with no evidence of gastric or intestinal involvement was analyzed. Demographics and medical information was obtained from an Argentinean GIST prospective database. Mutation analysis was performed with HPLCA. Descriptive statistical analysis was used. **Results:** Between 2004 and December 2013, 63 pts with eGISTs were included. Median age was 56 years old (16-87). Thirty three (52%) pts were female. Primary sites were: retroperitoneum 13 pts (21%), mesentery and omentum, 22 pts (35%), pelvis 17 (27%), peritoneum 9 pts, thoracic wall and pleura in two pts. Complete surgical resection was performed in 14 pts (35%). Initial pathology report was other than eGIST in 19 pts (30%). Median size tumor was 8 cm (1-39) and 47% had $>$10 mitoses/50 HPF. Positive C-KIT was in all pts. Median time to recurrence in pts was 11 months (1-12). Liver was the most frequent site of relapsed (9 pts). Exon 9,11,13, 17 KIT and 12, 14, 18 PDGFR mutations were evaluated in 24 pts. Exon 11 KIT deletion was the most frequent mutation (5 pts) and 12 (50%) were Wild type KIT and PDGFR. Imatinib was the systemic in 42 pts. Objective clinical benefit was 60%. **Conclusions:** eGISTs is a rare entity. In our series there was a female predominance located mostly in mesentery and omentum. Higher size and mitotic index was observed. One third of pts were complete resected and pathologic misdiagnosis. Better pre-operative approach should be required in this group of pts and more knowledge is necessary to improve outcome.

**10559 General Poster Session (Board #266), Mon, 8:00 AM-11:45 AM**

**Relationship of grade to prognosis in localized primary angiosarcoma of the breast (PAOB).** *Presenting Author: Manjari Pandey, The University of Tennessee Health Science Center/The West Clinic, Memphis, TN*

**Background:** PAOB is rare and institutional series have provided conflicting data on the impact of grade on prognosis. **Methods:** Using case listing session of SEER 18 (1973-2010) we examined outcomes for patients with PAOB. Analyses were conducted with SEER*Stat 8.1.2, Microsoft Excel 2007 and GraphPad Prism 6. Comparisons were made using the chi-squared test and log-rank test (Mantel-Cox); all p values were 2-sided. **Results:** 226 women with PAOB were identified; median age 49 (range 15-107); 82% white. 72% had localized disease, 15% regional disease, 7% distant disease; 14% had grade 1, 24% had grade 2 and 30% grade 3 disease. Median OS for patients (pts) with localized, regional, and distant disease was 172, 24 and 16 months, respectively ($p<0.001$). Median OS for pts with localized grade 1 and 2 disease was not reached versus 36 months for grade 3 disease ($p<0.0001$); 3-yr OS was 89% v 47%. There was a strong trend for pts with grade 3 disease to undergo mastectomy (44% v 23%) ($p=0.0695$) and 24% of all pts received radiation. Radiation did not improve survival for localized grade 1 and 2 disease ($p=0.6759$) or grade 3 disease ($p=0.5888$); surgery and grade subgroups were too small for meaningful comparisons regarding radiation. **Conclusions:** Histologic grade is a significant predictor of survival for patients with localized PAOB. Regardless of grade, adjuvant radiation did not confer a survival benefit for pts with localized disease.

**10560 General Poster Session (Board #267), Mon, 8:00 AM-11:45 AM**

**A phase I/II study of azacitidine in combination with temozolomide in patients with unresectable or metastatic soft tissue sarcoma or malignant mesothelioma.** *Presenting Author: Gleneara Elizabeth Bates, Columbia University Medical Center, New York, NY*

**Background:** Soft tissue sarcomas are rare tumors, for which complete surgical resection offers the best chance of survival. However, two thirds of diagnosed tumors are unresectable and/or metastatic, with a median survival of 12 months, and chemotherapy is the only treatment option. Temozolomide has been used in soft tissue sarcomas and has shown the most activity in leiomyosarcomas; response rates ranged from 5-15%. Azacitidine has not previously been used in the treatment of soft tissue sarcomas. Because of known effects of hypomethylating agents on caspase-8 genes, and the DNA repair gene MGMT involved in the action of temozolomide, we hypothesized that incorporating azacitidine into the treatment of soft tissue tumors with temozolomide could enhance its efficacy. **Methods:** Between June 2008 and July 2012, 28 patients with soft tissue sarcomas were enrolled. Among the 25 patients who completed the treatment, median age was 61 (range 41-83), 13 male and 12 female; 4 liposarcoma, 2 myxoid liposarcoma, 1 synovial sarcoma, 1 granular cell sarcoma, 1 epithelioid mesothelioma, 1 Ewing's sarcoma, 1 hemangioepithelioma, 7 leiomyosarcoma, 1 spindle cell sarcoma and 6 unspecified sarcoma. Treatment consisted of 10-11 cycles of azacitidine and temozolomide. Dosing: Azacitidine: dose level 1: 25mg/m$^2$ SQ qd; dose level 2: 50mg/m$^2$ SQ qd; dose level 3: 75 mg/m$^2$ SQ qd; combined with temozolomide: 200 mg/m$^2$PO qd x 5; both on days 1-5 of a 28-day cycle. Toxicity was graded by CTCAE IV. **Results:** Median number of cycles administered: 2 (range 1-6). There were nine drug-related adverse events experienced by 3 or more patients, none of which were dose-limiting. The maximum tolerated dose was 200mg/m$^2$ temozolomide and 75 mg/m$^2$ azacitidine. 15 patients died from their disease 2-59 months after enrollment; 10 patients are alive with stable disease. The median overall survival was 22 (95% CI:9-59) months, with a 1-year survival of 64% (95% CI:42-79%). **Conclusions:** We have not yet determined the antitumor effectiveness of this combination. These encouraging data show that temozolomide combined with azacitidine can be administered in their full doses with no dose-limiting toxicities. Clinical trial information: NCT00629343.

**10561 General Poster Session (Board #268), Mon, 8:00 AM-11:45 AM**

**Radiologic signs of adipocytic maturation (AM) in dedifferentiated liposarcoma (ddLPS) patients (pts) treated with trabectedin (T): Correlation with disease control.** *Presenting Author: Sree Harsha Tirumani, Dana-Farber Cancer Center Institute/Brigham and Women's Hospital, Boston, MA*

**Background:** T has been shown to induce histological AM in myxoid liposarcoma (mLPS), but this has not previously been described in ddLPS. In this retrospective analysis, we analyzed the imaging studies in pts with various LPS subtypes (ddLPS, mLPS, pleomorphic LPS (pLPS), unclassified LPS (uLPS)) treated with T to see whether radiologic AM is detectable in clinical assessments. **Methods:** This single institution study, which enrolled 55 pts with LPS, was conducted as part of an expanded access trial of T (NCT00210665). Assessable pre- and post-T imaging studies were available for 48 pts (33M, 15F), including 24 ddLPS, 16 mLPS, 4 pLPS, and 4 uLPS. Mean age at diagnosis was 50 yr (range 24 – 74 yr). T was administered until disease progression, and restaging scans were performed approximately every 6 weeks. Radiologic evidence of AM (change of tumor to fat density), changes in lesion density and size, and best response per RECIST 1.1 were assessed at final T cycle. Clinical benefit and rate (CBR) was based upon CR, PR or prolonged SD ($\geq$ 6 months). **Results:** Median T treatment duration was 11 mos (range, 1-44 mos). T was discontinued in 3 pts (5%) due to adverse events. Best response was PR in 8 (15%; 7 mLPS, 1 ddLPS), SD in 31 (56%; 9 mLPS, 14 ddLPS, 4 uLPS, 2 pLPS) and PD in 11 (20%; 9 ddLPS, 2 pLPS) pts. Radiologic evidence of AM was noted in 8 pts (15%; 6 ddLPS, 2 mLPS), all of whom had SD as best response. Decrease in tumor density was noted in 13 pts (27%; 9 mLPS, 4 ddLPS). Median T treatment duration was 6 months (1-44 mos) in all ddLPS and 13 mos (6-44 mos) in ddLPS with AM. There was a statistically significant correlation between radiologic AM and SD in ddLPS (p=0.0481; Fisher's exact test). Median progression-free survival was 6.5 mos (1 – 44 mos) for all patients and 6 mos for ddLPS. CBR was 60% in all pts and 50% in ddLPS. **Conclusions:** Radiologic AM in ddLPS pts treated with T is seen more often in patients receiving the drug for $\geq$6 mos, and is correlated with objective disease control.

**10562 General Poster Session (Board #269), Mon, 8:00 AM-11:45 AM**

**Detection of *MDM2* gene amplification in soft tissue sarcoma by FISH.** *Presenting Author: Hiroaki Kimura, Department of Orthopedic Surgery, Graduate School of Medical Science, Kanazawa University, Kanazawa, Japan*

**Background:** The *MDM2* (murine double minute-2) gene is an oncogene whose expression plays important roles in controlling the cell cycle and tumorigenesis. The *MDM2* is located on chromosome 12, and has been reported to be amplified in a subset of malignant tumors. In this study, we examined soft tissue sarcomas (STS) specimens for *MDM2* gene amplification by fluorescent in situ hybridization (FISH). **Methods:** 137 cases of formalin-fixed and paraffin-embedded specimens were used for this study. Surgical pathology reports, HE sections, and previous immunohistochemical slides were carefully reviewed. The pathological diagnoses were shown in the Table. The FISH probe for *MDM2* was co-hybridized with CEP12 probe that is specific for chromosome 12. The average number of *MDM2* and CEP12 ratio was calculated and a ratio>2.0 was considered amplified. **Results:** Of 137 STS, *MDM2* amplification was detected in 33 cases (24%). Of the WDLS/ALT, 93% (26/28) showed amplification of *MDM2*. A total of 4 of 4 (100%) DDLS showed amplification of *MDM2*. Two of 10 MPNST and 1 of 7 myxofibrosarcoma also showed amplification of *MDM2*. **Conclusions:** WDLS/ATL are often difficult to distinguish morphologically from benign lipomatous tumors, while DDLS may be challenging to distinguish from other high-grade sarcomas, especially on needle biopsy specimens that lack areas of WDLS. With the increased use of small needle core biopsy in which only limited tissue is available for histologic evaluation, increased utilization of molecular studies to identify the characteristic molecular aberrations of WDLS and DDLS may prove useful in clinical practice. *MDM2* amplification by FISH was a useful adjunct in the diagnostic approach for WDLS vs benignlipomatous tumors and DDLS vs pleomorphic or spindle cell sarcomas.

| Diagnosis | | FISH-positive |
|---|---|---|
| Liposarcomas | | |
| ALT/WDLS | 28 | 26 |
| MXLS | 28 | 0 |
| DDLS | 4 | 4 |
| MFH | 19 | 0 |
| Leiomyosarcoma | 18 | 0 |
| Synovial sarcoma | 12 | 0 |
| MPNST | 10 | 2 |
| Myxofibrosarcoma | 7 | 1 |
| Rhabdomyosarcoma | 7 | 0 |
| Low-grade fibromyxoid sarcoma | 4 | 0 |
| | 137 | 33 |

Abbreviations: ATL, atypical lipomatous tumor; WDLS, well-differentiated liposarcoma; DDLS, dedifferentiated liposarcomas; MFH, malignant fibrous histiocytoma; MPNST, malignant peripheral nerve sheath tumor.

**10563 General Poster Session (Board #270), Mon, 8:00 AM-11:45 AM**

**Phase I study of NBTXR3 nanoparticles, in patients with advanced soft tissue sarcoma (STS).** *Presenting Author: Sylvie Bonvalot, Institut Gustave Roussy (IGR), Villejuif, France*

**Background**: Functionalized hafnium oxide nanoparticles (NBTXR3) have been developed as selective radioenhancers, which may represent a breakthrough approach for the local treatment of solid tumors. This is a unique approach where crystalline nanomaterials with high electron density when exposed to radiotherapy, can allow penetrate into the cell and make feasible the absorption/deposition of a high energy dose within the tumor cell. A phase I/II trial was implemented in patients with locally advanced STS. **Methods**: Patients (pts)received a single intratumor (IT) injection of NBTXR3, volume escalated, followed by 50Gy RTx (see Table). Primary endpoints include feasibility of the IT implantation and safety. Secondary endpoints focus on efficacy such as pathological and RECIST response, IT residency of NBTXR3 over all the RTx period and operability. **Results**: Enrollment was completed for volume 1, 2, and 3 (15 pts). Feasibility of the IT injection was confirmed. The treatment was safe with no SAE, no early DLT and allowed the pts for completion of the planned RTx schedule. No grade 3-4 toxicity occurred, main grade 1-2 toxicities related to NBTXR3 were injection pain/reaction (4 pts), pyrexia (2 pts), abdominal pain (1 pt), pruritus (1 pt) and paresthesia (1 pt). Results demonstrated that a single injection of NBTXR3 provides adequate bioavailability of NBTXR3 IT over five weeks of radiotherapy. No leakage of NBTXR3 to the adjoining healthy tissues was observed. Further, NBTXR3 persistence was established by CT scan before surgery. **Conclusions**: Injection of NBTXR3 was well tolerated. All pts received the planned radiotherapy (50 Gy/25 fractions/ 5 weeks) followed by wide surgical resection of the sarcoma. NBTXR3 with RTx showed a very good safety profile. Encouraging signs of antitumor activity were observed in different sarcoma subtypes, such as undifferentiated sarcoma, rhabdomyosarcoma, and synovial sarcoma, which constitutes a promising feature for this subset of pts whose primary tumor is locally advanced and has an important risk of relapse. Clinical trial information: NCT01433068.

**Synovial sarcoma: Evaluation of response to treatment with gemcitabin and docetaxel.** *Presenting Author: Sausan Abouharb, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Synovial Sarcoma (SS) is one of the more common subtypes of soft tissue sarcomas, comprising 8-10% of this entity. It is well known that SS responds well to adriamycin/ifosfamide (AI) therapies, however responses to gemcitabine/docetaxel (GT) combination have not been well documented, although commonly used in practice. This study aimed to evaluate response to GT in patients with SS. **Methods:** We retrospectively reviewed medical records of patients diagnosed with SS from 2000 to 2012. All patients had confirmed SS by pathology review. Only patients who were metastatic and treated with GT concurrently were included. **Results:** The study included 51 patients with metastatic disease who received GT concurrently. Majority of patients were white (69%), with a mean age of 42 years (SD 15) when receiving GT. Median time from initial diagnosis to first metastasis was 15 months. Median overall survival from first metastasis was 2.3 years (95% CI 1.8-3.0 years). The majority of patients (96%) had received A and/or I prior to GT therapy, and 86% had documented disease progression prior to start of GT. 21% of patients were taken off GT due to side effects or other reasons. 79% were taken off due to progressive disease. As best response, 10% of patients (n=4) had: complete response (CR) (n=1), near CR (n=1) or partial response (PR) (n=2). 33% (n=14) had stable disease, and 57% (n=24) had disease progression (DP). 9 patients had missing data. Overall 43% may have derived some clinical benefit, and 57% had DP. Median duration of GT therapy was 2 cycles (range 1-3); median of 1.7 months (range 1.2-3.0) in patients who progressed; 4 cycles (range 2-8), median 3.0 months (range 1.6-10.0) in patients with SD, and 8 cycles (range 6-11); median 6.1 months (range 4.7-10.5) in patients with CR/near CR/PR. **Conclusions:** This data shows some efficacy of GT in metastatic SS. Rare responses were seen, and due to limited availability of other active agents in this disease it may not be unreasonable to consider GT after other lines of therapy, (such as A/I, dacarbazine, pazopanib) have been used.

**10565 General Poster Session (Board #272), Mon, 8:00 AM-11:45 AM**

**Clinical features, outcomes, and prognostic factors in patients with extraskeletal osteosarcoma.** *Presenting Author: Sheila Thampi, University of California, San Francisco, San Francisco, CA*

**Background:** Extraskeletal osteosarcoma (ESOS) is a rare subtype of osteosarcoma. We investigated patient characteristics, overall survival for ESOS as compared to skeletal osteosarcoma, and prognostic factors for ESOS. **Methods:** We identified cases of high-grade osteosarcoma with available data regarding tissue of origin (bone vs. soft tissue) in the Surveillance Epidemiology and End Results database from 1973 to 2009. Demographics were compared using chi-squared tests or t-tests. Overall survival was estimated using Kaplan-Meier methods and modeled using Cox proportional hazards methods. Competing risk analysis was utilized to determine differences in incidence of death from cancer. **Results:** 256 / 4,173 (6.1%) patients with high-grade osteosarcoma had ESOS. Patients with ESOS were more likely to be older, have axial tumors, have regional lymph node involvement ($p<0.0001$ for all comparisons), and be female ($p=0.002$). On univariate analysis, five-year overall survival for those with ESOS was inferior [37% (95% CI 30.6 to 43.3) vs. 50.8% (95%CI 49.1 to 52.50; $p<0.0001$]. However, on competing risk analysis, we found no difference in the cumulative incidence of death due to cancer between extraskeletal or skeletal osteosarcoma. This discrepancy was due to a significant interaction between age and tissue of origin such that older patients with ESOS had superior outcomes compared to older patients with skeletal osteosarcoma. On multivariate analysis of overall survival, ESOS was found to be favorable after controlling for differences in metastatic status, age, tumor site, gender, and year of diagnosis (hazard ratio 0.75; 95% CI 0.62 to 0.90; $p=0.002$). Independent adverse prognostic factors in patients with ESOS include distant metastatic disease, larger tumor size, older age, and axial tumor site. **Conclusions:** This analysis reveals distinct patient characteristics in ESOS but similar prognostic factors between ESOS and skeletal osteosarcoma. Contrary to previous reports, the incidence of death from osteosarcoma is similar between both types of osteosarcoma. While older patients have poor overall survival with high-grade osteosarcoma, extraskeletal origin predicts better outcomes.

**10566 General Poster Session (Board #273), Mon, 8:00 AM-11:45 AM**

**Patterns of chemotherapy administration in soft tissue sarcoma (STS) and impact on overall survival (OS): A National Cancer Database (NCDB) analysis.** *Presenting Author: Sujana Movva, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Patients with AJCC stage III STS (large, deep, high grade) have an expected OS of approximately 50% at 5 years. A meta-analysis of adjuvant chemotherapy in STS showed an absolute benefit in OS for the chemotherapy group. Despite these results, patterns of care and opinions with regard to adjuvant chemotherapy vary. Our aims were to identify factors associated with receipt/non-receipt of chemotherapy, and their impact on OS in patients with high risk STS. **Methods:** Individuals diagnosed with stage III STS between 1998-2010 were identified from the NCDB. Excluded from the analysis were patients who did not undergo surgery for the primary tumor and histologies considered resistant to chemotherapy. Chi-square tests and multivariate logistic regression were used to compare sociodemographic and tumor factors between the groups receiving and not receiving chemotherapy. All-cause mortality was analyzed using the Kaplan-Meier method and Cox proportional hazards regression. The survival analysis cohort was limited to patients diagnosed between 2003-2005 based on availability of survival and comorbidity data. **Results:** 12,198 individuals with stage III STS were identified. 29% of patients received chemotherapy. Patients who were <40, privately insured, earned a higher income, had no comorbidities, had synovial histology, and whose tumors were > 10 cm were more likely to receive chemotherapy on both univariate and multivariate analysis. Race, education level and type of treating facility were not significantly associated with receipt of chemotherapy. Median unadjusted OS in the chemotherapy and non-chemotherapy groups were 83.9 and 48.5 months respectively ($P<0.0001$). The benefit for chemotherapy was also seen on adjusted analysis, (HR 0.77; $P<0.0001$), when controlling for sociodemographic and tumor factors (15 total factors including age, comorbid conditions, race and insurance status). **Conclusions:** Our analysis demonstrates an OS benefit for chemotherapy in stage III STS after adjusting for comorbidities. To our knowledge this is the first retrospective OS analysis restricted to stage III patients that also adjusts for socioeconomic status.

**10567 General Poster Session (Board #274), Mon, 8:00 AM-11:45 AM**

**Phase II study of eribulin mesylate in patients (pts) with advanced soft tissue sarcoma (STS).** *Presenting Author: Yoichi Naito, National Cancer Center Hospital East, Chiba, Japan*

**Background:** Eribulin mesylate is a non-taxane microtubule dynamics inhibitor that has demonstrated an activity in pts with various types of tumor. The efficacy and safety of eribulin mesylate were evaluated in pretreated pts with advanced STS. **Methods:** This was an open-label, multi-center, single-arm, phase II study in Japanese pts with advanced STS. Pts with high or intermediate grade STS had received at least one standard chemotherapy, and also had ECOG performance status 0-1. Progressive disease had to be documented within the last 6 months. Eribulin mesylate (1.4 mg/m$^2$) was administered as a 2-5 minute intravenous infusion on day 1 and 8 of 21-day cycle. The primary endpoint was the progression-free rate at 12 weeks ($PFR_{12wks}$) in 2 independent strata of pts with STS: adipocytic (ADI) or leiomyosarcoma (LMS), and histological types other than ADI/LMS (OTH). Secondary endpoints included response, survival and safety. $PFR_{12wks}$ and responses were assessed by independent review using RECIST criteria. **Results:** A total of 52 pts were enrolled, and 51 pts received eribulin (ADI:16 pts, LMS: 19 pts and OTH:16 pts). Median age was 52 (range: 28-73) and 13 pts (25.5%) was intermediate grade and 38 pts (74.5%) high grade. Fifty-one pts (100.0%) had received anthracycline and 36 pts (70.6%) ifosfamide as prior therapeutic chemotherapy. The $PFR_{12wks}$ in ADI/LMS was 60.0% (21/35 pts; 95% CI 42.1-76.1%), OTH 31.3% (5/16 ; 11.0-58.7), and all subtypes (ALL) 51.0% (26/51 ; 36.6-65.2). The median progression free survival in ADI/LMS was 5.5 months (mo) (95% CI 2.8-8.2 mo), OTH 2.0 mo (1.2-4.1), and ALL 4.1 mo (2.6-5.6). There was no complete response (CR) or partial response (PR) in this study. Stable disease (SD) in ADI/LMS was 80.0%, OTH 50.0%, and ALL 70.6%. The clinical benefit rate (CR + PR + SD>11 weeks) in ADI/LMS was 74.3%, OTH 50.0%, and ALL 66.7%. 1-year overall survival rate in ADI/LMS was 60.0%, OTH 50.0% and ALL 56.9%. The most frequent treatment-related Grade 3 or above toxicities were neutropenia (86.3%), leukopenia (74.5%), lymphopenia (31.4%), anaemia (11.8%) and febrile neutropenia (7.8%). **Conclusions:** Eribulin has shown clinical activity in advanced pre-treated STS patients and it is well tolerated with no new safety signals. Clinical trial information: NCT01458249.

**10568 General Poster Session (Board #275), Mon, 8:00 AM-11:45 AM**

**Alliance A091103: A multicenter phase II study of the angiopoietin-1 and -2 peptibody trebananib (AMG386) for the treatment of angiosarcoma (AS).** *Presenting Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** AS is a rare, aggressive, malignant endothelial cell tumor constituting 1-2% of all soft tissue sarcomas with 35% 5-yr survival. Cytotoxic agents have demonstrated ~15% response rates (RR). Gene-array data has revealed up-regulation of endothelial associated genes, including active members of the angiopoietin system [eg, Tie2 and Angiopoietin 2 (Ang2)]. Trebananib (AMG386) is a novel agent targeting Ang1 and Ang2. **Methods:** Metastatic/unresectable AS, adequate performance status, organ function, and measurable disease (RECIST v1.1) were required. Trebananib 30mg/kg d1, 8, 15, and 22 was repeated q28 days until progressive disease (PD) or unacceptable toxicity. The primary endpoint is confirmed RR (partial or complete by RECIST v1.1); 1 response in 12 pts expanded enrollment to 25. Secondary endpoints include: toxicity, progression-free survival (PFS), and overall survival (OS). Correlatives include: 1) baseline expression of Ang2/Tie2 by immunohistochemistry (IHC), 2) serum levels of Ang1, 3) pre- and post-treatment phospho-receptor tyrosine kinase and 4) MYC/FLT4 amplification status. **Results:** 16 pts were enrolled from 5 participating sites [median age 68 yrs (24-91), 38% male, median number of prior therapies 2.5 (1-7)]. No confirmed responses were observed in 14 evaluable pts; one pt had an 18% decrease. 4/16 had SD, 12/16 have PD; 8/16 have died with a median follow-up of 2.9 mos (0.9-12.7). Estimated median and 12-week PFS rate are 7 weeks (95% 6-8) and 25% (95% CI 11-58%), respectively. Median OS is 28 weeks (95% CI 17-48). Common grade 3-4 adverse events include (pts): thrombosis (2), syncope (1), anemia (1). Two pts died of reasons unrelated to treatment (cardiac, respiratory failure). **Conclusions:** Trebananib was well-tolerated in this phase II study of AS, with no partial/complete responses. Prolonged PFS was observed in 4 pts, lasting 3.5-5.5 mos. Forthcoming results of the associations of correlatives (eg, Ang/Tie2 IHC expression and serum Ang levels) with outcome may help identify patients most likely to benefit. Clinical trial information: NCT01623869.

**10569 General Poster Session (Board #276), Mon, 8:00 AM-11:45 AM**

**Predictive biomarkers of trabectedin (TR) and olaparib (OL) synergism in preclinical models of bone and soft tissue sarcoma (BSTS).** *Presenting Author: Ymera Pignochino, Sarcoma Unit, Division of Medical Oncology, IRCCS Istituto di Candiolo, Candiolo, Italy*

**Background:** TR is a DNA damaging agent as 2nd line-therapy in STS. We speculated that its antitumor activity could be potentiated by a "synthetic lethality" approach targeting key molecules involved in DNA repair. PARP-1 inhibition impedes DNA repair promoting cell death.We tested the antiproliferative effect of PARP inhibitor OL in combination with TR against 20 BSTS cell lines and explored their mechanism of action. **Methods:** The combination of OL and TR was tested against 20 BSTS cell lines. Drug synergism was evaluated by Calcusyn software. Subcutaneous (s.c) and orthotopic BSTS models were obtained in NOD/SCID mice and tumor growth was monitored by caliper and by *in vivo*imaging, respectively. DNA repair machinery was studied by realtime PCR, western blot and immunocytochemistry. Silencing of PARP-1 was induced with specific siRNA. Cell cycle, apoptosis and P-H2AX were evaluated by flow cytometry. Damaged DNA was studied by comet assay. Pearson's correlation, t distribution and p value were calculated for statistical analysis. **Results:** We observed a strong synergism of TR-OL in 18/20 cell lines reaching significant dose reduction index (5.5-1.001). There is a 15-fold range of sensitivity among BSTS histotypes (Ewing's sarcoma > liposarcoma > leiomiosarcoma> osteosarcoma > UPS > fibrosarcoma). Synergism is related with increased G2/M cell cycle arrest, apoptosis and DNA damage. The antitumor and antimetastatic effects of TR-OL were confirmed in s.c and orthotopic models, respectively. Real time PCR, western blot and immunocytochemistry analysis demonstrated that PARP-1 expression and activation are higher in responsive cell lines vs. less sensitive ones. To confirm these data we down-modulated PARP-1 with silencing experiments showing a reduced TR-OL synergism (25±2%, $p<0.05$). mRNA expression analysis of DNA repair machinery in 20 BSTS cell lines showed that PARP-1, RAD51 and BRCA1 are significantly related to synergism. These data were confirmed at protein level in selected experiments. **Conclusions:** PARP-1, RAD51 and BRCA-1 are predictive of TR and OL synergism in BSTS preclinical models, and could represent good candidate biomarkers to be evaluated in clinical trials.

**10570 General Poster Session (Board #277), Mon, 8:00 AM-11:45 AM**

**Late relapse in soft tissue sarcoma: Prognostic factors for recurrence after 3 years.** *Presenting Author: Karim Boudadi, University of Michigan, Ann Arbor, MI*

**Background:** In patients (pts) with localized soft tissue sarcoma (STS), 80% of relapses occur within the first 2 years (yrs) after definitive resection. However, relapse after 3 yrs is not uncommon, and limited data exists to identify higher risk pts. While the possibility of late relapse suggests prolonged surveillance, we performed a retrospective study to identify prognostic factors for relapse > 3 yrs that may help guide long-term follow-up (f/u). **Methods:** A cancer center-based registry identified adult STS pts seen from 1999-2010 at University of Michigan. Pts with resected localized STS with >3 yrs of f/u and who remained disease free > 3 yrs were eligible. The primary endpoint was time-to-relapse, defined from resection to disease relapse. Pts were censored at last f/u if they remained disease free. The Kaplan-Meier method was used to estimate survival functions, and Cox proportional hazard model identified prognostic factors of relapse. **Results:** Of 750 pts with resected localized STS, 232 remained disease free > 3yrs. 37 pts relapsed, 18 (8%) locally, 15 (6%) distantly, and 4 (2%) with both, with a median f/u of 5.1 yrs (3.0-13.8). The relapse-free survival rates at 4, 5, and 6 yrs were 92%, 88%, and 81%, respectively. On multivariate analysis, thoracic location (HR=109.2, 95% CI 4.3-278.3, p=0.005), head/neck location (HR=109, 95% CI 5.7-209.5, p=0.002), size > 10 cm (HR=10.1, 95% CI 0.9-102.6, p=0.05) and positive margins (HR=28.9, 95% CI 5.8-144.1, $p<0.0001$) were associated with higher risk of relapse > 3 yrs. Grade, histology, or chemotherapy did not correlate with relapse in this selected group. For local relapse only, thoracic location, positive margins, and no radiotherapy were associated with increased risk, while positive margins was the sole factor for distant relapse. **Conclusions:** In our series, disease relapse after 3 yrs occurred in 16% of localized STS pts. Tumor size > 10 cm, thoracic or head/neck location and positive margins conferred an increased risk. For pts with high risk STS, standard practice is decreased intensity of surveillance beyond 2-3 yrs. Given the incidence of late relapse, continued f/u is important; strategies to minimize radiation exposure to pts during surveillance will be critical moving forward.

**10571 General Poster Session (Board #278), Mon, 8:00 AM-11:45 AM**

**Phase I study of neoadjuvant gemcitabine combined with radiation therapy for patients with high-risk extremity and trunk soft tissue sarcomas.** *Presenting Author: William W. Tseng, Department of Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Gemcitabine is used in many solid tumors as a sensitizer for radiation therapy. We sought to determine the maximum tolerated dose (MTD) of gemcitabine when given concurrently with preoperative external beam radiation (EBRT) for patients with high-risk extremity and trunk soft tissue sarcoma (STS). **Methods:** Fifty gray of EBRT was given in 25 daily fractions over 5 weeks. Gemcitabine was administered on days 1, 8, 22, 29, 43, and 50 at a starting dose of 400 mg/m$^2$. Dose escalation between cohorts by increments of 100 mg/m$^2$ was done using a toxicity severity weight method (TSWM), incorporating 6 different toxicities (Table). This method is a Bayesian procedure that repeatedly assesses the data to find the drug dose having a posterior total toxicity burden closest to a predetermined clinician-defined target (Bekele and Thall, 2004). Clinicopathologic and outcome data were also collected. **Results:** Thirty-six patients completed the study. Mean tumor size was 6.3 cm and 67% of patients had high grade tumors. Tumor histology consisted of MFH/UPS (n=20), myxoid liposarcoma (n=7), synovial sarcoma (n=5) and myxofibrosarcoma (n=4). Using a TSWM, the MTD for gemcitabine was 700 mg/m$^2$. All patients had tumor resected to microscopic negative margins. Most patients had no postoperative wound complications. Pathologic response with >90% tumor necrosis was achieved in 47% of patients. With a median follow-up of 6.2 years, 5 year overall survival was 86%, locoregional recurrence-free survival was 85% and distant metastasis-free survival was 80%. **Conclusions:** A toxicity severity weight method can be used to guide MTD determination for drugs given as part of multimodality treatment. Neoadjuvant gemcitabine and radiation therapy is feasible in high risk extremity and trunk STS. Major pathologic response can be achieved and after complete resection, disease control rates are excellent, supporting further evaluation of efficacy in phase II and III trials. Clinical trial information: NCT02046304.

**10572 General Poster Session (Board #279), Mon, 8:00 AM-11:45 AM**

**Trabectedin-related liver toxicity in soft tissue sarcoma patients: Always a good reason to discontinue the treatment?** *Presenting Author: Bruno Vincenzi, Department of Medical Oncology, Campus Bio-Medico University of Rome, Rome, Italy*

**Background:** A transient increase in liver enzymes is a well described side effect developed by almost 40% of soft tissue sarcoma (STS) patients treated with trabectedin, often leading to treatment delays or discontinuation. We retrospectively analysed the correlation between trabectedin-related liver toxicity and treatment outcome. **Methods:** Data from a total of 113 patients receiving trabectedin administered at the dose of 1.5 mg/m$^2$iv 24 hours in 3 reference centers were evaluated. This exploratory analysis was performed to assess the impact of liver toxicity (grade 3-4 AST and ALT increases) on the trabectedin efficacy and outcome in STS patients. All the patients included had metastatic disease or locally advanced inoperable and received at least one previous line of treatment containing anthracycline. All patients received standard steroids premedication. **Results:** Median age was 57 years (range: 27-79 ys) and male/female ratio was 71/42. STS histologies were: liposarcoma 32 cases, leiomeiosarcoma 27, pleomorphic sarcoma 17, synovial sarcoma 13, 24 other histologies. For 45 patients a G3-4 ALT increase in the first two cycles was reported while for 68 was not. Calculations show that hazard ratios for PFS and OS are not statistically significant (HR=1.124; p=0.734 and HR=0.104; p=0.850, respectively). Furthermore, the analysis was repeated dividing the population between patients with G3-4 ALT elevation during treatment vs. patients without such elevation. Again, hazard ratios for PFS and OS are not statistically significant (HR=0.791; p=0.309 and HR=0.930; p=0.810930, respectively). Finally, the analyses was repeated, splitting the population in patients with peak>15 ULN vs. patients with peak<15 ULN and one again no statistical significant differences were identified neither in terms of PFS (HR=0.821 p=0.227) neither in terms of OS (HR=0.927 p=0.463). **Conclusions:** Liver toxicity is a common event during treatment with trabectedin and does not affect outcome. These results should discourage the premature discontinuation of the drug due to the increase in liver enzymes.

**10573 General Poster Session (Board #280), Mon, 8:00 AM-11:45 AM**

**Nilotinib as co-adjuvant treatment with doxorubicin in sarcomas: Phase I trial results—A Spanish Group for Research on Sarcoma (GEIS) study.** *Presenting Author: Javier Martin Broto, Hospital Universitario Son Espases, Palma de Mallorca, Spain*

**Background:** Our group has recently published several relevant aspects of MDR proteins as potential targets in sarcomas: MRP1 expression was significantly correlated with poor prognosis in sarcoma patients, nilotinib was a strong inhibitor of MRP1/Pgp efflux activities and, finally, nilotinib plus doxorubicin (DX) showed to be synergistic regarding apoptosis in several sarcoma cell lines. Experiments in mice revealed that nilotinib plus DX did not increase either liver or cardiac toxicity. Supported by the previous information, a phase I/II trial was designed in order to explore the feasibility of nilotinib as co-adjuvant of DX by inhibiting MRP1/Pgp efflux activity. **Methods:** Nilotinib 400mg/12h was administered fixed from day 1 to 6 and DX on day 5$^{th}$ of each cycle. Three dose-escalation levels for DX at 60 mg/m$^2$; 65 mg/m$^2$ and 75 mg/m$^2$were planned. Cycles were repeated every 3 weeks for a total of 4 cycles. Eligible subtypes were retroperitoneal liposarcoma (LPS) and leiomyosarcoma (LMS) and metastatic high grade chondrosarcoma (CHO). Pharmacodynamic effects of nilotinib on the expression of MRP1 and Pgp RNA were measured by RT-PCR comparing day 1 and 5. **Results:** In the phase I trial, 13 patients were enrolled:7 CHO, 4 LPS and 2 LMS. In 46 administered cycles the most relevant non-hematological toxicities per patient were: alopecia (100%), asthenia (62%), nausea (54%), increased GGT (46%), increased ALP (38%), constipation (31%) and mucositis (23%). All of these were grade 1-2. Concerning non-hematological toxicity, there was 23% G1-2 neutropenia, 54% G3-4 neutropenia, and 61% G1-2 anemia. GCSF was recommended from day 11-17 after observing delayed neutrophil recovery on day 21. In general toxicity was easily manageable. Considering efficacy there were 2 PR (2 LPS), 8 SD (5 CHO, 2 LPS, 1 LMS), 3 PD (2 CHO and 1 LMS). Pgp and MRP1 RNA expression levels decreased by 58.47-fold and 1.47-fold respectively on day 5 of cycle. **Conclusions:** Combination of MRP1-Pgp inhibitor, nilotinib, as co-adjuvant with DX is feasible and it appears does not add substantial toxicity compared to DX alone. Pharmacodynamic study supports this concept. GEIS Group is currently conducting the phase II trial. Clinical trial information: 2011-002368-26.

**10574 General Poster Session (Board #281), Mon, 8:00 AM-11:45 AM**

**Prognostic value of peroxisome proliferator-activated receptor gamma expression on clinical outcome of myxoid liposarcoma.** *Presenting Author: Akihiko Takeuchi, Department of Orthopedic Surgery, Kanazawa University, Kanazawa, Japan*

**Background:** Myxoid liposarcoma (MLS) is considered as low-to-intermediate grade malignancy. However, it also have been reported that MLS metastases to extrapulmonary sites and the biomarker of prognosis has not fully discussed. Peroxisome proliferator-activated receptor gamma (PPAR$\gamma$) is a ligand-activated transcription factor that belongs to the nuclear hormone receptor superfamily. PPAR$\gamma$ plays a central role in the differentiation of adipocytes from precursor cells and is also reported to exhibit anti-tumorigenic effects on a certain malignancy. It has been reported that PPAR$\gamma$ is expressed in liposarcoma and the activation of PPAR$\gamma$ induced apoptosis and promote the terminal differentiation in liposarcoma cells. The purpose of this study is to evaluate the expression of PPAR$\gamma$ in MLS and correlation between PPAR$\gamma$ expression and clinical outcome. **Methods:** Forty-three patients were enrolled in this study. The median age was 45.5 years (range, 14-90 years) and the mean follow-up period was 91 months (range, 13-344 months). The expression of PPAR$\gamma$ was investigated by immunohisochemistry. **Results:** Ten cases showed the high expression of PPAR$\gamma$ (labeling index: LI $\geq$ 50%) and 33 cases were the low expression (LI $<$ 50%). Local recurrence was detected in 9 of 43 (20.9%) patients. Six of 43 (14.0%) patients developed extrapulmonary metastasis. The sites of metastasis were spine in 2 patients. Another 4 sites were femur, retroperitoneum, axilla, and lung, respectively. The metastasis-free survival was significantly higher in the patients with the low expression of PPAR$\gamma$ than those of the high expression (p=0.011). The overall cumulative 5 and 10-year survival of all patients was 97.4% and 92.3%. **Conclusions:** The low expression of PPAR$\gamma$ was a prognostic factor of the metastasis-free survival. It had been reported that FUS-CHOP, specific fusion protein confirmed in MLS, blocked the PPAR$\gamma$ pathways. So, we speculated the high expression of PPAR$\gamma$ might reflect the inhibition of the PPAR$\gamma$ pathways by FUS-CHOP fusion protein. Although the further analysis is necessary, the expression of PPAR$\gamma$ might be a novel prognostic marker of MLS.

**10575 General Poster Session (Board #282), Mon, 8:00 AM-11:45 AM**

**Locally advanced high-grade extremity soft tissue sarcoma: Response with novel approach to neoadjuvant chemoradiation using induction spatially fractionated GRID radiotherapy (SFGRT).** *Presenting Author: Mohammed Mohiuddin, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia*

**Background:** Improved local control and survival has been observed with increasing rate of tumor necrosis >90% with preoperative chemo-radiation for STS. However the rate of necrosis (90%+) following pre-operative chemo radiation remains low (<50%) and likely even less for locally advanced (>8 cm) tumors. The purpose of this study was to increase the rate of tumor necrosis following preoperative chemo-radiation in the management of soft tissue sarcomas (STS) using induction SFGRT. **Methods:** Fourteen patients with locally advanced extremity STS ranging in size from 8 cm to 26 cm (median 11.5 cm) were treated with high dose megavoltage radiation using an SFGRT technique. Single dose of induction SFGRT 18 Gy was delivered using 6 MV photons followed by external beam radiation 50 Gy combined with iphosfamide 2 gm/m2/day x 3 and mesna 2 gm/day x 3 in divided doses every three weeks followed by surgery 4-6 weeks after completing neoadjuvant therapy. **Results:** 12 patients completed the planned treatment. 1 patient had treatment interrupted due to Grade 3 skin reaction and 1 patient underwent an amputation of the foot mid treatment. Follow up ranges from 3 months to 43 months (median 14 mo). 13/14 patients underwent limb salvage surgery with 12 having negative margins. 2 patients have had delayed wound healing. 9/14 (65%) patients had > 90 % tumor necrosis with 2 patients having a pathological complete response. 2 additional patients have had greater than 80% necrosis. There have been no local recurrences and 12 patients are alive with no evidence of disease. **Conclusions:** The combined use of induction SFGRT and external beam radiation/chemotherapy is an effective way to enhance the necrosis and response to neoadjuvant chemo-radiation and potentially improve local control/ limb salvage and survival in locally advanced extremity STS.

**10576 General Poster Session (Board #283), Mon, 8:00 AM-11:45 AM**

**Survival and outcomes of critically ill sarcoma patients admitted to the intensive care unit.** *Presenting Author: Rohan Gupta, The University of Texas at Houston Internal Medicine Residency Program, Houston, TX*

**Background:** Survival and long-term outcomes of the critically ill patients with sarcoma who are admitted to the intensive care unit (ICU) are unknown. As a result, oncologists are often unsure of the utility of aggressive treatment measures in critically ill patients with these rare tumors. **Methods:** Objective: To determine factors that impact survival. We performed a retrospective chart review of all sarcoma patients admitted to the ICU at MD Anderson. Covariates such as histological diagnosis, site, stage, chemotherapy utilization, Charlson comorbidities index, Sequential organ failure assessment (SOFA) scores and reason for admission were reviewed and analyzed for impact on survival. **Results:** 212 ICU admissions were identified between 2005 and 2012. 23 patients had multiple ICU admissions. Of the remainder 191 patients, 17 surgical ICU patients were excluded, leaving a sample size of 172 patients (45.9% males) with the median age of 52 (17-89). Most common histological diagnoses were high grade unclassified sarcoma (25%), osteosarcoma (11%) and angiosarcoma (7.6%). Advanced metastatic disease was present in 73.3% patients. 25% of the patients were untreated at the time of admission to the ICU. Among patients on treatment, 34.3 % received doxorubicin based therapy and 11.6% received gemcitabine based therapy. 76.7% were alive after their first ICU admission. Post hospital, 30 days and 60 days survival were 70.3%, 60.5% and 55.2% respectively. Non-survivor group had maximum SOFA score of 16 (0-24) compared to survivor group 7 (0-22). 42.5% of the non survivors had $>$ 2 organ dysfunctions compared to 6.82% of survivors. Reasons for admission to ICU that predicted poor outcome were acute kidney injury (70% in non-survivors vs 34.8 % in survivors), acute respiratory failure (90% vs 31.8%), septic shock (40% vs 25%), cardiac arrest (17.5% vs 2.3%) and pneumonia (47.5% vs 23.5%). **Conclusions:** Significant numbers of critically ill sarcoma patients with advanced disease survive the initial ICU stay. Organ dysfunction can be predictive of survival of sarcoma patients being admitted to the ICU. Patients with disseminated disease with predictors of poor survival should be considered for early transition to supportive care or hospice.

**10577 General Poster Session (Board #284), Mon, 8:00 AM-11:45 AM**

**Prognostic factors for high-grade soft tissue sarcomas (STS) in the extremities treated by perioperative chemotherapy with ifosfamide (IFO) and doxorubicin hydrochloride (ADM): Using the data from Japan Clinical Oncology Group trial (JCOG0304).** *Presenting Author: Kazuhiro Tanaka, Oita University, Yufu, Oita, Japan*

**Background:** STS are rare malignant tumors and relatively resistant against chemotherapy. We have previously reported the efficacy of perioperative chemotherapy with ADM and IFO for STS in the extremities (JCOG0304) in ASCO 2011(abstract ID:#10078). In the present study, we carried out analysis of the factors influencing on survival of the patients in JCOG0304. **Methods:** Patients with operable, high-grade non-round cell STS (T2bN0M0) in the extremities were treated with preoperative ADM 60mg/m$^2$ plus IFO 10g/m$^2$ for 3 courses with 3-week interval, followed by operation and postoperative 2 courses of the same regimen. The histological grade of the tumor was assessed using both FNCLCC system (FNCLCC grade) and positivity of Ki67 in the tumor cells (MIB-1 grade). Promising prognostic factors identified by log-rank test were included in multivariate Cox regression model. **Results:** A total of 72 patients were enrolled in JCOG0304 and 70 all eligible patients were analyzed for this study. The clinical factors regarding age, sex, performance status, histologic subtype, tumor differentiation score, mitosis, and necrosis of biopsy specimen did not significantly influence on overall survival (OS). Although FNCLCC grade was also not associated with OS, histologic grade assessed using MIB-1 (grade 2 vs 3) was only the factor significantly associated with OS (HR 4.12 (95%CI:0.89-19.09), p=0.049). MIB-1 was also associated with OS on multivariate analysis (HR:4.05 (95%CI:0.86-19.15), p=0.077). **Conclusions:** Among factors tested in the present study, only MIB-1 grade was associated with survival of the patients treated in JCOG0304. This is the first clinical trial demonstrating that MIB-1 expression is prognostic factor of the patients with operable STS in the extremities. The results indicate that MIB-1 system might be useful for the better evaluation of histological grade of STS. Clinical trial information: C000000096.

**10578 General Poster Session (Board #285), Mon, 8:00 AM-11:45 AM**

**Primary epithelioid angiosarcoma.** *Presenting Author: Silvia Stacchiotti, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** Epithelioid angiosarcoma (EAS) is a rare sarcoma. Complete surgical resection, when feasible, is the mainstay of therapy. Relapse rate after complete resection of primary tumor ranges from 45 to 70%, with a median survival (OS) of about 5 years. A multidisciplinary approach combining surgery, radiotherapy (RT) and/or chemotherapy (CT) is advocated by many, but there are no definitive data on the efficacy of (neo)adjuvant CT. **Methods:** We retrospectively reviewed all primary, localized, completely resected EAS observed at our institution (INT) from 1/2005 to 6/2013. We considered patients (pts) in whom at least one phase of treatment (surgery and/or RT and/or CT) was performed at INT. We excluded pts not amenable to complete surgery. Diagnosis was centrally reviewed. **Results:** Fifty-one pts were identified (46 surgically treated at INT). M/F: 16/35. RT-related: 20. Primary tumor site: breast, 29 (skin/gland: 22/7); extremities, 10; other, 12. Single versus multifocal: 39/13. Median tumor size of monofocal lesions: 5 cm (range 1-21). 20/51 (39%) pts received RT; 31/51 (60%) pts were treated with CT, of whom 4 were unresectable at baseline and 11 multifocal. Median number of cycles: 5 (range 3-8). Regimens were: anthracycline + ifosfamide,12 pts; gemcitabine +/- taxanes, 18. Median follow-up (FU) was 34 months (range 5-96; 4 pts lost to FU). 14 pts relapsed (Local-LR/Distant-DR 4/10). All LR were observed in post-RT skin EAS. 3/10 DR occurred in $<$5 cm tumors. RFS and OS were 68/62% and 85/68% at 2/5 yrs. Median time to relapse was 8 months (range 2-35). Following distant relapse, OS from relapse was 22/22% at 2/5 yrs (13-month median OS). Among 31 pts treated with CT, RFS and OS were 62/62% and 88/60% at 2/5 yrs. Ten pts received GEMTAX; their RFS and OS were 75/75% and 100/100% at 2/5 yrs, as compared to the others receiving CT, whose RFS and OS were 69/50 and 83/50 at 2/5 yrs. **Conclusions:** In this series of 51 pts, RFS and OS were apparently better than in published studies. More than half of pts received CT. Those receiving CT had worse prognostic factors, but their outcome was similar to those who did not receive any (neo)adjuvant CT. Amongst CT regimens, GEMTAX was associated with a better outcome. In this rare sarcoma, these data suggest hypotheses to test in prospective studies.

**10579 General Poster Session (Board #286), Mon, 8:00 AM-11:45 AM**

**Pazopanib in uterine sarcoma (UtS): Review of two European Organisation for Research and Treatment of Cancer (EORTC) and GSK clinical trials 62043 and 62072 on pazopanib for soft tissue sarcoma (STS).** *Presenting Author: Isabelle Laure Ray-Coquard, Centre Léon Bérard, Lyon, France*

**Background:** Pazopanib has been introduced recently in the treatment for patients with advanced STS. Multiple chemotherapies have been investigated for the treatment of advanced and recurrent UtS, but most of them result in only moderate response rates (RR) and duration. **Methods:** In this retrospective analysis we investigated the outcome of UtS pts treated with pazopanib in the two EORTC clinical trials, the phase II 62043 (n= 142) and the phase III trial 62072 "Palette study" (n= 246). **Results:** Forty-four pts with a UtS were treated with pazopanib. Histology was leiomyosarcoma (89%) and undifferentiated UtS (3%), 84% had histological grade 3 disease. Median age was 55 years (range 33-79 ; 16% $>$ 70y), 41% had performance status (PS) 0, 59% PS 1. At start of pazopanib 73% had lung metastases, 27% bone metastases, 25% liver metastases, 39% other metastases, and 14% had local recurrence. Most pts (83%) stopped pazopanib due to progressive disease, 14% due to toxicity. 28/44 pts (64%) reported a grade 3-4 adverse event while on treatment similar to the toxicity profile reported in non UtS pts. Five pts achieved a partial response (PR), 25 patients had stable disease. Thus 68% pts achieved clinical benefit, similar to that reported with non UtS. Median PFS was 3.0 months (95% CI 2.5 - 4.7) versus 4.5 (95% CI 3.7 – 5.1) with other STS; median OS was 17.5 months (95% CI 11.1 – 19.6) versus 11.1 (95% CI 10.2 – 12.9). As subsequent treatment, 27 (66%) patients received futher chemotherapy after progression and 9 (22%) underwent surgery. Due to the limited number of pts we could not identify significant predictive factors for the outcome of these patients. But, comparing uterine leiomyosarcomas, RR is 12.8% in these two trials versus 5.3% with leiomyosarcomas of non-uterine origin. **Conclusions:** Pazopanib shows similar efficacy in UtS as in non UtS. Median OS for UtS is longer compared to other subtypes in this small group. As post-study treatments were more often given to UtS pts compared to other STS pts, this might have contributed to the better OS.

**10580 General Poster Session (Board #287), Mon, 8:00 AM-11:45 AM**

**Correlation of different CT densities of untreated dedifferentiated liposarcoma (ddLPS) with rate of growth.** *Presenting Author: Sree Harsha Tirumani, Dana-Farber Cancer Center Institute/Brigham and Women's Hospital, Boston, MA*

**Background:** The biologic behavior of ddLPS is spatially and temporally heterogeneous. On imaging, untreated ddLPS shows widely varied CT densities. In this study, we retrospectively analyzed tumor growth rate as a function of tumor density. **Methods:** We identified 44 patients (pts) with ddPLS (35M, 18F; mean age at diagnosis= 59 years, range, 35 – 82 years) who had one or more resections and no intervening chemo or radiotherapy. Two radiologists reviewed CT imaging immediately obtained before the surgical resection (pre-surgery) and up to a maximum of one year before the surgery (baseline) to note the density of the nonlipomatous elements and the rate of growth during that period. Clinical and histopathological data were extracted from the electronic medical records. **Results:** We observed three distinct densities of the nonlipomatous components in our study: soft tissue density (SD) (>20HU), fluid density (FD) (-10 to +20HU), and mixed density (MD) (combination of soft tissue, fluid or fat). Tumors were of intermediate grade (36 SD, 9 MD, 5 FD) or high grade (18 SD, 2 MD, 1FD). Grade was unavailable for 1 tumor. Pre-surgery scans showed 72 tumors including 55 SD, 11 MD, and 6 FD. Baseline scans were available for 35 of the 72 lesions and included 26 SD, 5 MD, and 4 FD. The respective median growth rates per month were 40% (SD), 28% (MD), and 72% (FD). There was a change in density in 1/ 5 MD lesions (to SD) and 3/4 FD lesions (to SD). **Conclusions:** ddLPS has three distinct densities on imaging. Fluid density lesions have rapid growth rate and often convert to soft tissue density. Whether fluid density lesions need more aggressive management given their rapid growth rate needs further evaluation.

**10581 General Poster Session (Board #288), Mon, 8:00 AM-11:45 AM**

**Improved survival in an exhaustive population based on a cohort of liposarcoma (LPS) patients treated in expert centers according to clinical practice guidelines (CPG'S): Experience from Rhone Alpes (RA) region.** *Presenting Author: Olfa Derbel, Centre Léon Bérard, Lyon, France*

**Background:** Liposarcoma (LPS) represents the most common soft-tissue sarcoma.The aim of this prospective and exhaustive population-based study is to explore the impact of medical practices conformed to CPG's on survival of patients with localized LPS in a region of 6 million inhabitants. **Methods:** Between 2005 and 2007, 133 patients out of 141 with an initial diagnosis of localized LPS and residing in the RA region (France), were enrolled. The prognostic impact of adherence to CPGs on progression-free survival (PFS) and overall survival (OS) was assessed with a multivariate Cox model analysis including all potential prognostic factors (PF). **Results:** The median age was 61 years (range 26-89). Sex ratio: M/F was 1.5; the histological subtypes were: well differentiated LPS (n=86, 64.5%), dedifferenciated LPS (n=29, 22%), myxoid (n=12, 9%) and pleiomorphic (n= 6, 4.5 %). Histological grade was low in 96 patients (73%), intermediate in 16 (17%) high in 12 (9%) and unknown in 2 (1%), 48.8% of tumors were localized in limbs (n=65), 44.3% in retroperitoneum (n=59) and 6.8% in other sites (n=9). The adherence to CPGs for patients with localized LPS was 53%, for initial surgery. In multivariate analysis, adherence of surgery to CPGs was the strongest independent prognostic factor (PF) of PFS (HR: 0·32; 95% CI [0·16-0·61]), along with age at diagnosis ≤60 years (HR: 0·42; 95% CI [0·21-0·83]), grade (low vs. high, HR: 0.16, 95% CI [0.07-0.37]; intermediate vs. high, HR: 0.8, 95% CI [0.34-1.85]) and tumor site (limbs vs. retroperitoneal tumors HR: 0·49, 95% CI [0·24-1·01]; head, neck and thoracic vs. retroperitoneal tumors HR: 0·12, 95% CI [0·02-0·93]). For OS, independent PF were adherence to CPGs for surgery (HR: 0.36 95% CI [0.15, 0.84]), age at diagnosis ≤60 years (HR: 0·34; 95% CI [0·14-0·85]) and grade (low vs. high, HR: 0.05, 95% CI [0.02-0.15]; intermediate vs. high, HR: 0.53, 95% CI [0.22-1.29]). **Conclusions:** In this exhaustive population-based study, adherence to CPGs is one of the major significant PF of survival for localized LPS patients. Organization of rare cancer care and physician's education are urgently needed.

**10582 General Poster Session (Board #289), Mon, 8:00 AM-11:45 AM**

**Predictors of overall survival in patients diagnosed with desmoplastic small round cell tumor (DSRCT).** *Presenting Author: Alexander Noor Shoushtari, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** DSRCT is a rare, aggressive, and poorly understood neoplasm characterized by the EWS-WT1 translocation. Prognosis is poor despite upfront multimodality therapy with surgery, radiation (RT), and high-dose chemotherapy. We performed a retrospective review of patients (pts) with DSRCT at Memorial Sloan Kettering Cancer Center (MSKCC) to assess the association between overall survival (OS) and various clinical and therapeutic variables. **Methods:** We collected demographic/clinical data on pts diagnosed with DSRCT from 1995-2011 who had pathologic review and ≥1 oncologic consultation at MSKCC. Living pts were censored at time of last contact. First-line therapies were classified as follows: optimal (R0/R1) vs suboptimal (R2) surgery; consolidative RT; auto transplant; and chemotherapy: high-dose cyclophosphamide (HDCy) vs. standard Ewing's regimen [sER] vs other. Univariate (UVA) and multivariate (MVA) analyses were performed. **Results:** 191 patients were identified; 152 (80%) male, median age 22.6 years (yr) (range 4-62), 67% Caucasian. Most common primary site was abdomen and pelvis (A/P, 94%). Pts had disease (dz) present in A/P only (40%) or A/P plus: liver/spleen (21%), extra-abdominal (17%), or multiple distant sites (21%). Median OS (mOS) was 2.4 yr (range 0.04-12) with a median f/u 6.5 yr. UVA revealed mOS varied by site of dz, with A/P alone superior to A/P plus liver/spleen or multiple distant sites (2.8 vs 2.5 vs 2.3 yr, p=0.001). Age was not associated with mOS (p=0.90). MVA for mOS in 148 pts with complete covariates identified: optimal surgery vs suboptimal (3.2 vs 2.4 yr; HR 0.48, CI 0.29-0.78, p=0.003); consolidative RT vs no RT (3.2 vs 2.4 yr; HR 0.53, CI 0.31-0.91, p=0.021); and sER chemotherapy vs HDCy (2.7 vs 2.4 yr; HR 0.59, 0.38 – 0.93, p=0.024) as associated with improved OS. **Conclusions:** This is the largest DSRCT case series reported to date and represents the first MVA of the impact of multimodality therapy. Although overall prognosis remains dismal, R0/1 surgery and consolidative RT were associated with improved OS. sER was associated with improved OS over HDCy, but the magnitude of benefit was small. Further research and collaborations are needed to improve outcomes in these patients.

**10583 General Poster Session (Board #290), Mon, 8:00 AM-11:45 AM**

**Defining the chemotherapy (CT) response in well-differentiated (WD) and dedifferentiated (DD) liposarcomas (LPS) of the retroperitoneum (RP): A tertiary referral cancer center experience.** *Presenting Author: Neeta Somaiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** WD/ DD LPS is the most common LPS subtype, predominantly arising in the RP. Surgery is the primary treatment, but recurrences are frequent. CT is usually reserved for unresectable cases and the reported RECIST response rate (RR) is 12% (Italiano et al. 2012). However, in our experience, RECIST does not capture morphological changes consistent with response on imaging. Our objective was to review RR to CT and describe radiologic patterns of response. **Methods:** Search of the tumor registry for patients (pts) with RP WD/DD LPS who received CT at MD Anderson Cancer Center from 2003-2013 yielded 48 pts. The pathology database registered 316 new pts with RP WD/DD LPS in the same time frame. Data was collected from the electronic charts and the Social Security Death Index. Here we report the results for the first 48 pts; updated analysis with RECIST and imaging characteristics by an independent radiologist will be presented at the meeting. **Results:** Of 48 pts, 40 had WD/DD confirmed on pathology and were included; 2 had only WD LPS. Median age was 58 (48-65). Male/female ratio was 22/18. Nineteen pts received neoadjuvant CT (Group 1); 15 received CT for recurrent disease after upfront surgery (Group 2) and 6 received CT only (group 3). Based on the radiology report, response to first-line CT was: partial response (PR) 15/40, stable disease (SD) 19/40 and progression (PD) 6/40. Majority (36) received combination CT, mostly doxorubicin (A)-ifosfamide (I) (RR by CT regimen summarized in Table 1). In Group 1, 15/19 recurred after a follow-up of 30.4 months (m) (15.6-42). In groups 2 and 3, progression-free survival after starting CT was 5.4 m (2.1-9.0). One/two-year survival was: Group 1 100%/79%; Group 2 100%/93%; Group 3 77%/39%. Median survival was 50.5 m (29-194) for all patients. **Conclusions:** Combination CT yields a RR of 37% in WD/DD LPS. Analysis of the imaging characteristics will help us better understand response patterns in relation to RECIST.

**Response to CT in WD/DD LPS.**

**10584 General Poster Session (Board #291), Mon, 8:00 AM-11:45 AM**

**Prognostic factors in hemangioendotheliomas (HE): Analysis based on the Surveillance, Epidemiology, and End Results (SEER) program.** *Presenting Author: Monica Reddy Muppidi, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** HE are rare vascular soft tissue (ST) tumors with variable clinical biology. Prognostic factors and treatment (rx) options are poorly defined. This study aimed to describe patient (pt) and tumor features of HE and identify predictors of survival using the SEER database (1973-2010). **Methods:** HE and epithelioid HE (EHE) pts were identified using codes 9130/3, 9133/3. Demographics, tumor features and rx were retrieved. We sorted age cohorts based on Adolescent and Young Adult Oncology Progress Review Groups into children (0-15 yrs), young adults (16-39), adults (40-64), elderly (>65). Overall survival (OS) and disease specific survival (DSS) were compared using multivariate (MVA) proportional hazards methods controlling for age, gender, race, grade, stage, radiation (RT), surgery (S), size, year and histology. Analyses were done using SAS version 9.4. **Results:** 606 pts (296 EHE) were identified; median age 52 yrs (0-97), 52% female. 72% pts were > 40 yrs and most were white (85%). 443 pts had grade (G) 3 tumors. 36% cases were diagnosed from 2001-10, compared to 20% from 1973-1980. 52% had locoregional disease and 29% were metastatic. ST (38%), liver (18%) and bone (14%) were most common sites affected. 65% underwent S and 24% received RT. Tumor size data available on 406 pts revealed 27% tumors < 5cm. At a median follow-up of 70 months (m), the median OS was 35m (95% CI 27, 46); 5-yr OS was 43%. 5-yr DSS was 58%. In a univariate model on 401 pts (excluding 205 pts with missing data), age > 40, tumor grade 2/3, size > 5cm, distant disease and absence of S predicted for poorer OS. MVA for OS confirmed worse prognosis for adults (HR 3.6; 95% CI 1.3, 9.97), elderly (HR 12.85; 4.57, 36.14), G2 tumors (HR 1.74; 1.01, 3), size 5-10cm (HR 2.92; 1.69, 5.06), size > 10cm (HR 2.45; 1.29, 4.63), distant disease (HR 3.04; 1.97, 4.7) and no S (HR 1.71; 1.22, 2.42); all p-values < 0.05. Females had improved DSS (HR 0.69; 0.48, 0.98; p=0.04) but similar OS. Race, EHE histology and RT did not affect DSS or OS. **Conclusions:** Recognizing inherent bias using SEER data, age, tumor size and grade were predictive factors for survival in this study, the largest of its kind in HE. Surgical resection is important for improving outcome in HE.

**10585 General Poster Session (Board #292), Mon, 8:00 AM-11:45 AM**

**Multicenter retrospective analysis of 31 patients with aggressive angiomyxoma.** *Presenting Author: Roberta Sanfilippo, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

**Background:** Aggressive angiomyxoma is a rare mesenchymal neoplasm of perineum and pelvic region. Surgery is the main treatment, but local recurrences are frequent. Responses to hormonal therapy have been anecdotally reported. **Methods:** Aggressive angiomyxoma patients (pts) treated since August 1999 at two institutions (Istituto Nazionale Tumori, Milan, Italy, and Centre Léon Bérard, Lyon, France), and within the Italian Rare Cancer Network (RTR) were reviewed. Data regarding surgical and systemic therapy and survival were collected. **Results:** We identified31 patients (mean age: 43 years; F/M= 25/6). Anatomic site of occurrence was the perineum in 11/31 pts (35%) and the pelvis in 20/31 (65%) pts. Twenty-nine pts (93%) underwent at least one surgical procedure (R0/R1= 19; R2=9). Following complete surgery (R0 and R1), the local relapse rate at 2 yrs was = 21% (4/19 pts), with a median relapse-free survival (RFS) of 39 mos, Eleven patients (35%) received hormonal therapy for locally advanced disease. Eight patients received GnRH agonist as first-line therapy (6 pts as a single therapy and 2 patients in combination with tamoxifen). Seven were evaluable for response, with 2 CR, 3 PR and 2 SD, and a median PFS of 22 mos. One of these 8 pts, stopped her treatment while in CR and restarted treatment at the time of progression, obtaining a new CR. Two pts treated with GnRH agonist as first-line therapy were added an aromatase inhibitor after progression and reached a CR and a PR, respectively. Two patients received aromatase inhibitors as first-line therapy and reached a SD as their best response. One pt received tamoxifen as first-line therapy, with a PR as her best response. Median overall survival has not been reached, since all patients were alive at the time of this analysis. **Conclusions:** This is a large series of pts with aggressive angiomyxoma. Our results confirm the high rate of local recurrences after surgery. Hormonal therapy is an effective therapeutic option, which is able to result in sustained CRs in a fraction of pts. Treatment strategy of this disease needs to be defined.

**10586 General Poster Session (Board #293), Mon, 8:00 AM-11:45 AM**

**The role of pazopanib in various histologic subtypes of metastatic soft tissue sarcomas.** *Presenting Author: Kwai Han Yoo, Department of Medicine, Division of Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** Soft tissue sarcomas (STS) are a rare and heterogeneous group of tumors, and known to have limited treatment options.We investigated the treatment outcome of pazopanib, an oral multi-tyrosine kinase angiogenesis inhibitor, in patients with advanced STS. **Methods:** A total of forty-four patients with relapsed or refractory STS with metastatic disease received pazopanib for salvage chemotherapy after one or more cytotoxic regimens. All patients were analyzed by histologic subtype, FNCLCC grade and existence of liver involvement and locoregional disease. **Results:** The majority of patients were male (n=26, 59%) and one (n=9, 20.5%) or two (n=15, 34.1%) previous chemotherapy was introduced. Common histologic subtypes were as follows; leiomyosarcoma (n=9), angiosarcoma (n=6), malignant perpheral nerve sheath tumor (n=5) and liposarcoma (n=2). 9 patients (20.5%) achieved confirmed partial response and 16 patients (.36.5%) revealed stable disease, resulting in disease control rate (DCR) of 56.8% (95% CI, 41.8-71.8). The median progression free survival (PFS) and overall survival (OS) were 100 and 199 days, respectively. The non-liposarcoma group (such as leiomyosarcomas, angiosarcomas and osteosarcomas, n=38) demonstrated significantly prolonged PFS than pediatric type and liposarcoma group (including rhabdomyosarcomas and small round cell sarcomas, n=6) (P<0.001). The median PFS were 132 and 115 days for angiosarcomas (n=6) and leiomyosarcomas (n=9), while rhabdomyosarcomas (n=3) and liposarcomas (n=2) patients demonstrated 27 and 39 days, respectively. **Conclusions:** Pazopanib demonstrated better antitumor activity for the patients with angiosarcoma and leiomyosarcoma compare to liposarcoma and pediatric type sarcoma.

**10587 General Poster Session (Board #294), Mon, 8:00 AM-11:45 AM**

**A phase 1b food effect study of the first-in-class, oral, selective inhibitor of nuclear export (SINE) selinexor (KPT-330) in patients (pts) with advanced sarcomas.** *Presenting Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Sarcomas are heterogeneous diseases with multiple genetic abnormalities. XPO1 inhibition can restore the activity of multiple tumor suppressor proteins (TSP) including p53, Rb, and p27; and reduce cyclins and Akt. Selinexor is an oral XPO1 inhibitor that showed potent anti-sarcoma activity in preclinical ASPS, lipo- and bone sarcomas, and preliminary clinical activity in a phase 1 study. **Methods:** Oral selinexor was given at 30 mg/m$^2$ twice weekly in capsule or tablet form based on an ongoing Phase 1. Appetite stimulants and anti-nausea agents were given. Pharmacokinetic (PK) analyses were performed under fasting and fed states (low vs high fat content). Paired tumor biopsies were obtained. Response evaluation was every 8 weeks (RECIST 1.1). All pts had documented progressive disease (PD) on study entry. **Results:** 16 evaluable pts (7 M/9 F; median age 55 yrs; median prior regimens: 3; ECOG PS 0/1: 11/6) including 5 leiomyo- (LMS), 4 lipo- (LPS), 3 synovial (SS), and 4 other sarcomas. Grade 3-4 toxicities in cycle 1 included thrombocytopenia without bleeding (12%) and hyponatremia (6%). The most common grade 1/2 AEs in cycle 1 were: nausea (59% G1/6% G2), fatigue (29%/29%), diarrhea (41%/6%), anorexia (18%/6%). PK in 11 patients showed similar exposures ($AUC_{0\text{-}inf}$ 3675 vs 3574 ng·hr/mL) of the drug in capsules or tablets; however, food (regardless of fat content) was associated with ~15% increased exposure versus fasted state. Analyses of tumor biopsies during treatment showed that selinexor resulted in nuclear localization of p53 and FOXO1, reduction in XPO1, reduced Ki67 index, increased apoptosis. Response was evaluable in 16 pts: (a) LMS: 3 stable disease (SD, 1 pt with 12% shrinkage), 2 PD; (b) LPS: 4 SD (1 pt with 10% shrinkage); (c) SS 3 PD; (d) chondrosarcoma: 1 SD, 1 PD; (e) chordoma: 1 SD; (f) spindle cell: 1 PD. 9 of the 16 pts remain on study (75-121 days). **Conclusions:** Selinexor should be taken with food and is generally well tolerated in pts with supportive care. Tumor shrinkage and disease stabilization was observed in a variety of soft tissue sarcomas leading to expansion of the study. Additional studies of selinexor in soft tissue sarcomas are planned. Clinical trial information: NCT01896505.

**10588 General Poster Session (Board #295), Mon, 8:00 AM-11:45 AM**

**Malignancy grade and immunohistochemical myogenic/rhabdomyoblastic differentiation as an outcome determinant in retroperitoneal liposarcoma.** *Presenting Author: Alessandro Gronchi, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

**Background:** To explore the impact of malignancy grade and myogenic/rhabdomyoblastic differentiation on the natural course of retroperitoneal liposarcoma, uniformly treated at a single institution. **Methods:** All consecutive patients affected by primary WD/DD retroperitoneal liposarcoma surgically treated at our institution between January 2002 and December 2011 were retrospectively evaluated. Tumors were stained for mdm2 and 5 myogenic markers (smooth muscle alpha-actin [1A4], h-caldesmon, calponin, desmin, myogenin). French National Federation of the Centers for the Fight Against Cancer criteria (FNCLCC grade: 1,2,3) were applied. A diagnosis of myogenic differentiation was rendered when at least one myogenic marker was expressed. A diagnosis of rhabdomyoblastic component was rendered only if myogenin was positive. Overall survival (OS), local recurrence free survival (LRFS) and distant metastases free survival (DMFS) were calculated according to grading and absence/presence/type of myogenic differentiation. **Results:** 146 patients were identified. Median follow-up was 35 months (IQ, 22-66). 54 patients were affected by WD and 92 by DD liposarcoma. Among the latter, 60 were G2 and 32 G3. Myogenic differentiation was present in 52 cases (29/59 G2, 23/32 G3). 8 cases had a rhabdomyoblastic component (3/59 G2 and 5/32 G3). 5-yr OS were 92%, 51%, 24%; LRFS were 77%, 43%, 45% and DMFS were 100%, 82%, 32% for WD liposarcoma, G2 and G3 DD liposarcoma, respectively ($p < 0.001$). The outcome on the short run was strongly associated to the absence/presence of myogenic differentiation or rhabdomyoblastic component (3-yr OS 70%, 56% and 38%, respectively $< 0.001$). In particular all patients affected by G3 DD liposarcoma with a rhabdomyoblastic component died within 1 yr, recurring shortly after surgery with widespread disease. **Conclusions:** Beside FNLCC grade, absence / presence of myogenic differentiation with or without rhabdomyoblastic component significantly predicted the outcome of retroperitoneal liposarcoma. They should be factored in the treatment decision making and possibly used to stratify patients in clinical trials.

**10589 General Poster Session (Board #296), Mon, 8:00 AM-11:45 AM**

**Extraskeletal myxoid chondrosarcoma: A retrospective analysis of 69 patients with localized disease and molecularly confirmed diagnosis.** *Presenting Author: Anna Paioli, Istituto Ortopedico Rizzoli, Bologna, Italy*

**Background:** Extraskeletal myxoid chondrosarcoma (EMC) is a rare sarcoma of uncertain origin, marked by specific chromosomal translocations: t(9;22)(q22.3;q12.2), t(9;17)(q22.3;q12) and t(9;15)(q22.3;q21.3), and usually characterized by indolent course. Surgery +/- radiotherapy is the mainstay of treatment. In order to better evaluate prognostic factors and outcome, a retrospective pooled analysis of all patients surgically treated for localized EMC in two referral institutions for treatment of sarcoma (Istituto Ortopedico Rizzoli, Bologna, Italy; Istituto Nazionale Tumori, Milano, Italy) was carried out. Diagnosis was centrally reviewed in all cases. **Methods:** All patients (pts) with molecularly confirmed diagnosis of localized EMC, surgically treated between period 1994-2012 at either institution, were included. **Results:** 69 pts were identified (22 female; 47 male); median age: 55 years (range: 15-81). Tumor location was: extremities 49 (71%), limb girdles or trunk 20 (29%), with a median size of 8 cm (range: 2-38). 56 (81%) pts had primary disease and 13 (19%) recurrent. Median overall survival (OS) was 47 months (range 1-284).OS at 5- and 10-year was 88% and 82% respectively. 35 (51%) pts relapsed [12 local recurrence (3 with lung metastasis) and 26 distant recurrence (20 lung and 6 locoregional lymphnodes)], with a 5-year post-relapse survival of 76%. Event free survival (EFS) at 5- and 10- year was 51% and 26%. Size influenced EFS (5 year EFS was 75%, 47% and 39% for size $<5$ cm, 5-9 cm and $>9$ cm, respectively; p 0.001), while sex, tumor location and radiotherapy did not. EFS did not significantly differ by type of translocation but the median time to recurrence was 60 months in pts with t(9:22) and 25 months with t(9:17). 13 pts received systemic treatment for metastatic disease with 3 PR. **Conclusions:** A prolonged survival can be expected in patients with EMC, despite a high rate of local and distance recurrence. Size is significantly associated with outcome. The use of radiotherapy does not increase the EFS. Patients bearing t(9:22) recur later than those with t(9:17). Some PR were reported after chemotherapy treatment.

**10590 General Poster Session (Board #297), Mon, 8:00 AM-11:45 AM**

**Aplidine in patients with dedifferentiated liposarcomas: A French Sarcoma Group (FSG) study.** *Presenting Author: Antoine Italiano, Institut Bergonié, Bordeaux, France*

**Background**: Dedifferentiated liposarcomas (DDLPS) exhibit a strong activation of the JUN/JNK pathway which plays a crucial role in the dedifferentiation process. Aplidine is a novel anticancer drug requiring an activation of the JNK pathway to induce apoptosis in several tumors models. **Method**s: This was a multicentric single-arm phase 2 clinical trial based on two-stage Simon's design which assessed safety and efficacy of aplidine in patients (pts) with advanced DDLPS. All pts had to have documented progressive disease (PD) as per RECIST 1.1 based on two imaging of less 3-months interval. Pts received aplidine 5 mg/m$^2$ every two weeks until PD or unacceptable toxicity. The primary endpoint was the 3-month non-PD rate according to RECIST. Based on the following hypotheses: 20% 3-month non-PD rate (H0), 40% acceptable 3-month non-PD rate (H1), 10% type I error rate, 90% power, a total of 37 assessable pts were necessary (17 for the first stage + 20 for the second stage). Following the inclusion of the first 17 pts, if $\geq$ four pts were progression-free at 3 months, the accrual was planned to continue. Accrual started in August 2012 and finished in May 2013 in six centers of the French Sarcoma Group. **Results**: As of May 27 2013, 24 pts (12 males, 12 females) were included in the study. Median age was 63 years (48-83). All the patients had at least one grade 1 or 2 adverse events (AE) possibly related to the drug whereas 11 pts (7.5%) had grade 3 or 4 AE. The most frequent adverse events were nausea, fatigue, anorexia and myalgia. The planned interim statistical analysis performed after central histological and radiological review showed that only one patient out of the first 17 evaluable patients had stable disease. Aplidine did not reach the primary endpoint to justify continuing accrual after the 1$^{st}$step of the study. Molecular analyses showed that JUN expression and amplification status were not correlated with outcome. **Conclusions**: The rapid accrual of this study demonstrates the feasibility of histology-specific research in sarcomas. Aplidine is not worth for further investigations in DDLPS. Clinical trial information: NCT01876043.

**10591 General Poster Session (Board #298), Mon, 8:00 AM-11:45 AM**

**Brain metastases in sarcoma patients: Incidence and outcome.** *Presenting Author: Mathias Hoiczyk, Department of Medicine (Cancer Research), West German Cancer Center, University Hospital Essen, University Duisburg-Essen, Essen, Germany*

**Background:** Soft tissue sarcomas (STS) are biologically heterogeneous tumors that share a similar clinical behavior. Metastases most often occur in the lung, bones and the liver. Little data is available on incidence, prognosis, treatment and outcome of patients with cerebral metastases. **Methods:** The institutional sarcoma patient database (n=1912) and the PACS system were queried for patients with sarcomas and cerebral metastases in the years of 2003-2013. Patient characteristics and outcomes were retrospectively analyzed and overall-survival was calculated from the time of diagnosis of cerebral metastases. **Results:** 17 male and 14 female patients were identified with a median age of 38 years (range 20-73). Synchronous metastases were found in 10 (< 6 months) and metachronous metastases in 21 patients. Most frequent histologies were leiomyosarcoma (n=5), undifferentiated pleomorphic/spindle cell sarcoma (n=5), alveolar soft part sarcoma (ASPS) (n=5 from a group of 14 patients), Ewing sarcoma (n=3) and liposarcoma (n=3). Median time from diagnosis of sarcoma to diagnosis of metastases was 12 months (range: 0–155 months). Imaging was performed following work-up of CNS symptoms. 10 out of 28 patients received metastasectomy which was associated with a trend towards an improved post-metastases survival (14 vs. 4 months; p=0.3). Median time from diagnosis of cerebral metastases until disease specific death or last follow-up was 8 months (range: 0–130 mo). 6 patients had isolated cerebral metastases among which 3 long-term survivors were observed (59, 75 and 130 months at last FU). Long-term survival was not seen in patients with additional metastatic sites (median OS of 6 months). **Conclusions:** Cerebral metastases from STS are exceedingly rare (<3%) especially at the time of diagnosis for localized tumors. Restriction of CNS imaging to patients with symptomatic disease is reasonable for the majority of STS. In contrast, the risk of CNS metastases is high in ASPS (36%) and imaging studies should be included in routine diagnostic work-up. Long-term survival can be observed in STS patients with isolated brain metastases who undergo local treatment.

**10592 General Poster Session (Board #299), Mon, 8:00 AM-11:45 AM**

**Activity of chemotherapy in a series of patients with locally advanced or metastatic pleomorphic rhabdomyosarcoma: A retrospective analysis.** *Presenting Author: Michela Libertini, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** Pleomorphicrhabdomyosarcoma (pRMS) of the adult is a rare and controversial sarcoma marked by skeletal muscle differentiation. Few data are available on the efficacy of chemotherapy in pRMS, and no definitive data support the efficacy of treatment strategies usually applied for other rhabdomyosarcoma subtypes. We reviewed response to chemotherapy in patients with pRMS treated within the Italian Rare Cancer Network (RTR). **Methods:** We retrospectively reviewed adult patients with pRMS treated at our institution or within RTR since 2001, focusing on patients treated with chemotherapy. Response was evaluated by RECIST. **Results:** Fifty-seven patients with pRMS were selected. Thirty-six of 57 patients received chemotherapy. Among them, 26 patients (M/F: 21/5–mean age: 55; range 21-80 years; locally advanced/metastatic at the onset 18/8) were evaluable for response. Twelve of 18 patients progressed to metastatic disease after local treatment. 12/20 patients in the advanced phase were evaluable having received at least one chemotherapeutic regimen. **Conclusions:** Our data suggesta moderate activity of chemotherapy in pRMS. Interestingly, 3/3 pre-treated patients who received gemcitabine in the advanced setting had a PR.

**Mitomycin C, doxorubicin, and cisplatin: as a safe and effective preoperative chemoradiation cocktail for soft tissue sarcomas.** *Presenting Author: Meera Sridharan, Mayo Clinic, Rochester, MN*

**Background:** Soft tissue sarcomas are rare malignancies, often treated with a multidisciplinary approach at high volume centers. This project investigates one such approach employed at the Mayo Clinic, utilizing mitomycin C 6 mg/m2/day, doxorubicin 30 mg/m2/day, cisplatin 45 mg/m2/day for two cycles concomitantly with radiation prior to surgical resection. **Methods:** Following institutional review board approval, the charts of 58 patients (39 male) who received the aforementioned regimen from 2008 through 2012 were retrospectively reviewed. Factors relevant to prognosis and survival were analyzed by Kaplan-Meier methods using JMP statistical software. Survival data was censored at 3 years. Patients with sarcomas greater or equal to 5 cm in dimension were selected for this treatment. **Results:** The histologic subtypes included: undifferentiated sarcoma, liposarcoma, leiomyosarcoma, synovial sarcoma, malignant peripheral nerve sheath tumor, rhabdomyosarcoma, mesenchymal chondrosarcoma and fibrosarcoma. The median age at presentation was 62 years (range 33-78 years) with a median follow up of 37 months (range 6-68 months). Tumors were located primarily in the extremities (44/58; 76%), with a median size of 9.9 cm (range 5 -22 cm). All patients were able to achieve surgical resection. Median tumor necrosis was 72.5% (range 5 -100%) with fibrosarcoma having the poorest response to treatment (median necrosis 20%, n=8). 37 patients (64%) received additional pre- or post-op chemotherapy with doxorubicin and ifosfamide. 23 patients (40%) received intraoperative radiation. The 3-year event free survival (EFS) was 71%. Two of 58 patients (3.4%) suffered a local relapse within 9 (7-11) months. Though not statistically significant, patients who achieved $>$ 90% necrosis or who received pre-or postoperative chemotherapy had superior EFS (84% vs 65% and 78% vs 57% respectively). The postoperative complications included: infection (14), wound dehiscence (1), hematoma (2), and fluid collections (5). **Conclusions:** Preoperative concomitant chemoradiation with mitomycin C, doxorubicin, and cisplatin is a safe and effective regimen for soft tissue sarcomas.

**10594 General Poster Session (Board #301), Mon, 8:00 AM-11:45 AM**

**Phase II study of gemcitabine (GEM) plus sirolimus (SIR) in previously treated patients with advanced soft tissue sarcoma (STS): A Spanish Group for Research on Sarcomas (GEIS) study.** *Presenting Author: Xavier Garcia del Muro, Institut Català d'Oncologia L'Hospitalet, Barcelona, Spain*

**Background:** Combination of chemotherapy and targeted agents could be a strategy to improve efficacy. In preclinical sarcoma models, combination of GEM with SIR enhances apoptosis in vitro and increases anti-tumor efficacy in vivo. A phase I study by our group showed that the combination of both drugs is feasible. **Methods:** Patients (pts) with advanced STS, previously treated with doxorubicin, no prior GEM, ECOG PS 0-2, and adequate hematological, renal and hepatic function, were included in this phase II study, receiving GEM 800mg/m$^2$ iv at 10mg/m$^2$/minute on days 1 and 8 every 3 weeks plus oral SIR at 5mg daily and, after an amendment because of toxicity, SIR was reduced to 3 mg for the remaining patients. Tumor samples from pts were examined for pS6 expression by immunohistochemistry. The primary endpoint was progression-free rate (PFR) at 3 months. A one-sample binomial design was used (PFR P0=20%, P1=40%, $\alpha$=0.15, $\beta$=0.20), requiring at least 9 of 25 pts free of progression at 3 months to be considered positive. **Results:** From May 12 to May 13, 28 pts were enrolled at 8 centers. 1 patient was ineligible because of histology. Median age was 53 (22-71). PS: 0-11, 1-14; 2-2 pts. Histologic types were: LMS 5, UPS 5, Lipo 3, SS 3, MPNST 2, EES 2, other 7 pts. All pts were pretreated with anthracyclines. 12 pts received 5 mg and 15 pts received 3 mg of SIR. The median number of cycles administered was 2 (1-6). PFR at 3 and 6 months was 44% and 20% respectively, with 12 pts being free of progression at 3 months. Median progression-free survival was 1.85 months (95% CI, 0.7-2.9) and median overall survival was 9.1 months (95% CI, 6.1-12.2). No objective responses were observed. Most common grade 3-4 toxicities were neutropenia (44%) with 2 episodes of neutropenic fever, infection (15%), thrombopenia, hepatotoxicity and pneumonitis (11% each). Other toxicities of varying grades included asthenia, emesis, diarrhea and mucositis. No association between pS6 staining and outcome was found. **Conclusions:** The study achieves its primary endpoint. Nevertheless, the combination of GEM and SIR appears to have modest clinical activity and significant toxicity in pts with advanced STS. Clinical trial information: NCT01684449.

**10595 General Poster Session (Board #302), Mon, 8:00 AM-11:45 AM**

**Diversity and heterogeneity in molecular analysis of advanced sarcomas: The clinical, regulatory, and financial challenge for drug development and precision medicine.** *Presenting Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Therapeutic options are limited for advanced sarcomas. Search for molecular alterations could lead to identification of novel therapies for refractory sarcoma patients. Rarity poses an extreme challenge in drug development. **Methods:** We reviewed the charts of patients with advanced sarcoma patients who were referred to the phase 1 clinic at MD Anderson Cancer center and had molecular profiling done by commercially available CLIA certified labs. We analyzed the preliminary responses to matched therapy in these patients. **Results:** Among the 57 pts analyzed, median age =48 years (M: F=25:32), median ECOG PS=1, median no. of prior therapies=3. Most common subtypes were leiomyosarcoma (n=13; 22%), rhabdomyosarcoma (n=8; 14 %), liposarcoma (n=7; 12 %), osteosarcoma (n=7; 12 %), clear cell sarcoma (n=3), and synovial sarcoma (n=3). Forty-five/57 (78%) patients had $>$ 1 genomic aberration. Each pt's aberration profile was distinct. For instance, in osteosarcoma no 2 ps had the same profile. In other soft tissue sarcomas, aberrations involved *CDKN2A/B* loss or mutation (n=10; 22 %), *TP53* alterations (n=15; 33%), *CDK4* amplification (n=8; 17%), *MDM2* amplification (n=7; 15%), and *RB1* loss/mutation (n=6; 13%). In addition, novel aberrations: *KIAA1549-BRAF* fusion protein in a spindle cell sarcoma, CD30 + in osteosarcoma, and *PTPRD* mutation in Ewing's sarcoma were identified. Molecularly matched therapy are ongoing (Table ). **Conclusions:** Based on the uniqueness and distinct biology of sarcoma, we conclude that the established model for drug development in sarcoma of "one size fits all approach" does not fit the reality of sarcoma biology. New creative models for precision medicine with regulatory approval, establishment of levels of evidence, modification of reimbursement policies by health care payers and innovative dynamic ways to collect N of 1 clinical data in real time with open access are warranted.

**10596 General Poster Session (Board #303), Mon, 8:00 AM-11:45 AM**

**14-day continuous infusion ifosfamide in advanced refractory sarcomas.** *Presenting Author: Arun S. Singh, University of California Los Angeles Medical Center, Santa Monica, CA*

**Background:** Ifosfamide is commonly used to treat bone and soft tissue sarcomas (STS) and its efficacy appears to increase with doses >9g/m2/cycle. Due to the toxicity associated with bolus dosing, 14 day CIV outpatient dosing of this medication is being explored as a less toxic, convenient approach. In this study, we present the results of 51 patients who were treated with this regimen. **Methods:** 51 Patients with advanced/metastic bone and STS refractory to standard therapies received 1g/m2/day x 14 days of CIV ifosfamide/MESNA; the dosing was adjusted for tolerance/toxicity. 41 patients were from a retrospective cohort and 10 patients are from a prospectively collected study approved by the Western IRB. Grade 3/4 toxicities were recorded. Patients were assessed for objective response via RECIST 1.1. **Results:** 51 patients received this regimen over the course of 3 years. The most common histologies were high grade leiomyosarcoma (n=18), synovial sarcoma (n=5), HGUPS(n=5), and osteosarcoma (n=5). 63% of patients had 2 or more lines of previous therapy. The response of 6 patients could not be assessed due to death from disease progression, lack of follow up scans or discontinuation of therapy. 1/51 patients had a CR (2%), 11/51 had a PR (23.5%) and the CBR (CR+PR+SD) was 64.5%. The median PFS was 12 weeks (range: 2-120 weeks). Of grade 3/4 hematologic toxicities, 53% had neutropenia, 22% had anemia and 8% had thrombocytopenia. Of grade 3/4 non-hematologic toxicities, 6 patients (11.7%) had confusion, 2 had nausea/vomiting, 1 had CHF and 1 patient died while receiving treatment. No patients had hemorrhagic cystitis. **Conclusions:** 14 day CIV ifosfamide is a viable option for advanced sarcomas with a CBR of 64.5%. The median PFS of 12 weeks compares favorably to the previously reported data. The data in this study has fostered a prospective evaluation of CIV in advanced sarcomas.

**10597 General Poster Session (Board #304), Mon, 8:00 AM-11:45 AM**

**Modified isolated lung perfusion technique for allowance of prolonged perfusion without acute lung injury: A preclinical study with doxorubicin.** *Presenting Author: Pedro Augusto Reck dos Santos, Latner Thoracic Surgery Research Laboratories - University Health Network - Toronto Medical Discovery Tower - University of Toronto, Toronto, ON, Canada*

**Background:** Isolated lung perfusion (ILP) can enhance the treatment of lung metastases, allowing the localized delivery of drugs to the lungs, without systemic exposure. Previously, short-term ILP (± 30 minutes) resulted in variable efficacy and frequent toxicity. We developed a technique that minimizes perfusion-related injury to the lung and allows an extended perfusion time. Using our strategy, our objective is to demonstrate the feasibility and safety of ILP with doxorubicin (Dox). **Methods:** In pigs, left pulmonary artery and veins (PVs) were cannulated and clamped. Left lung ILP with a protective mode of ventilation/perfusion was performed for 4h. Dox 75 mg/m$^2$ alone or with ifosfamide (Ifos) 6 g/m$^2$ is a standard regimen currently used systemically for patients with metastatic sarcomas. Based on this, Dox 75mg/m$^2$ (group 1, n=4), 150 mg/m$^2$ (group 2, n=2), 225 mg/m$^2$ (group 3, n=2), and Dox 75mg/m$^2$ + Ifos 6 g/m$^2$(group 4, n=3) were administered at the start of ILP. After 4h ILP, cannulas were removed and blood reperfusion was allowed for more 4h. Lung physiology (Lphys) was assessed with peak airway pressure (Pawp), dynamic compliance (Cdyn), pulmonary vascular resistance (PVR), and PVs oxygenation (P/F ratio). Lung biopsies were obtained before, after ILP and after reperfusion for histological assessment of acute lung injury (ALI). Lung tissue levels of Dox were measured at the end of reperfusion and systemic levels of Dox were analyzed hourly. **Results:** In groups 1 and 4, Lphys was stable during 4h ILP period and reperfusion, without histologic ALI (p=0.12 and p=0.36). In group 2, P/F ratio dropped at reperfusion, and in group 3, severe ALI happened during ILP (increase of Pawp and PVR, and drop in Cdyn). In groups 1 and 4, mean tissue levels of Dox were 70.3 ug/g, homogeneously distributed in the lung (p=0.12). No Dox was detected systemically during the experiment. **Conclusions:** ILP with standard doses of chemotherapy (groups 1 and 4) was well tolerated using our ILP strategy for an extended period of time and without measurable ALI. In these groups, comparing to previous large animal studies, we found 2-3 x higher tissue levels of Dox, demonstrating the protective effect of our ILP strategy.

**10598 General Poster Session (Board #305), Mon, 8:00 AM-11:45 AM**

**Predictive value of BRCA1 haplotype for trabectedin efficacy in patients with advanced soft-tissue sarcoma.** *Presenting Author: Audrey Laroche, Intitut Bergonié, Bordeaux, France*

**Background:** Trabectedin (T) has shown objective response and disease stabilisation in 5%–10% and 30-40% of unselected patients with advanced soft tissue sarcoma (STS) failing prior anthracyclines and/or ifosfamide chemotherapy. Although the precise mechanism of action of T is not elucidated, this drug has been found to be more active in tumor cells with a deficient homologous recombination (HR) repair system. BRCA1 is a key player of the HER system. Our aim was to determine whether the BRCA1 single nucleotide polymorphims status was associated with clinical activity of T in advanced STS patients. **Methods:** We have analyzed single nucleotide polymorphisms of *BRCA1* in a cohort of 135 patients with advanced STS from nine major referral European centres for STS. All patients were treated between 1999 and 2011 in phase I-II clinical trials or in the context of a compassionate-use programme. T was given at different doses (0.5-3 mg/m$^2$) with the use of two different schedules: a 3-h infusion or a 24-h continuous infusion. BRCA1 haplotype was also assessed in two independent cohorts of patients: (i) localized STS (n=85); (ii) advanced STS managed with doxorubicin (n=44). **Results:** 734 cycles of T were administered, with a median of 3 cycles per patient (range 1–23). One complete response, 16 partial responses, and 29 disease stabilizations that lasted for >6 months were observed. The 6-months non-progression rate was 40.5% for patients who had at least 1 allele of the most frequent BRCA1 AAAG haplotype vs 16.5% for patients with a different haplotype; P = .01). This was also associated with a significant difference in terms of overall survival (P = .009). BRCA1 haplotype was not associated with outcome in the two independents cohorts of patients with localized STS or advanced STS treated with doxorubicin. **Conclusions**: BRCA1 haplotype may represent a predictive DNA-based biomarker for T efficacy in advanced STS patients. In particular, sarcoma patients without AAAG allele (26.5% of patients in our study) are not likely to have sustained benefit from T. Such a biomarker assessable form paraffin-embedded tumor material could be easily integrable into routine practice provided it is validated in a prospective setting.

**10599 General Poster Session (Board #306), Mon, 8:00 AM-11:45 AM**

**Low-dose gemcitabine doxorubicin and docetaxel combination in patients with advanced/unresectable/metastatic sarcoma who failed prior chemotherapy: Updated analysis.** *Presenting Author: Vivek Narasimhan, Sarcoma Oncology Center, Santa Monica, CA*

**Background:** Gemcitabine with Docetaxel is active in soft tissue sarcoma. Doxorubicin is a standard agent for sarcoma with proven efficacy. The combination of Gemcitabine, Docetaxel and Doxorubicin has been studied, and is well tolerated and active in breast cancer and non-small cell lung cancer. This study assesses the safety profile and efficacy of Gemcitabine, Doxorubicin, and Docetaxel regimen in patients with advanced, metastatic and/or unresectable sarcoma. **Methods:** 31 patients with advanced unresectable/metastatic sarcomas who progressed through standard chemotherapy were enrolled with consent. Patients were treated with Gemcitabine 400 mg/m2, Doxorubicin 20 mg/m2, and Docetaxel 20 mg/m2 on days 1 and 8 of a 21 day cycle. Disease was assessed with RECIST 1.1 and median Progression Free Survival(PFS) and Response rates(RR) were calculated. Toxicity evaluation was done using NCI CTCAE 4.2. **Results:** All subjects had advanced metastatic disease and were treated with a median of 2 prior regimens(range1-6). The sarcoma subtypes were Leiomyosarcoma(29%), Dedifferentiated Liposarcoma(13%), Myxoid Liposarcoma(13%), Angiosarcoma(6%), Synovial Sarcoma(6%), Pleiomorphic Undifferentiated Sarcoma(6%) and other(27%). 31% patients were treated with prior Gemcitabine and Taxotere and 67% with prior Anthracycline. The median age was 53(range25-72). 31 patients were enrolled and 26 were evaluable for response. A partial response was observed in one patient and stable disease in 24 patients with a median PFS of 3.5 months. Grade 3 or 4 cytopenias were observed in 45% of patients(7neutropenia, 3Anemia, and 5thrombocytopenia). One patient was taken off study due to toxicity and no significant grade 3 or 4 non-hematologic toxicities were seen. **Conclusions:** The combination of Gemcitabine, Doxorubicin and Docetaxel is well tolerated with manageable toxicity profile. Though response rates were low, this heavily pretreated population demonstrated durable stable disease even when rechallenged with prior used agents. The role of this low dose combination is not well defined but should be considered as an option in the appropriate setting.

**TPS10600 General Poster Session (Board #307A), Mon, 8:00 AM-11:45 AM**

**Phase 1 dose escalation trial of intravenous radium 223 dichloride alpha-particle therapy in osteosarcoma.** *Presenting Author: Vivek Subbiah, Department of Investigational Cancer Therapeutics (Phase I Program), University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Prognosis of patients with osteoblastic metastases from osteosarcoma is extremely poor. Given the heterogeneity in the biology of osteosarcoma, a novel approach is needed to overcome the current therapeutic plateau. Preclinical studies in rodents with alpha particle $^{223}RaCl_2$ ($^{223}Ra$) showed avid skeletal deposition, and relative sparing of the bone marrow. Experience with $^{223}Ra$ in phase I, II and III trials in men with metastatic prostate cancer confirmed excellent activity against bone metastases and a low toxicity profile (i.e., a high therapeutic index) and has been US FDA approved for prostate cancer. Because of the unique physical properties of $^{223}Ra$, this agent is anticipated to be a highly effective and better-tolerated treatment for bone-forming sarcoma. We hypothesize that can be safely administered to osteosarcoma patients, and early response and / or resistance signals can be assessed by correlative imaging studies and biomarkers. **Methods:** We are conducting an investigator initiated, single institution, phase I, dose-escalation trial of $^{223}Ra$ in recurrent or metastatic osteosarcoma patients $>$ 15 yrs and $>$40 kg. To be eligible the patient must have recurrent osteosarcoma with indicator lesion that has uptake of $^{99m}Tc$-MDP on bone scan. The primary objective is to determine the MTD of monthly $^{223}Ra$ in recurrent osteosarcoma pts. The study design is a 3+3 Phase 1 dose escalation with expansion at highest safe dose (N=6). Comparison of safety and toxicity of 50, 75, and 100 kBq $^{223}Ra$ /kg will be made.The secondary objectives are to analyze change in objective measurements of alkaline phosphatase and bone turnover markers at baseline, before dose 4 (mid study) and at end of study (after dose 6) vs change in SUV of PET- scans (18FDG and /or 18FNa) and of SPECT CT for $^{99m}Tc$-MDP. Changes in uptake will be analyzed for dose response effects (between groups) and pre vs mid study and end of study (within group). The first dose cohort of the Phase 1 trial has been completed and the second cohort is being planned. The rationale and implementation of this novel radiopharmaceutical therapeutic approach for osteoblastic metastases in osteosarcoma patients will be discussed. Clinical trial information: NCT01833520.

**TPS10601 General Poster Session (Board #307B), Mon, 8:00 AM-11:45 AM**

**A phase I/II study of sunitinib in young patients with advanced gastrointestinal stromal tumor.** *Presenting Author: Arnauld Verschuur, Hôpital d'enfants de La Timone, Marseille, France*

**Background:** Gastrointestinal stromal tumor (GIST) in young patients (pts) is a rare disease with distinct features from GIST in adults. Most notably, >85% of adults have tumors arising from receptor tyrosine kinase (RTK) mutations, typically in the *KIT* and *PDGFRA* genes, whereas such mutations occur in <15% of young GIST pts, for whom succinate dehydrogenase dysfunction is emerging as a central oncogenic mechanism instead. Sunitinib is an oral multitargeted RTK inhibitor approved for treatment of imatinib-resistant/intolerant GIST. With an $IC_{50}$ of 245 nmol/L, sunitinib has a high in vitro activity against wild-type *KIT* compared with imatinib ($IC_{50}$of 3,132 nmol/L). It is therefore hypothesized that sunitinib will be more active than imatinib in young GIST pts. This is supported by an expanded-access study, but with few pts and some limitations in data collection. A phase I study of sunitinib in pediatric pts with solid tumors, previously treated with multiple regimens of systemic chemotherapy, found that the MTD was half the effective dose in adult pts. It is not known if this will be reflective of the MTD in young GIST pts and/or if sunitinib will be effective at this dose. **Methods:** A single-arm, multinational, multicenter, phase I/II trial evaluating the pharmacokinetics, safety, and preliminary antitumor activity of sunitinib in ptsages 6 to <21 yrs with advanced, unresectable or recurrent GIST is open in North America, Europe, and Asia with 26 sites currently participating. Pts must have a histological diagnosis of GIST, measurable disease by RECIST, and imatinib-resistant/intolerant GIST or the non-mutant *KIT* genotype of GIST or not have access to imatinib in their country. Pediatric pts (<18 yrs) will receive sunitinib at a starting dose of 15 mg/m$^2$/day on Schedule 4/2 (4 wks on treatment, 2 wks off) in repeated 6-wk cycles, with dose escalation permitted after cycle 1 based on tolerance and real-time pharmacokinetics; young adults will receive sunitinib 50 mg/day on Schedule 4/2. Thirty pts are planned, and 3 have been enrolled to date. This trial is currently enrolling. Contact Pfizer Oncology at 1-800-718-1021. Clinical trial information: NCT01396148.

**TPS10602 General Poster Session (Board #308A), Mon, 8:00 AM-11:45 AM**

**Rego-SARC: Activity and safety of regorafenib (RE) in patients with metastatic soft-tissue sarcoma (STS) previously treated with anthracyclin-based chemotherapy—A multinational, randomized, placebo-controlled phase II trial.** *Presenting Author: Stephanie Clisant, Centre Oscar Lambret, Lille, France*

**Background:** Angiogenesis plays a key role in sarcoma biology. RE, targeting VEGFR-2 and -3, and tumor cell signaling kinases (RET, KIT, PDGFR, and Raf), has recently been shown to be effective in imatinib and sunitinib-refractory GIST in a phase III trial [Demetri, Lancet 2013]. Furthermore, the Palette trial has shown that pazopanib, another anti-angiogenic agent, significantly improved the PFS without OS advantage in anthracycline-refractory STS [Van Der Graaf, Lancet 2012]. **Methods:** We are conducting a multinational (France, Austria and Germany) double-blind placebo-controlled randomized (1/1) phase II trial to assess the activity and safety of RE in doxorubicin-refractory STS (ClinicalTrials.gov: NCT01900743). Key eligibility criteria are: measurable disease, age ≥18, less than 4 previous lines of CT, metastatic disease not amenable to surgical resection. Applied stratification criteria are: histological types (liposarcoma, leiomyosarcoma, synovial s., and others), countries and previous use of pazopanib. The primary endpoint is PFS according to central radiological review. Each stratum defined by histology will be separately analyzed. Statistical assumptions are: PFS0=1.6 and PFS1=4.6 months; 1-sided $\alpha$=0.1; $\beta$=0.05 with a total sample size of 192 pts. Tumor assessment is done monthly during the 4 first months, and every 3 months thereafter. After central radiological confirmation of tumor progression, an optional cross-over is proposed. Secondary endpoints are: toxicity (NCI-CTC AE V4.0); TTP; growth modulation index in pts receiving RE after randomization (GMI=TTP with RE/TTP with the prior treatment), 3 and 6 months PFS-Rates, best RR, OS. The exploratory translational research program will further characterize the nature of the genetic change by exploring the mutational status of the tumor samples using the Ion AmpliSeq Cancer Panel. In addition tissue-micro arrays (TMA) from FFPE material will be generated to allow a large-scale evaluation of molecular aberrations and downstream effects on pathway activation. The study is enrolling since June 2013. Clinical trial information: ClinicalTrials.gov: NCT01900743.

**TPS10603 General Poster Session (Board #308B), Mon, 8:00 AM-11:45 AM**

**SARC023: Phase I/II trial of ganetespib in combination with sirolimus for refractory sarcomas and malignant peripheral nerve sheath tumors (MPNST).** *Presenting Author: AeRang Kim, Center for Cancer and Blood Disorders, Children's National Medical Center, Washington, DC*

**Background:** Combination treatments of Hsp90 inhibitors with the mTOR inhibitor rapamycin produce dramatic tumor shrinkage in a genetically engineered MPNST mouse model of human MPNST (DeRaedt *et al. Cancer Cell* 2011). Previously, targeted agents have not resulted in substantial tumor regression in these models. Ganetespib is a potent small molecule inhibitor of Hsp90 that enhances endoplasmic reticulum stress with a favorable safety profile and promising activity in a variety of cancers. Sirolimus is a commercially available mTOR inhibitor, which has been tolerated in combination with multiple cytotoxic and targeted agents. These agents have also demonstrated activity in a variety of pre-clinical bone and soft tissue sarcoma models. **Methods:** SARC023 is a multi-institutional SARC sponsored, Department of Defense funded open label phase I/II trial of ganetespib in combination with sirolimus in patients with refractory sarcoma including MPNST (NCT02008877). The primary objective of the phase I component is to determine the safety, tolerability, and recommended dose of this combination. Eligibility includes individuals ≥ 18 years of age with unresectable or metastatic MPNST who have progressed after ≥1 prior regimens of chemotherapy. The Phase I component is also open to patients with other refractory or relapsed sarcomas. Ganetespib is administered intravenously over one hour on days 1, 8, and 15 every 28 days. Sirolimus is administered orally once daily continuously (28 days = 1 cycle). Patients receive treatment until disease progression or unacceptable toxicity for a maximum of 13 cycles. Upon determination of the recommended dosing, the phase II primary objective will be to determine the clinical benefit rate (CR, PR, or stable disease ≥ 4 months using WHO criteria) of this combination for patients with refractory MPNST. Secondary objectives include determination of the pharmacokinetic profile, correlative studies evaluating pharmacodynamic parameters of Hsp and mTOR inhibition in tumor tissue and peripheral blood mononuclear cells, patient reported pain outcomes, and measurement of tumor size changes using volumetric MRI analysis. Clinical trial information: NCT02008877.

**TPS10604 General Poster Session (Board #309A), Mon, 8:00 AM-11:45 AM**

**A phase II study of tivozanib in patients with metastatic and nonresectable soft-tissue sarcomas.** *Presenting Author: Lauren Elizabeth Nye, Northwestern University, Feinberg School of Medicine, Chicago, IL*

**Background:** Despite the multi-modality approach, many patients with early stage soft tissue sarcomas will develop recurrent or metastatic disease. Complete responses to chemotherapy for metastatic sarcomas are rare and do not translate to improved overall survival (OS). Given the lack of efficacy with current chemotherapy, investigational studies are needed to identify new antitumor agents. Angiogenesis plays an important role in cancer progression. Most tumors overexpress vascular endothelial growth factor receptors (VEGFRs), which allow the tumor to grow and metastasize. VEGFR1, VEGFR2 and VEGFR3 are high affinity receptor tyrosine kinases localized in the endothelium of tumor vasculature and are involved in tumor angiogenesis. VEGFR tyrosine kinase inhibitors (TKI) block phosphorylation of the VEGFR and inhibit activation of angiogenesis and, indirectly, tumor growth. Previous phase II data with a VEGFR TKI demonstrated improved progression-free survival (PFS) in patients with relapsed or refractory soft tissue sarcoma. Tivozanib is a potent and highly selective VEGFR TKI with activity against all three VEGFRs and thus a potential novel agent in the treatment of metastatic sarcoma. **Methods:** A total of 54 patients with metastatic sarcoma who have failed one previous therapy will be enrolled. Key inclusion criteria include diagnosis of metastatic and/or locally advanced or recurrent disease and measurable disease. Patients with alveolar soft-part sarcoma, chondrosarcoma, dermatofibrosarcoma, Ewing sarcoma, GIST, Kaposi sarcoma, mixed mesodermal tumor/carcinosarcoma, osteosarcoma, low grade sarcomas, rhabdomyosarcoma, interdigitating dendritic sarcoma and giant cell tumor of bone are ineligible. Eligible patients will receive tivozanib 1.5mg oral daily for 21 days in a 28 day cycle. The primary endpoint is PFS. Secondary objectives include overall response rate, clinical benefit rate, OS, toxicity and correlation of clinical outcome with antibodies for VEGFR1 and VEGFR2. Enrollment began in 03/2013. As of 01/2014, 22 of 54 patients have been enrolled. Clinical trial information: NCT01782313.

**11000 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**A novel "diapeutic" molecular imaging agent for combined oncologic diagnosis and therapy in a broad spectrum of human cancers: Preliminary clinical experience with CLR1404.** *Presenting Author: Perry J. Pickhardt, University of Wisconsin, Madison, WI*

**Background:** Extensive preclinical investigation into CLR1404, an akylphosphocholine analog, has demonstrated highly selective uptake and prolonged retention within a variety of human cancer preclinical models. Radioiodine labeling using $^{124}$I and $^{131}$I may allow for combined oncologic imaging and treatment in humans, respectively, potentially bridging the gap between cancer imaging and therapy. We report preliminary imaging experience with this "diapeutic" agent in early phase human trials. **Methods:** Prospectiveimaging studies with $^{124}$I-CLR1404 PET/CT (n=14) and $^{131}$I-CLR1404 SPECT/CT (n=9) in 22 enrolled patients (mean age, 61 years; M:F 12:10) with proven metastatic cancer were analyzed and compared with $^{18}$FDG PET/CT and other imaging studies. Underlying primary cancer types included bronchogenic (n=7), colorectal (n=4), prostate (n=3), triple-negative breast (n=2), esophageal (n=2), head and neck (n=2), pancreatic (n=1), and melanoma (n=1). **Results:** There is preferential uptake of $^{124}$I- and $^{131}$I-CLR1404 within a variety of metastatic foci in all cancer subtypes. Persistent retention within sites of disease coupled with progressive washout of background activity favored more delayed imaging phases, days-weeks after injection. Distinct advantages in oncologic imaging over FDG PET include greater conspicuity of brain metastases (FDG false-negatives) and lack of uptake in areas of post-treatment false-positive FDG activity. CLR1404 uptake was also evident in nodal, skeletal, pulmonary, hepatic, and other sites of active metastatic disease. **Conclusions:** Selective tumor uptake with prolonged retention of CLR1404 was demonstrated within a broad spectrum of historically difficult-to-treat metastatic cancers. This novel molecular imaging agent appears to have distinct advantages over FDG for oncologic PET imaging. Combined diagnosis and therapy using same molecule (ie, a "diapeutic" approach with $^{124}$I and $^{131}$I labeling) could lead to truly personalized care by ensuring pre-treatment tumor-specific uptake, providing patient-specific dose planning, and enabling treatment-specific imaging surveillance.

**11001 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**PET/CT with 89Zr-trastuzumab and 18F-FDG to individualize treatment with trastuzumab emtansine (T-DM1) in metastatic HER2-positive breast cancer (mBC).** *Presenting Author: Geraldine Gebhart, Institut Jules Bordet – Université Libre de Bruxelles, Brussels, Belgium*

**Background:** So far, no biomarker beyond HER2 status by immunohistochemistry (IHC) or in situ hybridization (ISH), has been validated to predict treatment efficacy of T-DM1, a novel antibody-drug conjugate targeting HER2. Zephir is a multicenter study designed to explore the role of molecular imaging in identifying patients with HER2 positive mBC (pretreated with any number of treatment lines) unlikely to benefit from T-DM1. Here we report the results of a planned interim analysis. **Methods:** Fifty-two (of 105 foreseen) patients with HER2 positive BC (IHC 3+ or FISH ≥ 2.2) underwent one pre-treatment HER2 PET/CT (4 days after administration of 37 MBq zirconium-89-trastuzumab), and 3 serial FDG PET/CT: at baseline, before the 2nd cycle (early FDG), and after 3 cycles of T-DM1 (late FDG). Central standardization and validation of acquisition parameters were performed. A patient-based imaging analysis was conducted by two independent reviewers and discordances were revised by a third investigator. HER2 PET/CT was considered negative if all or the major part of the metastatic tumor load showed no or minimal tracer uptake (≤ local background). FDG PET/CT response was classified as negative if all or the major part of metastatic tumor load showed no significant metabolic response (cut-offs set at 15% for early and 30% for late FDG PET/CT). Negative and positive predictive values (NPV and PPV) of HER2 PET/CT, early FDG response, and their combination for the prediction of late FDG PET/CT response were assessed. **Results:** HER2 PET/CT was scored negative in 17 (32%) patients, reflecting substantial imaging heterogeneity between patients considered as HER2 positive. PPV and NPV of HER2 PET/CT, early FDG PET/CT and their combination are summarized in the Table. **Conclusions:** Pre-treatment HER2 imaging and early FDG response assessment after 1 cycle seem very promising in identifying patients unlikely to show a metabolic response after 3 cycles of T-DM1. Clinical trial information: NCT01565200.

**11002 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Detection of metastases in breast cancer: Is whole body PET/MR better than PET/CT?** *Presenting Author: Komal L. Jhaveri, New York University School of Medicine, New York, NY*

**Background:** Whole body (WB)PET/CT is commonly utilized in breast cancer (BC) patients (pts). Limitations include assessment of treatment response in bone metastases (mets), high physiologic uptake in brain and liver, and cumulative radiation exposure. The site of mets can have prognostic and therapeutic implications. PET/MR, an exciting new hybrid technology, delivers less radiation than PET/CT. Our aim was to compare the differences in metastatic lesion detection using PET/CT and PET/MR in all BC subtypes. **Methods:** Pts who had WB PET/CT for staging and assessment of treatment response also had WB PET/MR after a single 18-FDG injection. PET/MR and PET/CT images were each read by a radiologist blinded to prior exams or reports. The number of mets per organ was recorded. 2 experienced radiologists unblinded to imaging and pathology reports served as the gold standard. Clinical data were obtained. Trial accrual is ongoing. **Results:** 48 pts underwent PET/CT and PET/MR (28 MBC, 5 neoadjuvant & 15 adjuvant setting). Median age was 48; range 31-79 with 31 ER+/HER2-, 9 ER+/HER2+, 2 ER-/HER+, 5 ER-/HER2-, 1 unknown. 11 pts had no evidence of mets. In remaining 37 pts, PET/MR and/or PET/CT detected bone, liver, or brain mets in 23, 9 and 5 pts, respectively; some patients had ≥1 metastatic site. PET/MR accurately detected 1 bone (ER+/HER2), 3 liver (ER+/HER2-) and 5 brain lesions (2 ER+/HER2-, 2ER-/HER2+, 1ER+/HER2+) in 8 unique pts that were not identified on PET/CT. 2 liver and 2 brain mets identified on PET/MR were previously unknown. PET/MR accurately reported treated bone lesions in 10 pts. Per organ system, there were more false neg and false pos with PET/CT (Table). **Conclusions:** Our preliminary data suggest that PET/MR may be more sensitive and specific than PET/CT in detecting mets in breast cancer. Prospective studies of PET/MR are warranted to determine whether early detection of mets, including occult brain mets in HER2+ pts, impacts survival.

**11003 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**A pilot laboratory study comparing the 21-gene assay and PAM50-ROR.** *Presenting Author: Che Prasad, Marin Medical Laboratories, Novato, CA*

**Background:** The Onco*type* DX 21-gene Recurrence Score assay was developed in endocrine-treated patients (pts) and validated as a predictor of 10-yr distant recurrence risk and chemotherapy benefit in ER+ early-stage invasive breast cancer. The Prosigna assay (ROR) which uses 46 of the PAM50 genes, was validated on centrally processed samples as a prognostic assay only in endocrine treated, post-menopausal pts. To date no direct comparison data on paired samples from the same patients for these two assays has been reported and yet it's frequently believed that these assays are interchangeable. We performed a pilot study comparing test results from the two assays obtained from the same tumor blocks. **Methods:** Sequential breast cancer tumors from Marin Medical Laboratories with sufficient tumor material were tested with the standard 21-gene Recurrence Score assay. 40 cases stratified by the Recurrence Score (20 low, 10 intermediate and 10 high) were sent to an independent laboratory where the Prosigna assay for ROR and intrinsic subtype was performed with the operators blinded to the Recurrence Score results. Descriptive statistics were calculated for the results obtained from the two assays. **Results:** Of the 40 pts, 3 were excluded due to low RNA signal in the Prosigna assay and 4 were ER(-) by RT-PCR. Of the 33 remaining cases, 24 were ductal, 7 lobular and 2 other; 27 were N- and 6 were N+. The Spearman rank correlation between Recurrence Score and ROR was 0.40 (95% CI 0.06 – 0.65). Risk group assignment (low/intermediate/high) between Recurrence Score and ROR was in agreement in 56% (15/27) of N(-) pts. Prosigna classified 19 as luminal A, 12 as luminal B, 2 as HER2 enriched and 0 as basal. In both the luminal A and B groups there was a wide range of Recurrence Score results. **Conclusions:** Consistent with other comparisons between expression-based assays, it should not be assumed that these assays are interchangeable. While additional data from a larger independent analysis is needed, this pilot suggests that there is only a modest agreement between the Recurrence Score and ROR, with almost half of N(-), ER+ pts classified differently.

**11004 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Genomic heterogeneity in primary breast cancer: Clinical implications.** *Presenting Author: Lucy Rebecca Connolly, Wellcome Trust Sanger Institute, Camridge, United Kingdom*

**Background:** The targeting of new cancer therapeutics will be driven by genomic analysis of an individual's tumor. It is questionable that standard sampling approaches that utilize slices from single 'tissue blocks' or clinical biopsies would always reflect the full spectrum of clinically relevant changes in the breast tumor landscape. **Methods:** We explore the diversity between multiple samples (n=294) from 49 patient's primary breast tumors. Using a combination of targeted gene screens (n=285) and/or whole genome sequencing (n=25) mutation catalogues were compiled for each tumor. **Results:** To assess geographical heterogeneity within primary tumors we obtained multiple spatially separated samples (7-17) from 13 patients' primary surgical specimens. Somatic point mutation and insertion/deletion analysis identified branching heterogeneity in 11/13 surgical samples (including ER positive, triple negative and HER2+ subtypes). In 4 cases, potentially 'druggable' targets such as PIK3CA mutations occur in a single sampled region – indicating frequent sub-clonality, and spatial confinement, of cancer driver mutations. We observe divergent and convergent evolution involving cancer drivers within individual tumors. We exploit the resolution of whole genome sequencing to demonstrate that even when homogeneity of driver mutations is observed, mutational processes such as kataegis continue to operate independently in spatially distinct regions. The analysis is extended to clinical samples: Pre-treatment biopsies and post-surgical blocks from 36 patients who underwent neo-adjuvant chemotherapy were analyzed. Initial findings reveal genomic heterogeneity within cases of both complete response (n=10) and residual disease (n=26), but interestingly, sub-clonal driver mutations so far appear to be limited to those with residual disease. Our ongoing analysis incorporates copy number analysis, and explores the relationship between chemotherapy response and heterogeneity and compares the genomic landscape pre and post neo-adjuvant chemotherapy. **Conclusions:** Current sampling approaches can be expected to under-report clinically actionable genomic events in a significant proportion of breast cancers.

**11005 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Met heterogeneity evaluation by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) in nonsquamous non-small cell lung cancer (nsNSCLC).** *Presenting Author: Edurne Arriola, Hospital del Mar, Barcelona, Spain*

**Background:** Molecular selection of patients who may benefit from Met inhibitors is being based on immunohistochemistry (IHC) with no consensus in the field. We sought to evaluate the association between *MET* gene copy number (GCN) and protein expression in NSCLC samples. Moreover, we wanted to analyze the heterogeneity within the same tumor specimen and its implications in Met evaluation. **Methods:** First, surgical cases from patients with nsNSCLC were included in a tissue microarray (TMA) representing 2 distinct morphologic areas of the tumor (2 consecutive sections). Second, biopsies from newly diagnosed patients were analyzed. Met expression was assessed by IHC (Ventana) using H-scores and MetMAb criteria and *MET* GCN by FISH (*MET* and CEP7 probes from Vysis). Association between GCN and protein expression and their correlation with clinico-pathologic and molecular information (*KRAS, EGFR)* was investigated. Additionally, heterogeneity of *MET*GCN and protein expression within different tumor cores and within consecutive sections was assessed. **Results:** One hundred and twenty-seven samples (120 patients) were analyzed. Ninety percent were adenocarcinomas, 35% grade 3, 19% *KRAS* and 11% *EGFR* mutant. Median age was 66 years, 70% males, and 53% current smokers. Median Met H-score was 140 and according to MetMAb criteria, 48% were Met high. High Met expression was associated with advanced stage (p=0.001). No association was observed with *KRAS/EGFR* mutations. *MET* amplification was observed in 8 cases (6.3%). No association was observed between *MET* GCN and protein expression. Met IHC score was high (H-score 400) in amplified cases with *MET*/CEP7 ratio >2, but not in those with *MET* GCN>5. For Met IHC, intraclass correlation coefficient (ICC) was 0.8 between consecutive tumor sections and 0.4 between different tumor cores. For *MET*FISH, ICC was 0.5 and 0.7, respectively. For amplified cases, 4 out of 12 cores were negative by FISH. **Conclusions:** The definition of Met positivity in the clinical setting is challenging, due to tumor heterogeneity. Met IHC does not accurately identify Met driven tumors. More precise criteria are needed for defining "Met dependence".

**11006 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Emergence of new *ALK* mutations at relapse of neuroblastoma.** *Presenting Author: Gudrun Schleiermacher, Department of Pediatric Oncology and INSERM U830, Institut Curie, Paris, France*

**Background:** The *ALK* receptor tyrosine kinase is activated by point mutations in neuroblastoma and constitutes a potent therapeutic target in this disease. **Methods:** To evaluate the role of *ALK* mutations in neuroblastoma progression or relapse, we searched for *ALK* mutations in a large series of 54 paired diagnostic–relapse neuroblastoma samples using Sanger sequencing. When an *ALK* mutation was observed in one sample, deep sequencing was used to seek for a minor mutated component in the other sample. With a coverage of > 100,000, the background variability was 0.034% per base at each position, resulting in a sensitivity to detect low frequency mutations in 0.15%. **Results:** Among the paired samples, all 9 *ALK*-mutated cases at diagnosis demonstrated the same mutation at relapse by Sanger sequencing. Nevertheless, in one case, the mutation was detected in only one of several nodules at relapse. In contrast, in 5 cases, the mutation appeared relapse-specific. Among these, 4 cases could be further investigated by deep sequencing. In two cases no evidence of the mutation was observed at diagnosis. In one case, the mutation occurring at relapse could be identified at a sub-clonal level at diagnosis, whereas in another case, two different mutations resulting in identical amino acid changes could be detected at diagnosis and relapse. Further evidence of clonal evolution of *ALK*-mutated cells was provided by the observation of a minor *ALK*-mutated cell population in a tumour from which a cell line with *ALK* mutation in all cells was derived. **Conclusions:** These results indicate that, in neuroblastoma, *ALK* mutations newly detected at the time of relapse can be present in a subclone at the time of diagnosis with subsequent clonal expansion at relapse. With the advent of targeted therapy using *ALK* inhibitors, precise knowledge of the *ALK* status is mandatory. Our observation of a significant spatio-temporal variation of *ALK* mutations is of utmost importance in clinical practice, highlighting the potential of NGS and the importance of serial samplings for therapeutic decisions.

**11007 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**A new nationwide genomic screening system in Japan for the development of targeted therapies against advanced non-small lung cancers with rare driver mutations.** *Presenting Author: Shingo Matsumoto, Division of Translational Research, Exploratory Oncology Research & Clinical Trial Center, National Cancer Center, Kashiwa, Japan*

**Background:** A variety of targetable driver mutations other than *EGFR* mutations and *ALK*fusions occur in 1%-2% of NSCLCs. Efficient screening systems for these rare mutations are necessary for the successful development of targeted therapies. **Methods:** In February 2013, a new nationwide genomic screening system (LC-SCRUM-Japan) was established in Japan to screen advanced non-squamous NSCLCs without *EGFR* mutations for primarily *ALK/RET/ROS1*fusions. In November 2013, this system was amended to further screen for other driver mutations in fusion-negative cancers after the primary screening. Ten nanograms of genomic DNA extracted from biopsy or cytology specimens were subjected to the Ion Torrent AmpliSeq Cancer Hotspot Panel, version 2, and Ion Torrent next-generation sequencing, enabling the simultaneous analysis of ~2800 hotspot mutations in 50 cancer-related genes. **Results:** As of January 31, 2014, a total of 158 institutions were participating and 507 patients were enrolled in LC-SCRUM-Japan. Among the 148 cases that were enrolled after the protocol amendment, *ALK/RET/ROS1* fusions were detected in 1 (1%)/7 (5%)/8 (5%) cases, respectively, and 107 cases without fusions were transferred to the multiplex mutation screening. In the mutation screening, a total of 121 mutations were detected in 79 cases (74%), including 46 mutations in driver oncogenes in a mutually exclusive manner (23 *KRAS* mutations [21%], 7 *BRAF* mutations [7%], 5 *ERBB2* mutations [5%], 2 *PIK3CA* mutations [2%] and 1 *NRAS* mutation [1%]). In addition, 43 *TP53* mutations, 5 *CDKN2A* mutations, 4 *MLH1* mutations, 2 *PTEN* mutations, 1 *IDH1* mutation, 1 *IDH2* mutation, 1 *FBWX7* mutation, 1 *SMAD4* mutation and 1 *STK11* mutation were detected. Among them, a case with a *BRAF* V600E mutation was enrolled in a global phase II study of a BRAF inhibitor, dabrafenib (NCT01336634). **Conclusions:** This screening system enabled rare fusions and mutations in driver oncogenes, especially *RET, ROS1, KRAS, BRAF* and *ERBB2*, to be detected precisely and more frequently in limited amounts of samples from advanced NSCLCs, thereby contributing to the enrollment of patients in clinical trials for targeted therapies.

**11008 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Comprehensive genomic profiling of solid tumors from 677 adolescents and young adults for revealing a distinct spectrum of targetable genomic alterations.** *Presenting Author: Deborah Morosini, Foundation Medicine, Inc., Cambridge, MA*

**Background**: Adolescent and young adult (AYA, age 15-39) cancers (CA) pose unique clincial challenges, yet genomic alterations (GA) in AYA CA have not been widely profiled. To identify potential therapeutic targets, we profiled a consecutive series of 677 AYA solid tumors, and describe a case of matching GA to targeted therapy. **Methods:** Tumor DNA extracted from FFPE tissue underwent library construction and hybrid capture for all exons of 236 cancer-related genes and 47 introns of 19 genes frequently rearranged in cancers and was sequenced to an average depth of >700x. Sequence data were assessed for base substitutions, in/dels, copy number alterations, and rearrangements. Actionable alterations were defined as those for which approved or experimental targeted therapies could be identified. **Results:** Across 30 AYA tumor types profiled, the most common were breast (BC) (15%), sarcoma (14%), brain (13%), colorectal (CRC)(9%), unknown primary (9%) and lung (LC)(6%). An average of 3.4 GAs per sample was found (range 0-22). Potentially actionable GAs were found in 71% of cases, including 93% of brain, 87% of BC, 85% of CRC and 75% of LC. Initial comparison reveals that in 44 AYA LCs, 20% had *ALK* fusions vs. 4% in older adults (age >39). Of 23 GBM cases, 48% had loss of function of *ATRX* and 39% had *IDH1* mutations, whereas *ATRX/IDH1* mutations were each present in 2-3% of our older GBM cohort. In one case, a 19 yr old female with LC was admitted to hospice having failed standard of care chemotherapy. Prior testing was negative for *EGFR*, *ALK* and *ROS1*. Genomic profiling revealed a novel *ALK* rearrangement and she began crizotinib therapy. Within 5 days she was discharged and continues to improve after 2 mos of therapy. **Conclusions:** Comprehensive genomic profiling can be optimized to accurately detect all classes of genomic alteration across AYA CA. These data highlight differences in this population and demonstrate the feasibility of identifying clinically meaningful alterations that can potentially guide targeted treatment decisions.

**11009 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Effect of multiparametric MRI of the breast on diagnostic accuracy.** *Presenting Author: Katja Pinker-Domenig, Medical University Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Molecular and Gender Imaging, Vienna, Austria*

**Background:** Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) of the breast has been the mainstay of breast MRI with an excellent sensitivity but limited specificity. Available data suggests that the use of other functional MRI parameters such as diffusion-weighted imaging (DWI) and proton MR spectroscopic imaging ($^1$H-MRSI) may provide additional specificity. The aim of this study was to evaluate if multiparametric MRI using DCE-MRI, DWI and $^1$H-MRSI improves diagnostic accuracy in breast cancer diagnosis cancer in comparison to DCE-MRI alone and MP MRI with two parameters. **Methods:** One hundred and thirteen female patients (mean age, 52; range, 22–86) with an imaging abnormality (BI-RADS 0, 4-5) were included in this prospective IRB-approved study. Written informed consent was obtained in all patients. MP MRI of the breast at 3Tesla with DCE-MRI, DWI and 3D-$^1$H-MRSI was performed. The likelihood of malignancy was assessed for DCE-MRI and MP MRI with two (DCE MRI and DWI) and three (DCE MRI DWI and 3D$^1$H-MRSI) parameters separately. Histopathology was used as the standard of reference. Appropriate statistical tests were used to assess sensitivity, specificity and diagnostic accuracy for each assessment combination. **Results:** There were 74 malignant and 39 benign breast lesions. MP MR with three MRI parameters yielded significantly higher AUCs (0.936) in comparison to DCE-MRI alone (0.814) ($p<0.001$). MP MRI with just two parameters at 3T did not yield higher AUCs (0.808) than DCE-MRI alone (0.814). MP MRI with three parameters resulted in elimination of false-negative lesions and significantly reduced the false-positives ($p= 0.002$). **Conclusions:** MP MRI with three parameters increases the diagnostic accuracy in breast cancer diagnosis compared to DCE-MRI alone and MP MRI with two parameters.

**11010 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Exploratory biomarker analysis of a phase I study of AZD4547, an inhibitor of fibroblast growth factor receptor (FGFR), in patients with advanced solid tumors.** *Presenting Author: Elaine Kilgour, AstraZeneca Oncology Innovative Medicines, Macclesfield, United Kingdom*

**Background:** AZD4547 is a selective inhibitor of FGFR 1, 2, and 3, with activity in patient-derived explant models with FGFR gene amplification. Study 1C1 assessed safety and clinical activity of AZD4547 (80 mg bid continuous dosing), in patients with advanced solid tumors, prospectively selected for amplification of FGFR 1 or 2. FGFR gene amplification status was determined using fluorescent in situ hybridization (FISH) analysis of archival tumor tissue. **Methods:** Analysis of FFPE diagnostic tumor samples included FGFR expression by IHC, expression analysis of ~200 pathway related genes by Nanostring and targeted Next Generation Sequencing (NGS) of a 287 gene panel at Foundation Medicine. **Results:** Of 21 patients dosed with AZD4547, seven had high *FGFR* amplification (ratio FGFR: Centromeric probe $\geq$ 3.0) and three of these, a squamous NSCLC, breast and bladder cancer patients, had target lesion shrinkage or prolonged ($\geq$24 weeks) disease stabilization. NGS analysis of tumor from a partial response squamous NSCLC patient, confirmed high *FGFR1* amplification together with amplification of 11q13 genes FGF3/4/19 and CCND1. A breast cancer patient, with 25% reduction in target lesions, was highly *FGFR1* amplified by NGS and expressed FGFR1 protein. Four patients with high *FGFR* gene amplification by FISH had little sign of efficacy. Of these, one patient was not confirmed *FGFR* amplified by NGS analysis, likely due to tumor heterogeneity. The other three patient tumors had an additional Receptor Tyrosine Kinase (RTK) amplification (*IGF1R*, *HER2* or *EGFR)*, with accompanying high expression. Two out of three bladder cancer patients experienced prolonged disease stabilization, both with marked FGFR1 and FGFR3 expression, one with high *FGFR1*amplification while an FGFR3 ligand binding domain mutation was found in tumor from the other. **Conclusions:** In this AZD4547 Phase I study, evidence of FGFR pathway expression was observed in tumor samples from advanced cancer patients with signs of efficacy. Co-amplification of RTKs may confer resistance to AZD4547. FGFR1/3 expression, amplification and mutation are potential selection markers for bladder cancer patients. Clinical trial information: NCT00979134.

**11011 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Clinical outcome with correlation to disseminated tumor cell (DTC) status after DTC-driven secondary adjuvant treatment with docetaxel in early breast cancer (BrCa).** *Presenting Author: Bjorn Naume, Oslo University Hospital, 0424 Oslo, Norway*

**Background:** Presence of DTCs in bone marrow (BM) predicts reduced survival in early BrCa. The present study explores the use of DTCs to identify adjuvant (adj) insufficiently treated patients (pts) to be offered secondary adj treatment (Tx), and as a surrogate marker for Tx response. **Methods:** In this prospective trial, 1,121 early BrCa pts were enrolled after completion of 6 cycles of adj FEC chemotherapy from Oct 2003-08. BM aspiration was performed 8-12 weeks after FEC (BM1), followed by a second BM aspiration 6 months (mo) later (BM2). Presence of DTCs in BM was determined by immunocytochemistry using pan-cytokeratin mAbs. If $\geq$1 DTCs were present at BM2, 6 cycles (mean 5.8; range 3-6) of docetaxel (D)(100 mg/m$^2$, 3qw) was administered, followed by DTC analysis 1 mo and 13 mo after last D infusion (post-Tx). The primary endpoint was disease free survival (DFS). Log-rank statistics and Cox proportional-hazard model were used to compare outcome in pts treated with D with no DTCs after Tx to pts with DTC persistence, and in all pts according to primary tumor factors and DTC status. **Results:** Of 1,067 pts with available FU information (median 80.6 mo; end of FU Nov 2012) and a DTC result at BM2, 8.5% were DTC pos at BM1 and 7.2% at BM2. DTC pos pts at BM2 had higher pT- and pN-stage compared to BM2 neg pts ($p=0.035$ and $p=0.098$). Of 72 D-treated pts analyzed for DTCs after Tx, 15 (21%) had persistent DTCs. Pts with remaining DTCs had markedly reduced DFS (47% with relapse) compared to pts with no DTCs post-Tx (HR 6.9, 95% CI 2.2-21.7). Only 8.8% of D-treated pts with no DTCs post-Tx relapsed, compared to 12.7% of pts in the favorable group with no DTCs both at BM1 and BM2 ($p=0.378$, log rank). Separate analyses of pts with DTC neg status at BM2, showed that only ER neg pts with DTC pos status at BM1 had reduced survival, compared to those with no DTCs at BM1 ($p=0.029$). **Conclusions:** DTC status detects high-risk pts after FEC chemotherapy and DTC monitoring status after secondary Tx with D correlated strongly with survival. The results indicate that D contributes to improved prognosis for high-risk pts and emphasize the potential for DTC analysis as a surrogate marker for treatment effect in adj BrCa. Clinical trial information: NCT00248703.

**11012 Poster Highlights Session (Board #1), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Detection of *BRAF* mutations in urine and plasma cell-free DNA: Application to the diagnosis and management of histiocytic disorder patients.** *Presenting Author: Omar Ibrahim Abdel-Wahab, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Histiocytosis patients (pts) have a high frequency of *BRAF*V600E mutations and respond to RAF inhibition but low tumor content and stromal contamination make detection in tissue biopsies challenging. Quantitative assessment of *BRAF*V600E mutations in tumor derived cell-free (cf) DNA may provide a convenient and reliable means of detecting this established biomarker and monitoring response to RAF targeted therapy. Here we compare the results of urine and plasma cfDNA *BRAF*V600E testing to tissue biopsy mutation testing in a large series of histiocytosis pts. **Methods:** Quantification of *BRAF*V600E was performed in cfDNA using droplet digital (dd) PCR (Trovagene, San Diego, CA). *BRAF*V600E analysis in tumor tissue was conducted using a variety of highly sensitive methodologies including locked nucleic acid and next-generation sequencing in CLIA-certified labs. Concordance between mutational analysis in tissue, plasma, and urine was determined. **Results:** 22 histiocytosis pts underwent cfDNA mutational analysis (18 Erdheim Chester Disease, 4 Langerhans Cell Histiocytosis). 20 pts also had CLIA-certified *BRAF*V600E mutational analysis in tissue (10 mutant, 6 wildtype, 4 test failure). All 10 *BRAF*-mutant pts based on tissue testing had a concordant positive cfDNA result in urine. Similarly, all 6 *BRAF*-wildtype pts based on tissue testing had a concordant negative cfDNA result in urine. 95% CI for concordance was 79-100%. Urine cfDNA was positive in 2 additional pts where tissue testing was unsuccessful. Plasma cfDNA testing did not identify *BRAF*V600E mutant pts who were not also positive by urine testing. **Conclusions:** Detection of actionable *BRAF* mutations by ddPCR in cfDNA is feasible and was completely concordant with CLIA-certified tumor mutation testing. Moreover, the ability to detect *BRAF* mutations in the urine of pts with repeated tumor tissue testing failure is potentially practice changing and demonstrates the clinical utility of cfDNA technologies. Mutations in cfDNA should be further investigated for longitudinal assessment of RAF-targeted therapy in pts with histiocytoses.

**11013 Poster Highlights Session (Board #2), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Molecular and genomic characterization of invasive circulating tumor cells (iCTCs) from men with metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Terence W. Friedlander, University of California, San Francisco, San Francisco, CA*

**Background:** Molecular characterization and genomic analysis of CTCs may allow for a better understanding of the mechanisms of resistance to therapies in metastatic castration-resistant prostate cancer (mCRPC). The Vitatex VitaAssay platform captures invasive CTCs (iCTCs) in a cell surface marker-independent fashion based on their ability to invade a fluorescently-labeled cell-adhesion matrix (CAM), allowing for the analysis of multiple CTC subpopulations. Here we sought to estimate epithelial, mesenchymal, and stem-like iCTC subpopulation diversity in men with CRPC starting abiraterone acetate therapy, to compare the genomic profiles of iCTCs to matched metastatic biopsies, and to explore the potential for 2D and 3D CTC culture. **Methods:** iCTCs were isolated from men with mCRPC using the CAM platform, and paired metastatic biopsies were performed. iCTCs were defined as CAM+/CD45-/CD14-/DAPI+, mesenchymal iCTCs as vimentin+/CAM+/CD45-/CD14-/DAPI+, and stem-like iCTCs as CD44+/CAM+/CD45-/CD14-/DAPI+. iCTCs were enumerated and purified using FACS. Agilent array comparative genomic hybridization (aCGH) of iCTCs and paired biopsies was performed, and to explore the potential for ex-vivo cell expansion and spheroid formation, iCTCs were cultured separately in CAM and in matrigel for up to 10 days. **Results:** iCTCs were isolated using the CAM platform from 42 men, of whom seven have undergone paired metastatic biopsy. The median baseline iCTC count per 7.5ml was 46 (range 0-444). In a subset of 17 subjects the median baseline CD44+ iCTC count per 7.5ml was 75 (range 0-1,410), and in a subset of 5 subjects the median vimentin+ CTC count per 7.5ml was 10 (range 1-17). AR amplification is detectable in iCTCs, iCTC aCGH profiles resemble paired soft tissue biopsy, and iCTC spheroids were observed. **Conclusions:** Multiple CRPC iCTC subpopulations are identifiable from men starting abiraterone. iCTCs resemble metastatic CRPC tissue and can be expanded in vitro. Further enumeration, genomic profiling, and clinical correlation of serial iCTCs taken from men with mCRPC is underway, and may shed light on mechanisms of abiraterone resistance.

**11014 Poster Highlights Session (Board #3), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Monitoring *EGFR* T790M with plasma DNA in lung cancer patients treated with EGFR tyrosine kinase inhibitor in prospective observational study.** *Presenting Author: Naoko Sueoka-Aragane, Department of Internal Medicine, Faculty of Medicine, Saga University, Saga, Japan*

**Background:** Use of plasma DNA to detect mutations has spread widely as a form of liquid biopsy. The gatekeeper T790M mutation of *EGFR* has been observed in half of lung cancer patients who acquired resistance to EGFR tyrosine kinase inhibitor (EGFR-TKI). We recently developed a novel sensitive, fully-automated monitoring system, MBP-QP (mutation-biased PCR and quenching probe), to detect T790M using plasma DNA. To determine the usefulness of the MBP-QP method for monitoring T790M during treatment with EGFR-TKI, a prospective clinical study was performed. **Methods:** This was a prospective, multicenter, observational study involving lung adenocarcinoma patients carrying *EGFR* activating mutations, such as L858R and exon 19 deletions, who were treated with EGFR-TKI. The primary objective was to determine whether T790M could be detected using plasma DNA at the time of progressive disease (PD). The secondary objective was to assess correspondence between T790M measured using plasma and that using cancer specimens. The association between detection of T790M and effect of EGFR-TKI was also investigated as an exploratory objective. **Results:** Ninety non-small cell lung cancer patients treated with EGFR-TKI were enrolled from seven hospitals in Japan: 92.1% had adenocarcinoma, 62% at stage IV, and 29% had postoperative recurrent disease. According to the investigators' evaluations, T790M was detected in 26% (15/58) of the patients who acquired resistance to EGFR-TKI. A central review showed that the frequency of T790M positives among the patients with PD was 22% (12/55). When EGFR-TKI was discontinued because of PD, T790M was detected in 33% (17/52), whereas any patients who were discontinued for other reasons such as adverse effects did not show T790M positivity. Eight re-biopsy specimens were obtained at the time of occurrence of PD, and the concordance rate was 63%. **Conclusions:** T790M was detected in plasma DNA at the time of PD occurrence. Compared to the frequency using re-biopsy reported by other papers, liquid biopsy covered approximately half of the total patients with PD. The relationship between T790M positivity and detailed characteristics of progression was analyzed. Clinical trial information: UMIN000005131.

**11015 Poster Highlights Session (Board #4), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Circulating tumor DNA (ctDNA) as a marker of recurrence risk in stage II colon cancer (CC).** *Presenting Author: Jeanne Tie, Western Hospital, Melbourne, Australia*

**Background:** Markers that better define recurrence risk for patients (pts) with stage II CC are urgently required, potentially defining a subset that would most benefit from adjuvant chemotherapy (CTX) and intensive surveillance. An alternative strategy to standard analyses of the resected surgical specimen is to directly examine plasma for evidence of residual disease. Recently, ctDNA has shown promise as a blood biomarker in advanced colorectal cancer; here we explore the potential of this marker in stage II CC. **Methods:** In this prospective study, plasma samples are being collected at 4-10 weeks post-op in 250 stage II CC pts, with serial 3 monthly samples on a subset of 175 pts. Adjuvant CTX is at clinician discretion, blinded to ctDNA analysis. Surveillance includes 3 monthly CEA and 6 monthly CT imaging for 2 years. All samples were sent to Johns Hopkins Kimmel Cancer Center, where tumor tissue was analyzed for hotspot mutations in *TP53, APC, KRAS, NRAS, BRAF, PIK3CA, CTNNB1, SMAD4*, and *FBXW7* using a massively parallel sequencing platform (Safe-SeqS). The identified mutation was queried and quantified in plasma using the same platform, blinded to clinical data. **Results:** Preliminary data is available on 78 of the 190 pts enrolled to date. Median age is 66 years, 25/78 (32%) received adjuvant CTX. At least 1 mutation was found in all tumors, with matching ctDNA detectable in 6/78 (7.7%) plasma samples. 10 (12.8%) recurrences have occurred at a median follow-up of 507 days, including 5 of 6 pts with detectable ctDNA and 5 of 72 with no detectable ctDNA (Table). Pts with detectable ctDNA had a shorter recurrence-free survival (median 234 days vs undefined, HR 23.09, log-rank $p < 0.0001$). In an exploratory analysis of the correlation between ctDNA and clinicopathologic features, detectable ctDNA maintained prognostic significance, including for T3 tumors (HR for time to recurrence 80.55, log-rank $p < 0.0001$). **Conclusions:** Early data suggests ctDNA is a promising marker of recurrence risk in stage II CC. Preliminary analyses suggests this may be independent of clinicopathologic features.

| | Recurrence | No recurrence | Total |
|---|---|---|---|
| **Post-op ctDNA positive** | 5 | 1 | 6 |
| **Post-op ctDNA negative** | 5 | 67 | 72 |
| **Total** | 10 | 68 | 78 |

Fisher's exact $P < 0.0001$. RR = 12 (95% CI 4.79 – 30.06).

**11016 Poster Highlights Session (Board #5), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Noninvasive and ultrasensitive quantitation of circulating tumor DNA by hybrid capture and deep sequencing.** *Presenting Author: Scott Victor Bratman, Stanford University, Stanford, CA*

**Background:** No validated biomarkers exist for minimal residual disease (MRD) detection in non-small cell lung cancer (NSCLC). We aimed to design a next-generation sequencing-based method for quantifying circulating tumor-derived DNA in NSCLC and other cancers. **Methods:** We developed CAPP-Seq (Cancer Personalized Profiling by deep Sequencing), a novel method for noninvasive cancer burden measurement. Our strategy leverages affinity capture to enrich recurrently mutated genomic regions from tumor DNA and plasma cfDNA. After benchmarking sensitivity, we analyzed a set of NSCLC tumors and corresponding serial plasma samples collected before and after radiation therapy, chemotherapy, and/or surgery. **Results:** We show that CAPP-Seq detects multiple cancer-specific somatic mutation types within NSCLC DNA, including single nucleotide variants, insertions/deletions, and rearrangements. Benchmarking analyses demonstrate that CAPP-Seq accurately enumerates mutations within cfDNA at a fractional abundance of ≥0.02%. Applying CAPP-Seq to tumor/normal genomic DNA pairs from 17 NSCLC patients uncovered a median of 6 mutations per patient (range, 1-28). Plasma samples (35) from 13 patients were profiled by CAPP-Seq. The abundance of patient-specific cancer markers within plasma cfDNA was readily measured by CAPP-Seq in both early- and late-stage NSCLC. Importantly, circulating tumor DNA responded appropriately to diverse therapies, becoming undetectable in 7 patients (including after surgery, chemoradiation, and targeted therapy) and declining but remaining detectable in others. CAPP-Seq measurements correlated with tumor volume ($R2 = 0.97$) and allowed for detection of resistance mutations in patients being treated with targeted therapies. **Conclusions:** We describe a novel NGS-based approach to MRD testing in cancer patients. CAPP-Seq could have utility for monitoring disease burden and response to therapy, early detection of relapse, and risk stratification in early-stage NSCLC following surgery or stereotactic body radiation therapy. Ultimately, we envision CAPP-Seq becoming a routine clinical assay for measuring tumor burden in diverse cancers from plasma and other body fluids.

**11017 Poster Highlights Session (Board #6), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Gene expression profiles of primary tumors versus circulating tumor cells in metastatic breast cancer.** *Presenting Author: Wendy Onstenk, Erasmus MC Cancer Institute, Department of Medical Oncology and Cancer Genomics Netherlands, Rotterdam, Netherlands*

**Background:** Before considering circulating tumor cells (CTCs) as a liquid biopsy in metastatic breast cancer (MBC), the degree of molecular discrepancy between primary tumors (PTs) and CTCs has to be established. **Methods:** In 69 MBC patients with ≥1 CTC before start of first-line systemic treatment, our previously described panel of 55 tumor-associated gene transcripts was measured by quantitative reverse transcription polymerase chain reaction in both formalin fixed paraffin embedded PTs and CellSearch-enriched CTCs. From 11 patients, a lymph node metastasis (LN), obtained at the time of primary tumor resection, was available for comparison with PTs and CTCs. A Compare Batches normalization was used to correct for batch effects. Overall gene expression profiles and the expression of therapeutic targets *ESR1*/ER and *ERBB2*/HER2 were compared. Associations with clinical outcome (time-to-treatment switch, start first- to second-line treatment) were exploratory. **Results:** In 55% of patients, PT and CTC profiles did not cluster. Patients with non-clustering profiles more often had synchronous metastases (42% versus 3%, $\chi^2$ $P = .001$), and ER-positive tumors (68.4% versus 38.7%, $\chi^2$ $P = .03$) compared to patients with clustering profiles. Discrepant expression of ER and HER2 was found in 26% and 25% of patients, respectively. Whereas ER was equally lost and gained in CTCs compared to PTs (12% versus 15%, McNemar $P=.82$), HER2 was more often lost than gained (21% versus 5%, McNemar $P=.02$). Patients with concordant ER-positive expression in PTs and CTCs had the best prognosis, those with discordant expression performed worse, and prognosis for concordant ER-negative patients was worst (Log-rank test for trend $P < .001$). A similar pattern was observed for HER2, although this was not statistically significant ($P = .10$). In all 11 patients, LN profiles clustered with the PT profiles; in 2 patients CTCs mismatched with both PT and LN. **Conclusions:** Gene expression profiles of PTs and CTCs at time of MBC differ in a substantial proportion of patients. Expression of ER and HER2 is often discrepant between PTs and CTCs, which had prognostic implications in this patient cohort and may thus be of clinical relevance.

**11018 Poster Highlights Session (Board #7), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**BRCA1-like copy number profiles to predict benefit of high-dose alkylating chemotherapy in high-risk breast cancer (BC): Results from randomized WSG AM-01 trial.** *Presenting Author: Philip C. Schouten, Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

**Background:** DNA copy number profiles identify patients with a defect in BRCA1 associated with a homologous recombination DNA repair defect. We previously showed that patients with a BRCA1-like profile benefit from high-dose (HD) and tandem HD chemotherapy (CT) (carboplatin/thiotepa/cyclophosphamide; ifosfamide/epirubicin/carboplatin). WSG AM-01 trial reported superiority of tandem HD vs. dose-dense CT in high-risk BC patients. Subgroup analysis attributed this effect to triple-negative BC. **Methods:** Phase III WSG AM-01 trial randomized 403 patients with >9 positive lymph nodes to 2xEC q2w followed by tandem HD (epirubicin/cyclophosphamide, thiotepa) or DD 4xEC --> 3xCMF q2w CT. Tumor CN profiles from 98 patients were generated with high-throughput sequencing and classified as BRCA1-like or non-BRCA1-like. Correlations with prognostic factors were assessed and Cox regression was done to investigate predictive/prognostic impact of BRCA1-like status on event free survival (EFS). **Results:** 17 of 94 (18%; HD/DD: 10 (19%)/7 (17%)) patients had BRCA1-like profiles. BRCA1-like status associated with high tumor grade (p=0.005) and triple-negative status (p<0.001). In multivariate Cox analysis for EFS, only age <50 years entered (HR=1.9, p=0.02) as a main effect. In subgroup analysis, only BRCA1-like status predicted for efficacy of HD. HR=0.26 (95% CI: 0.07-0.94, p=0.04) for BRCA1-like vs. 0.76 (95% CI: 0.43-1.34; p: 0.35) for non-BRCA1 like. In exploratory Cox interaction analysis (backward elimination) with BRCA1-like status, therapy and their interaction, the model retained BRCA1 status (HR=2.25; 95% CI: 1.07-5.94) and the predictive interaction BRCA1*therapy (HR=0.22; 95% CI: 0.06-0.79). **Conclusions:** Retrospective analysis suggests that superiority of rapidly cycled tandem HD alkylating over standard dose-dense CT in high-risk BC is substantially attributable to BRCA1-like (rather than TN) status. Comparing with other studies, this effect seems less drug-specific and indicates rather higher sensitivity of BRCA1-like tumors to any HD alkylating CT. The results will be validated in the prospective WSG ADAPT TN trial.

**11019 Poster Highlights Session (Board #8), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Prognostic and predictive significance of PAM50 intrinsic subtypes in the NCIC CTG MA.21 phase III chemotherapy trial.** *Presenting Author: Karen A. Gelmon, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** Breast cancer intrinsic subtypes defined by the 50-gene PAM50 test were reported to be prognostic and predictive in endocrine therapy trials. MA21 randomized 2,104 patients to receive dose intense cyclophosphamide, epirubicin and flurouracil (CEF); dose dense, dose intense epirubicin, cyclophosphamide and paclitaxel (EC/T); or 3-weekly doxorubicin, cyclophosphamide and paclitaxel (AC/T). We previously reported that AC/T had reduced relapse free survival (RFS) compared to both CEF and EC/T. Here, we investigated the prognostic and predictive (taxane versus not) significance of PAM50 in MA.21. **Methods:** Patients were ≤60 years old with node-positive or high-risk node-negative breast cancer. Median follow-up was 8 years. Intrinsic subtypes (luminal A, luminal B, basal-like, HER2E) were determined with FFPE extracted total RNA by Nanostring PAM50. Univariate assessment was with a stratified log-rank test. Effects of intrinsic subtypes and baseline patient characteristics on relapse-free survival (RFS) were investigated with stratified step-wise Cox multivariate regression, adding a factor if p<0.05. **Results:** The 1,094 cases completing PAM50 intrinsic subtyping were not significantly (p<0.05) different compared to those who did not in terms of treatment and stratification factors. 27% were classified as luminal A; 23% luminal B; 32% basal-like; and 18% HER2E. Intrinsic subtypes had a significant (p<0.001) univariate association with RFS. In multivariate analyses, intrinsic subtype had a significant prognostic effect on RFS (p= 0.001). Compared with luminal A, the hazard ratios (HR) were: luminal B =1.47 (95% CI = 0.93-2.30, p=0.10); basal-like= 1.95 (CI = 1.10-3.47, p=0.02); and HER2E = 2.66 (95% CI = 1.63-4.34, p<0.001). The interaction term between intrinsic subtype and treatment was not significant (p>0.05). **Conclusions:** Intrinsic subtype defined by the Nanostring PAM50 test had a significant prognostic effect on RFS for breast cancer patients treated with CEF, EC/T and AC/T. Subtype was not predictive of outcome amongst these chemotherapy regimens. Clinical trial information: NCT00014222.

**11020 Poster Highlights Session (Board #9), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Biomarker modulation in patients (pts) receiving TRC105 (T) and bevacizumab (B) in a phase Ib clinical trial.** *Presenting Author: Yingmiao Liu, Duke University Medical Center, Durham, NC*

**Background:** Endoglin (END; CD105) is a membrane-bound cell surface receptor expressed on proliferating endothelial cells implicated in resistance to VEGF inhibition. T, an anti-End monoclonal antibody, potentiates anti-VEGF therapy in *in vitro* and *in vivo* models. The combination of T plus B was well tolerated and was active in pts who progressed on prior B treatment. **Methods:** Pts with advanced refractory solid tumors were treated with escalating doses of T plus B. Pts received 1 week of B monotherapy prior to the addition of T. Thirty-eight biomarkers related to tumor growth, angiogenesis, and inflammation were analyzed using an optimized multiplex ELISA platform. Samples from 38 pts were collected at baseline (BL), 1 week (C1D8), 2 week (C1D15), 4 week (C2D1), and end of study (EOS). Biomarker concentrations on study were compared to baseline using the Wilcoxon signed rank test with statistical significance assumed at $p<0.05$. **Results:** After 1 week of B monotherapy (C1D8), PlGF was elevated and ANG-2, soluble END (sEND), TSP2, and VEGFR1 were decreased. Following the addition of T, only Ang-2 remained significantly decreased, while the following analytes were significantly elevated at C1D15, C2D1 and EOS: CRP, sEND, E-Selectin, IL-6, PAI-1 (active and total), P-Selectin, SDF-1, TGF-b1, and VCAM-1. Increases in sEND and PlGF are consistent with observations from pts treated with either T or B alone, respectively. The inflammatory markers, CRP and IL-6, and TGFb-regulated proteins, PAI-1 active and sEND, all exhibited greater than a 5-fold increase on average at EOS. Interestingly, the elevation of the END ligand, TGFb1, in response to T plus B treatment, has not been observed in pts treated with either agent alone. **Conclusions:** Treatment of pts with either T or B alone is associated with modulation of multiple angiogenic and inflammatory biomarkers. However, the combination of both agents led to increases in many inflammatory and TGFb-related proteins that persisted throughout the study. The differences across the biomarker patterns from pts treated with T plus B suggest increased bioactivity for the combination and support the role of T potentiating anti-VEGF therapies in pts.

**11021 Poster Highlights Session (Board #10), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Enhancing the prognostic power of the Nottingham tumor grading system.** *Presenting Author: Ritu Aneja, Georgia State University, Atlanta, GA*

**Background:** The terms "actively proliferating cell" and "mitotically dividing cell" are often used synonymously in breast clinical pathology. Mitotic and Ki-67 indices (MI and KI, respectively) are evaluated in different fields and at different scales, despite their mutual non-exclusivity. Pathology-centric view regards Ki-67-positive cells as "actively dividing", leading to the mistaken view that an increase in KI reflects an increased proportion of mitotic cells. Since MI is an equally-weighted component of the Nottingham grading system (NGS), we examined contribution of mitotic scores to the prognostic value of tumor grade and evaluated if a modified score called Ki-67–adjusted mitotic score (KAMS), could replace MI in NGS to re-stratify GII patients and strengthen the prognostic power of tumor grade. **Methods:** In a retrospective study of 2,200 breast carcinoma patient records from Northside Hospital, Atlanta, GA, KAMS was calculated by transforming monotonic ordinal MI into percent mitotic cells and dividing it by KI. Grade wise trends in KAMS were evaluated and survival stratification was done via Kaplan-Meier estimator. An adjustment principle based on each patient's KAMS and mitotic score was applied to the MI component of the Nottingham sum to re-stratify Grade II patients. **Results:** Average KAMS decreased significantly ($p< 0.0001$) from 0.153 to 0.132 to 0.085 for Nottingham grades GI, GII and GIII, respectively. KAMS was then used to stratify GII patients into two groups whose survival probabilities were significantly different ($p= .01$): "above-average KAMS" group had 96.3% survival while the "below-average KAMS" group had an 88.7% survival. Thus, low KAMS predicts poor prognosis for high-grade patients. While nuclear grade contributes majorly, MI contributed minimally to the prognostic value of tumor grade. Thus, replacing MI with KAMS within NGS re-stratified Grade II patients who were either (i) adjusted into GI (23% of original GII), or (ii) were adjusted into GIII (62% of original GII). **Conclusions:** KAMS decreases with Nottingham grade. KAMS-based survival stratification of GII and GIII patients show that low KAMS is associated with poor prognosis. Replacement of MI with KAMS within NGS better stratifies GII patients.

**11022 Poster Highlights Session (Board #11), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Prognostic and predictive blood-based biomarkers of overall survival (OS) in patients (pts) with advanced colorectal cancer (CRC) treated with cetuximab (C): Results from CALGB 80203 (Alliance).** *Presenting Author: Ace Joseph Hatch, Duke University Medical Center, Durham, NC*

**Background:** Previously, we identified potential predictive biomarkers of C sensitivity related to EGFR signaling from archived tumor tissue from CALGB 80203. Due to the fact that blood-based markers are more convenient and can be monitored over the course of treatment, baseline plasma samples were also collected and five (EGF, HB-EGF, sEGFR, sHER2, sHER3) markers were evaluated in plasma. **Methods:** CALGB 80203 was a randomized (1:1) phase II trial of 238 pts with locally advanced or metastatic CRC comparing FOLFOX or FOLFIRI (chemo) vs. chemo plus C. Baseline EDTA plasma samples from 154 pts were analyzed for the five candidate markers; an ELISA for CD73 is currently being optimized for use. The levels of each analyte were correlated with the primary endpoint of OS using univariate Cox proportional hazards models. Potential predictive markers were identified using a treatment by marker interaction term in the Cox model and the markers with significant p-values are reported. Hazard ratios between treatment groups are reported for low or high marker levels dichotomized at the median. **Results:** Univariate analyses indicated that plasma levels of EGF and sHER3 were negative prognostic markers ($p<0.05$) that correlated with OS for the overall pt population. Across all pts (KRAS mutant and wild-type), sHER3 was identified as a potential predictive biomarker for C. Pts with higher sHER3 levels had significant OS benefit from C treatment (interaction $p=0.03$; HR=0.57, 95% CI 0.36-0.92). Low levels of EGF predicted for OS benefit from C in KRAS WT tumors (interaction $p<0.01$; HR=0.42, 95% CI 0.19-0.90) and lack of benefit in the KRAS mutant pts (interaction $p=0.03$; HR=2.69, 95% CI 1.04-6.94), but were not predictive for C across all pts. **Conclusions:** Blood-based profiling of EGFR axis members identified sHER3 and EGF as candidate predictors for benefit from C. These data are consistent with our findings using mRNA expression from archived tumor samples and suggest a role for receptor shedding in HER3 biology. If further validated, these markers may help guide the development and use of anti-EGFR therapies and combination regimens.

**11023 Poster Highlights Session (Board #12), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Relationship between RECIST response and variation of circulating tumor cells (CTC) for patients enrolled in phase I trials.** *Presenting Author: Christophe Massard, Gustave Roussy, University Paris Sud, Villejuif, France*

**Background:** Because CTC counting has been shown to be a marker independent of tumor type or treatment, it could represent a new parameter to improve evaluation of tumor response to drugs in phase I clinical trials. We hypothesized that early change of CTC counts could occur before detectable variation in tumor size evaluated by imaging using RECIST criteria. **Methods:** Consenting patients with advanced and metastatic cancer referred three phase I units (Gustave Roussy, Institiut Curie, Pitie Salpétrière) were enrolled prospectively in this study. CTCs from 7.5 mL of whole blood drawn before treatment initiation (baseline) and 4 weeks after starting experimental therapy were enumerated using the CellSearch system, and tumor response was assessed using RECIST Criteria at baseline and 2 months after treatment initiation. **Results:** Between March 2010 and May 2013, a total of 326 patients were enrolled in phase I trials across 3 centres, among which 215 were evaluable (48% were male, median age=57; main tumor types: lung (25), colon (54), bladder (14), breast (28)). At baseline we detected $\geq$ 1CTC/7.5 ml in 114/215 (53% ; median CTC count=4 (1-3,264)), and at week 4, we observed $\geq$ 1CTC/7.5 ml in 103/215 (48% ; median CTC count=3 (1-100)). Sensitivity and specificity of CTC variation to detect progressive disease were 41% (32-51%) and 80% (72-87%) respectively. At the first follow-up imaging visit, 10 (5%) of the 215 patients were classified as having partial response, with 9 of these patients having no CTC or a decrease in CTC count after therapy. In contrast of the 102 patients (47%) classified as having progressive disease, 22 patients (21%) had an increase of CTC. The remaining 103 patients (48%) were classified as having stable disease, 35 of them (33%) had a decrease in CTC count, possibly suggesting a therapeutic benefit despite the lack of criteria for objective response. **Conclusions:** Early CTC change following therapy does not correlate with RECIST response in patients with advanced cancer enrolled in phase I trials. However, our results suggest that this biomarker may still have some interest to identify stable diseases with a certain anti-tumor effect.

**11024 Poster Highlights Session (Board #13), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Recurrence score and quantitative ER expression to predict in late distant recurrence risk in ER+ BC after 5 years of tamoxifen.** *Presenting Author: Norman Wolmark, National Surgical Adjuvant Breast and Bowel Project; The Allegheny Cancer Center at Allegheny General Hospital, Pittsburgh, PA*

**Background:** Identification of molecular determinants predicting late recurrence (>5 yrs) in stage I and II breast cancer has become clinically important in light of data demonstrating a benefit for ten yrs of tamoxifen administration. Since the 21-gene Recurrence Score (RS) is commonly utilized in early stage BC, we wished to determine its utility in predicting distant recurrences beyond five yrs as a function of quantitative ER expression. **Methods:** The 21-gene RS was assessed in 1,065 chemo and tam-treated, ER+, node-positive pts from NSABP B-28 and 668 tam-treated, ER+, node-negative pts from NSABP B-14. Cox PH models, KM estimates and log rank statistics were used to assess the association of the RS with risk of DR by quantitative ER expression, using the 21-gene assay, in pts event-free after 5 yrs. We established an ER cut-point (high vs low) in B-28, and tested the cut-point in B-14, formally evaluating the interaction of RS and ER. **Results:** Median follow-up was 11.2 yrs (B-28) and 14.5 yrs (B-14). 832 B-28 pts and 564 B-14 pts were DR-free after 5 yrs. A reference normalized ER cut-point of 9.1 $C_T$was established in B-28 based on the association of the RS with DR after 5 yrs. Of the event-free pts at 5 yrs, 68% in B-28 and 88% in B-14 had ER>9.1. In B-28 the RS result was strongly associated with DR after 5 yrs in the higher ER expressing pts (log rank P=0.001), but not in the lower ER expressing pts (log rank P=0.87). It was confirmed in the B-14 data that RS was associated with DR after 5 yrs in higher ER pts (Table) but not in the lower ER pts (interaction P=0.03). **Conclusions:** For late recurrences (beyond 5 yrs), the RS is strongly prognostic in pts with higher quantitative ER expression (>9.1). The findings suggest that extending tamoxifen beyond 5 yrs may be most beneficial in pts with high (and intermediate) RS with higher quantitative ER expression and of limited benefit in pts with a low RS (>50% of population under study).

**DR Risk after 5 yrs in B-14 by RS risk group for pts with ER>9.1 $C_T$.**

| | | %DR KM estimate (95% CI) | |
|---|---|---|---|
| **RS risk group** | **N (%) pts** | **5 to 10 yrs %** | **5 to 15 yrs %** |
| **Low** | 289 (58%) | 4.7 (2.8 - 8.0) | 6.8 (4.4 - 10.6) |
| **Intermediate** | 111 (22%) | 4.1 (1.6 - 10.6) | 11.2 (6.2 - 19.9) |
| **High** | 97 (20%) | 12.6 (7.4 - 21.2) | 16.4 (10.2 - 25.7) |

**11025 Poster Highlights Session (Board #14), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Return of individual research results: Policies and experiences of cancer genomic researchers.** *Presenting Author: Lynn G. Dressler, Mission Health, Fullerton Genetics Center, Asheville, NC*

**Background:** Although it is not the intent of the International Cancer Genomics Consortium (ICGC) or The Cancer Genome Atlas (TCGA) studies to return individual research results (RIRR), clinically relevant results will be discovered. Debate about RIRR are well described in the literature, however little information exists regarding researcher experiences and institutional policies. **Methods:** The ICGC Ethics and Policy Committee developed an anonymous survey that was distributed electronically or by hardcopy to genomic researchers participating in ICGC and TCGA, asking about perspectives, experience and policy relevant to RIRR. Analysis was limited to researchers conducting human cancer genomic research. **Results**: 111/164 (66%) surveys were eligible for analysis. Compared to non US researchers, US researchers were significantly less likely to report a responsibility to consider whether a research result would have clinical relevance for the subject (83% v 57%; p=0.011). Fifty-one percent of researchers reported finding clinically relevant results important for the subject to know. The 3 most common findings were susceptibility to cancer/other chronic disease (46%); pharmacogenomic (42%), and Mendelian Disease (20%). Forty percent reported returning results to physicians (40% at least 1X; 15% > 5X) or individual research subjects (28% at least 1x). Most (80%) agreed that a result should be validated before return, yet there was no agreement even on how to analytically validate results. Regarding institutional policy, 28% reported an RIRR policy existed, including 9% whose policy was not to return results; 12% reported no policy; and 50% did not know if a policy existed. 17% reported that the informed consent (IC) never addresses RIRR; 30% reported the IC always addresses RIRR and 30% did not know what the IC addressed. **Conclusions:** Regardless of study intent, clinically relevant research results are being found and returned to physicians and individual research subjects. A critical need exists to develop consistent approaches for validating research results; raise researcher awareness of institutional policies and develop practical guidance for researchers involved in international collaborations.

**11026 Poster Highlights Session (Board #15), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**The use of whole-genome sequencing in therapeutic for decision making in patients with advanced malignancies.** *Presenting Author: Howard John Lim, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** We used information obtained from whole genome and transcriptome sequencing to aid in therapeutic decision-making in patients (pts) with advanced cancers. **Methods:** Eligible pts with incurable cancers with limited or no standard options, had several samples analyzed: a fresh tumor biopsy; a blood sample for normal comparison; and archival tumor tissue when available. Samples underwent both the Ion Torrent AmpliSeq cancer panel analysis and comprehensive DNA (80X) and RNA sequencing followed by in-depth bioinformatic analysis to identify somatic mutations, copy number alterations, structural rearrangements, and corresponding gene expression changes that may be cancer "drivers" or provide informative/diagnosticor actionable targets. Aberrant pathways were matched to drug databases and manual literature reviews were performed to identify drugs that may be useful or potentially contraindicated. A report was generated and discussed in a multidisciplinary team. **Results:** Between July 2012 - January 2014, 65 pts had consented (including 4 pediatrics cases) and 56 have been sequenced: 18 breast, 8 lung; 4 colorectal, 3 squamous, 3 adrenal; 2 pancreas; 2 sarcomas, 2 neurofibroma, 2 mesothelioma, and 1 of each of nasopharynx, primary unknown, CLL-peripheral mantle cell, parotid, anal, appendix, peripheral T-cell, prostate, ovary, endometrial, glioma, and leiomyoma. The median number of lines of chemo prior to sequencing was 3. The AmpliSeq panel only yielded actionable targets in 40% of cases. The full genomic data was more comprehensive about driver pathways and was informative in 70% of cases. Clinical data is available on 30 pts. In 21 pts data was actionable. In 3 pts, the diagnosis was changed and 9 pts died before the results could be used. Treatments were delivered based on the results in 8 pts, 6 (75%) of these pts derived clinical benefit from treatment based on genomic therapy. **Conclusions:** Whole genome sequencing based therapeutic decision-making in the management of advanced cancer is feasible. The information is more comprehensive than panels and yields clinically actionable data not identified by panel sequencing. Further studies are needed to determine the utility of this technology.

**11027 Poster Highlights Session (Board #16), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Comprehensive molecular profiling of advanced gastric cancer (AGC) using NGS and immunohistochemistry (IHC).** *Presenting Author: Yasutoshi Kuboki, Division of Gastrointestinal Oncology/Gastroenterology, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** In advanced gastric cancer, most of clinical trials are designed based on IHC/*in situ* hybridization in tissue. However, NGS screening allowed us to comprehensively profile tumor gene status recently. Our goal is to profile both gene alterations and conventional biomarker in gastric cancer for potential molecular targeted therapy. **Methods:** Formalin-fixed, paraffin-embedded (FFPE) tumor samples from 121 patients with stage III/IV gastric cancer who underwent gastrectomy were examined for HER2, EGFR, c-MET and FGFR2 expression using IHC. In addition, genomic DNA was extracted from each FFPE sample and a total of 15,991 regions in 409 cancer-related genes were sequenced to detect mutations using the Ion *AmpliSeq* Library kit 2.0 and Comprehensive Cancer Panel. In addition, to evaluate copy number variation of a gene, relative reading depth to the reference (RRDR) of an individual gene was calculated. Amplification was defined as an RRDR greater than 2. **Results:** The most frequently mutated genes were *TP53* (36.4%). In addition, mutations in oncogenes such as *PIK3CA* (7.4%), *ROS1* (4.1%), *HER2* (4.1%), *MET* (1.7%) and *ALK* (1.7%) were detected. The most frequently amplified gene was *SRC* (20.7%). Amplification was also detected for other genes such as *HER2* (14.9%), *CCNE1* (13.2%), *CCND1* (9.1%), *EGFR* (7.4%), *KRAS* (7.4%), *MET* (6.6%), *RET* (3.3%) and *FGFR2* (2.5%). The rate of over-expression (IHC 3+) was as follows: HER2 (16.5%), EGFR (23.1%), MET (9.9%) and FGFR2 (14.0%). Most of the cases with HER2 over-expression had *HER2* amplification. On the other hand, in a few cases with EGFR/c-MET/FGFR2 over-expression, amplification of these genes was not detected. Over-expression cases with EGFR or FGFR2 had other various gene alterations such as *PIK3CA* mutations and/or *KRAS* alterations. In contrast, HER2 or c-MET over-expression cases were mutually exclusive with respect to *PIK3CA* mutations. **Conclusions:** We identified several possible candidate genes that could be targets for personalized therapy. Comprehensive analyses including IHC will be necessary to design the optimal therapy with which to treat the right population of patients in future clinical trials.

**11028 Poster Highlights Session (Board #17), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Impact of next-generation sequencing (NGS) on treatment decisions in the community oncology setting.** *Presenting Author: Lindsay Carol Overton, Oregon Health & Science University, Portland, OR*

**Background:** Mutational testing has become standard of care in melanoma, lung, and colorectal cancers. The advent of Next Generation Sequencing (NGS) and increasing availability of new targeted therapeutics raise the question of how broader use of testing will impact care in the community setting. **Methods:** We conducted a retrospective chart review of patients (pts) seen at a network of community oncology practices whose tumors were tested with NGS for actionable mutations in AKT1, ALK, BRAF, DDR2, EGFR, ERBB2, FGFR1/3, GNA11, GNAQ, MAP2K1, HRAS, KDR, KIT, KRAS, MET, NF1, NRAS, NTRK1/2/3, PIK3CA, PIK3R1, PTEN, RET, STK11, TSC1, and TSC2. Under IRB approval, data were collected on diagnosis, date of testing, treatments, mutational results, treatment outcomes, and survival. **Results:** 632 pts had NGS, of whom 360 harbored actionable mutations (57%). Of these, 301 were included for review: 59 were excluded based on disease stage or insufficient clinical data. There were 26 different cancer types; lung, colorectal and breast cancers represented over half. As of December 2013, 45% of pts had started new therapies after NGS results were available. Mutational testing guided treatment in 34% of these pts, with over half enrolling on clinical trials targeting specific mutations. A minority (6.6%) was treated off label with FDA approved medications targeting the mutations. **Conclusions:** When performed in a timely manner, NGS had a clinically meaningful impact on treatment planning in one third of pts. The availability of molecularly targeted clinical trials played a significant role in the importance of the testing. Our data provide an initial view of how NGS can impact treatment decision making in the community setting.

**Next-generation sequencing (NGS)-based profiling of pancreatic acinar cell carcinoma for identification of a recurrent *SND1-BRAF* fusion.** *Presenting Author: Vincent A. Miller, Foundation Medicine, Inc., Cambridge, MA*

**Background:** Pancreatic acinar cell carcinoma (ACC) is a rare subtype of pancreatic cancer with a poor prognosis. Chemotherapy and radiation therapy have limited efficacy against these tumors, and novel treatment strategies are needed. Previous whole exome sequencing studies have classified these tumors as genomically heterogeneous with distinct genomic profiles from other pancreatic cancers (Jiao et al., 2013). To identify genomic alterations that could serve as potential therapeutic targets, we profiled a small set (n=3) of pancreatic ACC tumors. **Methods:** Extracted tumor DNA underwent hybrid capture for 3,769 exons from 236 cancer-related genes plus 47 introns of 19 genes frequently rearranged in cancer and was sequenced to an average median depth of 728x. Sequences were assessed for base substitutions, insertions and deletions, rearrangements, and copy number changes. We characterized signaling properties of confirmed molecular alterations by ectopic expression of engineered cDNAs in 293H cells. **Results:** We observed an average of two genomic alterations per tumor. A recurrent *SND1-BRAF* rearrangement was identified in two samples that lacked other known driver events. This fusion was similar in structure to other reported *BRAF* fusions, and preserves the serine-threonine kinase domain of the protein. In vitro studies of *SND1-BRAF* suggest that it activates MAPK signaling, which can be inhibited by trametinib and sorafenib. **Conclusions:** Although the number of samples in this study is small, fusions involving *BRAF* potentially occur at a high frequency in pancreatic ACC and may represent a novel therapeutic target in this disease. These alterations occur within intronic regions, and may be missed by sequencing methods that investigate exonic regions only. Preclinical data suggest that *SND1-BRAF* driven activation of MAPK signaling can be inhibited with existing targeted agents, suggesting that a subset of this virulent disease may be amenable to treatment with available therapies. NGS-based profiling of an expanded cohort of pancreatic ACC tumors is ongoing to determine the overall frequency of *BRAF* fusions in this disease.

**Multi-institutional multiplexed genetic analysis in lung adenocarcinoma (AC): The Lung Cancer Mutation Consortium (LCMC I) experience.** *Presenting Author: Dara L. Aisner, University of Colorado Cancer Center, Aurora, CO*

**Background:** Molecular analysis of lung AC has become standard of care for therapy selection. LCMC I collectively enrolled 1102 patients from 14 institutions with the goal of performing molecular analysis to identify therapy options. Technical aspects of the genomic testing, specimen and clinical correlations are presented. **Methods:** Testing for mutations in 8 genes (*EGFR, KRAS, ERBB2, AKT1, BRAF, MEK1, NRAS, PIK3CA*), and analysis of *ALK* and *MET* by FISH, was performed at 6 labs. Proficiency testing was carried out with blinded samples. Statistical analyses were performed for analysis completion, specimen types, testing methodology, mutation findings and clinical variables. **Results:** Five methodologies (SNaPshot®, mass spectrometry, Sanger +/- PNA, sizing) were variably employed for detection of mutations, with analytic sensitivities of ~5% allele frequency. All sites passed proficiency testing. 1006 specimens had at least one mutation analysis completed, 733 specimens had full genotyping results. Mutation detection rates did not vary according to method of analysis. Higher rates of specimen inadequacy were seen in biopsy (36/136; 23%) and cytology (23/65; 36%) compared to surgical (13/268; 5%) specimens at the site that analyzed the most cases. Biopsy and cytology samples, when acceptable showed no difference in mutation or FISH assay completion or positivity rate. Multiple analyses are summarized in the table. Double mutations were seen in 3.8% of samples. **Conclusions:** Molecular analysis is possible in a multi-institutional setting with consistent results. Cytology and small biopsy specimens were commonly sufficient for multiplex testing, although sample insufficiency was a common reason for exclusion (53% of excluded cases), and contributed to lack of assay completion. Multiple associations were identified between specific mutations and clinicopathologic features.

| Gene marker (% +) | Associations found (All p<0.01) |
|---|---|
| ***EGFR* (22%)** | Female, never smoker, Asian, bone metastases |
| ***KRAS* (25%)** | Tobacco exposure, lack of bone metastases, non-Asian, older age at dx |
| ***ALK* (9%)** | Never smoker, younger age at dx, liver metastases |
| ***MET* amp (3%)** | Male |
| ***ERBB2* (2%)** | Never smoker |
| ***BRAF* (2%)** | None |

**11031 Poster Highlights Session (Board #20), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A comprehensive analysis of molecular profiles across over 10,000 tumor and germ-line exomes across more than 20 tumor types: Novel mechanisms and targets for clinical treatment.** *Presenting Author: Shahrooz Rabizadeh, NantOmics LLC, Culver City, CA*

**Background:** Whereas the clinical world is familiar with genomic assays targeted to a limited number of mutations as a means to derive molecular insight to therapies, the power to deliver more comprehensive, non-assumptive, and stochastic molecular analysis is now available to guide treatment decision that is unbiased to traditional tissue-by-tissue assignment of therapeutics or a priori assumptions that a few hundred DNA mutations are drivers of the cancer. **Methods:** Over 10,000 tumor and germ line exomes and RNA-seq data representing over 5,000 patients across more than 20 tumor types were processed using Contrastor, a cancer genome differentiation algorithm designed to detect variants (germline and somatic), copy-number alterations (overall and allele-specific), and genomic rearrangements. RNA-seq data was used to confirm the presence of alterations in the transcript when available. Paradigm, an algorithm that integrates genomic and transcriptomics data and designed to identify key altered cell signaling pathways, was used to reveal shared pathways amongst independent tumor types. **Results:** Aggregating the top altered genes across tissues reveals very few genes are dominated with alterations present in single diseases. DNA repair and kinase signaling proteins appear to be the predominantly altered classes, with transcriptional proteins also highly altered (TP53, MLL, CREBBP). A surprising number of new targets for pharmaceutical discovery were uncovered, and particularly in patients with no clear therapeutic options based on the analysis of "actionable" genes. Despite patients having unique molecular profiles, Paradigm revealed shared pathways across tissue types driving tumor progression that are likely targets for therapeutic intervention. **Conclusions:** The vast landscape and ample number of mutations identified in this comprehensive analysis illustrates the complexity of cancer genomics and the need for transcriptomics driven pathway analysis to identify the focal points of therapeutic intervention.

**11032 Poster Highlights Session (Board #21), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Intratumor heterogeneity (ITH) of lung adenocarcinomas defined by multi-region whole exome sequencing (WES).** *Presenting Author: Jianjun Zhang, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Individual cancers are composed of populations of cells with distinct molecular and phenotypic features, a phenomenon termed ITH. ITH may have profound impacts on biopsy strategy, characterization of actionable targets, treatment planning, and drug resistance. The extent and architecture of ITH of lung cancers are largely unknown. **Methods:** We performed multi-region WES of 48 samples from 11 surgically resected lung adenocarcinomas and their matched peripheral blood leukocytes to an average of 267-fold sequencing depth. All tumor samples were analyzed for point mutations, insertions/deletions, and copy number alterations. All somatic variations were validated with targeted capture ultra-deep sequencing to an average of 869-fold sequencing depth. Sub-clonal analysis based on a Bayesian statistics approach process was performed in each tumor sample. Phylogenetic trees of these 11 tumors were constructed after clonal ordering. **Results:** 17,572 somatic point mutations, insertions, and deletions were identified and validated. The numbers of somatic alterations varied significantly among different patients and among different samples within the same tumor suggesting significant inter- and intra-tumor heterogeneity. Sub-clonal analysis suggested presence of multiple related populations in each sample with the distribution allele frequencies varying substantially across regions of the same tumor. The majority of known driver mutations (e.g., EGFR, KRAS) were present in all regions of the sampled tumors. There was no correlation with extent/structure of ITH and age, gender, tumor size, lymph node status, or smoking status. With a median follow-up of 2.5 years, 2 patients recurred. Of potential interest, these 2 patients had the most complex ITH architectures in their primary tumors. **Conclusions:** Different lung adenocarcinomas may have distinct ITH architectures. Although the sample size is very small, the fact that both patients who relapsed had complex ITH architectures suggests that complex ITH architectures may lead to unfavorable clinical outcomes. Studies on larger cohorts are needed to elucidate the clinical impacts of ITH.

**11033 Poster Highlights Session (Board #22), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**BRCAness in non-small cell lung cancer (NSCLC).** *Presenting Author: Saiama Naheed Waqar, Division of Oncology, Washington University School of Medicine, St. Louis, MO*

**Background:** Germline mutations in the *BRCA1* and *BRCA2* DNA repair genes confer susceptibility to breast and ovarian cancer, and are targets for PARP inhibitors. The term "BRCAness" broadly refers to somatic molecular defects in the cellular DNA repair machinery, resulting in a phenotype similar to that caused by BRCA germline mutations. We evaluated data from The Cancer Genome Atlas (TCGA) for molecular alterations in double strand DNA repair genes in NSCLC. **Methods:** We examined somatic molecular alterations in 20 homologous recombination (HR) and 16 Fanconi anemia (FA) genes in 230 lung adenocarcinoma (LUAD) and 178 squamous cell carcinoma (SQCC) samples from TCGA data using cBio portal. Alterations were classified into homozygous deletion, mutation, and amplification. Tendency towards co-occurrence and mutual exclusivity of mutations in these genes was described using odds ratios (OR) and calculated by Fisher's exact test using $\alpha = 0.05$. **Results:** Somatic molecular alterations involving at least 1 HR or FA gene were observed in 121 (53%) of LUAD and 90 (51%) of SQCC respectively. The most common homozygous deletions noted were in *RAD51* (3%) in LUAD and *XRCC1* (1%) in SQCC. Frequent somatic gene mutations in *BRCA2* (5%), *BRCA1* (3%), *RAD54B* (3%) and *BRIP1* (3%) were observed in LUAD, including the well-known nonsense S3376 and S2695 mutations in *BRCA2*. *BRCA1* and *RAD51D* mutations tended to co-occur (OR >10; p=0.03), while *BRCA2* mutations tended to co-occur with *FANCB* (OR >10; p=0.02) and *RAD54L* (OR >10; p=0.01) in LUAD. Commonly observed somatic mutations in SQCC included the following genes: *BRCA1* (6%), *BRCA2* (6%), *FANCA* (3%) and *PALB2* (3%), including the known Q94 and K1160 nonsense mutations in *BRCA1* and nonsense mutations Q499 and E187 in *BRCA2*. *BRCA1* and *PALB2* gene mutations tended to co-occur (OR>10; p=0.001) in SQCC. Amplifications were most commonly noted in *XRCC2*, *NBN*, *RBBP8* and *C19ORF40* in LUAD (2% each), and *FANCG*, *FANCL, C19ORF40* in SQCC (4% each). **Conclusions:** BRCAness is commonly observed in NSCLC and may be a target for PARP inhibition in molecularly selected patient populations.

**11034 Poster Highlights Session (Board #23), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Oncogenic ARAF as a new driver in lung adenocarcinoma.** *Presenting Author: Luiz H. Araujo, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

**Background:** We recently identified a novel somatic mutation in ARAF in a lung adenocarcinoma from a patient that demonstrated a remarkable response to sorafenib. The S214C lies in a negative regulatory domain of ARAF, distinct from the catalytic domain mutations commonly found in BRAF. The aim herein was to evaluate the oncogenic potential and characterize the mechanism of ARAF S214C activation. **Methods:** ARAF constructs were generated and ectopically expressed in an immortalized bronchial epithelial cell line (BEAS-2B). We evaluated the acquisition of anchorage independence, MEK activation, and cell morphology. COS7 cells were used for co-immunoprecipitation (IP) and kinase assays. **Results:** Cells expressingARAF S214C substantially increased soft agar colony formation relative to vector, wild-type, kinase-dead (D429A), and double-mutant (S214C+D429A) variants. Accordingly, ARAF S214C cells exhibited increased phospho-MEK levels, suggesting that the transforming potential is dependent on its kinase activity. We also demonstrated that cells expressing ARAF S214C with an additional RAS-binding domain mutation (R52L) lacked MEK activation and failed to form colonies, showing that RAS binding is essential for activity. Interestingly, ARAF S214C cells acquired an elongated, fibroblast-like shape, characteristic of MEK-active cells. Conversely, none of other variants presented this morphology. To determine if either BRAF or RAF1 were necessary for ARAF S214C activity, we performed BRAF and RAF1 knockdowns. ARAF S214C-induced MEK activation was not reverted by the knockdowns, suggesting that BRAF and RAF1 are not required. Subsequently, COS7 cells were co-transfected with tagged constructs of ARAF and either BRAF or RAF1, followed by co-IP. We showed that ARAF S214C does not heterodimerize, unless stimulated with sorafenib. Importantly, sorafenib-induced heterodimers lacked kinase activity, compatible with the clinical response reported. **Conclusions:** ARAF S214C demonstrates the *in vitro* features of a driver oncogene, and also a distinct mechanism of action. This oncogenic process can be successfully suppressed by RAF inhibitors like sorafenib, and could represent a new target for personalized therapy in advanced lung adenocarcinoma.

**11035 Poster Highlights Session (Board #24), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Efficacy of crizotinib in ROS1-rearranged lung cancer: The European experience.** *Presenting Author: Julien Mazieres, Hôpital Larrey CHU Toulouse, Toulouse, France*

**Background:** ROS1 chromosomal rearrangement (ROS1+) was described as an oncogenic driver in approximately 1% of non-small cell lung cancers (NSCLC). Due to the structural analogy of ROS1 and ALK, crizotinib is a potent inhibitor of both targets. An expansion cohort of a phase I trial reported promising activity [Ou et al., ASCO 2013]. Here, we describe the characteristics and outcomes of ROS1+ NSCLC patients treated with crizotinib in a large European case series. **Methods:** We conducted a retrospective study among European clinicians screening ROS1+ NSCLC. Eligible patients had advanced NSCLC, known ROS1+ NSCLC diagnosed by FISH and received crizotinib for at least 1 week at the dose of 250 mg BID through national access program or an individual off-label use basis. Treatment response was performed according to RECIST criteria version 1.1. Informed consent and IRB approval were obtained according to local regulations. Data were analyzed centrally. **Results:** We identified 28 ROS1+ NSCLC patients treated with crizotinib. Our population was characterized by a median age of 58 yr (34 to 78 yr), a gender-ratio of 17 women and 11 men and a high proportion of never smokers (n = 19, 67.9%). All the patients had stage IV disease and were pretreated with none (n=2), one (n = 8), two (n = 5), three (n = 3) or more (n = 10) lines of chemotherapy before the administration of crizotinib. All tumors were adenocarcinomas including 4 with lepidic pattern. ROS1 rearrangement was the exclusive driver except for 2 tumors with concomitant KRAS mutation. Twenty-six patients were evaluable for response (the waterfall plot will be presented at the meeting). We observed 3 progressive diseases, 3 stable diseases and 20 objective responses including 4 complete responses (overall response rate 77%, disease control rate 88%). Crizotinib primary resistance was associated with concomitant KRAS mutation or progression in the brain. Crizotinib was generally well tolerated and no unexpected adverse effects were observed. **Conclusions:** These results confirm the high crizotinib activity in ROS1+ NSCLC. Further patients should be treated in ongoing clinical trials to test the long-term activity of ROS1 inhibitors.

**11036 Poster Highlights Session (Board #25), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Identification of a lung cancer growth factor, LASEP1, as a serological and prognostic biomarker and a therapeutic target.** *Presenting Author: Atsushi Takano, Center for Antibody and Vaccine, Research Hospital, Institute of Medical Science, The University of Tokyo, Tokyo, Japan*

**Background:** Cancer-specific oncoantigens could be ideal targets for the development of novel diagnostic/prognostic biomarkers and/or therapies. **Methods:** To identify new oncoantigens, we screened up-regulated genes that encode secreted protein in 120 cases of non-small cell lung cancers (NSCLCs) by means of cDNA microarray containing 27,648 genes and examined clinicopathological significance of their protein expression by tissue microarray covering 374 NSCLCs. We further examined their growth/invasion effect on cancer cells by siRNA and Matrigel invasion assays. We also measured their protein concentration in serum by ELISA. **Results:** We identified *LASEP1* (Lung cancer Associated Serum Protein 1) as a candidate secreted protein. Immunohistochemical staining confirmed that positive staining of LASEP1 was observed in 210 (56%) of 374 NSCLCs. Multivariate analysis revealed that high level of LASEP1 expression was associated with poor prognosis for NSCLCs patients. The proportion of serum LASEP1-positive cases was 127 (38.6%) of 329 lung cancers, while 4 (3.9%) of 102 healthy volunteers were falsely diagnosed. Furthermore, suppression of *LASEP1* by siRNAs inhibited the growth of cancer cell through a significant increase in the number of cells at the G1 phase. In addition exogenous LASEP1 expression enhanced the growth and the cell mobility *in vitro*. LASEP1 interacts with its 50-kDa receptor (LASEPR) on the surface of cancer cells. siRNAs for *LASEPR* also inhibited the growth of cancer cells. The LASEP1-LASEPR interaction promoted the cell growth in an autocrine manner. The growth activity of the LASEP1-positive cells was neutralized by addition of originally developed anti-LASEP1 monoclonal antibodies into their culture media. The systemic administration of the anti-LASEP1 antibody to tumor-implanted mice significantly suppressed tumor growth without any adverse events. By gene expression analysis using microarray to determine down-stream genes of *LASEP1*, we identified *WHSC1* encoding an oncogenic histone methyltransferase as a LASEP1-target gene. **Conclusions:** LASEP1 was suggested to be a good candidate for the development of biomarkers and therapeutic target for lung cancer.

**11037 General Poster Session (Board #319), Sat, 1:15 PM-5:00 PM**

**Differences in circulating angiogenic biomarkers as prognosticator for outcome in bevacizumab-treated nonsquamous non-small cell lung cancer (NSCLC) patients.** *Presenting Author: Marta Batus, Rush University Medical Center, Chicago, IL*

**Background:** Trials evaluating role of bevacizumab in patients with advanced NSCLC have shown only modest impact in outcomes. The objective of this study was to evaluate predictive value of panel of circulating biomarkers important in cancer-induced angiogenesis in frontline treatment. **Methods:** Chemonaïve non-squamous patients were assigned to regimens of standard platinum-doublet chemotherapy either alone (CTx; n=20) or in combination with bevacizumab (CTx+bev; n=21). Paired pretreatment and post first cycle sera from each patient were evaluated using Human Angiogenesis Growth Factor Panel (EMD Millipore) which contains angiopoietin-2, BMP-9, EGF, endoglin, endothelin-1, FGF-1, FGF-2, follistatin, G-CSF, HB-EGF, HGF, IL-8, leptin, PLGF, VEGF-A, VEGF-C, and VEGF-D on a FlexMAP 3D system (Luminex Corp.). Serum pretreatment and differential (pre- vs. post-treatment) levels of each analyte were associated with progression-free survival (PFS) and overall survival (OS) and compared between regimens. Multivariate Cox PH analyses were used to identify interaction of markers with CTx/CTx+bev on PFS and OS. **Results:** Increasing levels of VEGF-A in first cycle of treatment were differentially associated (HR=4.98; $p<0.001$) with a worse PFS in the CTx+bev cohort versus CTX. Alternately, increasing levels of IL-8 were differentially associated with poor PFS and OS in CTx patients ($p=0.003$, 0.02, respectively). Increasing leptin levels were associated with a favorable OS in CTx+bev cohort, versus CTX (HR=0.36, $p=0.02$). Large increases in angiopoietin-2, HGF, follistatin, VEGF-C, and VEGF-D were associated with a poor OS ($p<0.05$), whereas large increases in FGF-1, and endothelin-1 were associated with more favorable OS ($p<0.01$). **Conclusions:** Significant relationship betweenchanging levels of angiogenic biomarkers and PFS/OS observed in our relatively small groups of patients suggests that further evaluation of angiogenic biomarkers in longitudinal studies is warranted to substantiate value of molecules for prognosticating and identifying patients more likely to benefit from frontline bevacizimab therapy.

**11038 General Poster Session (Board #320), Sat, 1:15 PM-5:00 PM**

**Biologic pathways associated with breast cancer metastases to the brain.** *Presenting Author: Vinay Varadan, Case Comprehensive Cancer Center, Cleveland, OH*

**Background**: Brain metastases (BM) associated with breast cancer are difficult to treat, with a median survival less than 1 year for these patients. While basal-like and HER2+ breast cancers are at higher risk of developing brain metastases, no effective treatments exist for these patients. Comprehensive characterization of the transcriptome of matched primary breast (PB) tumors and BM allows for discovery of pathways mediating BM in breast cancer to improve treatment for this deadly disease. **Methods**: Pathology records were searched for patients who underwent surgical resection of BM from PB and archival FFPE material was obtained along with clinical data from the medical record and tumor registry. TMA sections were stained with ER, PR and HER2 to confirm receptor status. Tumor DNA/RNA was extracted from macrodissected 2 mm cores from FFPE. Gene expression profiling was performed using Affymetrix HTA 2.0 arrays on 96 FFPE samples for whom sufficient RNA was available. PAM50 subtypes were derived and differential gene expression between BM and PB was estimated using the Mann-Whitney-Wilcoxon test followed by multiple testing correction. Pathway enrichment analysis was performed using the KEGG and NCI Pathway Interaction Databases. **Results**: Differential gene expression analysis between the 46 BM and 26 PB showed enrichment ($p<0.05$;FDR$<0.1$) of B1 and B3 integrin, IL8 and CXCL2/4, UPA/PAI, Osteopontin, RAC1, BMP, TGF$\beta$, PI3K and Ras pathways in KEGG and NCI-PID. The matched subset of 27 BM and PB samples showed persistent enrichment for all these pathways and showed differential expression of angiogenesis (PDGFR, c-MET, Angiopoetin) lymphangiogenesis (VEGFR-3) and HIF-1-alpha and Jak-STAT signaling pathways. Differential expression of non-genomic ER signaling was seen in both cohort-level and matched PB/BM pairs and Androgen receptor signaling was modulated in paired samples. A subset of BM showed upregulation of the Creighton AKT geneset, which was confirmed using a predefined AKT activity signature. **Conclusions**: Our study shows significant modulation of driver pathways in brain metastases when compared with matched primary breast tumors. Orthogonal validation of these findings using IHC and functional studies will be presented.

**11039 General Poster Session (Board #321), Sat, 1:15 PM-5:00 PM**

**Antitumor activity of MP0250, a bispecific VEGF- and HGF-targeting darpin, in patient-derived xenograft models.** *Presenting Author: Ulrike Fiedler, Molecular Partners AG, Zurich-Schlieren, Switzerland*

**Background:** The interplay of tumor cells and their microenvironment is crucial in the growth of solid tumors. Key mediators of such interaction are the VEGF/VEGFR and the HGF/cMet pathways, which drive tumor survival, growth, angiogenesis, invasion and metastasis. It is anticipated that simultaneous inhibition of the VEGF/VEGFR and HGF/cMet pathways will interfere with crucial steps of tumor growth as well as with the onset of treatment resistance. MP0250 is a bispecific DARPin targeting both pathways simultaneously by specifically neutralizing VEGF and HGF. Its low toxicity offers the potential for combination with chemotherapy and other targeted therapies. **Methods:** Antitumor activity of MP0250 was tested in kidney, liver, lung and gastric patient-derived xenograft (PDX) models and compared to standard of care (SoC) therapies. **Results:** MP0250 showed consistent antitumor activity in 6 out of 7 investigated models. Its potency was superior to SoC in renal and gastric carcinoma models, and similar to SoC in liver and one lung cancer (NSCLC) model. Of note, neither MP0250 nor SoC (5-FU) showed potency in one SCLC lung cancer model. Tumor regression was induced by MP0250 in one liver and one renal model with optimal T/C values of 6.9% and 8.9%. Tumor growth inhibition was recorded in the other liver and one lung model (T/C values of 37% and 26%) whereas moderate efficacy was observed in the second renal cancer model (T/C value of 56%). Interestingly, MP0250 increased the potency of the SoC drug paclitaxel in the gastric cancer model (T/C values: MP0250 37%; paclitaxel 46%, MP0250/paclitaxel 21%). No toxicity of MP0250 was observed as monotherapy or in combination with SoC. **Conclusions:** MP0250, a bispecific DARPin blocking HGF and VEGF, is a potent inhibitor of tumor growth in PDX models, often surpassing the efficacy of SoC therapy. In a gastric cancer model, MP0250 increased potency of SoC. These results indicate that MP0250 has the potential to be used as monotherapy in a range of solid tumors and, as a result of its good safety profile, the possibility exists that it may be also combined with SoC and other tumor targeting molecules, i.e. TKIs. A phase I clinical trial is in preparation.

**11040 General Poster Session (Board #322), Sat, 1:15 PM-5:00 PM**

**A Markov chain model of a longitudinal breast cancer data set.** *Presenting Author: Paul K. Newton, University of Southern California, Los Angeles, CA*

**Background:** Cancer cell migration patterns are critical for understanding metastases and clinical evolution. Breast cancer spreads from one organ system to another via hematogenous and lymphatic routes. Although patterns of spread may superficially seem random and unpredictable we explored the possibility that this is not the case. **Methods:** Based on a data set of 453 breast cancer patients from Memorial Sloan Kettering Cancer Center—all non-metastatic at time of diagnosis—we created a Markov chain model of metastasis. This describes the probabilities of metastasis occurring at a given anatomic site together with the probability of spread to additional sites, based on observations. **Results:** Using actual data, we have learned (i) how to create the Markov transition matrix governing the probabilities of cancer progression from site to site; (ii) how to create a systemic network diagram governing disease progression modeled as a random walk on a directed graph; (iii) how to classify metastatic sites as ″sponges″ that tend to only receive cancer cells or ″spreaders″ that receive and release them; (iv) how to model the time-scales of disease progression as a Weibull probability distribution function; (v) how to perform Monte Carlo simulations of disease progression; and (vi) how to interpret disease progression as an entropy-increasing stochastic process. **Conclusions:** We have found that the patterns of metastatic spread in breast cancer are not unpredictable. Furthermore, the novel concept of classifying organ sites as sponges or spreaders may motivate experiments seeking a biological basis for these phenomena. This model may also be useful in mapping the accumulation of genomic aberrations not only over time, but also over space.

**11041 General Poster Session (Board #323), Sat, 1:15 PM-5:00 PM**

**A pilot study for cellular detection of circulating tumor cells and disseminated tumor cells of patients with hepatocellular carcinoma.** *Presenting Author: Nozomi Minagawa, Gastroenterological Surgery 1, Hokkaido University Graduate School of Medicine, Sapporo, Japan*

**Background:** Circulating tumor cells (CTC) in peripheral blood (PB) and disseminated tumor cells (DTC) in bone marrow (BM) have been recently focused as predictive and prognostic markers in solid tumors. But hepatocellular carcinoma (HCC) usually lacks epithelial antigens, only a few reports described CTC or DTC at a cellular level. The aim of this study is to establish methodology for detecting CTC and DTC in HCC at a cellular level, and to analyze with clinicopathological findings. **Methods:** PB (n-36) and BM samples (n-20) were preoperatively collected from patients with HCC between October 2011 and July 2013. Mononuclear cells were collected by Ficoll gradient separation. CD45+ cell population was deleted through magnetic activated cell sorting system. Subsequently, double immunofluorescence for AFP, Arginase-1 or Hep-Par1 and CD45 was performed. PB samples from 20 healthy volunteers and BM samples from 3 patients with benign disease were used as controls. Our protocol has been approved by the ethical committee of Hokkaido University Hospital and written informed consent was obtained from all enrolled patients. **Results:** Positive rates of CTC and DTC were 63.8% (23/36) and 65.0% (13/20). No CTC or DTC was found in the control groups. Detection of CTC or DTC was closely correlated with preoperative tumor marker and portal invasion. Positive rates of preoperative AFP and PIVKA-II in $CTC^+$, $DTC^+$ patients were statistically higher than that of $CTC^+$ or $DTC^+$ patients (AFP:73.9%, 84.6% vs 38.4%, 28.6%,p=0.04, PIVKA-II: 86.9%, 92.3% vs 53.8%, 57.1%, p=0.02). Detection of CTC or DTC is also correlated portal invasion (60.8%, 61.5% vs 7.7%, 0%,p=0.04). There're higher risk of distant metastasis in $CTC^+$ or $DTC^+$ patients, compared with that of $CTC^-$ or $DTC^-$ patients (47.8%, 53.8% vs 7.7%, 0%, p=0.04).There're significant differences in the distant metastasis-free survival (p=0.01), but not in the overall survival and in the liver recurrence-free survival (p= 0.94, 0.05). **Conclusions:** Our protocol might provide highly specific detection of CTC, DTC from HCC patients. Detection of CTC or DTC might contribute to considering postoperative therapeutic strategies.

**11042 General Poster Session (Board #324), Sat, 1:15 PM-5:00 PM**

**Effect of exemestane plus everolimus on CTC counts and Ki-67 expression on CTCs in patients with advanced hormone receptor-positive, HER2-negative breast cancer.** *Presenting Author: Sofia Agelaki, Department of Medical Oncology, University General Hospital of Heraklion, Heraklion, Greece*

**Background:** The utility of CTCs in predicting patient (pt) outcome has been demonstrated in metastatic breast cancer treated with chemotherapy or endocrine therapy. In this trial we evaluated the prognostic impact of CTC assessment in pts treated with exemestane plus the targeted therapy everolimus. **Methods:** Forty pts with HER2-negative metastatic breast cancer received exemestane plus everolimus. Blood was drawn for CTC assessment by CellSearch System and immunofluorescence (IF) analysis (7.5 and 10 ml, respectively) on day 1 of cycles 1 (n=40), 2 (n=39), 4 (n=28), on each disease evaluation and on relapse, whichever occurred first. Cytospins ($10^6$cells) of peripheral blood mononuclear cells (PBMCs) from 31 of 40 pts were double stained with pancytokeratin (CK) along with Ki-67 antibodies. **Results:** Using CellSearch 25 (62.5%) pts had detectable CTCs (cut-off ≥ 1 CTC) at baseline, 12 (30.8%) post-$1^{st}$ and 9 (32.1%), post-third cycle. In 9 pts no CTCs were observed at any time point. CTCs ≥5 were identified in 10 (25%), 6 (15.4%) and 3 (10.7%) pts at baseline, post-firstand post-third cycles, respectively. Four (40%) pts with baseline counts of CTCs ≥5 turned to <5 post-first ycle. Total CTC counts declined from 332 at baseline (mean number/pt 8.3, range 0-103) to 90 (mean 2.3, range 0-34) and 46 (mean 1.64, range 0 - 16) post-first and -third cycles, respectively. Using IF, 7 (22.5%) pts had detectable CK(+) CTCs (cutoff ≥ 1 CTC) at baseline; 8 (25.8%) of 31 and 7 (28%) of 25 were CTC(+) post -first and -third cycles, respectively. Total CTC numbers were 197 at baseline (mean, 16.42, range, 0-192) and 58 (mean 1.87, range 0-34) and 336 (mean 13.44, range 0 - 290) post-first and -third cycle, respectively; the ratio of Ki-67(+)/CK(+) CTCs declined from 32% to 13.8% and 13.4%, post-first and -third cycle, respectively. **Conclusions:** Exemestane plus everolimus effectively decreases CTC counts and the population of Ki-67(+) CTCs in HER2-negative metastatic breast cancer. Correlations with patient characteristics and outcome will be presented.

**11043 General Poster Session (Board #325), Sat, 1:15 PM-5:00 PM**

**Tumorspheres cultured from circulating epithelial tumor cells (CETCs) as diagnostic marker in patients with solid cancers.** *Presenting Author: Katharina Pachmann, Transfusion Center Bayreuth, Bayreuth, Germany*

**Background:** Metastatic disease is a serious threat and the most common cause of *cancer*-associated death in patients with solid tumors. The presence of CETCs is closely related to tumor metastasis, but it is still unclear whether all CETCs are capable to proliferate and generate metastasis. Therefore we investigated their proliferative capacity by analyzing the frequency of tumorsphere formation with subsequent phenotypic characterization of the tumorspheres arising in patients with solid tumors. **Methods:** 37 patients with solid cancer and early metastatic disease and detectable CETCs were enrolled in the present study. 10 patients had breast, 10 colorectal, 10 prostate and 7 lung cancer. CETCs were determined using the maintrac method and the CETCs were cultured in suspension culture in the context of the other white blood cells allowing for epithelial sphere formation. Cell viability, stem cell marker expression and ALDH 1 activity was evaluated by fluorescence scanning microscope (Olympus Scan R). **Results:** Sphere formation was observed in 90 %, 90 %, 80 % and 85.7 % of patients with breast, colorectal, prostate and lung cancer, respectively. Among solid cancer patients the number of tumor spheres increased significantly with tumor progression, especially with development of distant metastasis. The selectivity for distant metastasis of the area under ROC curve for the number of tumorspheres was 0.72 ($p < 0.02$). Five or more tumorspheres grouped metastatic disease with a sensitivity and specificity of 88.2 % and 75 %, respectively. Analysis of surface marker expression profile of tumorspheres showed that tumorspheres cultured from CETCs had typical phenotype of cancer stem cells and tumorspheres in patients with breast cancer possessed a high enzymatic activity for ALDH 1 with the ALDEFLUOR assay. There was no sphere formation in 20 healthy donors. **Conclusions:** Here, we describe for the first time the identification of CETCs which are capable of forming tumorspheres with proliferative activity and stem cell characteristics. This may contribute to the design of tools for early detection of progression and treatment in solid cancer.

**11044 General Poster Session (Board #326), Sat, 1:15 PM-5:00 PM**

**Bisphosphonate treatment of primary breast cancer patients with disseminated tumor cells in the bone marrow.** *Presenting Author: Andreas D. Hartkopf, Department of Gynecology and Obstetrics, University of Tuebingen, Tuebingen, Germany*

**Background:** The role of the addition of bisphosphonates (BPs) to adjuvant breast cancer treatment is unclear. Recent trials have reported different results in terms of survival. In a large meta-analysis, menopausal status was found to predict efficacy of BPs. As BPs primarily target the skeletal system to modify disease progression, we aimed to investigate whether primary breast cancer (PBC) patients that harbor disseminated tumor cells (DTCs) in their bone marrow (BM) might benefit from adjuvant BPs. **Methods:** BM aspirates were collected from patients that underwent surgery for PBC at Tuebingen University Hospital, Germany between 01/2001 and 01/2013. DTCs were identified by immunocytochemistry (pancytokeratin antibody A45/B3) and cytomorphology. Patients with a DTC-positive BM were included into this retrospective analysis. The influence of BP therapy on disease free (DFS) and overall survival (OS) was analyzed in an univariate (log-rank test) and multivariate analysis (cox regression). **Results:** 794 patients were available for this retrospective analysis. In 329 (41%) of these patients, BPs were added to conventional adjuvant therapy. Univariate analysis revealed that there was a significant risk reduction in terms of DFS (hazard ratio (HR)=0.42 [95% confidence interval (CI): 0.25-0.69], $p<0.001$) and OS (HR=0.49 [95% CI: 0.30-0.82], $p=0.006$) in patients treated with BPs. In a subgroup analysis, BPs significantly enhanced DFS ($p=0.018$) but not OS ($p= 0.235$) in premenopausal patients; in postmenopausal patients BPs improved DFS ($p=0.014$) and OS ($p=0.009$). In a multivariate analysis, independent predictors of reduced DFS were BP treatment and nodal status and independent predictors of reduced OS were BP treatment, nodal status and PR status. **Conclusions:** Adjuvant BP therapy can improve survival in primary breast cancer patients that harbor DTCs in the BM. Whether the DTC status is predictive for BP treatment efficacy must be evaluated in prospective trials.

**11045 General Poster Session (Board #327), Sat, 1:15 PM-5:00 PM**

**Epithelial-to-mesenchymal (EMT) markers and nanomechanical signatures of circulating tumor cells (CTC) for prediction of men with castrate-sensitive versus castration-resistant prostate cancer (PCa).** *Presenting Author: Devalingam Mahalingam, Cancer Therapy and Research Center, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

**Background:** Advance PCa patients (pts) on androgen-deprivation therapy (ADT) eventually develop castrate-resistance (CR) disease. Men failing to achieve PSA $\leq$ 4ng/mL after 7 months of ADT have the greatest risk of early death from advance PCa. The challenge is to distinguish indolent vs. aggressive cancer, castrate sensitive (CS) vs. CR early for better disease control. During PCa progression CTC shed from tumor into bloodstream is subject to physical forces, epigenetic modifications and EMT transition. Little is known if EMT transition and the nanomechanical signatures of CTC can predict sensitivity to ADT. **Methods:** We obtained CTCs from 29 pts with advance PCa. CTCs were isolated from pts blood (~15 ml) using microfiltration system (ScreenCell). We analyzed CS and CR PCa cell lines, and correlated CTCs from pts with CS or CR using high throughput microfluidic single-cell RT-PCR. CTCs from 18 pts were subjected to nanomechanical analysis with atomic force microscopy (AFM) using PeakForce QNM Catalyst (Bruker). Elasticity, deformation and adhesion were evaluated as elements of nanomechanical phenotype. **Results:** 20pts with CR and 9pts with CS advance PCa were enrolled. Median age 65 (47-91). Median PSA 40.77 (0.1-2368.31ng/ml). A median of 1.6 (0–15) CTC/ml were detected. Increased expression of EMT genes was found in CR PCa cells and CTCs compared to CS counterparts. IPA indicated that these EMT genes are closely related to AKT, $\beta$-catenin, Myc and NF$\kappa$B pathways. AFM show that CTCs of CR pts are $\geq$ 3 fold more elastic, ~5 fold more adherent and ~3 fold more deformable than CTCs of CS pts. Using Young modulus elasticity value $<$2.91 kPa, adhesion value $>$ 120 pN and deformation value of $>$ 412nm, combined analysis of all 3 parameters gives a $>$ 99% power of detecting a nanomechanical phenotype of CR PCa ($p=0.0002$). **Conclusions:** CTCs isolated from CR PCa pts often lose the typical features of prostate epithelial cells, display incremental EMT-related gene expression and have a distinct nanomechanical phenotype compared to CS PCa, and could serve as biomarker for early CR detection, treatment stratification and subsequent disease monitoring.

**11046 General Poster Session (Board #328), Sat, 1:15 PM-5:00 PM**

**Identification through genome-wide association study (GWAS) of single nucleotide polymorphisms (SNPs) associated with extreme phenotypes of tobacco-induced non-small cell lung cancer (NSCLC) risk.** *Presenting Author: Jose Luis Perez-Gracia, Department of Oncology. Clinica Universidad de Navarra, Pamplona, Spain*

**Background**: SNPs may modulate individual susceptibility to carcinogens. We used GWAS to identify SNPs associated with individuals presenting extreme phenotypes of sensitivity and resistance to develop tobacco induced NSCLC. We hypothesized that selection of extreme phenotypes would enrich the frequencies of alleles that contribute to the trait, thus increasing the power to identify them. **Methods:** From an identification cohort (n=3631) we selected caucasian heavy smokers that either developed NSCLC at an early age (cancer cohort) or that did not present NSCLC at an advanced age (cancer free cohort). We analyzed their genomic DNA using the array Illumina HumanOmni 2.5 Quad that includes over 2 million powerful markers selected from the 1000 Genomes Project, targeting genetic variation down to 1% minor allele frequency. **Results:** 96 patients (48 per cohort) were selected. Mean age for the cancer and cancer free cohorts was 49 (range 38-55) and 76 years (72-84). Mean tobacco consumption was 41 (range 18-99) and 68 pack-years (40-120). GWAS identified 8 SNPs differentially expressed by logistic regression and 54 SNP by Fisher´s test ($p<10^{-5}$). Odds-ratio ranged between 0.08-0.29 for protective SNP and 3.4-11.2 for SNP that increased NSCLC risk. Candidate SNPs were located within or in adjacent regions of genes related to: a) oncogenic and tumor-suppressor pathways: *CSMD1, FOXF1, MSX2, SOX11*; b) tobacco induced NSCLC: *ABCB5*; c) regulation of transcription: *DROSHA, HDAC9, KIAA0947*; d) regulators of inflammation through the NF-kappa pathway: pellino E3, *TRIM9*; e) previously linked to carcinogenesis and cancer prognosis: *ABHD6, GRIK1, RAB40B, SCN1A, SLC24A2, SLC25A26, ZFYVE26*; and f) not previously linked to cancer: *ACER3,* AP000946.2, *ATP10A, ATP10D,* CNTN5, *CYYR1*, LINC00572, *PDE10A, RP11-115D19.1, RP11-202D1.3, RP11-521E5.1, SYTL5, ZPBP*. **Conclusions:** We identified candidate SNPs potentially associated with the risk of developing tobacco induced NSCLC in individuals with extreme phenotypes. Validation of the most significant SNPs in an independent set of individuals with similar phenotypes is ongoing.

**11047 General Poster Session (Board #329), Sat, 1:15 PM-5:00 PM**

**Systematic review of a personalized strategy in cancer clinical trials leading to FDA approval.** *Presenting Author: Denis Leonardo Fontes Jardim, University of Campinas, Campinas, Brazil*

**Background:** Evidence for the hypothesis that personalization of therapy optimizes benefit is a subject of debate. We compared efficacy between US Food and Drug Administration (FDA) approved cancer treatments deploying a personalized strategy vs. those without a biomarker-based rationale. **Methods:** We reviewed registration trials (based on package inserts from Drugs@FDA) that evaluated new agents receiving FDA approval (Sept. 1998 to June 2013) for cancer. Pooled analysis of response rate (RR), progression-free survival (PFS) and overall survival (OS) for all trials and hazard ratios (HRs) for time-to-event endpoints for randomized trials were compared between personalized (defined as using a drug matched to a biomarker or in a population where $>$ 50% of patients harbor the cognate target) vs. non-personalized trials. **Results:** A total of 58 approved drugs were included (57 randomized [32% personalized] and 55 non-randomized trials [47% personalized]; N=38,104 patients). Personalized trials more often included oral drugs (68% vs. 35%, P=0.001), single agents (89% vs. 71%, P=0.036) and more frequently allowed crossover to experimental arms than non-personalized trials (67% vs. 28%, P=0.009). RR was significantly higher (49% vs. 25%, P$<$0.001) and PFS was longer (8.5 vs. 5.5 mos, P=0.001) with a personalized approach. In the multilinear regression analysis, personalized therapy was selected as an independent factor predicting a higher RR (P$<$0.001) and longer PFS (P=0.002). Median HR for PFS of experimental to control arms was 0.37 for personalized vs. 0.58 for non-personalized trials (P=0.003), indicating that, in randomized trials, the personalized experimental arm had significantly more improvement in PFS. Personalized trials also showed a longer OS (median= 18.2 vs. 13.5 mos, P=0.035 in the multilinear analysis), even though crossover was allowed more frequently in personalized trials. Median treatment-related mortality did not differ (0.4%, personalized vs. 1.0%, non-personalized, P=0.22). **Conclusions:** Personalized trials were associated with more pronounced clinical benefit, expressed by significantly higher RR and longer PFS and OS, despite the latter being confounded by more frequent crossover.

**11048 General Poster Session (Board #330), Sat, 1:15 PM-5:00 PM**

**Targeted next-generation sequencing (NGS) of carcinoma of unknown primary site (CUP): Actionable genomic alterations (GA) and new routes to targeted therapies.** *Presenting Author: Jeffrey S. Ross, Albany Medical College, Albany, NY*

**Background:** CUP comprises 3% of adult malignancy in the US. Evaluation for a primary site is often unrevealing and may involve invasive studies. We performed NGS to identify potential therapeutic targets not currently tested for in routine care of CUP patients. **Methods:** Hybridization capture of 3,769 exons from 236 cancer-related genes and 47 introns of 19 genes commonly rearranged in cancer was applied to ≥ 50ng of DNA extracted from 200 CUP FFPE specimens and sequenced to high, uniform median coverage (756X) and assessed for all 4 classes of GAs. Elligible CUP were uniformly negative for site-specific IHC, FISH or mRNA biomarkers. Actionable alterations were defined as those for which cancer drugs on the market or in registered clinical trials could be identified. **Results:** 63% of CUP were adenocarcinomas (ACUP) and 37% were non-adenocarcinomas (non-ACUP). 54% were female and 46% male (median age 59). IHC workup was performed on 95% and mRNA profiling on 3%. 841 GA were identified in 121 genes for an average of 4.21 GA/CUP. 192/200 (96%) CUP had at least 1 GA. 169 (85%) CUP had at least 1 actionable GA (2.00 actionable GA/CUP). The most common actionable GA were *KRAS* (25% ACUP, 12% non-ACUP), *CDKN2A* (19% ACUP and non-ACUP), *MCL1* (10% ACUP, 8% non-ACUP), *PTEN* (8% in both ACUP and non-ACUP), *PIK3CA* (8% in ACUP and 9% in non-ACUP), *BRAF* (6% in ACUP and 2% in non-ACUP) and *NF1* (5% in ACUP and 3% in non-ACUP),. Mutations and amplifications of *ERBB2* (*10%), EGFR* (8%) and BRAF (6%) were common in ACUP but not present in non-ACUP. 5 (3%) CUP had rearrangements involving *ERBB3*, *FGFR1* and *FGFR2.* The greater frequency of actionable GA in the RTK/RAS signaling pathway observed in 90 (72%) ACUP cases compared to the 29 (39%) of non-ACUP cases was significant ($p<0.0001$). **Conclusions:** 85% CUP patients had at least one actionable GA with the potential to impact therapy selection with GA in the RTK/RAS/MAPK pathway more frequent in ACUP tumors. Given the poor prognosis of CUP, comprehensive genomic profiling may identify targeted therapeutic approaches to improve outcomes for this disease while potentially reducing the often costly and time consuming search for anatomic site of origin.

**11049 General Poster Session (Board #331), Sat, 1:15 PM-5:00 PM**

**Noninvasive monitoring of dynamics of acquired EGFR-T790M mutation and discovery of its heterogeneity in patients with advanced NSCLC treated with EGFR-TKI.** *Presenting Author: Di Zheng, Shanghai Pulmonary Hospital, Department of Medical Oncology, Tongji University School of Medicine, Shanghai, China*

**Background:** EGFR-T790M mutation, a valuable target for next generation of EGFR-TKI, accounts for about half of acquired resistance to current EGFR-TKI therapy in EGFR sensitive mutation positive NSCLC patients. Noninvasive detection of EGFR-T790M in plasma circulating free DNA (cfDNA) has been proved to be feasible as re-biopsy of tumor tissue was challenging. However, clinical application of T790M plasma testing remains to be explored, particularly the rate and timing of detection, the status of co-existence with a sensitive mutation, and its potential impact on chemotherapy following EGFR-TKI resistance. **Methods:** A highly sensitive digital PCR method for EGFR mutation testing in plasma was developed and its high sensitivity and specificity were validated in testing cfDNA from EGFR-TKI-naïve NSCLC patients. This method was applied to detect T790M in plasma cfDNA from 66 post disease progression (PD) NSCLC patients, who developed acquired resistance to EGFR-TKI. Plasma samples before PD were available for some patients. **Results:** Overall, EGFR-T790M was detected in 36 out of 66 post-PD patients (54.5%). Among 10 of the 36 post-PD T790M+ patients, 5 (50%) were detected T790M+ during 1.5-3.5 months before PD. While T790M co-exists with a sensitive mutation in 30 of the 36 T790M+ patients (83.3%), T790M presents alone in 6 of the 36 patients (16.7%). Furthermore, dynamic quantitative changes of sensitive mutations and T790M in a few patients who received chemotherapy plus TKI after PD showed preliminary insight that, even in double mutant cases, T790M and sensitive mutant DNA might not always come from the same tumor cell populations, and the T790M heterogeneity status could affect outcome of chemotherapy following EGFR-TKI resistance. **Conclusions:** Noninvasive monitoring of plasma cfDNA could detect T790M with a positive rate similar to that reported in tumor tissue in advanced NSCLC patients treated with EGFR-TKI. T790M could be detected in plasma up to 3.5 months before clinical PD. T790M may present with or without EGFR sensitive mutation in tumor cells, and its heterogeneity status could affect outcome of chemotherapy following EGFR-TKI resistance.

**11050 General Poster Session (Board #332), Sat, 1:15 PM-5:00 PM**

**Clinical utility of the 12-gene DCIS score assay: Impact on treatment (Tx) recommendations.** *Presenting Author: Michael Alvarado, Helen Diller Family Comprehensive Cancer Center Carol Franc Buck Breast Care Clinic, San Francisco, CA*

**Background**: About 20% of breast cancers (BC) are DCIS. Local recurrence (LR) rates with surgery alone are 15-60%; about 50% are invasive. Radiation (XRT) reduces LR by 50% but has not impacted survival. Clinicians and patients (pts) must decide between multiple options including breast conserving surgery, mastectomy, partial or whole breast XRT, and hormonal manipulation. Traditional clinicopathologic (CP) factors provide an average LR risk derived from population studies. The validated Onco*type* DX 12-gene assay for DCIS gives additional, independent, individual estimates of 10-year risk of any LR and invasive LR. We report the first study to assess the impact of the DCIS Score result on XRT recommendations for pts with DCIS. Baseline (BL) characteristics are described here; final results on change in Tx recommendations from pre- to post-assay will be presented at the meeting. **Methods**: 11 U.S. sites enrolled pts with DCIS from 9/2012-1/2014. Pts with LCIS but no DCIS, invasive BC, or planned mastectomy were excluded. Data were prospectively collected on CP factors, physician estimates of LR risk, DCIS score, and Tx recommendation before and after the assay result was known. The study received IRB approval. **Results**: 110 pts had a mean age of 60.1 yrs (SD: 9.9); 75.5% were postmenopausal. Mean DCIS size was 13.5mm (SD: 15.8); 20% had nuclear grade of 1, 46.4% grade 2, and 33.6% grade 3. Necrosis was noted in 63.6% (focal in 29.1%). Median distance from closest margin was 3mm. ER and PR IHC tests were positive in 85.5% and 78.2%. Mean physician-assessed 10-yr risk of LR was 20.8% (range 6-40%) for any LR and 10.9% (3-25%) for invasive LR. Anti-estrogen Tx was recommended in 72.7%, aromatase inhibitor in 20.9%, XRT in 72.7%, and additional surgery in 18.2%. **Conclusions**: The DCIS Score use may reduce both under- and overtreatment; establishing its impact on treatment decisions is critical to understanding the utility of this genomic assay in clinical practice.The BL characteristics of the cohort, the LR risk estimate and the pre-assay Tx recommendations are consistent with current practices, including 73% recommended XRT. The full analysis will assess the clinical utility of incorporating the DCIS Score result into clinical practice.

**11051 General Poster Session (Board #333), Sat, 1:15 PM-5:00 PM**

**Targeted deep sequencing from circulating plasma DNA as a multipurpose biomarker in pts (pts) referred for phase I trials.** *Presenting Author: Jean-Sebastien Frenel, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

**Background:** Plasma from pts with cancer contains cell free DNA (cfDNA) that can be interrogated by next generation sequencing (NGS). We assessed the use of plasma NGS as a multi-purpose biomarker in advanced cancer pts referred for Phase I trial participation. **Methods:** Between 12/2012 and 12/2013, the plasma of pts with known mutations in tumor biopsies completing at least 2 courses of investigational targeted drug therapy was collected monthly until disease progression. cfDNA was extracted and NGS performed on the PGM platform with the Ion AmpliSeq Cancer Hotspot Panel v2 starting from 10ng of DNA. This panel amplifies 207 amplicons covering 2,800 COSMIC mutations from 50 oncogenes and tumor suppressors. **Results:** The mean sequencing coverage across the experiments was 1,685x. Overall, 37 pts (colon (n=11), ovary (10), breast (7), bladder (2), kidney (2), glioblastoma (2), endometrium/melanoma/penile/lung (n=1) receiving inhibitors of the PI3K-AKT-mTOR pathway (n=23), MEK (n=7), PARP (n=3)) or others targets (n=4) were included. *TP53, KRAS* and *PIK3CA* were the most commonly mutated genes in tumor biopsies. At Phase I trial initiation (C1D1), 20 of 37 pts (54%) had at least one mutation identified in cfDNA. Pts with only nodal or peritoneal disease were less likely to have a mutation detected: 1/6 (17%) having a cfDNA mutation. Thirty-six different mutations were identified at C1D1 in 20 pts: *TP53* (n=15) with an allele frequency (AF) ranging from 2% to 57%; *KRAS* (n=6; AF 4-51%); *PIK3CA* (n=6; AF 5-58%); *APC* (n=4; AF=15-33%); *SMAD4, HRAS, FBXW7, CDKN2A, ATM* (n=1). Three mutations identified in cfDNA were not identified in tumor: *TP53* (Y220C; AF 4.5%), *ATM* (R337C; AF 18%), *TP53*(R342fs*2; AF 23%). In 15 pts, subsequent AF mutation monitoring showed that 75% (3/4) of pts with a >30% decrease in AF at C2D1 compared to baseline had stable disease or a partial response by RECIST after 2 cycles. Conversely 87.5% (7/8) of pts with an increasing AF >20% at C2D1 had progressive disease by RECIST after 2 cycles, while a stable AF at C2D1 ($-20\% < \Delta AF < +30\%$) was associated with SD in 2/3 pts. **Conclusions:** NGS of plasma is feasible even with low DNA input and may be of utility as a predictive and response biomarker.

**11052 General Poster Session (Board #334), Sat, 1:15 PM-5:00 PM**

**Prediction of recurrence with the Onco*type* DX recurrence score in node-positive, HR-positive, breast cancer patients treated with adjuvant chemotherapy: Results from PACS01 trial.** *Presenting Author: Frederique Madeleine Penault-Llorca, Centre Jean Perrin, Clermont-Ferrand, France*

**Background:** The Recurrence Score (RS) predicts outcome in node- and node+, ER+ pts treated with endocrine therapy and predicts chemotherapy benefit. We studied the prognostic impact of RS in node+, HR+ pts treated with adjuvant chemotherapy plus endocrine therapy in PACS01 **Methods:** PACS01 compared FECX6 with FECX3+ docetaxel X3(FEC-D) in 1999 pts. After a protocol amendment, HR-positive pts received 5 yrs of tam after chemo. The current study includes 530 pts from the PACS01 parent trial who were central IHC HR+ with sufficient tissue for Onco*type*DX. The primary objective was to estimate the association between RS and distant recurrence free interval (DRFI). Secondary endpoints included disease free survival (DFS) and overall survival (OS). Median follow-up time was 7.7 yrs **Results:** Of the 530 pts, 209 (39.4%) had low RS; 159 (30.0%) intermediate RS; and 162 (30.6%) high RS. 74.2% were treated with tam. In the primary analysis, RS was a significant predictor of DRFI (HR= 4.1 for a 50 point difference, $P<0.001$), DFS (HR=3.3, $P<0.001$) and OS (HR=5.0, $P<0.001$). In multivariate analyses, RS provided independent prognostic information beyond clinicopathologic factors including treatment, age, tumor size & grade, number of + nodes, surgery type and Ki-67 status ($P<0.001$). RS was a significant predictor of DRFI, DFS, and OS in both treatment arms ($P<0.001$). There was no statistically significant interaction between RS and treatment arm in predicting distant recurrence ($P=0.79$). **Conclusions:** The 21-gene RS maintains significant prognostic impact in HR+, node+ pts who have received FEC or FEC-D adjuvant chemotherapy. These findings emphasize the need to target pts with high residual risk for recurrence with additional therapies to overcome unfavorable biology, potential endocrine and/or chemotherapy resistance.

**Kaplan-Meier estimates of 5-yr DRFI, DFS, and OS.**

| End point (95%CI) | RS low n=209 | RS intermediate n=159 | RS high n=162 | Log-rank p-value |
|---|---|---|---|---|
| **DRFI %** | 93.7 (89.4-96.3) | 87.3 (81.0-91.6) | 69.3 (61.5-75.8) | p<0.001 |
| **DFS %** | 90.8 (86.0-94.1) | 84.9 (78.3-89.6) | 64.6 (56.7-71.4) | p<0.001 |
| **OS %** | 99.0 (96.2-99.8) | 95.6 (90.9-97.9) | 85.6 (79.1-90.2) | p<0.001 |

**11053 General Poster Session (Board #335), Sat, 1:15 PM-5:00 PM**

**Molecular abnormalities of 17 types of gastrointestinal cancer in an international cohort of 11,324 patients.** *Presenting Author: Gargi Dan Basu, Caris Life Sciences, Phoenix, AZ*

**Background:** Gastrointestinal cancers (GICs) are classified based on both organ and tissue of origin, but might be better classified based on their molecular profile. We performed a multiplatform biomarker analysis of the main 17 types of GICs to identify molecular abnormalities and their associations. **Methods:** We analyzed 11,324 cases of GIC (96% from USA) using gene sequencing (up to 44 different genes, Sanger, NGS), protein expression by immunohistochemistry (up to 28 gene products) and gene amplification by CISH or FISH (up to 8 genes). Further, we performed heat map analysis of the 70 molecular anomalies in 17 GIC sites. **Results:** Steroid receptor (ER, PR) expression was distinctively high in neuroendocrine cancers (CA) (10-40%) while AR expression was elevated in hepatocellular carcinoma (HCC) (20%). HER2 overexpression and amplification was distinctively elevated in gastric, GEJ, esophageal and gall bladder CA (up to 20%). Overexpression of TOP2a was noted in most of the GICs, reflecting their highly proliferative and aggressive nature. Overexpression of cMET (up to 82%) and EGFR amplification (up to 32%) was noted in a majority of GICs suggesting benefit from cMET and EGFR targeted therapies. HCC had a high frequency of CTNNB1 (19%, 11/58) and low frequency of ABL1 mutation (3%, 2/59). Distribution of APC mutations in GIC ranged from 10-73%. PIK3CA mutation and PTEN loss were frequent events (up to 15% and 89% respectively) in a majority of GIC, suggesting potential benefit of targeting the PI3K pathway. Based on the RAS/RAF and PI3K/PTEN/Akt/mTOR pathway alterations, colon and rectal CA share similar molecular signatures but gall bladder and biliary tract CA, as well as colon and appendix CA, are molecularly distinct. Small bowel and duodenal CA exhibited different molecular signatures based on APC, ATM, SMAD4 and p53 mutations. **Conclusions:** Molecular profiling of GICs might allow us to reconsider clinical trial design and disease management based on individual cancer molecular abnormalities. Protein expression and copy number alterations should be considered together with mutational analysis to refine cancer treatment in GI tract malignancies.

**11054 General Poster Session (Board #336), Sat, 1:15 PM-5:00 PM**

**Quantification of T790M mutation in *EGFR*-mutant lung adenocarcinoma with nanofluidic digital PCR arrays.** *Presenting Author: Kazutoshi Isobe, Department of Respiratory Medicine, Toho University Omori Medical Center, Tokyo, Japan*

**Background:** Patients with EGFR-mutant lung adenocarcinoma develop acquired resistance to EGFR-TKI (TKI) in 10-16 months. About 50% of patients with acquired resistance to TKI have T790M mutation (T790M). However, repeat biopsy to monitor mutation status is not practical. Digital PCR arrays limiting dilution of DNA and can detect single molecules, thus enabling extremely sensitive detection and quantification. We evaluated the usefulness of nanofluidic digital PCR arrays in EGFR-mutant lung adenocarcinoma. **Methods:** We enrolled 12 patients with primary lung adenocarcinoma and *EGFR* mutation (exon 19 deletion in 8; L858R in 4) at the pretreatment primary site who acquired resistance to gefitinib. Patients were divided into 2 groups according to T790M status after TKI resistance, as confirmed by rebiopsy. Nanofluidic digital PCR arrays (BioMark HD System, Fluidigm Japan K.K. Tokyo, Japan) were used to quantify T790M in genomic DNA from the pretreatment primary site and serum cell-free DNA (cfDNA) after TKI resistance. Numbers of mutant molecules were estimated by the number of positive chambers in the digital PCR chip and were corrected using the Poisson equation. We assessed the ratio of the number of positive T790M molecules to the number of positive exon 2 molecules. **Results:** The digital PCR array detected and quantified T790M (0.00-1.21%) in samples from the pretreatment primary site and serum cfDNA after TKI resistance. On digital PCR, the rebiopsy-positive T790M group (n=4) had a significantly higher quantified T790M at the pretreatment primary site than did the T790M-negative group (n=8) ($0.59\pm0.58\%$ vs $0.07\pm0.09\%$, $p < 0.001$). However, the results of analysis of serum cfDNA after TKI resistance did not significantly differ ($0.09\pm0.14\%$ vs $0.05\pm0.15\%$, respectively, $p = 0.41$). T790M at the pretreatment primary site as quantified by digital PCR significantly positively correlated with progression-free survival (PFS) after gefitinib therapy ($r = 0.71$, $p < 0.001$). **Conclusions:** Use of digital PCR to quantify T790M at the primary site of EGFR-mutant lung adenocarcinoma was useful for predicting T790M positivity in rebiopsies after TKI resistance and PFS after gefitinib therapy.

**11055 General Poster Session (Board #337), Sat, 1:15 PM-5:00 PM**

**Prognostic potential of *MDM2* 309T>G polymorphism in stage I lung adenocarcinoma.** *Presenting Author: Kimihiro Shimizu, Division of Thoracic and Visceral Organ Surgery, Gunma University Graduate School of Medicine, Maebashi, Japan*

**Background:** The MDM2 protein plays an important role in regulating cell proliferation and apoptosis by ubiquitination and proteosome-mediated degradation of p53. *c.309 (rs2279744)* polymorphism (*T>G*) in the *MDM2* intronic promoter has been reported as a susceptibility and/or prognostic factor in various cancers. The purpose of this study was to investigate the risk factors for worse survival in patients with pathological (p-) stage I lung adenocarcinoma. **Methods:** We retrospectively reviewed 179 stage I lung adenocarcinoma patients. Clinicopathological and genetic characteristics including *MDM2 SNP309, p53 codon72,* as well as *EGFR, KRAS,* and *p53* mutation were analyzed. Associations between these factors and survival outcome were analyzed by cox proportional hazards models. We further evaluated the associations of prognostic effects of *SNP309* and smoking status or gene mutation status by stratified analyses. **Results:** A significant association was found between pleural invasion or lymphatic invasion and *SNP309 TT* genotype (TT vs. TG+GG, p= .027, p= .008, respectively; $\chi 2$ test) Overall-survival (OS) of patients with *MDM2 TT* genotype was significantly shorter than that with *TG* genotype and *GG* genotype (p= .048 and p= .009, respectively by log-rank test). A multivariate analysis of OS showed that *MDM2* genotype (TT; Hazard Ratio [HR] =3.7, 95% confidential interval [CI] 1.5 to 9.2, p= .005) was an independently significant prognostic factor. Subgroup analysis also showed that *TT* genotype was especially associated with worse OS among smoker group (HR=6.75, 95%CI 1.90 to 24.0, p= .005), *EGFR* wild-type group (HR=3.75, 95%CI 1.22 to 11.6, p= .022), *p53* wild-type group (HR=7.00, 95%CI 2.30 to 21.3, p= .001), and *p53 codon72 RR+RP* group (HR=5.44, 95%CI 1.91 to 15.5, p= .002). **Conclusions:** Our findings suggest that *MDM2 TT* genotype is associated with worse OS among p-stage I lung adenocarcinoma patients, particularly in the smoker group, *EGFR* wild-type group, *p53* wild-type group, and *p53 codon72 RR+RP* group.

**11056 General Poster Session (Board #338), Sat, 1:15 PM-5:00 PM**

**Association of KRAS mutations in cell-free circulating tumor DNA with occurrence of resistance to TKIs in NSCLC.** *Presenting Author: Marzia Del Re, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

**Background:** EGFR activating mutations predict sensitivity to tyrosine kinase inhibitors (TKIs) in NSCLC. Although initial responses are commonly observed, patients inevitably progress as a consequence of acquired resistance. Secondary mutations in the EGFR domains (Gainor JF, Shaw AT. J Clin Oncol 2013;31:3987) or in cross-talking pathways (i.e., KRAS, Martin P, et al. J Thorac Oncol 2013;8:530) have been detected in biopsies of resistant cancers. However, the location of the tumor and the risk of complications are serious limitations to re-biopsies in NSCLC. Alternatively, detection of somatic mutations in circulating cell-free DNA (ccfDNA) in plasma could be instrumental to a better understanding of the dynamics of the genetic shift of tumors under stress conditions caused by drug treatments. **Methods:** Twenty-eight NSCLC patients displayed an activating EGFR mutation or ALK translocation in the primary tumor and received a TKI against EGFR (gefitinib or erlotinib, n= 25) or ALK (crizotinib, n= 3). Blood (5 ml) was collected after tumor progression and DNA was extracted from plasma using QIAamp circulating nucleic acid kit and tested for EGFR and KRAS mutations using Rotor-Gene Q PCR (Qiagen, Valencia, CA) or digital droplet PCR (Bio-Rad, Hercules, CA). **Results:** EGFR mutations of the primary tumor were confirmed in ccfDNA of 35.7% patients after progression under TKIs (L858R 7.1%, exon 19 insertions/deletions 28.6%). The EGFR T790M mutation was in 10.7% of patients' ccfDNA. Interestingly, 10 (35.7%) patients displayed a codon 12 KRAS mutation in ccfDNA, including all patients with ALK+ tumors, after TKI treatment. The KRAS mutations were not detectable in their primary tumor using conventional diagnostic approaches. Pre-treatment plasma samples were available in only two patients and KRAS mutations were not detected. **Conclusions:** The observation of KRAS mutations in plasma of patients with tumors carrying EGFR mutations or ALK rearrangements after TKI treatment suggests an important role of this oncogene in acquired resistance.

**11057 General Poster Session (Board #339), Sat, 1:15 PM-5:00 PM**

**Genomic characterization of metastatic cisplatin-resistant samples from urothelial cancer patients.** *Presenting Author: Yohann Loriot, Department of Cancer Medicine, INSERM U981, Gustave Roussy, Cancer Campus, Grand Paris, Villejuif, France*

**Background:** Although several studies have reported genomic characterisation of primary urothelial carcinoma (UC), little is known about the genomic alterations of the metastatic cisplatin-resistant tissues. We sought to define the prevalence and co-occurrence of actionable genomic alterations in patients with metastatic cisplatin-resistant lethal UC. **Methods:** Patients with metastatic UC, who progressed after at least one line of standard therapy, were enrolled in a prospective molecular screening trial (MOSCATO 01) at Gustave Roussy. CT-Scan or ultrasound-guided biopsies were performed in metastases to carry out a comprehensive molecular characterization. DNA was extracted from fresh tumor samples and analyzed by comparative genomic hybridization (CGH) (≥ 30% tumor cells required) and by Next Generation Sequencing (NGS) for up to 74 target genes (≥ 10% tumor cells required). Whole-exome sequencing (WES) was performed retrospectively in selected cases. **Results:** From December 2011 to December 2013, 30 heavily pretreated patients with metastatic UC were included in the MOSCATO 01 trial. Median age was 61 (37-73); All patients had been treated with platin-based chemotherapy with a median number of lines of 2.5 (1-5). Out of them, a tumor biopsy could be performed in 26 patients (87%). CGH and targeted exome sequencing profiles were assessed in 19 (73%) and 23 (88%) of them, respectively. A total of 19 patients (73% of biopsied patients) were profiled for both sequencing and CGH. WES was performed in 16 (62%) pairs of metastatic tissue and normal DNA (Integragen Inc, Hiseq platform). Our analyses identified potential therapeutic targets in 61 % of the tumours, including 31% with targets in the PI3K/AKT/mTOR pathway, 31% with targets in the FGF/FGFR pathway and 15% with targets in the RTK/MAPK pathway (including ERBB2). Others frequent aberrations were found in the chromatin regulatory genes (MLL gene family) and cell-cycle regulatory genes (E2F3, CDKN2A/B genes). **Conclusions:** Lethal platin-resistant UC exhibit high-level of genomic heterogeneity. The majority of these tumors harbour actionable genomic alterations that can be targeted with selective agents currently in clinical development or registered.

**11058 General Poster Session (Board #340), Sat, 1:15 PM-5:00 PM**

**Aromatase inhibitors in elderly patients with advanced breast cancer: An exploratory pharmacogenetic study.** *Presenting Author: Enrica Rumiato, Immunology and Molecular Oncology Unit, Istituto Oncologico Veneto IOV - IRCCS, Padova, Italy*

**Background**: Aromatase inhibitors (AIs) are the first choice for older patients (pts) with estrogen-receptor (ER) positive advanced breast cancer (BC). Yet, response is variable and difficult to predict. Some pts exhibit very good long-lasting response whereas others rapidly progress even after initial response. Factors such as tumor subtype (i.e., luminal A vs B) or BMI have been reported to correlate with response but so far no predictive marker is available. The aim of this study was to identify gene variants associated with AIs response in elderly pts with advanced BC. **Methods**: Genomic DNA from peripheral blood of 55 pts with locally advanced or metastatic breast cancer was analyzed with DMET Plus GeneChip array (Affymetrix, Santa Clara, CA), appropriateness of data was evaluated with DMET Console and statistically relevant variants were assessed with DMET-Analyzer. Median age was 79 years (IQR, 73-86), all patients had ER-positive HER-2 negative BC. Clinico-pathologic factors were evaluated for their impact on response. Bivariate analysis was used with the non-parametric tests Chi-square and Fisher's exact. **Results**: Pts had locally advanced (30 pts) and metastatic (25 pts) BC. All pts had ER positivity ≥70%, 31 pts had Ki67 <20%, 13 pts had grade 3 tumors. Median BMI was 26, median 17-ß-estradiol level was 80 pmol/L. Overall, 23 pts had complete or very good partial response, 28 pts partial response <50% or disease stabilization, 4 pts progressive disease as best response at 6 months. No significant correlation was observed between any of the baseline variables (tumor subtypes, BMI, Ki67, estradiol level) and response. None of the 11 aromatase gene (*CYP19A1*) polymorphisms present in the DMET array achieved the statistical significance. However, when considering only pts with locally advanced BC, the *ABCG1* rs3788007 and *UGT2A1*rs4148304 were associated with objective response. The association of these variants with response was confirmed when the analysis was extended to metastatic pts. **Conclusions**: This exploratory study indicates DMET array as a valid approach to discover new predictive gene variants in AIs-treated elderly pts with advanced BC. Our data need to be validated in a larger cohort.

**11059 General Poster Session (Board #341), Sat, 1:15 PM-5:00 PM**

**The FGFR landscape in cancer: An analysis of 4,869 cases.** *Presenting Author: Teresa L Helsten, University of California, San Diego, La Jolla, CA*

**Background**: Fibroblast growth factor receptors (FGFRs) are highly conserved tyrosine kinase receptors involved in development and carcinogenesis. Humans have 4 FGFRs. Germline FGFR mutations cause craniosynostosis and dwarfism. **Methods**: DNA extracted from 4869 formalin-fixed, paraffin embedded cancers was assayed by next generation sequencing (CLIA) (mostly FoundationOne, Cambridge, MA). Data were curated and interpreted by N-of-One (Lexington, MA). Histology was defined by ordering physicians. Our objective is to characterize the nature/frequencies of FGFR aberrancies in these cancers. **Results**: 356 aberrations were identified in 345 cases (7%; some harbored > 1 FGFR aberration). Aberrations in FGFR1 were most common (N = 170), with FGFR3 (N = 93), FGFR2 (N = 70), and FGFR4 (N = 23) less common. The most common abnormalities were amplifications in FGFR1 (N = 152), FGFR2 (N = 35), and FGFR3 (N = 24). The Table shows cancers with ≥ 75 cases. In urothelial tumors, 12% of aberrations were somatic mutations in FGFR3 (the same as those in dwarfism). In lung squamous cell carcinomas, FGFR1 was amplified in 9% and 3% harbored somatic FGFR3 mutations associated with dwarfism; in lung adenocarcinomas, only 4% were FGFR abnormal. **Conclusions**: Gene amplifications and activating missense mutations are frequent in cancer, suggesting that they may be actionable targets for the FGFR-targeting drugs already available.

| | | Frequency of aberrations (% of cases) | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| **Cancer** | **N** | **All** | **FGFR1** | **FGFR2** | **FGFR3** | **FGFR4** | **Amplification** | **Mutation** | **Rearrangement** |

**11060 General Poster Session (Board #342), Sat, 1:15 PM-5:00 PM**

**Evaluation of PI3K-pathway–activation status in matched primary (P) and metastatic (M) ER+/HER2- breast cancer (BC) lesions according to PIK3CA-mutation status.** *Presenting Author: Debora Fumagalli, Jules Bordet Institute, Breast Cancer Translational Research Laboratory, Brussels, Belgium*

**Background:** Despite the high frequency of PIK3CA mutations (mut) in BC, their role in tumor progression is uncertain. We have previously shown that PIK3CA mut status was highly concordant between Ps and matched Ms in ER+/HER2- BCs (89%). We sought to evaluate the levels of PI3K pathway activation concordance in Ps and matched Ms. **Methods:** For a series of 119 P ER+/HER2- BCs and 31 matched Ms with known PIK3CA mut status, the expression of 400 genes was obtained with the Nanostring technology. The expression of a PI3K pathway activation gene signature (PIK3CA-GS by Loi S PNAS 2010) and of single genes (ESR1 and AURKA) was derived. For 97 of the Ps and 27 of the Ms, the copy number data of 40 genes was obtained with an EvaGreen qPCR assay. **Results:** 43% of all samples had a PIK3CA mut. The PIK3CA-GS was able to predict moderately samples' mut status (AUC 0.641, p 0.004). When considering only the Ps, 65% (36/55) of PIK3CA mut and 42% (27/64) of wild type (WT) samples had an expression of PIK3CA-GS higher than the median value, indicating PI3K activation status. The proportion of CCND1 amplified cases was moderately higher in WT compared to mut samples (p 0.06) while the proportion of FGFR1 (p 0.001) and ZNF703 ($p<0.001$) amplified cases was higher in GS low compared to GS high samples. When considering the 31 pairs, we observed a moderate correlation between PIK3CA-GS values in Ps and matched Ms (Spearman rho=0.50, $p<0.01$). In each pair, the expression level of the GS could change substantially: in 6 (19%) cases it went up, in 6 (19%) it went down and in 19 (61%) it remained the same. Compared to matched Ps, Ms looked biologically more aggressive with significantly higher levels of proliferation as measure by AURKA (p 0.04) and lower levels of ESR1 (p 0.01) despite maintaining an ER+ status at IHC. **Conclusions:** Despite the high concordance of PIK3CA genotype between Ps and matched Ms, activation of downstream signaling seems to vary. This suggests that, beside genotyping, additional investigations should be performed in each lesion to assess the level of pathway activation. Evaluation of downstream effectors using phosphorylated antibodies at IHC is ongoing (pAKT, pMTOR, pERK1/2, pS6).

**11061 General Poster Session (Board #343), Sat, 1:15 PM-5:00 PM**

**Prognostic and predictive role of circulating angiopoietin-2 in multiple solid tumors: An analysis of approximately 500 patients treated with lenvatinib across tumor types.** *Presenting Author: Ignace Vergote, Department of Oncology,University Hospitals Leuven and Katholieke Universiteit Leuven, Leuven, Belgium*

**Background:** Lenvatinib is an oral tyrosine kinase inhibitor targeting VEGFR1-3, FGFR1-4, RET, KIT, and PDGFR$\alpha$. Two phase 3 trials in differentiated thyroid cancer [DTC] and hepatocellular cancer [HCC] are ongoing. Baseline levels (BL) of circulating cytokines and angiogenic factors (CAFs) were evaluated across multiple phase 2 trials in 6 different types of solid tumors. **Methods:** BL serum or plasma samples from a total of approximately 500 patients were analyzed for about 50 CAFs using ELISA and multiplex assay platforms* in 5 phase 2 trials of lenvatinib for thyroid cancer (DTC and medullary thyroid cancer [MTC]), HCC, glioblastoma, endometrial cancer (EC), and melanoma (with or without BRAF V600E). Correlation with clinical outcomes (objective response rate [ORR], overall survival [OS]) was performed using Wilcoxon signed-rank test and univariate Cox proportional hazard model, respectively, whereas correlation with tumor size prior to lenvatinib treatment was performed using the Spearman's rank correlation test. **Results:** Among 50 CAFs, BL angiopoietin-2 (Ang-2) correlated with tumor size (p) in DTC (0.004), MTC (0.004), EC ($<0.001$), melanoma [WT ($<0.001$), MU ($<0.001$)] and HCC (0.046) among multiple phase 2 trials. BL Ang-2 levels showed consistent correlation with clinical outcomes per tumor types across trials and with OS (p/hazard ratio per standard deviation) in DTC (0.001/3.2), MTC ($<0.001$/3.2), EC ($<0.001$/1.8), and melanoma [WT (0.001/1.5), MU ($<0.001$/2.0)]. Correlation with ORR was observed only for a minor subset of analyzed CAFs; only BL Ang-2 levels correlated with ORR in $>1$ tumor type, specifically in DTC (0.034*), MTC (0.025) and EC (0.001). In EC, almost 50% of BL CAFs showed a significant correlation with tumor size, potentially suggestive of an EC-specific tumor micro-environment and the contribution of Ang-2 to tumor angiogenesis in EC. **Conclusions:** BL Ang-2 levels correlated with tumor size and OS across majority of solid tumors in multiple lenvatinib phase 2 trials. Only BL Ang-2 levels also correlated with ORR in a subset of tumors including EC. Clinical trial information: NCT00784303,NCT01111461,NCT01136967,NCT00946153, NCT01433991,.

**11062 General Poster Session (Board #344), Sat, 1:15 PM-5:00 PM**

**Prognostic ability of CD44 expression in ER-positive breast cancer.** *Presenting Author: Yesim Gokmen-Polar, Indiana University School of Medicine, Indianapolis, IN*

**Background:** CD44, a cell surface receptor, is implicated in both progression and suppression of metastatic cascade. CD44 has gained attention as a breast cancer stem cell marker and is considered a therapeutic target. However, loss of CD44 expression is also associated with high-grade tumors and metastasis. Earlier studies have been small, therefore, we analyzed the value of CD44 expression in larger gene expression datasets to clarify its prognostic and predictive ability in breast cancer. **Methods:** CD44 expression levels were analyzed based on ER-status, molecular subtypes and other clinico-pathological parameters using 11 publicly available Affymetrix datasets. Association of outcome was investigated for each patient cohort with distant metastasis free-survival (DMFS) as endpoint and 10 year censoring in the following subgroups: 1) all 1,881 tumors, 2) ER positive tumors (n=1,225), 3) ER-negative tumors (n=395), 4) systemically untreated patients (n=927), and 5) patients treated with tamoxifen alone (n=326). **Results:** Lower expression of CD44 was associated with ER positivity (P=0.01), and higher histological grade (grade 3)($P\leq0.00001$). Expression was highest in luminal A tumors with progressive decrease in basal, luminal B and HER2 subtypes respectively. In multivariate analysis, high CD44 expression correlated with higher DMFS in ERpos tumors [(P=0.004; HR= 0.7 (95%CI 0.55-0.9)], ERposLNneg tumors [(P=0.002; HR= 0.64 (95%CI 0.48-0.85)], grade 2 tumors [(P=0.02; HR=0.51 (95% CI 0.29-0.91)] and TAM treated tumors [(P=0.002; HR 0.1 (95% CI 0.03-034)], whereas low CD44 expression was associated with lower DMFS in TAM treated tumors [(P=0.02); HR= 2.21 (95% 1.12-4.38)]. Of all tumors, CD44 was most prognostic in ERpos and ERposLNneg groups ($P\leq0.001$) followed by HU_Luminal B and PAM50_HER2 enriched groups (P=0.02). Of eight gene modules analyzed, CD44 expression was negatively correlated with checkpoint genes, M-phase and immune response, while positively correlated with basal phenotype. **Conclusions:** The analysis provides relevance of the prognostic and predictive utility of CD44 in ER+LN- breast cancer. This also suggests the importance of patient stratification in the management of these patients and therapeutic strategies.

**11063 General Poster Session (Board #345), Sat, 1:15 PM-5:00 PM**

**INDUCT: A risk score to predict relapse in estrogen-receptor–positive breast cancer.** *Presenting Author: Steven Buechler, University of Notre Dame, South Bend, IN*

**Background:** Early stage ER+ breast cancer may be treated with hormone therapy and/or chemotherapy. Currently available prognostic tools (e.g. Oncotype DX, Mammaprint and ProSigna) assess the risk of recurrence and the benefit of hormone and chemotherapy. However, these tests do not outperform traditional parameters such as tumor size, grade and patient age. New assays are needed to improve the prediction of relapse in ER+ patients. **Methods:** A continuous risk score (INDUCT score) predictive for relapse was developed using integrative analysis of publicly available microarray datasets and FFPE- based qRT-PCR assay. The INDUCT score was validated in (1) Affymetrix datasets consisting of 5 independent patient cohorts and 2) in a cohort of METABRIC dataset. The INDUCT score was further compared to traditional clinico-pathological parameters as well as to current prognostic assays such as Oncotype DX, Mammaprint and Prosigna. **Results:** The continuous INDUCT score (0-100) was developed to predict relapse in patients with ER+, lymph-node negative (LN-) breast cancer. A low INDUCT score ($<42$) based the expression of five genes (*ESPL1*, *MKI67*, *SPAG5*, *PLK1* and *PGR*) identified a good prognosis group (8 year relapse-free survival probabilities $\geq 0.93$) of 68% patients in both Affymetrix and METABRIC datasets. Importantly, the high expression of more than two genes was needed to achieve a score greater than 42, suggesting that the combinatorial effect of these genes is required to promote metastasis. The INDUCT score is significant in both LN negative [$P=1.7\times10^{-4}$; HR=3.4 (95%CI 1.7-6.9)] and positive [$P=2.8\times10^{-5}$ ; HR=2.5 (95%CI 1.6-4.0)] patients and in the presence [$P=1.9\times10^{-5}$ ; HR=2.7 (95%CI 1.8-4.1)] or absence [$P=5.6\times10^{-4}$; HR=4.0 (95%CI 1.8-9.3)] of tamoxifen therapy INDUCT is not improved by the addition of clinico-pathological parameters in LN- breast cancer and exhibits superior prognostic and predictive ability than Oncotype DX, Mammaprint and ProSigna assays. **Conclusions:** The five-gene INDUCT score demonstrates superiority to the traditional parameters as well as current prognostic assays in predicting the likelihood of relapse. This may further improve personalized management for patients with ER+ breast cancer.

**11064 General Poster Session (Board #346), Sat, 1:15 PM-5:00 PM**

**Classifying endometrioid endometrial cancer by long noncoding RNA profiling: Indication of prognosis and therapy selection.** *Presenting Author: Yunyun Jiang, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The Cancer Genome Atlas (TCGA) has recently reported an integrative analysis of endometrioid endometrial carcinoma (EEC) . However, the landscape of long non-coding RNAs (lncRNA) and its role in defining tumor subtypes with clinical relevance have not been addressed. **Methods:** Using TCGA molecular RNAseq profiles related to 304 primary endometrioid endometrial tumors (serous and mixed tumors were excluded), we performed genomic analysis of GENCODE lncRNAs. Furthermore, we established lncRNA expression-based subtypes with distinct signatures, and described global correlations of lncRNA expression-based subtypes with genomic aberrations and clinico-pathological tumor features. **Results:** Using stringent criteria, we identified 1,931 lncRNAs and predicted those that are potential drivers through integrative analysis. Unsupervised clustering of lncRNA expression revealed three robust subtypes, one of which displayed a worse overall survival as compared to the other two (Cluster C3, p=0.029). Pathological grade 3 tumors were enriched in this cluster (p<0.0001) in which microsatellite-unstable (MSI) and POLE ultramutated/hypermutated subgroups were also enriched (p<0.0001). In Cluster C3, integrative analysis with copy-number alteration and mutation revealed significant enrichment of KRAS mutation and STK11 loss, recently shown to dictate response to metformin. The coupled overexpression of lncRNA HOTAIR with EZH2 and exclusive enrichment of the EED polycomb gene targets in the same cluster indicate the association between the polycomb repressive complex 2 (PRC2) and aggressive disease, suggesting application of histone deacetylase inhibitor related therapies. Conversely, we found significant enrichment of CTNNB1 mutations in Cluster C2, suggesting WNT pathway related therapeutic methods. **Conclusions:** Our results revealed the application of systematic characterization of a large cohort of clinically annotated EEC with a poor prognosis cohort clearly identified. The application of lncRNA profiling can potentially be utilized as a tool for clinical outcome prediction and targeted therapy selection.

**11065 General Poster Session (Board #347), Sat, 1:15 PM-5:00 PM**

**Prediction of late relapse in patients with estrogen-receptor–positive breast cancer.** *Presenting Author: Steven Buechler, University of Notre Dame, South Bend, IN*

**Background:** Proliferation plays an important role in the prediction of early relapse of ER+ breast cancer. This constitutes the basis of almost all of the currently available prognostic tools including gene expression based signatures (e.g. Onco*type*DX, Mammaprint, and ProSigna). However, these tools are poor predictors of late relapses (greater than 8 years from initial diagnosis) and there is a dire need for a classifier that can accurately identify patients who remain at high risk of long-term relapse in spite of standard therapy. A better understanding of the mechanisms leading to late relapse could lead to improved strategies for management of these patients. **Methods:** Gene expression of 1,518 primary tumors from the METABRIC dataset, which contains long-term follow up for breast cancer specific survival (BCSS), was divided into training and validation sets balanced for late relapse cases. An innovative multistate gene methodology was used to identify predictors of late relapse in the training set and confirmed in validation set. **Results:** Analysis of the training set (n=382; 48 late relapse cases) identified 20 genes that were most predictive of late relapse. Late Relapse Score (LateR) was developed using these genes to optimally separate patients into low and high risk groups (P=0.002). In the validation set (n= 367; 47 late relapse cases), the LateR risk stratification (61% low risk) predicted late relapse (low LateR 0.87 (95%CI 0.80-0.95); high LateR 0.70 (95%CI 0.60-0.81); p=0.03). Furthermore, the combination of INDUCT score and LateR lead to more accurate prediction (p=0.002). In the LateR high risk group, pro-inflammatory cytokines are significantly up-regulated and genes involved in immune response are significantly down-regulated. **Conclusions:** Immune system plays a major role in the development of late relapse. LateR accurately predicts the likelihood of late relapse for patients with ER+ breast cancer. Together with the INDUCT test for early relapse, LateR provides a valuable tool for assessing the likelihood of relapse and might help the patient and their physicians make appropriate long-term treatment decisions.

**11066 General Poster Session (Board #348), Sat, 1:15 PM-5:00 PM**

**A 5-gene signature based on TLR4 signaling as predictive of risk of distant relapse in breast cancer treated with taxane-anthracycline neoadjuvant chemotherapy.** *Presenting Author: Joseph A. Pinto, División de Investigación, Oncosalud - Auna, Lima, Peru*

**Background:** TLR4 is typically activated by gram (-) bacterial lipopolysaccharide; however, recent reports describe that paclitaxel could trigger the TLR4 signaling pathway leading to chemotherapy resistance. Our purpose was to evaluate influence of genes involved in TLR4 signaling in the distant-recurrence free survival (DRFS) in breast cancer patients treated with neoadjuvant taxane- anthracycline chemotherapy. **Methods:** We retrieved normalized gene expression data from a public database (GSE25066) with 508 samples of breast cancer patients profiled with the U133A microarray and treated with neoadjuvant Taxane-Anthracycline chemotherapy. Division of discovery and validation sets was according to Hatzis et al (2011). Housekeeper-normalized transcript counts were log2 transformed and data were row z -score standardized. The intensity of each gene expression was transformed to an ordinal coding level according to the ranking of the gene expression level in each gene and was coded as 1, 2, 3,or 4, respectively. The gene expression was ranked ≤ 25th, > 25th and ≤ 50th, > 50th and ≤ 75th, or > 75th percentile for each gene expressions. **Results:** The signature was developed on the training set and a multivariate stepwise Cox analysis selected 5 genes independently associated with DRFS: IRAK1 (HR=1.32, p=0.025), IRF3 (HR=0.66, p=0.001), NFKB1 (HR=0.58, p<0.001), NEMO (HR=1.50, p=0.002), TRIM5 (HR=1.40, p=0.007). These 5 genes were combined into a linear score weighted according to the coefficients of the Cox model, (Risk Score= 0.279 IRAK1 - 0.421 IRF3 - 0.548 NFKB1 + 0.404 NEMO + 0.336 TRIM5). The linear score was highly associated with DFS (HR=2.8, 95%CI=1.7-4.7, p<0.001). Patients were classified as having a high-risk gene signature or a low-risk gene signature, with the 50th percentile (median=0.0082) of the risk score as the threshold value. The score resulted highly associated with DRFS also in the validation set (p=0.001) Five-gene signature was an independent prognostic factor for DFRS in the validation group. **Conclusions:** The 5-gene signature based in TLR4 signaling has a good discriminating ability.

**11067 General Poster Session (Board #349), Sat, 1:15 PM-5:00 PM**

**Genomic profiling of breast cancer in African American women.** *Presenting Author: Raquel Nunes, Washington Cancer Institute, MedStar Washington Hospital Center, Washington, DC*

**Background:** Molecular profiling of breast cancer (BC) identifies intrinsic subtypes with distinct gene expression and clinical characteristics. In the US, BC is less frequent in African-American females (AAF); however mortality is higher, particularly among younger women. **Methods:** Gene expression in tumors from AAF presenting with early stage or locally advanced BC was evaluated using the Symphony platform on fresh and paraffin-embedded tissue (Agendia inc), a microarray-based method which classifies tumors according to prognosis (MammaPrint, MP), molecular subtype (BluePrint, BP) and estrogen receptor (ER), progesterone receptor (PR) and Human Epidermal Growth Factor Receptor 2 (HER2) mRNA levels (TargetPrint, TP). Genomic information is correlated with clinical and pathologic characteristics and Oncotype DX recurrence score (RS) when available. Patients (pts) will be followed for 5 years. **Results:** Results are available in 88 pts, with 12 pending for an accrual goal of 100. Median age 60 years (range 22-98), 37 stage I, 36 stage II, 15 stage III disease. 67% of pts had High Risk (HR) MP. Age ≤ 40 and grade were significantly associated with HR MP (p=0.022 and < 0.0001, respectively), while stage was not. 20 cancers were triple negative (TN) by IHC;18 of these were Basal-type and 1 HER2-type (1 not evaluable). In the 10 cases ER positive by IHC but negative by TP, 5 were Basal-type and 5 were HER2-type. Of the 12 pts HER2 positive by IHC/FISH, 4 were Luminal-type and 1 was Basal-type; none of these was HER2 positive by TP. 24 pts had Oncotype RS results: 2 were HR both by Oncotype and MP; 5 had intermediate RS, 3 were HR by MP; 17 had a low RS, 8 of which were HR by MP and Luminal-type by BP. **Conclusions:** AAF with stage I to III BC often present with High Risk disease, particularly at younger ages and irrespective of stage. Molecular subtyping confirmed the biologic heterogeneity in TN, HER2 positive and ER positive tumors. Oncotype RS and MP offered different prognostic information. Follow up will be needed to determine correlation with outcome. Funding: MP, BP and TP test provided by Agendia. Biostatistical support by GHUTTCS-CTSA.

| | MP | | ER/PR positive | | HER2 positive | |
|---|---|---|---|---|---|---|
| BP | Low risk (n=29/32%) | High risk (n=59/67%) | IHC | TP | IHC/FISH | TP |
| Luminal | 29 | 25 | 54 | 54 | 4 | 0 |
| Basal | 0 | 25 | 5 | 0 | 1 | 0 |
| HER2 | 0 | 8 | 5 | 0 | 7 | 7 |

**11068 General Poster Session (Board #350), Sat, 1:15 PM-5:00 PM**

**Incidence of inconsistent driver mutations between multiple lung ground-glass nodules in patients with non-small cell lung cancer.** *Presenting Author: Shengxiang Ren, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China*

**Background:** Intertumor heterogeneity had been observed in various kinds of malignant tumors including non-small cell lung cancer. Comparing with extra-pulmonary metastasis, patients with multiple pulmonary nodules have a significantly higher rate of heterogeneity. The aim of this study was to compare the known driver mutations distribution among non-small cell lung cancer(NSCLC) patients with multiple intrapulmonary ground-glass nodules(GGNs). **Methods:** 35 consecutively resected lung cancer patients with multiple lung GGNs at a single institution (Tongji University, Shanghai, China) were analyzed for mutations in EGFR, KRAS, HER2, BRAF and PIK3CA together with genes fusion in ALK, ROS1 and RET. **Results:** The median age was 60 years old, male/female:12/23, never smoker/smoker: 25/10, PS 0/1: 22/13. Totally, 72 lesions were included into this analysis, including 9 of adenocarcinoma in situ, 9 minimal invasive adenocarcinoma and 54 invasive adenocarcinoma. Among them, 33 (45.8 %) tumors harbored EGFR mutations, including 13 were deletions in exon 19, 18 were L858R missense changes, and two were 19 deletion together with L858R mutations. 5 (6.9 %) harbored EML4-ALK fusions, 4 (5.6%)had HER2 mutations, 3(4.2%)had KRAS mutations, 1 had ROS1 fusion and BRAF mutation respectively. A majority of the mutations were mutually exclusive, except 1 both with EGFR mutation and ALK fusion. The discordant frequency rate of the driver mutation distribution was 68.6%(24/35) in the whole population, while it was 80%(24/30) in the patients harbored at least one of the detected driver mutations. In one of the 2 cases who had 3 resected lung lesions, exon21 L858R point mutation, exon 19 deletion, and L858R point mutation together with ALK fusion were found in the 3 tumor samples separately. **Conclusions:** The high incidence of inconsistent driver mutations distribution between multiple intrapulmonary nodules in this study suggested that these GGNs might arise as independent events and contributed to the higher rate of heterogeneity in intrapulmonary nodules. Patients with multiple GGNs should be given a separate staging and treatment strategy.

**11069 General Poster Session (Board #351), Sat, 1:15 PM-5:00 PM**

***TP53*-mutation status by gene-expression signature (*TP53* signature) and prediction of efficacy of neoadjuvant chemotherapy (NAC) and recurrence after surgery in breast cancer.** *Presenting Author: Shin Takahashi, Tohoku University, Sendai, Japan*

**Background:** *TP53* mutation is an independent poor prognostic factor in breast cancer. We have reported that status of the *TP53* mutation is predictable by expression profile of 33 genes ('TP53 signature') in breast cancer and that the TP53 signature can predict overall survival and recurrent free survival of early breast cancer (Cancer Sci. 99: 324-32, 2008). The aim of this study is to determine whether the TP53 signature can also predict both the efficacy of NAC and the recurrence after surgery in breast cancer. **Methods:** An open-access data of the NAC cohort (E-GEOD-25066) that contains 508 patients with HER2 negative breast cancer is used. Among the genes previously used TP53 signature, 20 up-regulated and 5 down-regulated genes in breast cancer with *TP53* mutation were selected and the *TP53* status was determined by the ratio of the sum of expression values of 20 up-regulated genes to that of the 5 down-regulated genes. If the ratio (5 down-regulated genes / 20 up-regulated genes) was less than 0.325, the tumor was determined as a*TP53* mutant. If it was greater than or equal to 0.325, the tumor was determined a*TP53* wild-type. **Results:** Fifty percent (255 of 508) of tumors was determined as a *TP53* mutant. The pathological CR (pCR) rate is significantly higher in *TP53* mutant tumor than in *TP53* wild-type tumor (34.7% vs 5.4%). In Stage I and II patients (n=280), recurrence free survival (RFS) was significantly better in patients leading to pCR than in patients not leading to pCR (P=0.047), supporting the previous reports. Patients with *TP53* wild-type tumor showed better RFS than patients with *TP53* mutant tumor (P=0.0018). Patients with *TP53*mutant tumor not leading to pCR showed significantly worse RFS than the other patients (P<0.001). **Conclusions:** TP53 signature has the ability to predict the efficacy of NAC and recurrence after surgery in breast cancer. The TP53 signature was especially useful to predict the recurrence in combination with pCR status. Our data suggests that patients with *TP53* mutant tumor not leading to pCR after NAC may need adjuvant chemotherapy after surgery to improve prognosis of these patients.

**11070 General Poster Session (Board #352), Sat, 1:15 PM-5:00 PM**

**Whole-genome sequencing (WGS) to identify *H. pylori* and its impact on the gastric microbiome.** *Presenting Author: Manish A. Shah, Weill Cornell Medical College, New York Presbyterian Hospital, New York, NY*

**Background:** Although *H. pylori* is a WHO class I carcinogen for gastric cancer (GC), nearly all infected patients do not develop GC, and *H. pylori* eradication does not reduce GC risk. We used WGS to examine the hypothesis that changes in the gastric microbiome associated with *H. pylori* infection may play a role in GC development. **Methods:** Patients (pts) undergoing upper endoscopy were categorized as follows: (1) active *H. pylori* infection (*H. pylori* identified on biopsy or positive CLOtest), (2) prior *H. pylori* infection (previous *H. pylori* treatment or ELISA IgG positive), and (3) GC. Endoscopic biopsies from 3 locations in the antrum/body were freshly frozen for WGS (50bp paired-end) on a HiSeq2000 platform at ~10X coverage. We developed a custom computational pipeline algorithm that successively removes human sequences, with remaining un-mapped reads aligned to ~1,400 unique bacteria genomes. Bacterial species were validated by PCR. **Results:** 15 pts have enrolled: active *H. pylori* infection (n=6), prior *H. pylori* infection (n=5), and GC (n=4), with WGS performed in 10 thus far. A total of 16 microbial species are identified (Table). *H. pylori* was identified in all patients regardless of *H. pylori* infection state (i.e. active v. prior), as well as in the GC cohort. **Conclusions:** Multiple bacterial species are identified in gastric mucosa. *H. pylori* is identified in all pts, including previously treated pts. *H. pylori* treatment fails to eradicate *H. pylori*, thus possibly explaining why *H. pylori* treatment fails to reduce cancer risk. This is the first demonstration of detailed unbiased microbiome detection performed from gastric endoscopic biopsy samples using WGS.

**Gastric microbiome identified using WGS.**

| | Active | Active | Prior | Prior | Prior | GC |
|---|---|---|---|---|---|---|
| **Bacterial species** | 05-An | 08-An | 07-An | 09-An | 10-An | 11-An |
| **Helicobacter_acinonychis** | 3 | 15,306 | 9 | 1,421 | 14,817 | 47 |
| **Helicobacter_cetorum** | 0 | 873 | 0 | 87 | 753 | 0 |
| **Helicobacter_pylori** | 19 | 81,762 | 43 | 10,914 | 245,231 | 815 |
| **Lactobacillus_gasseri** | 0 | 0 | 0 | 1 | 89 | 322 |
| **Lactococcus_lactis** | 0 | 0 | 0 | 2 | 906 | 0 |

| **Streptococcus_thermophilus** | 3 | 0 | 2 | 1 | 461 | 4 |

Values are the number of read counts mapped to the respective bacteria species. Top 8 species are shown in subset of pts.

**11071 General Poster Session (Board #353), Sat, 1:15 PM-5:00 PM**

**Concomitant mutation and amplification of the ERBB2 (HER2) gene in human tumors.** *Presenting Author: Tobias Grob, Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

**Background:** Amplification of the ERBB2 (HER2) gene is a well-known genetic aberration in many tumor entities. Up to 20% of breast and gastric cancer show ERBB2 gene amplification and anti-HER2 targeting therapies are well established for these tumors. In other tumor entities such as lung cancer, colorectal cancer and bladder cancer the fraction of ERBB2 amplified tumors is considerably lower. In contrast to breast cancer, these tumors show heterogeneity of ERBB2 amplification in a substantial proportion. Oncogenic EGFR mutation with subsequent EGFR amplification is a common phenomenon in lung cancer. In analogy, primary ERBB2 mutation could explain the observed heterogeneity of ERBB2 amplification in some tumors. **Methods:** 100 tumors showing ERBB2 amplification by fluorescence in situ hybridization were examined for ERBB2 mutation: 50 breast cancer samples, including 10 cases with borderline gene amplification, 10 cases with heterogeneous gene amplification and 11 samples of metastatic lesions as well as 15 colorectal carcinomas, 12 gastric carcinomas, 12 non-small cell lung cancers and 10 urothelial carcinomas. Tumor DNA was extracted and examined for mutations in the tyrosine kinase domain (exons 18-23) of the ERBB2 gene by Sanger sequencing. **Results:** ERBB2 mutation was found in two metastatic lesions of breast cancer, two lung cancers and two colorectal cancers. In five of these cases short in-frame insertions in exon 20 were found. In one case of a breast cancer lung metastasis a missense mutation in exon 19 (p.L755S) was detected. The semi-quantitative chromatograms show an overrepresentation of the mutations indicating a selective amplification of the mutated allele. **Conclusions:** In certain tumor entities the heterogeneity of ERBB2 amplification indicates a late genetic event. The finding of a concomitant mutation in ERBB2 amplified tumors might explain the heterogeneity in some of these tumors. The effect of a primary oncogenic ERBB2 mutation might be increased by selective amplification of the mutated allele resulting in an additional growth advantage. If ERBB2 amplified tumors with a primary ERBB2 mutation also benefit from an HER2 targeted therapy needs to be elucidated.

**11072 General Poster Session (Board #354), Sat, 1:15 PM-5:00 PM**

**A tool to predict post-transcriptional instability related to the dysregulation of the SETD2 histone methyltransferase in renal cell carcinoma (RCC).** *Presenting Author: Mia D. Champion, Mayo Clinic, Scottsdale, AZ*

**Background:** Recent studies report that dysregulation of the SETD2 histone methyltransferase in (RCC) decreases global histone 3 lysine 36 trimethylation (H3K36me3), resulting in mis-regulation of alternative splicing of associated exons. It remains unclear how disruptions of chromatin-based modifications contribute to tumorigenesis and can be leveraged to develop more potent treatment strategies. **Methods:** We performed ChIP-, RNA-, and exome- sequencing on matched human RCCs (SETD2 wt /mutant), and RCC cell lines. These datasets were used to develop a tool, ChIP-RNA-seqPRO, to identify regions of dysregulated epigenomic modifications and altered transcript splicing present in the tumor, but absent in a normal sample. The tool provides annotations relevant to post-transcriptional processing and known disease associations (e.g. cancer-associated RNA editing sites). In addition, ChIP-RNA-seqPRO calculates a Modification Association Score (MAS) from changes in ChIP-seq peak distribution, transcript splicing, and associated sequence repeats and variations in order to predict post-transcriptional instability that is correlated with the clinically aggressive tumor phenotype and identify novel therapeutic targets. **Results:** In addition to identifying novel, tumor-unique predicted transcript isoforms and regions of chromatin modification alteration, we have also identified tumor-unique RNA variations shared between samples. Greater than 40% of these sites are known RNA editing sites also identified in other cancers. In addition, gene lists with applied MAScores were analyzed for pathway enrichment. Pathways associated with predicted post-transcriptional instability in SETD2-deficient RCC included regulation of Hypoxia-Inducible Factor (HIF), MAPkinase associated signaling pathways, and the p73 transcription factor network (p-value $< 0.05$). **Conclusions:** Our findings demonstrate the utility of our methods in profiling the regulatory association between epigenomic modification and post-transcriptional processing, and offer unprecedented insight into how the instability of these processes drives the progression of RCC.

**11073 General Poster Session (Board #355), Sat, 1:15 PM-5:00 PM**

**GBM cell microvesicles carrying gDNA oncogenic sequences cross the BBB and reach the peripheral blood.** *Presenting Author: Esther Holgado, Hospital de Madrid, Madrid, Spain*

**Background:** Glioblastoma (GBM) is the most common primary malignant brain tumor in adults accounting for 60-75% of astrocytic tumors. It corresponds to WHO grade IV. Microvesicles (MVs) are vesicles that can be found in body fluids from patients with different types of cancer. These MV can be classified into apoptotic breakdown (up to several $\mu$m), plasma membrane blebbing (100 to 1,000 nm), and exosomes (less than 100 nm) released by fusion of endosomal-derived multivesicular bodies They play a crucial role in tumor progression since they can mediate intercellular communication, inflammation, angiogenesis and coagulation. We have identified, for the first time, the presence of genomic DNA sequences corresponding to oncogenes from all three types of MVs. These three types of MVs can cross the bbb and reach the peripheral blood where gDNA sequences might be used as biomarkers to stratify patients and evaluate response to treatment. **Methods:** GBM-initiating cells were isolated from surgical samples and cultured. A collection of primers targeting specifically human gDNA were designed and validated. Using a modification of the protocol proposed by Skog group we isolated apoptotic, blebbing, and exosomes. Afterwards, we isolated total gDNA from supernatant of cells and mice plasma with brain tumor. This gDNA was used as a template for de detection of gDNA oncogene sequences. Finally, we confirmed the presence of such sequences within all three type of MVs isolated from peripheral blood of GBM patients. **Results:** We found gDNA oncogene sequences within all three types of MVs. We demonstrated that MVs secreted by tumor cells into the brain can cross the bbb and reach the peripheral blood, were they contribute to the total number of circulating MVs y mice model. gDNA oncogenic sequences can be also detected in all three types of MVs isolated from peripheral blood of GBM patients. **Conclusions:** gDNA sequences can be introduced into apoptotic and blebbing MVs, and exosomes. These three types of MVs can cross the bbb and reach the peripheral blood where they can be detected by using low invasive procedures. The presence of gDNA will be useful for the detection of specific mutations, and/or epigenetic changes in the producer tumor cell.

**11074 General Poster Session (Board #356), Sat, 1:15 PM-5:00 PM**

**Variation in the *ESR-1* gene as a prognostic marker in early breast cancer survival.** *Presenting Author: Danny Houtsma, Department of Clinical Oncology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Variation in the genes coding for the estrogen receptor (ESR-1), CYP2c19 and UGTB15 is associated with worse outcome in tamoxifen treated early breast cancer patients. It is unclear whether this variation is a predictive marker for tamoxifen efficay or if it is a prognostic marker for breast cancer outcome. The aim of this study was to examine if SNP's in these genes are also associated with survival in early breast cancer patients treated with adjuvant exemestane as to explore a prognostic potential of these markers. **Methods:** Patients of whom tissue was available were selected from the Tamoxifen Exemestane Adjuvant Multinational (TEAM) trial. DNA was isolated from tumor samples. The following 4 SNPs were genotyped using Taqman assays: rs9340799 and rs2234693 in the ESR-1 gene, rs1902023 in the UGTB15 gene and rs4244285in the CYP2c19 gene. Primary endpoint was relapse-free survival (RFS) and secondary endpoint was overall survival (OS). A Kaplan-Meier analysis was performed and Cox proportional hazards models assessed survival differences. Analyses were adjusted for age at diagnosis, tumor size, nodal status, histological grade, surgery, adjuvant radiotherapy and chemotherapy. **Results:** 807 patients were included in the analyses and genotypes were obtained in 84%-96% of the samples. No association was found with the primary endpoint of relapse free survival with any of the four SNPS. However, the rs2234693 variant in ESR1 was associated with worse overall survival with an odds ratio of 1,4 ($P = 0.016$) consistent with a prognostic rather than a predictive drug response effect. **Conclusions:** Variation in the ESR-1 gene is related to overall survival in early breast cancer patients. Variation in the ESR-1 gene may be used as a prognostic marker of early breast cancer survival regardless of which endocrine treatment is used.

**11075 General Poster Session (Board #357), Sat, 1:15 PM-5:00 PM**

**Whole-genome bisulfite sequencing of a complex karyotype AML and identification of regulatory aberrations distinct from normal karyotype AML.** *Presenting Author: Stephen Capone, University of Southern California, Los Angeles, CA*

**Background:** We characterized the methylome and transcriptome of blasts from a 20 year old man with a metastatic mediastinal immature teratoma who developed a complex karyotype acute myeloid leukemia (CK-AML) while on treatment. We performed low-input whole genome bisulfite sequencing (WGBS), RNA sequencing (RNAseq), and HumanMethylation450 (HM450) assays. RNAseq and (when present) matching HM450 results from normal CD34+ cells (N=6), normal karyotype (NK-AML, N=10) and CK-AML blasts (N=10) were compared. **Methods:** We purified patient bone marrow blasts and CD34+ cells from healthy volunteers (N=6) by fluorescence assisted cell sorting (FACS). We prepared 200ng (HM450) and 50ng (WGBS) of DNA, the latter by EpiGnome Methyl-Seq Kit (Epicentre). Sequencing on a HiSeq 2,000 yielded ~60 million mapped 50bp reads per sample. WGBS alignment and SNP calls were by BWA and Bis-SNP. 5ng RNA generated ~30 million mapped reads per sample, which we aligned with STAR. HM450 and RNAseq data from McNerney's (Blood, 2013) and TCGA NK- and CK-AML samples were also reprocessed. **Results:** The patient's blasts homozygously expressed mutant *TP53* (R282W), *TP53INP1*, *NCKAP1L*, *UBR4*, and *IL17RB*. HM450 data revealed copy number aberrations and a signature common to TCGA CK-AMLs. Focal hypermethylation overlapped Polycomb repressor complex binding sites in CD34+ cells and, in contrast to NK-AML, affected *HOXA* and *HOXB* clusters. Megabase-scale blocks of hypomethylation overlapped those seen in B-cell immortalization (Hansen, 2013) and IMR90 senescence (Cruickshanks, 2013). Non-coding RNAs (e.g. *HOTAIRM1*) distinguished CK-AML from NK-AML and normal CD34+ cells. **Conclusions:** This is the first characterization of an AML methylome using WGBS. The methylome of the CK-AML patient shows changes associated with senescence and transformed cells: genome-scale hypomethylation, focal hypermethylation, and promiscuous transcription. Genome-wide DNA methylation changes in the patient's blasts broadly parallel those seen with immortalization and senescence in other cell types. The genetic and epigenetic heterogeneity observed in CK-AML may nonetheless contribute to its malignant evolution and poor outcomes.

**11076 General Poster Session (Board #358), Sat, 1:15 PM-5:00 PM**

**Next-generation sequencing (NGS) as part of pathologic diagnostic armamentarium.** *Presenting Author: Lorna Rodriguez-Rodriguez, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

**Background:** Because genomic alterations inform tumor biology, treatment decisions, and new research opportunities, we established a Molecular Tumor Board. Cases with NGS results from a CLIA certified assay are presented and therapeutic strategies are suggested when appropriate. Cases called for re-consideration of final pathologic diagnosis are presented as example of the utility of NGS in aiding final diagnosis and recommending treatment of unusual cases. **Methods:** NGS on formalin-fixed, paraffin embedded tumors (N=101 patients) was done using hybridization-captured, adaptor ligation–based libraries to high, uniform coverage for 3,230 exons of 182 cancer-related genes plus 37 introns from 14 genes frequently rearranged in cancer. Data curation was performed by Precision Medicine physicians at Rutgers Cancer Institute of New Jersey. Cases were presented formally at the Molecular Tumor Board where systems biologists, oncologists, pathologists, and scientists discussed de-identified data. **Results:** Five cases had ambiguous diagnoses: three gynecologic malignancies, a brain tumor of unknown origin (presented in detail elsewhere), and a presumed lung carcinoma with concomitant pancreatic cancer. One case had two tumor foci sharing almost all of the genomic alterations and were more similar to those found in sarcoma than in GIST, the final diagnosis was metastatic ovarian carcinosarcoma. In another, a presumed recurrence of ovarian cancer had alterations that were more consistent with pancreatic primary. By tumor board recommendations, the patient underwent endoscopic biopsy of the pancreas that uncovered a primary pancreatic cancer. In two cases, mutational analysis revealing shared mutations between two tumor foci overcame diagnostic dilemma of new primary versus metastasis. **Conclusions:** NGS assays are useful to identify actionable genomic changes and challenge pathologic diagnosis, translating into patient benefit. Genomic alteration signatures should be validated for tumors that are rare, difficult to diagnose or unusually recalcitrant to treatment. NGS should become part of the pathologic armamentarium for tumor diagnosis.

**11077 General Poster Session (Board #359), Sat, 1:15 PM-5:00 PM**

**Inferring clonal composition from multiple sections of a breast cancer.** *Presenting Author: C. Anthony Blau, Center for Cancer Innovation, University of Washington, Seattle, WA*

**Background:** Cancers arise from successive rounds of mutation and selection, generating clonal populations that vary in size, mutational content and drug responsiveness. Ascertaining the clonal composition of a tumor is therefore important both for prognosis and therapy. **Methods:** Mutation counts and frequencies resulting from next-generation sequencing (NGS) potentially reflect a tumor's clonal composition; however, deconvolving NGS data to infer a tumor's clonal structure presents a major challenge. We propose a generative model for NGS data derived from multiple subsections of a single tumor, and we describe an expectation-maximization procedure for estimating the clonal genotypes and relative frequencies using this model. **Results:** We demonstrate, via simulation, the validity of the approach, and then use our algorithm to assess the clonal composition of a primary breast cancer and associated metastatic lymph node. After dividing the tumor into subsections, we perform exome sequencing for each subsection to assess mutational content, followed by deep sequencing to precisely count normal and variant alleles within each subsection. By quantifying the frequencies of 17 somatic variants, we demonstrate that our algorithm predicts clonal relationships that are both phylogenetically and spatially plausible. **Conclusions:** Applying this method to larger numbers of tumors should cast light on the clonal evolution of cancers in space and time.

**11078 General Poster Session (Board #360), Sat, 1:15 PM-5:00 PM**

**Pathway-based signature analysis of RNA-seq data to reveal new targetable avenues for metastatic castration-resistant prostate cancer (mCRPC) patients (pts): Preliminary results from the SU2C/PCF/AACR West Coast Prostate Cancer Dream Team (WCDT).** *Presenting Author: Adrian Bivol, Department of Biomolecular Engineering, University of California, Santa Cruz, Santa Cruz, CA*

**Background:** The mechanisms of resistance to agents such as abiraterone or enzalutamide in pts with mCRPC are poorly understood, and progressive mCRPC has been challenging to biopsy and characterize on a molecular basis because of its bone tropism. As part of the WCDT project, which aims to identify genetic pathways underlying primary and acquired resistance to these agents, RNA-sequencing following laser capture microdissection of mCRPC biopsies was undertaken, along with a panel of 37 mutated cancer genes. Interpreting these data is challenging as few computational approaches exist that can leverage external data (e.g. TCGA) to shed light on pathways that drive cancer progression in an individual patient. **Methods:** RNA-seq and mutation data from mCRPC biopsies is interpreted by mapping onto a comprehensive pathway database connecting a tumor sample with genetic regulatory logic. Pathway mapping occurs either prior to inferring predictive signatures using the PARADIGM engine, or after differential gene expression analysis. Topological analysis reveals possible drug targets within the inferred networks. **Results:** 60 of 300 planned mCRPC pts have undergone a metastasis bx, RNA-seq data from 9 samples has been analyzed. PARADIGM-based signatures revealed expected neurotransmitter pathways discriminating neuroendocrine from non-NE samples. Gene expression-based signatures mapped onto pathways revealed RB1, Reelin, and VEGF signaling characteristic of liver metastases compared to mets from other tissues. Finally, gene expression-based signatures uncovered several pathways enriched in Abiraterone naive compared to resistant samples (FDR $<$ 5%). **Conclusions:** Significant pathways can be inferred and potential drug targets identified on very small cohorts with this approach. Methods that harness existing datasets using pathway-guided descriptions may raise the interpretability of omics datasets collected in personalized medicine settings.

**11079 General Poster Session (Board #361), Sat, 1:15 PM-5:00 PM**

**A national platform for molecular diagnostics: Results of the Cancer Research U.K. Stratified Medicine Programme.** *Presenting Author: Emily Shaw, Cancer Research UK, London, United Kingdom*

**Background:** Increasing demand for testing multiple markers for targeted therapies requires a platform to incorporate molecular diagnostics in the normal pathway of care. This programme was planned to demonstrate the applicability of a nationwide platform of testing, linked to healthcare records in a central database. **Methods:** From 8/2011 to 6/2013, patients with breast, colorectal, prostate, lung or ovarian cancer, or melanoma, were approached at 26 hospitals for consent to centralised molecular testing of routine biopsies. Formalin-fixed paraffin-embedded sections were forwarded with peripheral blood samples to 3 technical hubs for analysis of a small panel of abnormalities by Sanger sequencing, pyrosequencing or similar mathods, and fluorescent in-situ hybridisation for chromosomal structural changes. Results were transmitted directly to clinical centers for inclusion in medical records. A routine clinical dataset was collected from all patients using the national cancer registration system. **Results:** 10,754 patients (98% of those approached) consented to analysis of material, with 9010 samples sent for analysis. Of 1,889 lung cancers, 35% had at least one abnormality, only 0.65% had more than one. kRAS was most often mutated (26%), followed by EGFR (8.3%), Alk rearrangement (1.9%) and BRAF (1%). In 1634 colorectal cancers, 47% had one abnormality, 30% two and 3% three. Commonest abnormalities were mutated TP53 (25%), double mutated TP53 and kRAS ( 17%), kRAS only (17%) and BRAF (5%). In 535 melanomas there were 42% BRAF mutants, 22% NRAS mutant and only 2.4% with double abnormalities. There was heterogeneity between the laboratories in turnaround time and failure rate, especially for non-standard analyses. A multiplex next-generation sequencing (NGS) panel was piloted for samples collected in the last 3 months of the programme, showing high levels of concordance in comparison to conventional sequencing. **Conclusions:** A broad system of molecular diagnostics is feasible and highly acceptable to patients. The efficiency is improved with NGS analysis, and the system is now being used to support prescreening of patients with lung cancer for entry into a multiarm study of novel therapeutics.

**11080 General Poster Session (Board #362), Sat, 1:15 PM-5:00 PM**

**FGFR and FGF ligand overexpression in lung cancer: Implications for targeted therapy.** *Presenting Author: Krishna Maddula, HTG Molecular Diagnostics, Tucson, AZ*

**Background:** Fibroblast growth factor receptors (FGFR) have been shown to be frequently dysregulated in non-small cell lung cell carcinoma (NSCLC). To determine the impact of dysregulation of FGFR pathway in NSCLC, we profiled 100 samples using a sensitive gene expression assay for FGFR and its ligands. **Methods:** FGFR and FGF gene expression in formalin fixed paraffin embedded (FFPE) samples was performed using a sensitive quantitative nuclease protection assay. This gene expression panel includes all four FGFRs, all 22 FGF ligands and known FGF interacting proteins KLOTHO and KLOTHO beta. Using this array we profiled 100 NSCLC samples (45 squamous, 55 non-squamous). **Results:** Gene expression analysis of the FGFR family in lung cancer showed overexpression by 3X over median levels of FGFR2 and FGFR3 predominantly in squamous subtype (28% and 19% respectively), FGFR4 overexpresion mainly in non-squamous subtype (25%) and FGFR1 overexpression evenly distributed between squamous and non-squamous subtypes (9 %). There were rare instances of joint overexpression of more than one FGFR, FGFR 1 and 2 together (6%), FGFR 1 and 3 together (2%) and FGFR 3 and 4 together (2%). Overexpression of FGFs was seen in ~35% of all NSCLC samples with FGF19 overexpression being the most common, with increases seen in 20 % of all NSCLC samples. **Conclusions:** We report for the first time a sensitive and comprehensive FGF and FGFR gene expression analysis of 100 lung cancers. Our expression profiling did not confirm frequent overexpression of FGFR1 in squamous NSCLC in contradiction to frequent gene amplification at this locus suggesting that DNA amplification may not result in transcriptional alteration in many cases. Additionally, we detected frequent overexpression of FGFR2 and 3 in squamous NSCLC and FGFR4 overexpression in adenocarcinoma subtype of NSCLC. The receptor overexpression is frequently associated with overexpression of FGF ligands suggesting a paracrine effect. Expression profiling data support frequent FGFR pathway dysregulation in lung cancer and highlight that gene expression profiling is an important modality for identifying potential responders to novel anti-FGFR therapies.

**11081 General Poster Session (Board #363), Sat, 1:15 PM-5:00 PM**

**Effects of concomitant therapies on $\gamma\delta$ T-cell responses to zoledronate in patients with advanced prostate cancer.** *Presenting Author: Deborah Enting, Department of Immunobiology, King's College London, London, United Kingdom*

**Background:** $\gamma\delta$ T cells have attracted interest as a biological tool for cancer therapy owing to demonstrated tumour cytocidal potential in vitro, and their correlation with improved outcome in patients with malignancies. They are also not MHC-restricted, offering opportunities beyond individual-specific therapies. Indeed, clinical trials with bisphosphonate-activated $\gamma\delta$ T-cell-based immunotherapy are ongoing. However any clinical adoption of $\gamma\delta$ immunotherapy will need to be in the context of other therapies ('standard-of-care'). The influence of concomitant therapies such as chemotherapy on the effector function of $\gamma\delta$ T cells remains largely unexplored. **Methods:** We developed an immunomonitoring protocol to determine the $\gamma\delta$ T cell response to zoledronate (ZOL) in the context of hormonal therapy with or without docetaxel chemotherapy in patients with advanced prostate cancer. Blood samples were collected prior to ZOL and chemotherapy and 6 days later, with a second collection cycle after 4 weeks. Phenotypic and functional analyses were performed on purified peripheral blood mononuclear cells from each of the four successive collection points. **Results:** Many patients receiving ZOL show a markedly low percentage of $\gamma\delta$ T cells. Moreover, the percentage of NKG2D$^+$ $\gamma\delta$ T cells is significantly reduced in both treatment groups, although the majority of patients experienced a conspicuous boost in this compartment after ZOL treatment. However, this 'bounce-back' effect was lost in patients who have received ZOL long term. **Conclusions:** Thus, ZOL modulates $\gamma\delta$ T cell phenotypes *in vivo* but repeated long term ZOL treatment could lead to exhaustion of this immune compartment. This observation could have important clinical implications with regards to the duration of bisphosphonate treatment, which currently is undetermined. Furthermore, in the form of an interventional clinical trial, we are now assessing whether adjuvant IL-2 therapy can prolong the activation potential of $\gamma\delta$ T cells in the context of ZOL, offering a simple immune-enhancement potential that might usefully be adopted for particular cohorts of patients.

**11082 General Poster Session (Board #364), Sat, 1:15 PM-5:00 PM**

**Effect of lymphoid tissue inducer cells on lymphatic tumor cell invasion via activation of the RANKL/RANK axis within triple-negative breast cancers.** *Presenting Author: Sheeba Irshad, Breakthrough Breast Cancer Research Unit, London, United Kingdom*

**Background:** Inflammation and infiltration of the tumor tissue by host immune cells have been shown to promote tumor cell invasion and metastasis. The exact molecular mechanisms mediating tumor cell entry and persistence within the lymphatics remains unclear. We previously reported the novel identification of retinoic acid receptor related orphan receptor (ROR)gt$^+$lymphoid tissue inducer cells (LTIs) within breast cancer tumor microenvironments. The presence of these cells was shown to be associated with a high expression of a lymphoid chemokine gene signature; correlating also with an increased lymphatic vessel density and tumor invasion into lymphatic vessels. Here we report on the mechanistic relationship between LTi cells and tumor cell invasion. **Methods:** Both *in vitro* and *in vivo* experiments were carried out to further investigate the correlations observed within our human dataset. **Results:** We report the temporal sequence of LTi cell recruitment into first the primary tumors and then into the draining lymph nodes during tumour progression within a triple negative breast cancer (4T1.2) mouse model. These changes were closely associated with changes in the serum levels of associated lymphoid chemokines (CCL21 and CXCL13) and RANKL (a key regulator of LTi cell function). The administration of blocking antibodies for CCL21, CXCL13 or RANKL *in vivo* demonstrated i) LTi recruitment into tumors was dependent primarily on CCL21; ii) migration of LTi cells from the tumors to the draining lymph nodes was likely to be dependent on CXCL13; and iii) RANKL blocking was associated with significantly delayed onset of metastasis within the draining lymph node. Our *in vitro* studies demonstrate that an increase in stromal CXCL13 concentration within the tumor microenvironment following LTi recruitment promotes an EMT phenotype in the 4T1.2 cancer cell line, possibly via activation of the RANKL/RANK axis promoting an increase in tumor cell motility. **Conclusions:** We propose a pivotal role for LTi cells, through stromal cell interactions in the tumor microenvironment, in facilitating lymphatic invasion of tumor cells through modulation of the local lymphoid chemokine profile.

**11083 General Poster Session (Board #365), Sat, 1:15 PM-5:00 PM**

**PD-L1 specific tumor infiltrating lymphocytes occur frequently in melanoma and HNSCC patients.** *Presenting Author: Niels Junker, Department of Oncology and Center for Cancer ImmuneTherapy, Department of Hematology, Copenhagen University Hospital Herlev, Herlev, Denmark*

**Background:** Emerging immunotherapeutic strategies targeting the potent immune inhibitory PD-1/PD-L1 pathway in patients with advanced melanoma and squamous cell carcinoma of the lung, and TIL based adoptive therapy of patients with advanced melanoma are very promising. In order to identify relevant tumor associated targets of TIL based therapy our study aimed to identify the occurrence of PD-L1 specific T-cells in *ex vivo* expanded TIL from 30 patients, six of which were head and neck squamous cell carcinoma (HNSCC) patients and 24 were melanoma patients. The latter include 18 melanoma patients from our ongoing phase II trial NCT00937625. **Methods:** Upon PD-L1 peptide stimulation, TILs were screened for IFNgamma secretion using direct Elispot assays (Mabtech). In addition, PD-L1:tetramer (in house) analysis of TIL from selected patients was performed identifying PD-L1 specific cytotoxic T-cells. A standard $^{51}$Cr-release assay was used to assess killing of T2 cells presenting PD-L1 peptide. **Results:** In five of six HNSCC patients and in 17 of 24 melanoma patients, respectively, functional PD-L1 specific T-cells were identified in *ex vivo* expanded TIL, as determined by IFNgamma release. Moreover, it should be noted, PD-L1 responses were detected in four of five clinical responders (PR/CR), but in only two of five non-responders (SD/PD). Sequential analysis of specific binding to PD-L1:tetramers and the killing of PD-L1 presenting T2 cells confirmed the PD-L1 derived epitopes as a valid immunogenic target. **Conclusions:** These data demonstrate that counter immune inhibitory effector T-cells are present in tumors of different origin, and that they have the potential to effectively engage PD-L1, a known potent antitumor immune inhibitor. These findings may lead to the notion that effective immunotherapeutic approaches rely on the presence of effector T-cells specifically targeting both tumor and endogenous immune inhibitory pathways.

**11084 General Poster Session (Board #366), Sat, 1:15 PM-5:00 PM**

**Incidence and localization of tumor-infiltrating CD163$^+$ macrophages and T-cells in early breast cancer patients.** *Presenting Author: Anna Koumarianou, Fourth Department of Internal Medicine, Attikon University Hospital, Athens, Greece*

**Background:** CD163$^+$ macrophages (MΦ) infiltrate malignant tissue of breast cancer patients (BrCa) and suppress immunity, through a Th2 microenvironment characterized by high numbers of CD4$^+$ and low numbers of CD8$^+$ T-cells. We examined the associations between immune cell counts and clinicopathological characteristics. **Methods:** Serial sections of 59 paraffin-embedded BrCa tissues were immunohistochemically analyzed for the presence of total MΦ, their CD163$^+$ subpopulation, helper and cytototoxic T-cells by antibodies to CD68, CD163, CD4, and CD8 markers, respectively. Cells were counted in the intratumoral and peritumoral compartments by two independent observers, and expressed as number of cells for high power field. The medical records of the patients were retrospectively evaluated for various clinicopathologic parameters. Statistical analyses were performed by Tukey's multiple comparison tests and/or t-tests, or Spearman's correlation test. **Results:** Highly significant associations were found between the occurrence of CD163$^+$ MΦ cells and CD4$^+$ ($p<0.0001$) or CD8$^+$ ($p=0.0005$) T-cells as well as between total CD68$^+$ MΦ and CD4$^+$ T-cells ($p=0.01$), detected intratumorally. Importantly, intratumoral CD68$^+$ MΦ were positively correlated to relapse ($p=0.003$), and negatively correlated to survival ($p=0.01$) in patients treated only with chemotherapy ($n=19$). Among patients treated with both chemotherapy and hormonal therapy ($n=18$), relapse was positively associated with peritumoral CD163$^+$ MΦ ($p=0.04$) and negatively with intratumoral CD163$^+$ MΦ ($p=0.03$). The grade of the disease was correlated with the number of total CD4$^+$ T-cells peri- and intratumorally ($p<0.05$), while the CD4$^+$ peritumoral population was also associated with nodal disease ($p=0.03$). Moreover, a positive correlation was revealed between CD8$^+$peritumoral T-cells and p53 intense staining ($p=0.01$). **Conclusions:** Our study provides evidence that tumor associated macrophages, and specifically their CD163$^+$ subpopulation may serve as significant prognostic factors in BrCa, and supports the need for analysis also in terms of localization rather than solely incidence of infiltrating cells in the tumor tissue.

**11085 General Poster Session (Board #367), Sat, 1:15 PM-5:00 PM**

**Prognostic role of immune checkpoint-related genes in resectable lung adenocarcinomas.** *Presenting Author: Marta Usó, Fundación para la Investigación del Hospital General Universitario de Valencia, Valencia, Spain*

**Background:** Immune checkpoints blockade has demonstrated promising clinical results in NSCLC patients. In this study we have investigated the prognostic role of immune checkpoint markers (CTLA4, PD1 and PDL1) in resectable lung adenocarcinoma (ADC). **Methods:** RNA was isolated from fresh-frozen lung specimens (tumor and normal lung) from resectable ADC patients ($n=92$). RT-PCR was performed to analyze the expression of CTLA4, PD1 and PDL1 by the use of hydrolysis probes. Relative gene expression was assessed by Pfaffl formula and normalized by CDKN1B and ACTB as endogenous genes (selected by geNorm algorithm). Statistical analyses were considered significant at $p<0.05$. **Results:** Patient's median age was 64 [37-82], 77.2% were male, 73.9 % have a performance status of 0 and 58.7% presented stage I at the time of the diagnosis. We found a significant positive correlation between expression levels of PD1 and PDL1 ($r^2=0.436$; $p<0.0001$) and between PD1 and CTLA4 ($r^2=0.458$; $p<0.0001$). Survival analyses revealed that patients with higher levels of CTLA4, PD1 and PDL1 presented longer progression free survival (PFS) (Table 1), and in the case of CTLA4 also increased overall survival (OS) (median 32.30 *vs* 81.23 months $p=0.044$). Furthermore, the group of patients with high levels of both PD1 checkpoints (PD1$^{high}$ & PDL1$^{high}$) showed longer PFS (Table 1). The multivariate Cox regression analysis revealed that CTLA4 is an independent prognostic marker for PFS (HR 0.38 [0.19-0.79] p= 0.009) and OS (HR 0.38 [0.17-0.85] p=0.019]. **Conclusions:** Expression of immune checkpoint genes seems to have a prognostic role in lung ADC. Among these, CTLA4 has been found to be an independent prognostic marker highlighting the importance of these immune-markers in the prognosis of resectable lung ADC.

**PFS for CTLA4, PD1, and PDL1 in lung ADC patients.**

| | Median (months) | *p*-value |
|---|---|---|
| **CTLA4 (≤ median *vs* > median)** | 19.23 *vs* 81.23 | 0.008 |
| **PD1 (≤ median *vs* > median)** | 19.13 *vs* 49.30 | 0.048 |
| **PDL1 (≤ median *vs* > median)** | 19.23 *vs* 66.96 | 0.034 |
| **Combined checkpoints (Other combinations *vs* PD1$^{high}$ PDL1$^{high}$)** | 19.23 *vs* NR | 0.008 (0.048*) |

* *p* -value with Bonferroni correction.

**11086 General Poster Session (Board #368), Sat, 1:15 PM-5:00 PM**

**Gene-expression profiling to demonstrate select neutrophils from breast cancer patients versus healthy women as cytotoxic against breast cancer cells via novel chemokine-mediated mechanisms.** *Presenting Author: Elizabeth Anne Comen, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** We have previously shown that neutrophils, entrained by a primary breast tumor, inhibit metastatic seeding and are cytotoxic to cancer cells in mouse models (Granot et al., 2010). We further demonstrated that neutrophils from human breast cancer patients are cytotoxic to breast cancer cells, and show a significantly higher cytotoxicity than neutrophils from cancer-free controls. We identified the cytokines IL1a, MCP-1, and TNF as being associated with neutrophil cytotoxicity and showed that these cytokines stimulate neutrophil cytotoxicity against breast cancer cells in cell culture assays. To further investigate neutrophil cytotoxicity, we preformed RNA-seq analyses on neutrophils from breast cancer patients and cancer-free controls. **Methods:** We purified neutrophils from 50 newly diagnosed pre-operative breast cancer patients and 25 cancer-free controls. Neutrophil cytotoxicity against MDA-MB-231 breast cancer cells was assessed in these samples by previously described methods. (Granot et al., 2010). RNA-seq was performed on 61 of these samples (36 breast cancer patients and 25 controls) using the Illumina HiSeq2500 platform. Comparative analyses were performed to identify genes differentially expressed between patients and controls and between samples showing high and low cytotoxicity. **Results:** Preliminary comparative analyses of the RNA-seq derived gene expression profiles identified 138 genes to be differentially expressed between patients and controls. Confirming our previous observations, IL1 family members and TNF were overexpressed in patient samples in comparison to cancer-free controls. Comparative analyses also identified 43 genes differentially expressed between patient samples with high cytotoxicity and those with low cytotoxicity. **Conclusions:** Our results have identified unique gene expression profiles associated with neutrophil cytotoxicity against breast cancer cells. We are currently evaluating the mechanism of action of neutrophil cytotoxicity as well as the prognostic and therapeutic roles of cytotoxic neutrophils in breast cancer patients.

**11087 General Poster Session (Board #369), Sat, 1:15 PM-5:00 PM**

**Prognostic and predictive value of tumor infiltrating lymphocytes (TIL) in two phase III randomized adjuvant breast cancer (BC) trials.** *Presenting Author: Maria Vittoria Dieci, University of Padua and Medical Oncology 2, Istituto Oncologico Veneto IRCCS, Padova, Italy*

**Background:** TIL have been proposed as a new prognostic factor for triple negative BC [Dieci MV, 2014]. Here we seek to evaluate the prognostic and predictive role of TIL in BC patients enrolled in two prospective adjuvant trials. **Methods:** The % of intratumoral (It) and stromal (Str) TIL were evaluated on H&E slides of tumors from 817 patients from two randomized trials comparing anthracycline-based to no chemotherapy [Arriagada R, 2005]. Samples were classified as High-TIL if ItTIL and/or StrTIL >=50%. CD3, CD8 and CD20 were also evaluated. Association with Disease-free survival (DFS) and interaction with chemotherapy were studied. **Results:** 781 of 817 cases were evaluable for TIL. High-TIL patients were more likely Grade 3 and ER-negative ($P<0.001$ for both). In multivariate analyses including age, tumor grade, tumor size, nodal status, ER, HER2 and treatment arm, both continuous It-TIL and Str-TIL variables were significantly associated with DFS. Each 10% increase in ItTIL or StrTIL was associated with 14% and 13% reduction in risk relapse (HR 0.86, 95%CI 0.78-0.94, P=0.001; HR 0.87, 95%CI 0.80-0.94, P<0.001), respectively. There was no prognostic effect in the ER+/HER2- subgroup, whereas both continuous ItTIL and StrTIL showed a significant prognostic value in multivariate analyses for both the ER-/HER2- and the HER2+ groups ($P=0.05$, $P=0.04$ for ItTIL and $P=0.02$, $P=0.01$ for StrTIL respectively). In the ER-/HER2- group 10yrs DFS rate was 85% and 53% for High-TIL and Low-TIL patients, respectively (HR 0.43 95%CI 0.20-0.94, $P=0.03$), whereas in the HER2-positive group 10yrs DFS rate was 74% and 54% for the High-TIL and Low-TIL groups, respectively (HR 0.48 95%CI 0.21-1.07, $P=0.07$). Either continuous ItTIL or StrTIL did not predict for the efficacy of anthracyclines, either in the whole study population or in different molecular subgroups (test for interaction: $P>0.2$). **Conclusions:** TILs did not predict anthracycline efficacy. We confirmed in prospective randomised trials the prognostic value of TIL for early triple negative BC patients and we suggested a prognostic impact in HER2+ patients. Analyses of TIL composition (CD3, CD8, CD20) are ongoing and will be presented at the meeting.

**11088 General Poster Session (Board #370), Sat, 1:15 PM-5:00 PM**

**Preclinical profile of ASPH_0047, a potent and selective antisense oligonucleotide targeting transforming growth factor beta 2 (TGF-β2).** *Presenting Author: Michel Janicot, Isarna Therapeutics GmbH, Munich, Germany*

**Background:** Transforming Growth Factor beta (TGF-β) proteins are members of a large family of related cytokines comprised of at least 33 members in mammals encoded by different genes, and which regulate a host of activities ranging from embryonic development to tissue homeostasis. The three bona fide TGF-β isoforms (TGF-β1, -β2 and -β3) play critical, pleiotropic roles in the pathophysiology of various human diseases. In cancer, correlations between TGF-β expression, disease stage and clinical parameters have been reported and linked to poor clinical outcome. TGF-β has been associated with a wide range of tumor-promoting processes, including tumor cell invasion and migration, angiogenesis, immunosuppression, as well as tumor stem cell maintenance and protection. More specifically, the TGF-β2 isoform has been reported to be a key molecular determinant of immunosuppression and invasiveness, and consequently playing a major role in metastasis. Therefore, inhibiting TGF-β2 appears as an attractive therapeutic intervention in Oncology. **Methods:** Based on the sequence of the human TGF-β2 mRNA, we have identified and engineered ASPH_0047, a LNA-modified antisense oligodeoxynucleotide gapmer, which shows potent and selective target mRNA and protein downregulation in various tumor cell-based assays, and promising anti-tumor activity in animal models. **Results:** In preclinical species, ASPH_0047 features plasma and tissue pharmacokinetics profile similar to previously reported profiles for LNA gapmers, strong metabolic stability and long-lasting tissue distribution with marked tissue penetration in liver, kidney and spleen. Preliminary safety assessment of ASPH_0047 in rats and *Cynomolgus* monkeys upon repeated 30-min infusion consistently points at dose-related stimulation of the immune system in several organs, including accumulation of distended macrophages in lymph nodes, and degenerative renal and liver changes at high doses. **Conclusions:** Key preclinical features of ASPH_0047 supporting rapid advancement to clinical development will be presented.

**11089 General Poster Session (Board #371), Sat, 1:15 PM-5:00 PM**

**Enabling a genetically informed approach to cancer medicine: A retrospective evaluation of the impact of comprehensive tumor profiling using a targeted next-generation sequencing panel.** *Presenting Author: Douglas Buckner Johnson, Vanderbilt-Ingram Cancer Center, Nashville, TN*

**Background:** Oncogenic genetic alterations "drive" neoplastic cell proliferation. An increasing number of potentially actionable alterations (PAAs) can be targeted by small molecules and antibodies. Since most patients (pts) do not have PAAs detectable by conventional clinical assays, NGS may identify these targets and increase treatment options. To determine the clinical impact of extensive genetic profiling, we reviewed our experience using a targeted NGS platform (FoundationOne) in advanced cancer pts. **Methods:** We retrospectively assessed demographics, NGS results, and therapies received for pts undergoing targeted NGS (exonic sequencing of 236 genes and selective intronic sequencing from 19 genes) from April 2012 to August 2013. PAAs were defined as somatic genetic changes inferred to confer sensitivity to approved or investigational agents. Co-primary endpoints were the proportion of pts with PAAs uncovered by NGS and the proportion who received genotype-directed therapy (GDT). **Results:** Samples from 103 pts were tested; most frequently breast carcinoma (26%), head and neck cancers (23%), and melanoma (10%). Most samples (83%) harbored ≥1 PAA; 6% had no detected mutations. Identified PAAs included alterations in the following pathways: cell cycle regulation (44%), PI3K-AKT (31%), and mitogen-activated protein kinase (19%); *TP53* was the most commonly altered gene (32%). With median follow up of 4.1 months, 21% received GDT. Of these, 61% were on clinical trials and 39% received approved or off-label GDT; several heavily pre-treated pts experienced significant benefit. Rationale for not administering GDT to pts with PAAs included assignment to standard therapy during follow up (35%) and clinical deterioration (13%).Additionally, a novel BRAF fusion was identified in melanoma. **Conclusions:** A targeted NGS panel identified PAAs in the majority of advanced cancer pts in our experience. The assay identified treatment options, facilitated enrollment in clinical trials, and identified novel PAAs. As time progresses, NGS results will be used to guide therapy in an increasing proportion of pts.

**11090 General Poster Session (Board #372), Sat, 1:15 PM-5:00 PM**

**$^{89}$Zr-bevacizumab PET imaging of disease manifestations in patients with Von Hippel-Lindau disease.** *Presenting Author: Sjoukje Oosting, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Patients withvon Hippel-Lindau (VHL) disease develop benign and malignant vascular tumors. Local vascular endothelial growth factor (VEGF)-A production is likely involved in the development of disease manifestations and is a treatment target for antiangiogenic therapy. Bevacizumab binds VEGF-A. We aimed to assess whether $^{89}$Zr-bevacizumab positron emission tomography (PET) can visualize VHL manifestations and differentiate progressive from non-progressive lesions, and to compare PET results with plasma VEGF-A levels. **Methods:** Adult VHL patients with ≥ 1 measurable hemangioblastoma were eligible. The tracer $^{89}$Zr-bevacizumab (37 MBq) was injected 4 days before the PET scan. Maximum standardized uptake values (SUVmax) were calculated. PET scans were fused with routine MRI of the central nervous system (CNS) and abdomen. Progressive lesions were defined as new lesions, lesions that became symptomatic and lesions ≥ 10 mm that increased ≥ 10% and ≥ 4 mm on repeat anatomic imaging within 12 months. Plasma VEGF-A was measured before $^{89}$Zr-bevacizumab injection and with follow-up anatomic imaging. **Results:** Twenty-two patients were enrolled. $^{89}$Zr-bevacizumab PET visualized 59 known VHL manifestations (0-17 per patient, 24 in the CNS) with a median SUVmax of 8.5 (range 1.3-35.8) and a detection rate of 30.8% for lesions ≥ 10 mm. Two of 7 hotspots on PET without substrate on baseline anatomic imaging were detected as lesions on MRI during follow-up at 10 and 12 months. Nine out of 25 progressive lesions and 27 out of 175 non-progressive lesions were visible on PET (positive predictive value 25%, negative predictive value 90%). Progressive and non-progressive lesions had similar SUVmax (median 4.8, range 0.9-8.9 versus 6.7, range 1.3-35.8, $P$= .14). Plasma VEGF-A did not correlate with imaging results and was similar in patients with and without progressive lesions. **Conclusions:** VHL manifestations can be visualized with$^{89}$Zr-bevacizumab PET. $^{89}$Zr-bevacizumab uptake and plasma VEGF-A cannot be used to predict progression. High SUVmax in VHL lesions proves local bevacizumab accumulation and could potentially be used to select patients for bevacizumab treatment. Supported by the VHL Family Alliance. Clinical trial information: NCT00970970.

**11091 General Poster Session (Board #373), Sat, 1:15 PM-5:00 PM**

**Highly sensitive and quantitative detection of *EGFR* T790M mutationin tumor samples by nanofluidic digital PCR.** *Presenting Author: Eiji Iwama, Faculty of Medical Sciences Department of Comprehensive Clinical Oncology, Kyushu University, Fukuoka, Japan*

**Background:** Although treatment with epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have a pronounced clinical benefit for patients with *EGFR* activating mutations, such patients inevitably develop drug resistances mainly due to the second mutation of T790M. In usual laboratory test, T790M emergence is reported qualitatively as presence or absence of the mutation. **Methods:** We evaluated the emergence of T790M with a highly sensitive and quantitative method, Nanofluidic Digital PCR. We compared digital PCR and Scorpion Amplification Refractory Mutation System (ARMS) in the sensitivity of detecting T790M. Digital PCR was used to calculate the ratio of T790M to the number of activating mutation alleles (T/A ratio) in 28 samples (15 pre- and 13 post-TKI treatment samples) obtained from 19 NSCLC with *EGFR*activating mutations. We also calculated the ratio of double-stranded DNA (dsDNA) to DNA concentration (dsDNA/DNA ratio) to evaluate the quality of each sample DNA. **Results:** Digital PCR detected T790M more sensitively compared with ARMS (pre-TKI: 14 of 15 samples, 93.3% *v* 2 of 15 samples, 13.3%, $p<0.001$; and post-TKI: 13 of 13 samples, 100% *v* 4 of 13 samples, 30.8%, $p<0.001$). In 8 patients whose both samples (pre- and post-TKI) were available, T/A ratios in post-TKI samples was higher than that in pre-TKI samples (37.3% *v* 5.4%; $p<0.01$). Digital PCR could not detect T790M only in one formalin-fixed, paraffin-embedded tissue (FFPE) sample. The dsDNA/DNA ratios were low in FFPE samples compared with those in cryopreserved cells (0.96 *v* 0.07; $p<0.001$). The possible explanation is that DNA extracted from FFPE samples used in this study was so fragmented that T790M could not be detected by PCR. **Conclusions:** This study indicates that T790M is present in all tumor samples before EGFR-TKI treatment. It is possible to calculate the ratio of T790M allele in well-preserved samples by digital PCR. This method is useful to develop treatment strategy to overcome the resistance to EGFR-TKI treatment.

**11092 General Poster Session (Board #374), Sat, 1:15 PM-5:00 PM**

**Quality assurance study of real-time targeted massive parallel sequencing (MPS) comprehensive cancer panel (CCP) and network pathway analysis in early breast cancer (EBC).** *Presenting Author: Paul N. Mainwaring, ICON Cancer Care, South Brisbane, Australia*

**Background:** We undertook a prospective quality assurance study in 63 women with early breast cancer (EBC) identifying technical issues that required modification for real-time integration of MPS with clinical and pathology parameters for clinical decision making. **Methods:** Pre-operatively, patients underwent a 2 step formal informed consent process. Samples were collected fresh into Qiagen PaxGene Tissue Container preserving both morphology and biomolecules with lysis of tissues overnight. Day 2 and 3; DNA extraction was performed using the Qiagen DSP kit over 1 hour. DNA and RNA MPS Ampliseq CCP was performed on Life technologies Proton P1 chip using in-house modifications in order to increase the fidelity of library preparation. Days 4-6 manually curated bioinformatics against publicly available mutation databases (e.g. COSMIC etc.) Day 7 communication of results. **Results:** The median age was 55, (32-84), 43 (66%) were postmenopausal. Histopathology IDC 47 (72%), ILC 8 (12%), NOS 5 (8%) metaplastic 2 (3%), mucinous 1 (2%). TNM Staging: Tis 1 (2%), T1a 2 (3%), T1b 13 (20%), T1c 25 (38%) T2 21 (32%); N0 48 (74%), N1mi 1 (2%), N1a 3 (45%), N2a 1 (2%), N3 5 (8%). Hormone receptors antibodies: ER (Roche SP1) Strong 46 (71%), Moderate 3 (5%), Weak 3 (5%), Negative 12 (18%); PR (Roche 1E2) Strong 25 (38%), Moderate 20 (31%), Weak 4 (6%), Negative 15 (23%); HER2 IHC (Ventana 4B5) Strong 2 (3%), Moderate 116 (17%), Weak 19 (29%), Negative 31 (48%); HER2 SISH (Ventana inform single probe); 2 SISH positive (mean copy number 20 & 29.6); 12 patients (18%) triple negative. Molecular aberrations identified included oncogenes TP53 7(13%), PIK3CA 16(29%) HRAS 2(4%), RUNX1 1(2%), STK11 1(2%), AKT1 1(2%) JAK2 1(2%); tumour suppressor genes MLL3 3 (5%), MSH6 1(2%), ARID1A 1(2%) UBR5 4(7%), and in the germline in tumour suppressor genes EPHB6 1(2%) NF1 1(2%) and LTK 1(2%). CNV, MethylSeq & RNASeq data will be presented in the context of network analysis. **Conclusions:** In summary, many challenges face the clinical laboratory developing high throughput desktop MPS. However, multilevel genomic information integration is possible within clinically relevant time-frames.

**11093 General Poster Session (Board #375), Sat, 1:15 PM-5:00 PM**

**Circulating tumor DNA (ctDNA) as a molecular monitoring tool in metastatic breast cancer (MBC).** *Presenting Author: Laura Katherine Austin, Thomas Jefferson University Hospital, Philadelphia, PA*

**Background:** MBC is an incurable disease with complex molecular features including somatic mutations that evolve in relation to genomic instability and selective treatment pressure. Circulating DNA fragments carrying tumor-specific sequence alterations (ctDNA) are found in blood and offer the possibility of longitudinal non-invasive molecular monitoring of the disease by detecting actionable mutations. **Methods:** This is a prospective evaluation of 18 patients with locally advanced or metastatic breast cancer who failed standard therapies and had plasma analyzed for ctDNA detection. Selection criteria: progression of disease after standard therapies, need to detect novel molecular abnormalities for possible therapeutic targeting, or confirmation of genomic abnormalities already demonstrated in tissue analysis. Guardant Health performed the plasma analysis; first ctDNA was isolated from plasma using a Qiagen circulating nucleic acid kit, then a panel of 54 gene mutations associated with solid tumors as reported in the COSMIC database were sequenced using single-molecule digital sequencing technology. **Results:** 89% of patients had metastatic disease; 55% of patients were ER+/HER2-, 6% ER+/HER2+, 22% ER-/HER2+, 17% ER-/HER2-, and 78% had IBC. All patients with MBC had ctDNA alterations. The most common mutations: *TP53* (44%), *PIK3CA* (44%), *ALK* (39%), *ERBB2* (33%), and *EGFR*(28%). Seven patients also had NGS analysis of tissue biopsy and 71% of these patients demonstrated having at least one concordant mutation. HER2 targeted therapy was continued in 3 patients with HER2+ disease after ctDNA confirmed ERBB2 alteration or amplification. Moreover, HER2 targeted therapy was initiated on two HER-2 negative patients that had ERBB2 mutations in ctDNA. Two patients were initiated on everolimus (Afinitor) combinations prior to ctDNA testing, had therapeutic benefit and ctDNA revealed alternations in PIK3CA. **Conclusions:** This is a sensitive test, 100% of patients with MBC had ctDNA alterations. ctDNA offers the possibility of non-invasive genomic analysis of MBC, providing tailored information on mutation status, new molecular targets for therapeutic interventions and allowing molecular monitoring of disease.

**11094 General Poster Session (Board #376), Sat, 1:15 PM-5:00 PM**

**Detection of EGFR mutations of serum circulating DNA.** *Presenting Author: Zongfei Li, MicroDiag Biomedicine Ltd. Co., Suzhou, China*

**Background:** As one of the EGFR-targeted drugs, EGFR tyrosine kinase inhibitors (TKI) play important roles in the treatment of NSCLC patients. It was established that EGFR mutation in tumor is a reliable marker for cancer response to EGFR-TKI. Herein, we assessed the concordance of EGFR mutations in serum circulating DNA (ctDNA) and tumor, and the possibility to predict the efficacy of EGFR-TKI by blood test. **Methods:** Samples (tissue and serum) from 404 NSCLC patients were analyzed retrospectively. EGFR mutations (exons 18-21) of tumor tissues and serum ctDNA were analyzed by sequencing and MCA-qASA assay respectively. MCA-qASA assay combines melting curve analysis and allele specific qPCR, which is expected to carry advantages of both. **Results:** We assess MCA-qASA assay first; the assay is capable to detect mutated DNA with low abundance (0.1 ng/$\mu$L) and low mutation rate (0.01%), probably the lowest ever. As summarized in the Table, among 123 tumor samples with EGFR mutations determined by DNA sequencing, we found 99 samples carrying EGFR mutations in their corresponding serum samples. We only found 15 serum samples carrying EGFR mutations among those whose corresponding tumor tissue samples did not carry EGFR mutations determined by DNA sequencing. The sensitivity and specificity for serum ctDNA EGFR mutation test using MCA-qASA assay as an alternative method for tumorous EGFR mutation test by DNA sequencing are 80.5% (99/123) and 94.7% (266/281) respectively. Kappa coefficient and Youden's index are 0.767 and 75.2% respectively. **Conclusions:** EGFR mutation occurrences are consistent in serum ctDNA and tumor tissues, with Youden index as high as 75.2%, which is the highest reported ever, which is ascribed to the high sensitivity and specificity of the MCA-qASA assay. We propose ctDNA EGFR mutation test for NSCLC patients without tumor tissues before the medication of EGFR-TKI.

**Comparison of EGFR-mutation status of NSCLC tumor tissues and serum ctDNA.**

**11095 General Poster Session (Board #377), Sat, 1:15 PM-5:00 PM**

**Phase I imaging study of the HER3 antibody RG7116 using $^{89}$Zr-RG7116-PET in patients with metastatic or locally advanced HER3-positive solid tumors.** *Presenting Author: Frederike Bensch, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Human epidermal growth factor receptor 3 (HER3) can play a critical role in tumor growth, proliferation and progression. The glycoengineered humanized monoclonal HER3-targeting antibody RG7116 is currently in phase I development (NCT01482377). Knowledge about whole body target expression, drug biodistribution and organ pharmacokinetics is lacking from many phase I designs. The aim of this imaging study is to determine *in vivo* biodistribution and tumor targeting characteristics of RG7116 by means of immunoPET using $^{89}$Zr-RG7116. **Methods:** Patients with HER3-positive metastatic or locally advanced solid tumors underwent $^{89}$Zr-RG7116-PET before treatment with RG7116. To determine optimal tracer dose and imaging schedule patients received $^{89}$Zr-RG7116 with increasing doses of unlabeled RG7116 followed by up to 3 PET scans until 7 days post injection (pi). Tracer uptake in organs of interest and tumor lesions was quantified as standardized uptake value (SUV) and tumor-to-background ratios (TBR) were calculated. **Results:** 13 patients participated without experiencing major safety issues. Initially, 7 patients received 37 MBq $^{89}$Zr-RG7116 containing 10, 50 or 100 mg unlabeled RG7116. The optimal dose was 100 mg and PET 2 days pi did not add valuable information. Subsequent patients (n=6) were evaluated at the 100 mg dose with PET scans 4 and 7 days pi. In all 13 patients tracer uptake in tumor lesions was seen, including in 12/13 biopsied HER3-positive lesions. In 3 of the 13 patients previously unknown brain and bone metastases were also detected. At the 100 mg dose 37 tumor lesions (9 patients) were quantifiable, with mean SUVmax 4 days pi of 4.2 ($\pm$1.8 SD). Normal antibody tissue distribution was seen with mean SUVmax 4 days pi for liver 8.1, intestine 6.5, blood pool 6.2, kidney 5.0, spleen 4.9, and low uptake in the vertebrae 2.7, lung 1.4, muscle 1.1 and brain 0.5, resulting in mean TBR of 3.60 (range 1.10-9.53). **Conclusions:** With $^{89}$Zr-RG7116-PET biodistribution of RG7116 was determined and tumor specific uptake of $^{89}$Zr-RG7116 was shown in patients with HER3-positive metastatic cancer. Analysis of HER3 saturation by repeated $^{89}$Zr-RG7116-PET scanning is ongoing. Clinical trial information: NCT01482377.

**11096 General Poster Session (Board #378), Sat, 1:15 PM-5:00 PM**

**Usefulness of I-[3-$^{18}$f]-$\alpha$-methyl tyrosine ($^{18}$F-FAMT) PET as therapeutic monitoring for patients with advanced lung cancer.** *Presenting Author: Kyoichi Kaira, Department of Oncology Clinical Development, Maebshi, Japan*

**Background:** L-[3-$^{18}$F]-$\alpha$-methyl tyrosine ($^{18}$F-FAMT) PET has a high specificity for detecting malignant lesions, and the high uptake of $^{18}$F-FAMT within tumor cells could be a useful marker for predicting worse outcome. However, it remains unknown whether $^{18}$F-FAMT PET has a potential of therapeutic monitoring after chemotherapy. Thus, we evaluated $^{18}$F-FAMT PET for therapy response and survival in patients with advanced lung cancer, as compared with $^{18}$F-FDG PET. **Methods:** $^{18}$F-FAMT PET and $^{18}$F-FDG PET were performed before and 4 weeks after chemotherapy in patients with untreated advanced lung cancer. Uptake of tracers was measured by standardized uptake value (SUV) in the primary tumor. The maximum SUV ($SUV_{max}$) on pre-treatment and post-treatment, and metabolic response (MR) were correlated with the survival time estimated by Kaplan-Meier method. **Results:** Of 111 enrolled patients, 95 patients eligible for post-treatment $SUV_{max}$ analyses on both $^{18}$F-FAMT PET and $^{18}$F-FDG PET. Seventy patients received systemic chemotherapy alone as first-line treatment, and 25 patients were treated with concurrent thoracic chemoradiotherapy. The histological type included 87 non-small cell lung cancers and 8 small-cell lung cancers. Post-treatment $SUV_{max}$ and MR on $^{18}$F-FAMT PET were significantly correlated with tumor response by Response evaluation criteria in solid tumor (RESCIST), but pre-treatment $SUV_{max}$ was not. In all patients (n=95), post-treatment $SUV_{max}$ on $^{18}$F-FDG and $^{18}$F-FAMT PET, and MR on $^{18}$F-FAMT PET were significant prognostic marker for predicting poor outcome by univariate analysis. Multivariate analysis confirmed that MR on $^{18}$F-FAMT PET was a significant independent prognostic factor. MR on $^{18}$F-FAMT PET was also an independent prognostic predictor in 70 patients who received chemotherapy alone. **Conclusions:** MR on $^{18}$F-FAMT PET may be a potential parameter to predict the prognosis after first-line chemotherapy in patients with advanced lung cancer.

**11097 General Poster Session (Board #379), Sat, 1:15 PM-5:00 PM**

**Copenhagen prospective personalized oncology (CoPPO): Sequencing and array-based pipeline for selection of patients to phase 1 studies.** *Presenting Author: Ida Elisabeth Viller Tuxen, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*

**Background:** Advanced genomics technology can be used to characterize genomic alterations (GA) that potentially drive tumor growth. We have established a sequencing and array based pipeline to identify GA to select patients (pts) who might benefit from novel targeted treatments and to enrich the population in Phase 1 trials with pts that harbor specific targets. **Methods:** Pts with advanced solid tumors referred to a dedicated Phase 1 Unit were offered mapping of GA to identify pts who could benefit from a personalized treatment. Two ultrasound-guided biopsies were obtained and stored in RNA*later* for DNA and RNA purification. A third biopsy for histology was paraffin embedded. SNP-array from tumor and whole exome sequencing (WES) from DNA (tumor and blood) were performed using sequence capture and Illumina sequencing to call tumor specific mutations. Expression levels of therapeutic targets were revealed by expression Array and RNA-seq from tumor RNA. Results were reviewed by a tumor board. Patients with specific genetic profiles that could be targeted with marketed drugs or drugs in development, were, if possible, offered individualized treatment. **Results:** From May 2013 to December 2013, 30 heavily pretreated patients with solid tumors were included. In 28 patients (93%) a dedicated biopsy was obtained. An actionable target was identified in 15 patients (53%) and 6 patients (21%) were offered treatment according to the findings of either mutations or RNA expression levels of oncogenes. Median time from biopsy to result was 38 days. We were able to define a hypothetic driver for tumor growth in 80% of the cases. **Conclusions:** Establishing sequencing and array-based pipeline for enrichment of pts to phase 1 trials is feasible.

**11098 General Poster Session (Board #380), Sat, 1:15 PM-5:00 PM**

**Integrative whole-genome copy number analysis and mutation profiling of FFPE brain tumor specimens and potential in designing multi-arm clinical trials.** *Presenting Author: Shakti Ramkissoon, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Multi-dimensional cancer genotyping has the potential to advance clinical diagnostics and improve results of clinical trials by identifying targetable genomic aberrations for glioblastoma (GBM). However, prospective use of formalin-fixed paraffin-embedded (FFPE) clinical samples for multiplex copy number and somatic mutation genotyping in clinical trials is not yet routinely performed. We evaluated feasibility and implemented a combined copy number and clinical research mutation-testing program (PROFILE) in a CLIA-certified laboratory. **Methods:** We collected molecular profiling results from clinical and clinical research testing on 250 GBM patients from the Brigham and Women's Hospital Center for Advanced Molecular Diagnostics. These data included array comparative genomic hybridization (OncoCopy, n=250), mass spectrometry-based mutation genotyping (OncoMap, n=86), and targeted cancer exome sequencing of 275 known cancer genes (OncoPanel, n=98). **Results:** We successfully reported OncoCopy profiles for 42 relevant loci in 97% of samples and demonstrated that analysis of 250 GBMs reliably detected amplifications or structural variations in common drug targets for clinical trials (*EGFR*, *EGFRvIII, MET*, *MDM2*, *MDM4*, *PDGFRA*, *CDK4*, and *CDK6)* at expected frequencies. OncoMap results for 86 GBMs revealed recurrent mutations in *IDH1*, *BRAF, PIK3CA,* and *PIK3R1* while less frequent mutations were detected in tumor suppressor genes *TP53*, *PTEN* and *RB1*. OncoPanel results were reported on >90% of patients and comprehensively detected known mutations of diagnostic, prognostic and therapeutic relevance (e.g. *IDH1* p.R132H, *BRAF* p.V600E). Tumor suppressor gene mutations and variants were robustly detected allowing for integrative OncoCopy and OncoPanel reporting in 65% of cases. **Conclusions:** These complementary clinical assays allowed efficient and reliable identification of diagnostic aberrations that serve as clinically actionable drug targets, which could be incorporated into genomically stratified multi-arm clinical trial design for GBM.

**11099 General Poster Session (Board #381), Sat, 1:15 PM-5:00 PM**

**Correlation of circulating miRNA levels with progression-free survival (PFS) and overall survival (OS) in early-stage lung adenocarcinoma.** *Presenting Author: Francesco Grignani, Department of Experimental Medicine, University of Perugia, Perugia, Italy*

**Background:** Surgically resected early-stage non-small lung cancer (NSCLC) display a highly variable outcome in terms of PFS and OS. Currently used clinico-pathological parameters may not precisely predict individual risk of relapse. Here, we correlated the levels of circulating miRNAs levels with PFS and OS in early stage fully resected NSCLCs. **Methods:** We analyzed the levels of the 84 most abundant circulating miRNAs (Qiagen PCR array) in sera from patients with stage IàIIIA resected NSCLC. All the sera were collected at the time of diagnosis. Total serum RNA was purified and miRNA levels were measured by real time PCR. Normalization was obtained by using a spike-in control miRNA and multiple endogenous unvariable control miRNAs. **Results:** We analyzed 94 sera, of which 44 were derived from patients who remained free of relapse for at least 2 years, while 50 sera from patients who relapsed within 2 years from the diagnosis. No significant correlation was found between miRNA levels and age, sex and smoking habits. In squamous cell lung cancer no significant correlation was found between miRNA levels and clinical outcome. Conversely, we were able to identify significant associations between the levels of a number of miRNA and PFS in samples from adenocarcinoma patients. The most significant ones were found in stage I and II patients where miR-15b levels were significantly higher in relapsed patients (p= 0.01). Also, high levels of serum miR-223 had a strong negative correlation with OS (p= 0.001). A miRNA signature could be derived which correlated with PFS with a specificity of 75% and a sensitivity of 84% (p<0.01) . The signature includes miR-15b, miR-27a, miR-106b, miR-191 and miR-223. The same miRNA signature gave similar data when OS was considered. Normalization with multiple endogenous miRNA levels was mandatory to obtain reliable statistics. **Conclusions:** The analysis of serum miRNA levels in resected early stage NSCLC seems to have limited usefulness as prognostic tool for early squamous cell carcinoma, whereas it may reliably predict clinical outcome in adenocarcinoma, with both high sensitivity and specificity. Prospective studies are warranted.

**11100 General Poster Session (Board #382), Sat, 1:15 PM-5:00 PM**

**Correlation of hypoxia measured by fluorine-18 fluoroerythronitroimidazole ($^{18}$F-FETNIM) PET/CT and the malignant progression of gliomas.** *Presenting Author: Man Hu, Shandong Cancer Hospital, Jinan, China*

**Background:** Hypoxia is important in the biology of human gliomas. PET offers a noninvasive method to differentiate individual tumor biology and modify treatment accordingly. The development of PET tracers provides further tools to evaluate the hypoxia of human tumors. The aim of this study was to determine whether hypoxia, as measured by fluorine-18 fluoroerythronitroimidazole ($^{18}$F-FETNIM) PET/CT, was associated with malignant progression of gliomas. **Methods:** Fifteen patients with suspected primary glioma and who were referred for surgical treatment were enrolled prospectively in this study. All patients had $^{18}$F-FETNIM PET/CT studies before surgery. PET/CT imaging was performed at 120 min after $^{18}$F-FETNIM injection. For semi-quantitative analysis, the maximum standardized uptake value (SUVmax) was obtained by drawing regions of interest (ROI) on the PET images for tumor tissues. Hypoxia, angiogenesis, aggression, and cellular proliferation related markers hypoxia-inducible factors-1alpha (HIF-1a), vascular endothelial growth factor (VEGF), matrix metallo proteinase 9 (MMP-9), and Ki-67 expression were estimated in tissue specimens by immunohistochemistry. **Results:** SUVmax, HIF-1a, VEGF, MMP-9, and Ki-67 expression in high-grade gliomas were significant higher than those in low-grade (2.03 ± 0.49 vs.1.04±0.37, 40.63% ± 11.16% vs. 20.71% ± 12.05%, 71.88% ± 15.57% vs. 37.86% ± 13.5%, 68.13% ± 17.92% vs. 35% ± 10.8%, and 28.13% ± 18.11% vs. 3.7% ± 1.25%, respectively. $p$ = 0.001, 0.006, 0.001, 0.001, 0.007, respectively). Furthermore, $^{18}$F-FETNIM uptake data were divided into 2 groups using the mean of SUVmax as a basis for the division. Significant differences were observed between high $^{18}$F-FETNIM uptake and low uptake in HIF-1a, MMP-9, VEGF, and Ki-67 expression ($p$= 0.004, 0.004, 0.001, 0.046, respectively). **Conclusions:** $^{18}$F-FETNIM PET/CT provides a noninvasive assessment of hypoxia in glioma. It is useful to understand the mechanisms by which hypoxia affect malignant progression of glioma. $^{18}$F-FETNIM PET/CT may have a role in evaluating novel therapeutic agent targeting tumor hypoxia in clinical trials.

**11101 General Poster Session (Board #383), Sat, 1:15 PM-5:00 PM**

**Sensitivity and specificity of an oral uracil-loading test dose for screening for DPD deficiency.** *Presenting Author: M C van Staveren, Scheper Hospital Emmen, Emmen, Netherlands*

**Background:** 5-fluorouracil (5FU) and capecitabine (CAP) are extensively metabolised by dihydropyrimidine dehydrogenase (DPD). DPD deficiency can lead to severe toxicity after 5FU or CAP. Uracil (U) can be used as a probe to determine the systemic DPD activity by measuring uracil and its metabolite dihydrouracil (DHU) in plasma. This study was performed to assess the sensitivity and specificity of an uracil loading dose for detecting DPD deficiency. **Methods:** All cancer patients who suffered from CTC grade III or IV toxicity after the first or second cycle of 5-FU or CAP-based treatment were asked to participate. Uracil 500 mg/m$^2$ was administered orally followed by multiple blood sampling, plasma concentrations of U and DHU in plasma were determined. DPD activity in PBMCs was determined and patients were divided in 2 groups: DPD activity in PBMCs $<$ 5 nmol/mg/hour (deficient group) and with activity $\geq$ 5 (normal group, controls: 9.9 ± 2.8 nmol/mg/hour). In the deficient group, PCR amplification of all 23 coding exons and flanking intronic regions of DPYD was performed. Plasma concentrations of U and DHU were determined by HPLC. A one-compartment uracil pharmacokinetics model was developed and used to determine $V_{max}$ of the DPD enzyme of each patient. Sensitivity and specificity of $V_{max,}$ U concentration and the U/DHU concentration ratio were determined using ROC analysis. **Results:** 47 patients were included (19 DPD deficient, 28 DPD normal). Sensitivity and specificity of the estimated pharmacokinetic parameters are displayed in the Table. PCR amplification in the DPD deficient group revealed the following pathogenic mutations: c.1129-5923C>G (n=4), c.2579delA (n=2), c.2846A>T (n=3), c.1905+1G>A (n=10), c.1679T>G (n=1). **Conclusions:** The sensitivity of 80% and specificity of 98% of the U/DHU ratio at t=120 min show that the oral uracil loading dose can effectively monitor DPD activity and can be used as a pre-emptive tool to identify patients with reduced DPD activity.

**Sensitivity, specificity, and cut-off levels for Vmax, U/DHU, and uracil concentration.**

| Test parameter | Cut-off level | Sensitivity (%) | Specificity (%) |
|---|---|---|---|
| Vmax (mg/h/1,85m$^2$) | 665 | 79 | 79 |
| U/DHU$_{120min}$ ratio | 2.4 | 80 | 98 |
| U$_{120\ min}$ (mg/l) | 6.4 | 80 | 96 |

**11102 General Poster Session (Board #384), Sat, 1:15 PM-5:00 PM**

**ImmunoPET imaging with $^{89}$Zr-cetuximab in patients with advanced colorectal cancer.** *Presenting Author: Catharina Wilhelmina Menke, Department of Medical Oncology, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Inhibition of epidermal growth factor receptor (EGFR) with cetuximab is part of treatment for patients with wild type (wt) KRAS advanced colorectal cancer (mCRC). Sixty percent of these patients do not benefit from cetuximab treatment. Potential causes include mutations in the EGF signaling cascade or other RAS mutations. Alternatively, pharmacokinetic factors like sequestration of cetuximab in organs with high EGFR expression such as liver could lead to sub-therapeutic intratumoral drug levels. We performed an exploratory study to evaluate biodistribution and tumor uptake using Positron Emission Tomography (PET) with $^{89}$Zr labeled cetuximab in patients with wt KRAS mCRC. **Methods:** Eight patients with wt KRAS mCRC who were candidate for cetuximab monotherapy, received 37 ± 1 MBq $^{89}$Zr - cetuximab immediately after the first therapeutic dose of cetuximab. Serial whole body PET was performed from one hour to 10 days post injection (p.i.). Non-hepatic tumor lesions were visually assessed as positive or negative for uptake and quantified by Standard Uptake Value (SUV). Tumor response was analyzed every 8 weeks according to RECIST 1.1. **Results:** Sequential PET showed in 4 of 8 patients accumulation of cetuximab over time in non-hepatic tumor lesions. Visual tumor assessment was optimal with PET images acquired on day 6 p.i. with tumor $SUV_{peak}$ ranging from 2.3 to 7.5. Organ biodistribution was reproducible between patients, $SUV_{mean}$(CoV) levels observed were 7.8 (24) for liver, 2.2 (26) for the kidneys, 1 (44) for lung and 1.8 (34) for spleen. As expected, analysis of hepatic metastases was hampered due to high background activity in the liver. In two of 4 patients with cetuximab uptake clinical benefit was observed compared to progressive disease in 3 of 4 patients without uptake. EGFR-expression and RAS/BRAF mutation analyses on archival tumor material will be presented. **Conclusions:** PET-imaging with $^{89}$Zr-cetuximab is feasible and differential tumor uptake can be demonstrated. Further investigations are needed to determine whether the correlation between tumor uptake and the effect of dose escalation of cetuximab on tumor response in patients with wt RAS-mCRC can be used as an individualized treatment approach. Clinical trial information: NCT01691391.

**11103 General Poster Session (Board #385), Sat, 1:15 PM-5:00 PM**

**Preclinical evaluation of anti-MET antibodies for immunohistochemical staining.** *Presenting Author: Hartmut Koeppen, Genentech, Inc., South San Francisco, CA*

**Background:** The monovalent anti-MET antibody onartuzumab in combination with erlotinib showed clinical benefit in a phase II trial in advanced non-small cell lung cancer (NSCLC); this benefit was limited to MET-positive tumors as determined by immunohistochemistry (IHC) using the CONFIRM anti-total MET rabbit monoclonal antibody (Ventana). The trial results demonstrate the importance of a reliable IHC assay to distinguish MET-positive from MET-negative cancers. Therefore, it is important to gain a pre-clinical understanding of available antibodies that may warrant further investigation. The aim of this study was to evaluate nine anti-MET antibodies for sensitivity and specificity using various standard staining conditions. **Methods:** All antibodies were evaluated on eight formalin-fixed paraffin-embedded (FFPE) cell lines with known RNA and protein (ELISA) MET expression levels. Antibodies with adequate sensitivity and specificity were then analyzed on a NSCLC tissue microarray (TMA) and on whole sections of NSCLC and gastric adenocarcinoma (GAC) of known MET status. The antibody evaluation included four autostainers (Ventana Benchmark XT, Leica BOND-III, Dako Autostainer Plus and Dako Omnis), 14 antigen retrieval (AR) methods and 7 detection methods. **Results:** The SP44 and D1C2 antibodies showed staining on cell lines, NSCLC TMA, and large sections of NSCLC and GAC of adequate sensitivity and specificity when used under the following conditions: (1) Ventana Benchmark XT with CC1 standard and CC1 extended AR, (2) Leica BOND-III with ER2 AR, (3)DAKO Autostainer with EnVision FLEX Target High pH AR. All other antibodies and AR/detection methodologies showed inferior staining characteristics due to insufficient sensitivity and/or specificity. **Conclusions:** SP44 and D1C2 showed staining performance similar in sensitivity and specificity to the CONFIRM anti-Total MET antibody. Additional validation on larger cohorts of clinically annotated tissues is required prior to any clinical application.

**11104 General Poster Session (Board #386), Sat, 1:15 PM-5:00 PM**

**The NIH genetic testing registry: Hereditary, pharmacogenetic, and somatic tests for oncology practice.** *Presenting Author: Wendy S. Rubinstein, National Institutes of Health, Bethesda, MD*

**Background:** Oncology professionals need to access and gauge information about tests for hereditary cancer predisposition, biomarkers, pharmacogenetic dosing and risk-based chemoprevention. NIH has created the Genetic Testing Registry (GTR; http://www.ncbi.nlm.nih.gov/gtr/), a freely available, web-based resource to enable centralized access to comprehensive information about genetic tests and improve transparency. **Methods:** GTR was implemented by the National Center for Biotechnology Information (NCBI) with oversight by the NIH Office of the Director, extensive input from diverse stakeholders, and ongoing consultation with two advisory committees and other Federal agencies. Data are voluntarily submitted by laboratory providers (e.g., indications, methods, targets, FDA review status, CPT molecular pathology codes) and supplemented by NCBI (e.g., practice guidelines and informative web links to molecular, literature and other resources). **Results:** As of February 2014, GTR has 13,878 registered tests for 4,051 conditions offered by 395 labs from 39 countries. Next-generation sequencing (NGS), a component of 10% of molecular tests, is used in 113 tests to evaluate hereditary cancer syndromes, the largest a 107-gene panel. BRCA1 gene testing is a component of 32 clinical tests offered by 11 U.S. labs. Somatic test submission was enabled in late 2013; new test purposes include predictive, prognostic, recurrence, and therapeutic management. Registered tests include several targets used to guide treatment such as BRAF, BCR/ABL1, FLT3, KRAS, JAK2 and complex cytogenetic panels. GTR has 64 pharmacogenetic tests for 18 genetically influenced drug responses (e.g., tamoxifen, irinotecan, thioguanine, fluorouracil). Algorithm-based tests that employ variants discovered in genome-wide association studies to inform chemoprevention decisions are also in scope. **Conclusions:** GTR reflects trends in the genetic testing landscape such as the clinical use of NGS and the immediate effect of the U.S. Supreme Court patent ruling on the availability of BRCA testing. Growing participation in GTR by oncology test providers and clinicians will improve the utility of this resource to the community.

**11105 General Poster Session (Board #387), Sat, 1:15 PM-5:00 PM**

**Incorporation of FGFR1 and FGFR2 amplification status determination in routine molecular prescreening for targeted therapies.** *Presenting Author: Ludmila Prudkin, Molecular Pathology Laboratory, Vall d'Hebron Institute of Oncology, Barcelona, Spain*

**Background:** Enriching PhI trials with patients harboring alteration in the FGFR pathway is key to the successful development of FGFR pathway inhibitors. FGFR1 and 2 amplification (amp) are considered a driver event in many carcinomas. **Methods:** ISO-accredited FGFR1 and 2 FISH assays were run in samples from candidates to enter a PhI clinical study. FGFR amp status was defined as a ratio gene/centromere ≥2.2. FGFRs status was correlated with available PTEN expression (IHC) and mutations data (AKT, KRAS, BRAF, PIK3CA, among others). **Results:** From January 2012 we screened 272 samples for FGFR1 and 190 for FGFR2. Samples came from primary tumors in 196 cases (PT=71.8%), and 141 (PT=74.2%); and metastatic disease in 61 cases (MET=22.3%), and 41 (21.6%) for FGFR1 and FGFR2, respectively. Rest of cases was of unknown (UKN) origin. Overall, FGFR1 gene amp was observed in 11% and FGFR2 in 3% of cases with amplification rates similar between PT and MET. After subgrouping by tumor origin, FGFR1 ampl was most frequently observed in breast cancer (19%) followed by lung cancer (8%). FGFR2 was amplified in 5% of gastric and gynecological cancers, followed by breast cancer (2.5%). No associations were observed with FGFR1 and 2 amplifications and PTEN loss. Mutation results were available in 141 and 122 samples with FGFR1 and 2 amp data, respectively. Only one point mutation in AKT and one in PIK3CA genes were observed in FGFR1 amplified samples, while none in FGFR2 amplified cases. **Conclusions:** Incorporation of FGFRs gene amp status in a routine molecular prescreening is feasible and may provide clinicians with a tool to select patients to targeted therapies.

**FGFR1**

| Organ | PT (n.) | MET (n.) | PT FGFR1 ampl | MET FGFR1 ampl |
|---|---|---|---|---|
| Breast | 86 | 30 | 15 (17,5%) | 7 (23.3%) |
| Lung and pleura | 30 | 6 | 2 (6,7%) | 1 (16,6%) |
| Gyn | 23 | 1 | 1 (4.3%) | 0 |
| Stomach | 28 | 3 | 1 (3,6%) | 0 |
| Others / unknown* | 29 | 21 | 1 (3.5%) | 0 |
| FGFR1 | 196 | 61 | 20 (10,2%) | 8 (13,1%) |

**FGFR2**

| Organ | PT (n.) | MET (n.) | PT FGFR2 ampl | MET FGFR2 ampl |
|---|---|---|---|---|
| Breast | 60 | 21 | 1 (1.7%) | 1 (4,7%) |
| Lung and pleura | 2 | 3 | 0 | 0 |
| Gyn | 20 | 1 | 1 (5%) | 0 |

**11106 General Poster Session (Board #388), Sat, 1:15 PM-5:00 PM**

**Identification of a rare germ-line variant in the *TP53* 3'UTR in individuals with the Li-Fraumeni-like phenotype: A new mechanism of cancer predisposition?** *Presenting Author: Gabriel de Souza Macedo, Universidade Federal do Rio Grande do Sul/ Hospital de Clínicas de Porto Alegre/CPE-Laboratório de Medicina Genômica, Porto Alegre, Brazil*

**Background:** Li-Fraumeni Syndrome (LFS) and Li-Fraumeni-like Syndrome (LFL), are inherited disorders characterized by increased predisposition to multiple early-onset cancers and are associated to *TP53* germline mutations. The rs78378222 (A>C) SNP, a rare variant located within the polyadenylation signal of *TP53*, was recently identified in a GWAS. It occurs at a frequency = 0.019 in Icelandic population and leads to impaired 3'-end processing of mRNA, conferring susceptibility to certain types of cancer. **Methods:** Considering that regulatory gene regions has not been considered in the *TP53* molecular diagnostic, the purpose of this study was to assess the allelic frequency of this variant in a patients group composed by LFS/LFL families with (n=57) and without (n=131) *TP53* germline mutation. To support the association, we also studied the evolutionary conservation of the *TP53* polyadenylation signal in vertebrate species and the p53 immunohisthochemical pattern in tumors from carriers of different *TP53* mutations. **Results:** The heterozygous genotype to rs78378222[C] was found in 7 patients fulfilling LFL criteria who tested negative for coding germline *TP53* mutations. In the group of patients with coding region *TP53* germline mutations we did not encounter rs78378222 [C] carriers. We also investigated the *TP53* sequence at the polyadenylation signal of 63 therian mammals. None of these organisms presented any variation in the locus of the variant, evidencing strong evolutionary conservation. Finally, we assessed p53 expression by immunohistochemistry in tumors of carriers of known germline pathogenic *TP53*mutations and of the 3´UTR variant. In the first group we observed intense nuclear accumulation of p53 and in the second weak and a focal p53 immunostaining was identified. **Conclusions:** This is the first description of rs78378222[C] in LFL families, and our findings suggest a new carcinogenesis mechanism associated to this variant. However, further functional characterization studies and analysis of larger series of families with the LFS/LFL phenotype should be undertaken to confirm the s78378222[C] as a pathogenic variant associated with this disorder.

**11107 General Poster Session (Board #389), Sat, 1:15 PM-5:00 PM**

**Subtype analysis from the GEICAM/2003-02 study: High-risk, node-negative breast cancer patients treated with adjuvant fluorouracil, doxorubicin, and cyclophosphamide (FAC) versus FAC followed by weekly paclitaxel.** *Presenting Author: Federico Rojo, Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain*

**Background:** Adding taxanes to standard anthracycline-based adjuvant therapy improves survival outcome in node-negative breast cancer (BC) patients (pts) with high risk of recurrence. Due to the small magnitude of the benefit and to avoid toxicity, biomarker analyses aimed to identify subpopulations benefiting the most from taxanes are warranted. **Methods:** After surgery, 1,925 node-negative BC pts with at least one high-risk factor for recurrence (St. Gallen 1998 criteria) were randomly assigned to receive 6 FAC cycles or 4 FAC cycles followed by 8 weekly paclitaxel doses (FAC-wP); 108 out of the 181 HER2+ pts did not receive trastuzumab. With a median follow-up of 63.3 months, 93% and 90.3% of pts receiving FAC-wP or FAC, respectively, remained disease free (hazard ratio [HR]: 0.73; 95% CI: 0.54-0.99; log-rank p= 0.04; Martin JCO 2013). We performed central immunohistochemistry (IHC) for ER, PR, Ki-67 and HER2/FISH; pts were grouped in intrinsic BC subtypes according to the Prat et al. classification (JCO 2012): Luminal A: RE+, PR>20%, HER2-, Ki67<14%; Luminal B1: RE+, HER2-, PR≤20% and/or Ki67≥14%; Luminal B2: RE+, PR+/-, HER2+; HER2: RE-, PR-, HER2+; TN: RE-, PR-, HER2-. We report here the correlation between these variables and Distant Metastases-Free Survival (DMFS). Cox regression and log-rank test were used for analysis. **Results:** Central biomarker expression and subtype classification is currently available for 1,084 and 946 pts, respectively. DMFS in the 1,084 pts were 97.8% vs 94.8% (HR: 0.52; 95% CI: 0.28-0.97; p=0.035). In the univariate analysis, FAC-wP therapy, ER and PR positive status, low Ki67 proliferation and Luminal A and B1 subtypes were significantly associated with better DMFS. Absence of PR and Luminal B1 were predictive for FAC-wP benefit. The multivariate analysis showed that intrinsic subtype classification was predictive of DMFS (p=0.010). **Conclusions:** Our study suggests that IHC-based intrinsic subtypes provide prognostic value and could identify a subpopulation of node-negative BC pts (the luminal B1) who obtains more benefit from FAC-wP adjuvant therapy.

**11108 General Poster Session (Board #390), Sat, 1:15 PM-5:00 PM**

**Development of a histology-guided gene expression tumor classifier for cancer of unknown primary (CUP).** *Presenting Author: Linda R. Mileshkin, Peter MacCallum Cancer Center, Melbourne, Australia*

**Background:** Accurate identification of the primary tumor in cases of cancer of unknown primary (CUP) is required for effective treatment selection and improved patient outcomes. Here we present the development and clinical validation of a histology-guided gene expression classifier. **Methods:** RNA from 450 formalin-fixed paraffin embedded tissue samples of known origin comprising 18 tumor groups were used to train and develop the classifier. Whole-genome expression data was collected from each sample using Illumina DASL bead-based arrays. A hierarchical tumor classifier utilizing both conventional histopathology and gene expression data was developed using a binary support vector machine, together with recursive feature elimination. The classifier was then validated on an independent cohort of 94 tumors of known origin and 58 CUP samples. **Results:** Based on the validation set of tumors, the classifier demonstrated an accuracy of 89% for the highest predicted tumor class, increasing to 98% for the correct prediction within the two highest similarity scores. When applied to CUP samples having a presumed final clinical diagnosis of a primary site six months following gene expression analysis (n=49), the classifier was found to improve the accuracy of histology alone from 33% to 78% for a single prediction and from 73% to 90% within the two highest predicted tumor class scores. **Conclusions:** This study demonstrates that combining gene expression data and conventional histopathology improves the accuracy of determining the primary site of origin in cases of CUP.

**11109 General Poster Session (Board #391), Sat, 1:15 PM-5:00 PM**

**Effect of clinical NGS-based cancer genomic profiling on physician treatment decisions in advanced solid tumors.** *Presenting Author: Fadi S. Braiteh, Comprehensive Cancer Centers of Nevada, Las Vegas, NV, and US Oncology Research, Houston, TX*

**Background:** Next generation sequencing (NGS) of routinely fixed tissue from pts with advanced solid tumors may inform treatment planning. Foundation Medicine has developed a CLIA-certified, CAP-accredited test (FoundationOne, F1) to simultaneously characterize all 4 classes of genomic alterations in 236 (originally 182) cancer genes. Primary study objective was to determine how many physicians would change treatment approach based on F1 results (switch rate=SR). An exploratory objective was to compare PFS impact of any switches. **Methods:** This was a prospective, multicenter, single-arm trial in pts with refractory metastatic solid tumors of any type. Eligible pts must have been receiving second- or third-line therapy (first-line for pancreatic) and were initially registered within 10 weeks of beginning a regimen and before response assessment reimaging. Tumors were assayed with F1 after initial registration. Upon progression and documentation of next proposed therapy, they were re-registered and results of F1 were provided to doctors. If F1 caused a change in proposed therapy, a switch was recorded. **Results:** 233 pts were eligible; 103 were not re-registered (pt died, investigator decision, withdrew consent). Two questionnaires were missing; 128 pts were included in this analysis. Median age 61 yrs; female (65.6%). Tumor types mainly included breast (20%), lung (16%), and colon (13%). The SR was 28.1% (36 switch, 92 no switch). For 95 treated pts, the SR was 27.4% (26 received switch drug, 69 received initial recommendation; [33 pts did not receive Rx due to PD, death, hospice, or pt decision]). All of the major tumor types above had switch rates above 20%. In 77% of nonswitch cases, physicians reported that there were "not enough" treatment options available. Data collection for PFS analysis and correlation of results to tumor genomic profiles are ongoing. **Conclusions:** Comprehensive NGS-based profiling resulted in altered therapeutic choice in 28% of advanced solid tumor patients in the community setting, highlighting the current broad applicability of this approach. As more targeted therapeutics advance to larger trials and become approved, the impact of comprehensive testing may be expected to increase.

**11110 General Poster Session (Board #392), Sat, 1:15 PM-5:00 PM**

**PET/CT assessment of tumor perfusion in metastatic renal cell carcinoma (RCC) before and during sunitinib: A comparison of $^{15}$O-water with $^{62}$Cu-ETS.** *Presenting Author: Theodore F. Logan, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

**Background:** RCC is a vascular cancer treated with antiangiogenic agents. Tumor perfusion (TP) can be measured by PET using $^{15}$O-water ($H_2{}^{15}O$), but its short physical half-life limits use to PET centers with a cyclotron. We studied a new "microsphere-like" perfusion agent with 9.7 min half-life, $^{62}$Cu-ETS, in RCC patients before and during sunitinib. As a generator-based agent, the kit-formulated $^{62}$Cu-ETS can be made available to virtually any PET camera from a central manufacturing site. And, since the $^{62}$Cu label is trapped after perfusion-rate-limited delivery, PET/CT whole-body imaging is possible, allowing evaluation of both primary tumor and distant metastases. **Methods:** Consented RCC patients were entered on this IRB approved protocol. PET/CT imaging was performed in 14 RCC patients with $H_2{}^{15}O$ and $^{62}$Cu-ETS, both before and during week 3-4 of Sunitinib (50mg/day X 4 wks on/2 wks off). PET/CT was performed after i.v. $H_2{}^{15}O$ (10-minute list mode), followed 10-minutes later by i.v. $^{62}$Cu-ETS, with the heart and at least one tumor in the PET field-of-view (6-min list mode). Whole body scan (WBS) of the $^{62}$Cu-ETS was then carried out from 6-20 min using 2-3 min/bed. Proportional Technologies, Inc. provided the $^{62}$Zn/$^{62}$Cu-generators, and kits for $^{62}$Cu-ETS preparation (IND #75,018). Blood flow ($k_1$) was quantified for both normal and malignant tissues in a 21.7 cm dynamic FOV. Arterial input functions were derived from the left atrium. **Results:** Paired $k_1$ data were available for 14 metastatic lesions before and post Rx. The average pre-Rx TP was similar with both $H_2{}^{15}O$ and $^{62}$Cu-ETS, (0.97 $\pm$ 0.51 and 0.97 $\pm$ 0.40 ml/min/g, respectively). The average TP for the two agents dropped significantly during Rx to 0.51 $\pm$ 0.35 and 0.56 $\pm$ 0.32 ml/min/g, p=0.010 and 0.0002 by paired T-tests. The correlation ($r^2$) between the $k_1$ values of both agents for normal and tumor tissues was 0.87 (y=0.88x+0.13). **Conclusions:** TP ($k_1$) measured by $H_2{}^{15}O$ and $^{62}$Cu-ETS using PET/CT in RCC was highly correlated. Sunitinib significantly decreases TP in metastatic RCC. $^{62}$Cu-ETS appears to be an excellent agent for the assessment in TP in RCC patients. Clinical trial information: NCI-2012-00051.

**11111 General Poster Session (Board #393), Sat, 1:15 PM-5:00 PM**

**First-in-human phase I study of a selective c-Met inhibitor volitinib (HMP504/AZD6094) in patients with advanced solid tumors.** *Presenting Author: Hui Kong Gan, Austin Health, Heidelberg, Australia*

**Background:** Volitinib is a selective oral small molecule inhibitor of cMet kinase with potent in vivo inhibitory effects on a variety of human tumor xenografts. **Methods:** This phase I, first-in-human dose-escalation study was conducted to determine the maximum tolerated dose (MTD), dose-limiting toxicities (DLTs), pharmacokinetics (PK) profile, and preliminary antitumor activity of volitinib. **Results:** By Dec 31, 2013, 32 patients (pts) had been enrolled and treated with volitinib at doses of 100-1000mg QD or 300-400mg BID. Pts had a median age of 61 (27-78) yrs, 66% were male. The most common tumor types were papillary renal cell carcinoma (PRCC, 6) and CRC (5). The most common adverse events were constipation, diarrhea, fatigue, nausea, vomiting, dizziness and peripheral edema, mostly grade (G) 1/2. Four pts reported 5 DLTs: 1 G3 elevated ALT (600mg QD), 1 G3 fatigue (800mg QD), and 2 G3 fatigues and 1 G3 headache (1000mg QD). 800mg was identified as MTD of the QD regimen. Dose-escalation in the BID cohort is currently ongoing at 400mg BID. PK analysis showed volitinib was rapidly absorbed with Tmax around 2 hours and half-life around 5 hours. Both Cmax and AUC displayed dose-proportional increase and no obvious accumulation occurred. Two PRCC pts in the 600mg QD cohort (one with ongoing treatment at 1 year) and 1 PRCC pt in the 300mg BID cohort achieved partial response. A CRC pt in the 600mg QD cohort achieved 29% tumor reduction. A PRCC pt in the 1000mg QD cohort achieved 27% tumor reduction and remains on study. Analysis of pre-treatment tumor sample showed that the responders had either gene copy number increase (Chromosome7 gains or MET gene amplification) or high MET protein expression. **Conclusions:** Volitinib was well tolerated at doses up to 800 mg QD and demonstrated promising anti-tumor activity in pts with evidence of dysregulated MET signaling. It demonstrated linear PK without marked drug accumulation. Further clinical studies are warranted. Clinical trial information: NCT01773018.

**11112 General Poster Session (Board #394), Sat, 1:15 PM-5:00 PM**

**Effect of adoptive T-cell therapy and intratumoral heat-killed bacteria on large tumors.** *Presenting Author: David C. Binder, The University of Chicago, Chicago, IL*

**Background:** Preventing tumor relapse as antigen-loss variants remains a challenge in T cell therapy. T cells eradicate tumors by secreting cytokines that mediate bystander killing of tumor stromal cells and antigen-negative cancer cells. However, when tumors express a lower "natural" level of antigen, T cells are unable to eradicate tumors due to insufficient antigen cross-presentation. We recently published that vaccination with live antigen-bearing bacteria can rescue T cell function in long-established tumors. Here, we studied the use of heat-killed (HK) bacteria to enhance adoptive T cell therapy. **Methods:** MC57 fibrosarcoma cancer cells expressing a low level of the SIYRYYGL (SIY) peptide were injected into OT-1 mice. Tumors were long-established (>14 days and >250 $mm^3$) prior to treatment with adoptively-transferred SIY-specific 2C T cells and/or intratumorally-injected HK *Salmonella* Typhimurium A1-R. Tumor stroma viability and composition were analyzed by flow cytometry. Cytokine analysis was conducted by cytometric bead array. **Results:** All tumors treated with only T cells or HK bacteria relapsed (antigen-loss variants were found in T cell-treated tumors). However, T cells and HK bacteria combined to eradicate tumors in 83% of mice, with eradication requiring cognate antigen recognition by T cells. HK bacteria alone induced tumor microenvironment changes by 1 day post-treatment including: (i) macrophage death, (ii) monocytes replaced by neutrophils, and (iii) higher levels of IFN-g, TNF-a, IL-6, and IL-10. **Conclusions:** HK bacteria synergize with T cells, allowing them to eradicate large tumors expressing a low level of antigen. By increasing release of pro-inflammatory cytokines into the tumor stroma and inducing macrophage death, HK bacteria likely make the tumor microenvironment more conducive for T cell-mediated destruction. These data support the idea that the addition of HK bacteria to adoptive T cell therapy protocols can lead to successful eradication of cancers expressing mutated antigens at a low level.

**11113 General Poster Session (Board #395), Sat, 1:15 PM-5:00 PM**

**First-in-human phase 1 dose-escalation study of AV-203, a monoclonal antibody against ERBB3, in patients with metastatic or advanced solid tumors.** *Presenting Author: John Sarantopoulos, Institute for Drug Development, Cancer Therapy and Research Center, University of Texas Health Science Center San Antonio, San Antonio, TX*

**Background:** AV-203 is an IgG1k humanized monoclonal antibody with high affinity and specificity for the anti-v-erb-b2 erythroblastic leukemia viral oncogene homolog 3 (ERBB3) receptor. Based on promising preclinical activity and resistance prevention data, a phase 1 study was conducted (NCT01603979). **Methods:** A phase 1 study using a 3+3 dose-escalation design evaluated the safety, tolerability, recommended phase 2 dose (RP2D), pharmacokinetics (PK) and pharmacodynamics of AV-203. AV-203 was given IV at 2, 5, 9, 14 or 20 mg/kg once every 2 wks (1 cycle = 28 days, 2 doses per cycle). Included patients (pts) had advanced solid tumors and progressed on standard therapies or had no proven treatment options. **Results:** AV-203 was administered to 22 pts (15M/7F; median age 68 y, range 31-82; ECOG PS 0/1: 8/13). Enrolled tumor types included colorectal (4), non–small-cell lung (NSCLC; 4), squamous cell carcinoma of the head and neck (2) and other solid tumors (12). There was a single dose-limiting toxicity of inability to tolerate the study drug (serious Grade 3 diarrhea and multiple concurrent adverse events [AEs]) at 2 mg/kg in an 80-y-old pt. The maximum administered dose of 20 mg/kg was well tolerated. All grade AEs observed in ≥25% of pts were: diarrhea (68%); decreased appetite (41%); hypokalemia, dry skin and hypomagnesemia (36% each); headache, dehydration, dizziness and dyspnea (27% each). Grade 3 and 4 AEs of anemia, diarrhea and hypokalemia occurred in ≥2 pts. The most common treatment-related AEs were diarrhea (59%), dry skin and decreased appetite (32% each), hypomagnesemia (27%) and pruritus (23%). No deaths were attributed to AV-203. Preliminary data show approximately dose proportional PK and no detection of anti-drug antibodies. Median time on treatment for all pts was 43 days (range: 1-491), with 15 pts discontinuing due to progressive disease during this time. There was one confirmed partial response (PR; 6 cycles) in a pt with squamous NSCLC which expressed high levels of neuregulin 1. **Conclusions:** AV-203 was well tolerated in the dose range tested; RP2D is 20 mg/kg IV every 2 wks. The PR in a pt with squamous cell NSCLC warrants further testing of AV-203 in this indication. Clinical trial information: NCT01603979.

**11115 General Poster Session (Board #397), Sat, 1:15 PM-5:00 PM**

**Clinical next-generation sequencing to identify actionable alterations in a phase I program.** *Presenting Author: Genevieve Marie Boland, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Due to affordable high-throughput technologies Clinical Laboratory Improvement Amendments (CLIA)-certified next-generation sequencing platforms for genomic characterization have emerged. Given the expansion of molecularly-targeted therapeutics, there is a huge opportunity to use genomic testing for patient selection in clinical trials. We sought to determine the frequency of alterations across tumor histologies in patients with advanced cancer using a deep sequencing approach to assess for mutations in hotspot regions of 46 cancer-related genes. **Methods:** We examined data from the first 500 patients with advanced cancer prospectively enrolled on an IRB-approved protocol through the Department of Investigational Cancer Therapeutics at MD Anderson Cancer Center. Archival tumor DNA was tested for hotspot mutations in 46 genes (Ampli-Seq Cancer Panel) using an Ion Torrent PGM Sequencer (Life Technologies, CA) at the clinical molecular diagnostics laboratory. The data were analyzed using R Statistical Software (R Foundation for Statistical Computing, Vienna, Austria). **Results:** Patients with 38 tumor types were enrolled. Of 500 patients analyzed, 293 had at least one detectable mutation. The most commonly mutated genes were *TP53* (38%), *KRAS* (11%), and *PIK3CA* (10%). Of tumor types tested (n ≥ 10), sarcoma (20%) and kidney (30%) had the fewest alterations, while pancreas (100%), colon (91%) and melanoma (87%) had the highest proportion. 46 patients had both primary tumors and metastases analyzed; of mutations seen in primaries or metastases, 91% were seen in both. Across all samples, there was a strong pattern of mutual exclusivity between *TP53* mutations and *PIK3CA* mutations. Alterations in potentially actionable genes were detected in 291 (58%) patients. Both rare mutations in common tumor types and potentially actionable (directly/indirectly druggable) mutations in rare tumor types were identified. **Conclusions:** Implementation of multiplex testing in the CLIA environment facilitates genomic characterization across multiple tumor types to identify novel opportunities for genotype-driven trials. Matching patients to molecularly targeted therapies is underway.

**11116 General Poster Session (Board #398), Sat, 1:15 PM-5:00 PM**

**A chemogenomic screening platform for identification of protein kinase CK2 as a novel target for prosenescence therapy in PTEN-null tumors.** *Presenting Author: Madhuri Kalathur, Institute of Oncology Research (IOSI), Bellinzona, Switzerland*

**Background:** *Pten* loss-induced cellular senescence (PICS) is characterized by the absence of hyper-replication, as well as lack of DNA damage response. Therapeutic enhancement of cellular senescence in tumors triggers an irreversible cell growth arrest and activation of a tumor immune response that can be used for cancer therapy. Currently, there are only a limited number of targeted therapies that act by increasing senescence in cancers but these therapies are not selective for cancer cells. **Methods:** We developed a combined chemical and shRNA screening platform to identify compounds that selectively enhance senescence in Pten deficient cells without affecting normal cells. By using this approach, we identified several Casein Kinase II (CK2) inhibitors as highly effective and selective pro-senescence compounds in Pten null cells and tumors. **Results:** We have identified CK2 inhibitors through our chemogenomic platform and furthur validated using shRNA kinase library. These compounds have enhanced the cellular senescence in Pten deficient cells. Mechanistically, we find that CK2 mRNA and protein levels are strongly up regulated in *Pten* null cells and PML is downregulated. Interestingly, CK2 transcription depends on the activation of signal transducer and activator of transcription 3, STAT3 that is highly phosphorylated in *Pten* null tumors. Treatment of *Pten* null prostate tumors with CK2 inhibitors has lead to the stabilization of PML thereby restoring its tumor suppressor activity; which then prompts more cells to enter senescence leading to tumor regression. **Conclusions:** Using our novel platform technologies we have discovered better pro-senescence compounds and systematically validating them *in vitro* and in *vivo.* We disocvered the possible mechanism behind the target based selective enhancement of senescence in *Pten* loss prostate cancer. These present findings for the first time showcase the proof-of-concept for the pro-senescence therapy.

**11117 General Poster Session (Board #399), Sat, 1:15 PM-5:00 PM**

**Frequency of concurrent gene mutations and copy number alterations in circulating cell-free DNA (cfDNA) from refractory metastatic CRC patients.** *Presenting Author: M. Pia Morelli, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** cfDNA allows non-invasive assessment of gene mutations, but has not been reported with copy number alterations. Methodologies to integrate mutation and copy number would allow improved insights into mechanisms of resistance and therapeutic opportunities. **Methods:** cfDNA extracted from metastatic CRC patient (pt) plasma samples were analyzed by GUARDANT sequencing technology for mutation and amplification of 54 genes. The lower limit of detection was 0.1% mutant alleles in a wild-type background. All patients were enrolled in the ATTACC program for mCRC patients who progressed on standard treatment, and had sequencing of the primary tumor performed for a 46-gene panel. **Results:** 71 pt plasma samples were analyzed. All pts were refractory to 5-FU-based therapy, with 49 pts previously treated with anti-EGFR monoclonal antibodies (mAbs). In patients treated with EGFR mAbs, 30% of pts (n=15) had detection of KRAS mutations not detectable in the primary tumor, compared to 5% (n=1) of pts without EGFR mAb treatment (odds ratio 8.6, P=0.027). In 6 of the 15 cases, newly detectable KRAS mutations were associated with KRAS gene amplification, compared to 0 of 16 cases with KRAS mutations detected in the primary tumor (P=0.007). 7 ectodomain mutations in EGFR that may alter binding affinity of EGFR mAbs were detected in EGFR mAb treated patients, including S492R (n=4) and three previously unreported mutations G465V, I491R, K467I; concurrent EGFR amplifications were present in 6 of the 7 cases. 14% of EGFR mAbs treated patients developed detectable MET amplifications, which co-existed with KRAS or EGFR mutations in 4 of the 7 cases. Amplifications in EGFR, BRAF, MYC, and SMO were detected in the plasma in 23%, 11%, 11%, and 4% of cases, respectively, representing rates higher than reported in untreated primary tumors. **Conclusions:** Advances in sequencing and bioinformatics allow detection of copy number alternations from cfDNA in plasma. Copy number alterations in treatment refractory mCRC are more common than previously described, and frequently co-exist with mutations after EGFR mAb treatment.

**11118 General Poster Session (Board #400), Sat, 1:15 PM-5:00 PM**

**Clinical significance of CD169-positive lymph node macrophages in human malignant tumors.** *Presenting Author: Koji Ohnishi, Department of Cell Pathology, Graduate School of Medical Sciences, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan*

**Background:** CD169 (sialoadhesin) is a sialic acid receptor that is expressed on specific macrophages such as lymph node sinus macrophages. Animal studies have suggested that $CD169^+$ macrophages have tumor-preventing activities, however, the role of these cells in human diseases has not been clarified. **Methods:** To examine the role of CD169 in anti-tumor immunity, we examined the expression of CD169 in regional lymph nodes (RLNs) and their relations with overall survival and clinicopathological factors in colorectal carcinoma (83 cases), melanoma (93 cases) and endometrial carcinoma (77 cases) by immunohistochemistry. To clarify the mechanism of CD169 expression in human macrophages, culture experiments were performed. **Results:** High density of $CD169^+$ cells was significantly associated with longer overall survival in these tumors ($p = 0.009$, $p = 0.001$ or $p = 0.007$, respectively). In colorectal carcinoma and melanoma, multivariate analysis showed that the density of $CD169^+$ cells was an independent prognostic factor. We also found that the density of $CD169^+$ macrophage was positively correlated with the number of $CD8^+$ cytotoxic T cells infiltrating into tumor tissues. The majority of $CD169^+$ macrophages were in direct contact with $CD8^+$ T cells expressing CD43, a major ligand of CD169, and many interferon (IFN) $\alpha$-producing cells were detected surrounding the $CD169^+$ cells. Furthermore, in our *in vitro* experiments with human macrophages, IFN$\alpha$ induced strong expression of CD169. These data suggest that $CD169^+$ macrophages in RLNs promote $CD8^+$ T-cell-mediated anti-tumor immunity and are associated with a better prognosis for cancer patients. **Conclusions:** $CD169^+$ macrophages in RLNs may thus be a useful marker for assessing clinical prognosis and monitoring anti-tumor immunity in patients with colorectal carcinoma, melanoma and endometrial carcinoma.

**11119 General Poster Session (Board #401), Sat, 1:15 PM-5:00 PM**

**Mesothelin expression as a predictive biomarker of breast cancer outcomes.** *Presenting Author: Yun Rose Li, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

**Background:** Mesothelin, previously-shown to be expressed in triple negative breast cancer (TNBC) tumors, is a potential therapeutic target and prognostic marker in breast cancer. **Methods:** We analyzed clinical data from two cohorts: a 141 patient-cohort treated between 2009 and 2011 at the UPHS (discovery) and the 844 patient-cohort from The Cancer Genome Atlas (TCGA) (validation). Mesothelin expression was quantified by immunohistochemistry (IHC) (discovery) or RNA transcript levels by whole-transcriptome sequencing (validation). **Results:** Median follow up for our discovery cohort was 3.54 years. Univariate analyses demonstrated that tumor size (HR=1.30, 95% CI 1.115-1.515, $p < 4.58 \times 10^{-4}$), number of positive axillary lymph nodes (HR=1.131; 95% CI 1.06-1.21; p-value $< 9.20 \times 10^{-5}$), tumor stage (HR (Grade III to I) = 21.294, 95% CI 2.69-168.69, $p < 3.40 \times 10^{-5}$), at least one lymph node removed (HR=1.07, 95% CI 1.021-1.116, $p < 2.45 \times 10^{-3}$), and most importantly, mesothelin expression (HR= 2.377; 95% CI 1.12-5.02; $p < 3.01 \times 10^{-3}$) were associated with both overall and disease-specific survival. We used a Cox-proportional hazard (Cox-PH) model to adjust for the only other independent predictors of survival, namely axillary lymph nodes involved and tumor size, and stratifying by African American race, we found a significant association between mesothelin expression and overall and disease-specific survival in the discovery cohort (HR = 3.138, 85% CI 1.38-7.10, $p < 6.14 \times 10^{-3}$). Using the TCGA dataset, we confirmed that, over a median follow-up of 16.0months, patients with mesothelin-expressing tumors had poorer overall survival (HR=1.463; 95% CI 1.053-2.033; p<0.021). On Cox-PH analysis, mesothelin-positivity was independently predictive of poorer survival, after adjusting for the number of involved axillary lymph nodes and tumor size (HR = 1.688; 95% CI 1.174-2.425; $p<4.67 \times 10^{-3}$). **Conclusions:** Our results suggest that mesothelin is a prognostic breast tumor marker and that its expression in a large proportion in TNBC holds promise that existing targeted therapy directed against mesothelin may be effective for the treatment of TNBC. Further work is needed to elucidate the mechanistic role of mesothelin in breast cancer.

**11120 General Poster Session (Board #402), Sat, 1:15 PM-5:00 PM**

**Hedgehog signalling in primary cervix xenograft (OCICx) models: A potential new therapeutic target in combination with chemoradiotherapy.** *Presenting Author: Naz Chaudary, Ontario Cancer Institute/The Campbell Family Institute for Cancer Research,Princess Margaret Cancer Centre Toronto, Ontario, Canada, Toronto, ON, Canada*

**Background:** Overcoming treatment resistance and repopulation in patients undergoing chemo-radiotherapy for primary treatment of cervical cancer is critical in order to improve long-term survival. Upregulation of Hh gene expression in women with cervical cancer prior to chemoradiotherapy is associated with a worse outcome. Aim: to investigate inhibition of the Hh pathway in combination with chemoradiotherapy in orthotopic primary cervical cancer xenograft models (OCICX). **Methods:** mRNA expression levels of Hh pathway members were characterized using qRT-PCR analysis in OCICx models. To simulate clinical treatment 5E1 (antibody blocking SHH and IHH ligand interaction with PTCH1) was administered to mice bearing cervix xenografts (20 mg/kg/weekly) with localized fractionated irradiation (15 x 2Gy fractions given 5 days/wk over 3 wks). Tumor growth delay, lymph node metastases, survival and toxicity were assessed. **Results:** The OCICX models exhibited matched levels of Hh gene expression compared to the patient tumor samples. The OCICX models recapitulate the stroma of the orginal tumor. OCICX models with higher tumor to stroma content showed higher human Hh gene expression. Higher mouse Hh gene expression was seen in tumors with more stroma. Combination radiochemotherapy plus 5E1 treatment caused greater growth delay than irradiation or 5E1 alone, reduced lymph node metastasis with increase in survival. No overt toxicity was observed in the mice treated with 5E1 or in combination with radiation. **Conclusions:** Combination treatment with fractionated irradiation and 5E1 shows increased efficacy consistent with an additive effect. In addition, inhibition of the Hh pathway significantly reduced lymphnode metastasis in the mice. Further investigation of Hh pathway inhibition in combination with chemo-radiotherapy in cervix cancer is warranted including exploration of predictive imaging markers of response.

**11121 General Poster Session (Board #403), Sat, 1:15 PM-5:00 PM**

**Reduction rate of the maximal value of the baseline standardized uptake value on fluorine-18 fluorodeoxyglucose positron emission tomography/computed tomography to predict response of breast cancer to neoadjuvant chemotherapy.** *Presenting Author: Takayuki Kadoya, Department of Surgical Oncology, Hiroshima University, Hiroshima, Japan*

**Background:** [18F]-fluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT) is potentially useful to predict response of breast cancer to neoadjuvant chemotherapy. **Methods:** 114 breast cancer patients (mean age: 53.7±11.0) with clinical Stage I~III between January 2006 and December 2011, were prospectively evaluated. Patients underwent a whole-body FDG PET/CT before and after neoadjuvant chemotherapy. The reduction rate of maximal value of the baseline standardized uptake values (ΔmaxSUV) before and after neoadjuvant chemotherapy with sequential regimen of anthracyclines and taxanes were assessed for predicting pathological complete response (pCR). For the evaluation of relationship between ΔmaxSUV and prognostic factors, statistical analyses were performed using Student t test and log-rank test, and p values of less than 0.05 were considered to indicate statistically significant differences. **Results:** Clinical stage included were I (n =10), II (n=81) and III (n=23). Tumors with estrogen receptor (ER) positive and HER2 positive were 79 (69.3%) and 30 (26.3%), respectively. Patients were divided into two groups according to cut-off ΔmaxSUV established on the basis of receiver operating characteristic analysis (>80.4% vs 80.4% ≤, AUC=0.676). There was a significant difference in pCR between two groups (p=0.006) and, ER, progesterone receptor, HER2, clinical T factor were found strong relation to ΔmaxSUV. ER, HER2, tumor size and ΔmaxSUV were predictive factors with multivariable analysis using cox proportional hazard regression model (p<0.01, p<0.01, p=0.02 and p=0.04, respectively). **Conclusions:** The reduction rate of maxSUV on FDG PET/CT before and after neoadjuvant chemotherapy has a predictive value for pCR in operable breast cancer.

| Factors | Favorable | Unfavorable | Hazard ratio (95%CI) | p value |
|---|---|---|---|---|
| **Clinical T factor** | T1 | T2, T3, T4 | 0.200 (0.050-0.797) | 0.02 |
| **Clinical N factor** | N0 | N1,N2,N3 | 1.103 (0.319-3.818) | 0.88 |
| **ΔmaxSUV** | > 80.4% | 80.4%≤ | 3.816 (1.059-13.745) | 0.04 |
| **ER** | (+) | (-) | 0.068 (0.018-0.258) | <0.01 |
| **HER2** | (-) | (+) | 12.625 (3.295-48.375) | <0.01 |

**11122 General Poster Session (Board #404), Sat, 1:15 PM-5:00 PM**

**The CXCL12/CXCR4 pathway, bone marrow-derived myeloid cells, and survival in locally advanced cervical cancer.** *Presenting Author: Naz Chaudary, Ontario Cancer Institute/The Campbell Family Institute for Cancer Research,Princess Margaret Cancer Centre Toronto, Ontario, Canada, Toronto, ON, Canada*

**Background:** Cervical cancer is a global health problem. There is a need to improve standard treatment with radiotherapy (RT) and concurrent cisplatin (CT). Tumors are known to recruit myeloid cells from the bone marrow (BMDCs) via the CXCL12/CXCR4 and other chemokine pathways, which in turn influence tumor vascular function and RT response. The objective of this study was to explore the impact of the CXCL12/CXCR4-BMDC axis on clinical outcome in cervical cancer patients treated with RT, and ways of inhibiting this response. **Methods:** A total of 258 patients with cervical cancer (cT1b-T3b, N0-1, M0) were treated with RT +- concurrent CT. Tumor hypoxia, interstitial fluid pressure (IFP – a biomarker of abnormal vascular function) and CXCR4 expression were measured prior to treatment. The median follow-up was 5.3 years. Orthotopic cervical xenografts were developed from patient biopsies for evaluation of the chemokine inhibitor Plerixafor. **Results:** The pretreatment bloodpolymorphonuclear neutrophil (PMN) count was normal (<$7.5X10^9$/L) in 83% of cases.In patients treated with RT+CT, high pretreatment PMNs were associated with inferior disease-free survival (DFS) but only in the setting of high tumor IFP. This was independent of tumor stage, size and LN status, and was validated in a separate cohort of patients treated with RT alone. Patients with high PMNs displayed high peri-vascular tumor infiltration by CD11b+ or CD66b+ myeloid cells. There was 5-fold variation in CXCR4 mRNA expression by qRT-PCR, and 58% of cases showed high CXCR4 protein expression by IHC.Patient-derived orthotopic cervical tumors were treated with fractionated,image-guided RT and CT +- Plerixafor (5 mg/kg). Combined treatment with Plerixafor produced substantial tumor growth delay and prolonged survival compared to standard RT+CT alone. There was no difference in acute GI toxicity with the addition of Plerixafor to standard treatment. **Conclusions:** TheCXCL12/CXCR4 pathway and BMDCs influence RT response and clinical outcome in patients with cervical cancer via a vascular-dependent mechanism. Inhibition of CXCL12 signaling can mitigate this effect and should be considered for translation to phase I/II clinical trials.

**11123 General Poster Session (Board #405), Sat, 1:15 PM-5:00 PM**

**Investigations into the antiradition effects of BP-C2, a benzene-poly-carboxylic acid complex with molybdenum.** *Presenting Author: Stig Larsen, University of Oslo, Oslo, Norway*

**Background:** BP-C2 is an innovative oral radio-protective drug based on a benzene-poly-carboxylic acid complex with molybdenum with important detoxifying properties and a new globular polydentant ligand BP-Cx-1 known for its detoxifying, free radical scavenging and anti-oxidant activity. We have previously demonstrated that administration of BP-C2 results in highly significant survival advantage in animals receiving either lethal or sub-lethal doses of gamma irradiation. LD50/30 6.56 GY. No adverse side effects using BP-C2 have been observed *in vitro* (LDH release) or *in vivo*. **Methods:** In the skin radiation injury prophylactic group, age matched white mice were treated with BP-C2 on the day of irradiation and hereafter treated three times a week for 5 weeks. In the post irradiation treatment group the animals were treated with BP-C2 three times per week for five weeks after the occurrence of skin injuries**.** The effects on skin injuries were investigated by H and E histopathology, cytokine and gene expression by immunohistochemistry. Animals were irradiated at 30 GY in the one hind leg. **Results:** All control mice developed severe skin injury in the leg. In contrast no skin injury was observed in mice treated prophylactically with BP-C2. In the treatment group with BP-C2 all mice were cured after five weeks of treatment. The expression of several oncogenes were decreased significantly whereas tumor suppressing genes where increased. BP-C2also stimulated the innate immune system.The effect is properly mediated via several cytokines (TNF-alpha, INF-gamma, GM-CSF, IL-1 beta, IL-6, Il-25) and apoptotic genes. **Conclusions:** BP-C2 has a potential for clinical use to protect patients from radiotherapy injuries of the skin prophylactically as well as post irradiation treatment.

**11124 General Poster Session (Board #406), Sat, 1:15 PM-5:00 PM**

**WNT inhibitory factor-1 (WIF-1): A new role in carcinogenesis?** *Presenting Author: Tan Wei Chow, INFORMM USM, Pulau Pinang, Malaysia*

**Background:** Carcinogenesis is an orchestrated expression and depression of oncogenes and tumor suppressor genes at cellular level. The early involvement of epidermal growth factor receptor (EGFR) and wingless and integration site growth factor (WNT) signaling pathways in cell development has attracted much interest among researchers and clinicians. Aberrant activity in both signaling pathways may contribute to cancer formation. By tackling the potential key players in the study of cancer cell signaling pathways, alternative cancer treatment could be promoted in current cancer context. WIF-1 is a physiological inhibitor for WNT signaling pathway used to prevent carcinogenesis resulted from the activation of WNT signaling pathway. The structure of WIF domain is known to have a binding site that interacts with WNT molecules while the function(s) of its EGF-like domain is still unknown. **Methods:** To study the potential involvement of WIF-1 in EGFR signaling pathway, *in silico* protein-protein docking between WIF-1 and EGFR was carried out. Co-immunoprecipitation and western blot were designed to study the *in vitro* binding of EGFR/WIF1 and the potential resulting activation of EGFR downstream signaling pathways. **Results:** *In vitro* and *in silico* experimental results suggested that WIF-1 might play additional role in EGFR signaling pathway via its EGF-like domain. The binding energy of WIF-1/EGFR (-616.40 kcal/mol) was comparative to that of EGF/EGFR binding (-627.18 kcal/mol). Further results indicated that WIF-1 was bound to, and hence was co-immunoprecipitated with, EGFR. Downstream key factors in EGFR signaling pathway were found to be activated following the binding of WIF-1 to EGFR. In addition, the results obtained showed a prominent activation of downstream WNT signaling pathway via crosstalk from WIF-1 activated EGFR signaling pathway. **Conclusions:** As EGFR signaling pathway plays a crucial role in carcinogenesis, and the possibility to activate WNT signaling pathway via crosstalk between the WIF-1 activated EGFR signaling pathway and downstream of WNT signaling pathway, the use of WIF-1 in the treatment of cancer probably need to be reviewed for the safety of patients undergoing the treatment and prevent undesired outcomes from happening.

**11125 General Poster Session (Board #407), Sat, 1:15 PM-5:00 PM**

**Combined immunophenotyping of tumor-infiltrating lymphocytes as a prognostic factor in resected patients with non-small cell lung cancer.** *Presenting Author: Ross A. Soo, National University Health System, Singapore, Singapore*

**Background:** Current evidence has highlighted the potential role for tumor infiltrating lymphocytes (TILs) in determining the survival of non-small cell lung cancer (NSCLC) patients. Whilst multiple studies have investigated the prognostic role of various subtypes of TILs, data is limited on the co-expression of TILs subpopulations and its clinical relevance. Identifying immune prognostic markers may help select postoperative NSCLC patients with a poorer prognosis for treatment with immunotherapy. We aim to identify NSCLC subgroups according to combined immunophenotypes and investigate their clinical relevance. **Methods:** A tissue microarray was constructed from 105 cases of resected NSCLC. Immunohistochemistry for TILs with CD3, CD8, FoxP3 and Granzyme B (GZMB) Ab was performed with an autostainer. TILs were quantified using the Vectra Automated Multispectral Imaging System. Low (-) and high (+) densities of TILs were dichotomised by the medians. *EGFR* and *KRAS* mutations were determined with Sanger sequencing. Clustering was performed using the heatmap function of R v3.0.2. Associations with clinicopathological variables were assessed by Chi-square analysis, and association with disease-specific survival (DSS) was performed using Cox proportional hazards model analysis. **Results:** The median age of patients was 64 years, 70% were male, 59% were stage I, and 57% of tumors were adenocarcinoma. Unsupervised clustering revealed 4 major subgroups based on the co-occurrence of high and low densities: FOXP3+/CD3+ (29% of cases), FOXP3+/CD3- (11%), FOXP3-/GZMB+ (28%) and FOXP3-/GZMB- (31%). The FOXP3+/CD3+ phenotype was significantly associated with squamous cell histology (p=0.047). There was no association with other features, including *EGFR* or *KRAS* mutation status. Patients with FOXP3+/CD3+ phenotype had a worse DSS (HR 2.17, 95% confidence interval [1.08-4.36], p=0.034) compared to those in other subgroups. **Conclusions:** Combined immunophenotyping suggests NSCLC may be comprised of four major subgroups. The FOXP3+/CD3+ phenotype may indicate a worse prognosis for patients with resected NSCLC and thus identify patients for immune directed adjuvant therapy.

**11126 General Poster Session (Board #408), Sat, 1:15 PM-5:00 PM**

**The association of treatment-emergent proteinuria (TEP) with baseline/ treatment variables in patients (pts) treated with antiangiogenic tyrosine kinase inhibitors (AA-TKIs): A pooled analysis of NCIC Clinical Trial Group (NCIC CTG) trials.** *Presenting Author: Maria Bonomi, NCIC Clinical Trials Group, Kingston, ON, Canada*

**Background:** TEP is an expected effect of AA-TKIs. This pooled analysis of NCIC CTG trials aimed to assess its incidence, risk factors and clinical impact. **Methods:** 423 pts with baseline (BL) and ≥ 1 on treatment urinalysis were included in 2 cohorts: 1) AA-TKI (VEGFR2/PDGFR/KIT; VEGFR2/MET) ± other targeted agent; 2) AA-TKI (panVEGFR/KIT) + chemotherapy (CT; platinum based regimens capecitabine). Cohort 1 (138 pts) included ovary, cervix, mesothelioma, lymphoma, breast, non small cell lung cancer (NSCLC); cohort 2 (285 pts) colorectal and NSCLC. BL uncontrolled HTN and abnormal renal function were always excluded; BL > G1 proteinuria only in cohort 2 (all but 1 trial). Dose modifications and algorithms for treatment emergent (TE) HTN or TEP were provided. TEP was defined as any value > BL and ≥ G2. BL/treatment variables considered were age, PS, sex, proteinuria, HTN, diabetes, obesity, nephrotoxic and nephroprotective drugs, TE HTN, increased creatinine, hypoalbuminemia. **Results:** Incidence of TEP in cohort 1 and 2 was 10.1% and 18.2% (p .03 Fisher's exact test). Median onset of TEP was 12.4 vs 6.4 weeks (wks) in cohort 1 and 2 (p 0.005 log rank). Only TE HTN and increased creatinine were significantly associated with TEP in a stratified logistic regression (table). Median time on AA-TKIs in pts with (TEP +) and without TEP (TEP-) was 19.3 vs 16.0 wks (cohort 1), and 23.5 vs 20.6 wks (cohort 2). Neither renal nor cardiovascular nor thromboembolic complications were more common in TEP + vs TEP – pts. G3 TEP caused treatment discontinuation in 2 pts (cohort 1). **Conclusions:** In this population, TEP was more common and began earlier if CT was added to AA-TKIs . TEP was associated with other AA-related effects but was not predicted by BL variables evaluated. It rarely caused treatment discontinuation, did not affect time on treatment, and had little clinical impact.

**11127 General Poster Session (Board #409), Sat, 1:15 PM-5:00 PM**

**Essential experimental steps and estimates of renal carcinoma initiating cells.** *Presenting Author: Craig Gedye, Ontario Cancer Institute, Toronto, ON, Canada*

**Background**: Rare cancer stem cells (CSC), proposed to be solely responsible for tumor propagation and re-initiation, are functionally identified as tumor-initiating cells (TIC) from *ex vivo* tumors using xenotransplantation and clonogenic limiting dilution assays (LDA). TIC have not previously been described from *ex vivo*human clear cell renal cell carcinoma (ccRCC). **Methods**: Primary human ccRCC samples (n=120) from patients undergoing nephrectomy were processed and implanted as subcapsular fragments or cell suspension injection LDAs with Matrigel in NOD/SCID/IL2R$\gamma^{-/-}$ (NSG) mice, and observed for at least 6 months. *In vitro* clonogenic LDAs assays were performed from primary cell suspensions and ccRCC cell lines. LDAs were supplemented with human stromal cells and proteins, and the Y-26732 ROCK inhibitor. Multiparametric flow cytometry and immunofluorescence were used to investigate tumor heterogeneity and cell viability. **Results**: ccRCC TIC appeared rare from injected suspensions, but xenografts engrafted frequently from tiny fragments, and clonogenic frequencies were $10^3$-$10^4$greater than TIC frequencies, suggesting that LDAs underestimated ccRCC tumor cell potential. We systematically identified multiple methodological steps that distort quantitation and identification of ccRCC TIC. For example cell viability was highly variable prior to processing, disaggregation itself destroyed up to 99% of tumor cells, standard assays substantially overestimated tumor cell viability in suspensions, and supplementation with human extracellular cells or proteins, or inhibition of anoikis by Y-26732 increased clonogenic and TIC frequencies in cell lines and primary ccRCC suspensions. Annexin-V staining revealed that tumor cells were more apoptotic then normal stromal cells, and that tumor cells positive for CD44 (a putative CSC marker) were more viable than CD44- tumor cells. **Conclusions**: We describe multiple, unappreciated and largely unavoidable observational errors in essential methods used to study TIC in ccRCC. ccRCC TIC may be more common than appreciated. Re-examination of the CSC hypothesis in other solid tumors is warranted in view of these previously unexplored methodological biases.

**11128 General Poster Session (Board #410), Sat, 1:15 PM-5:00 PM**

**RANKL circulating levels in the evaluation of bone response in breast cancer (BC) patients.** *Presenting Author: Toni Ibrahim, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) s.r.l., IRCCS - Osteoncology and Rare Tumors Center, Meldola, Italy*

**Background:** Bone Metastases (BM) are responsible of the high morbidity, low quality of life and poor prognosis of patients with BC. The evaluation of bone response to treatment is still controversial. **Methods:** This is a prospective study on 36 consecutive BC patients with BM for the evaluation of RANK, RANKL and OPG transcripts by Real-Time PCR and NTX levels by ELISA. Patients enrolled had at first diagnosis of bone metastases and had not previously undergone bone targeted treatment. They underwent the standard Zoledronic Acid schedule of a 4-mg infusion every 28 days and standard antitumor therapy. Patients were monitored for about 1 year and blood samples were collected before the first infusion of ZA and every 4 months. The primary aim was to study the predictive role of different circulating markers in the response to ZA respect to objective response (MD Anderson criteria). **Results:** The NTX levels were not different in patients that underwent to progression respect to those with stable disease or partial response to ZA Treatment. Instead a decrease of 30% and 15% was observed in OPG and RANKL levels in non responders patients. ROC curves evaluation for all markers showed RANKL was the most accurate, with an AUC of 0.70 (95%CI 0.48-0.93). We observed for RANKL/OPG an AUC of 0.64 (95%CI 0.44-0.84) and for NTX an AUC of 0.60 (95%CI 0.38-0.82). Considering as a cut off a variation of markers of at least 25%, the positive predictive value (PPV) for RANK was 26.6%, 9.1 for RANKL, 30 for OPG and 13.3 for the ratio RANKL/OPG. NPV for these markers ranged from 79.2 to 84.6 %. NTX PPV and NPV were respectively 0 and 84.6%. **Conclusions:** The most accurate marker for the evaluation of bone response was RANKL, the key molecule in the pathogenesis of BM and the target of Denosumab. NTX, the marker most used up to now, failed to show a predictive power of response with aspecific decrease both in responder and non responder patients. Further research should be done to improve our knowledge in this field.

**11129 General Poster Session (Board #411), Sat, 1:15 PM-5:00 PM**

**Association of stromal cell gene expression with response to neoadjuvant chemotherapy in locally advanced breast cancer.** *Presenting Author: Rene Aloisio da Costa Vieira, Hospital de Cancer de Barretos, Barretos, São Paulo, Brazil, São Paulo, Brazil*

**Background:** There is increasing evidence that breast cancer behavior is a reflection of an interactive signaling between the malignant epithelial compartment and the surrounding microenvironment. A high stromal gene expression, characterizing a reactive stroma, was associated with resistance to neoadjuvant chemotherapy, in indirect analysis. Our aim was to detect a stromal cell signature associated with response to neoadjuvant chemotherapy in locally advanced breast cancer, using a direct approach, consisting of stromal cell selection, through laser microdissection. **Methods:** Twenty one patients treated at Hospital de Câncer de Barretos were included. Patients were diagnosed with invasive ductal carcinoma, except one (lobular invasive carcinoma); median age was 44.5 years; all presented stage III disease; mean tumor dimension was 6.89 cm. Eleven tumors were luminal HER2 negative; 5 HER2 positive [3 ER(+); 2 ER(-)] and 5 triple negative. All patients were submitted to neoadjuvant chemotherapy (4AC followed by paclitaxel). Response was defined as down staging to a maximum pT1pN0 and according to these criteria, seven patients had a responsive disease. Pre-chemotherapy samples, after stromal cell selection through LCM, were analyzed in an Agilent microarray platform. Expression levels were evaluated using MEV software (t-test with Bonferroni correction). **Results:** Twenty three sequences were found differentially expressed, 16 more expressed in stromal cells from down staging samples (responsive) and 7 more expressed in stromal cells from non-down staging (non-responsive) samples, including 17 known genes. Unsupervised hierarchical clustering and bootstrapping using these sequences identified two branches with high confidence, one including 6/7 down staging (responsive) samples and the other including all non-down staging (non-responsive) samples. **Conclusions:** Breast cancer stromal cells transcriptional profile may separate tumors with major response from non-responsive to neoadjuvant chemotherapy, indicating these cells may be involved in chemosensitivity. These findings however, need to be confirmed in an extended group of samples.

**11130 General Poster Session (Board #412), Sat, 1:15 PM-5:00 PM**

**Patient-derived xenografts from breast cancer patients before and after neoadjuvant chemotherapy: A prospective study.** *Presenting Author: Judy Caroline Boughey, Mayo Clinic, Rochester, MN*

**Background:** Use of next generation sequencing (NGS) in the neoadjuvant setting results in identification of drug targets/pathways associated with chemotherapy resistance. PDX may be superior to cell line models for validation given their similarity to parental tumors. There are no data on PDX from percutaneous needle biopsy (PNB) prior to chemotherapy or from residual disease after neoadjuvant chemotherapy. **Methods:** The Breast Cancer Genome Guided Therapy Study (BEAUTY) is a prospective study of high-risk breast cancer patients (pts) treated with neoadjuvant paclitaxel +/- trastuzumab followed by anthracycline based chemotherapy. PNB at baseline and surgical residual disease after chemotherapy are obtained for NGS and PDX. Tumors were implanted in flanks of estradiol supplemented NOD-SCID or NSG mice. Definitions: outgrowth rate - % pts with 1+ PDX tumor volume >50 mm3, take rate - % pts with 1+ stably transplanted PDX. **Results:** Pretreatment PNB from 83 unique pts were implanted in 266 mice (2-4 mice/pt) from 3/2012-7/2013. PDX outgrowth rate was 37.3% (31/83) and take rate 31.3% (26/83) Take rates were triple negative (TN) 51.9% (14/27), ER+/Her2+ 41.7% (5/12), ER-/Her2+ 27.3% (3/11), Luminal B 17.4% (4/23) and Luminal A 0% (0/10) and did not differ by Ki67. Histological assessment of the first 8 PDX demonstrated similarity to parent tumor in histology (ductal tumors-8/8) and grade (7/8). Tumor subtype in the PDX was concordant in TN tumors (5/5); however ER expression was lost in PDXs from Luminal B tumors (2/2). Residual tumor at surgery from 17 pts was injected into 83 mice (median 5 mice/pt). Outgrowth rate was 35% (6/17) and take rate 17% (3/17). All were TN grade III tumors with Ki67 ≥90% at surgery. PDXs generated were concordant with the residual disease histology, tumor subtype and grade. **Conclusions:** These are the first data to show PDX generated in the neoadjuvant setting both before and after chemotherapy. PDX take rate varies by tumor subtype with highest take in TN and ER+/Her2+ tumors. Early data suggest that the ER expression may be lost in PDX from luminal B tumors. The generation of PDX from tumors resistant to chemotherapy may provide an important resource for drug testing and development. Clinical trial information: NCT02022202.

**Immune responses induced by the TLR-4 agonist-based adjuvant prothymosin alpha.** *Presenting Author: Pinelopi Samara, Department of Animal and Human Physiology, Faculty of Biology, University of Athens, Athens, Greece*

**Background:** The immunomodulator prothymosin $\alpha$ (proT$\alpha$) stimulates immune subpopulations via generating an optimized cytokine milieu. The decapeptide proT$\alpha$(100-109) restores the deficient immune responses of cancer patients *in vitro* equally well to proT$\alpha$. ProT$\alpha$(100-109) and proT$\alpha$ ligate TLR-4, signal through TRIF- and MyD88-dependent pathways, promote the phenotypic and functional maturation of dendritic cells. These elicit $T_H1$-type immune responses and prime tumor antigen-reactive T cell functions. We assessed whether proT$\alpha$(100-109) and proT$\alpha$ can function similarly *in vivo*. **Methods:** PBMCs and cells from various cancer lines incubated with proT$\alpha$(100-109) or proT$\alpha$ were tested for induction of toxicity/apoptosis by MTT and Annexin V/PI staining. C57BL/6 mice were subcutaneously inoculated with syngeneic melanoma B16.F1 cells and upon palpable tumor formation were intraperitoneally treated with 2 cycles of GM-CSF, proT$\alpha$(100-109) or proT$\alpha$, in conjunction with a B16.F1-specific peptide extract (AWE). Tumor growth and animal survival were monitored. Splenocytes from selected animals were tested for their *ex vivo* cytotoxicity by $^{51}$Cr-release assay and CD107 expression. Serum concentrations of IFN-$\gamma$ and IL-4 were determined. **Results:** ProT$\alpha$(100-109) and proT$\alpha$ are not cytotoxic to normal or cancer cells and do not induce PBMC or cancer cell apoptosis/necrosis. In agreement with our *in vitro* data, both peptides when administered therapeutically in melanoma-bearing mice in the presence of cancer antigens, retard tumor growth and prolong animals' survival by 25 days. *Ex vivo* cytotoxicity of mouse splenocytes verified the induction of B16.F1-specific and non-specific responses, mediated by activated cytotoxic T and NK/LAK lymphocytes, respectively. Sera from proT$\alpha$(100-109) or proT$\alpha$-treated animals contained more IFN-$\gamma$, whereas IL-4 concentration was marginally increased. **Conclusions:** We propose that the TLR-4 ligands proT$\alpha$ and its immunoactive decapeptide proT$\alpha$(100-109), induce $T_H1$-biased immune responses to coadministered tumor antigens, both *in vitro* and *in vivo*. As they are non-toxic to normal cells, their adjuvanticity to orchestrate anti-tumor immune responses may eventually be used therapeutically.

**TPS11132 General Poster Session (Board #414A), Sat, 1:15 PM-5:00 PM**

**DETECT III/IV: Two combined clinical trials based on the phenotype of circulating tumor cells (CTCs).** *Presenting Author: Susanne Albrecht, Universitätsfrauenklinik Ulm, Ulm, Germany*

**Background:** Although the prognostic value of CTC enumeration in metastatic breast cancer (MBC) is well understood, the value of taking into account the molecular characteristics of CTCs in treatment decision requires further investigation. Trial Design: The DETECT studies are prospective, multicenter, open-label clinical trials designed for patients with HER2-negative MBC and CTCs in the peripheral blood. DETECT III is a two-arm, phase III study for patients with HER2-positive CTCs, randomized to physician's choice chemotherapy with or without additional HER2-targeted treatment with lapatinib. DETECT IV is a single-arm phase-II study including postmenopausal women with hormone-receptor-positive, HER2-negative MBC and HER2-negative CTCs that will be treated with the mTOR-inhibitor everolimus in combination with an endocrine therapy of physician's choice. Specific aims: The primary objective of both trials is to estimate the clinical efficacy of treatments, assessed by the CTC clearance rate for DETECT III and progression-free survival (PFS) for DETECT IV. Present and target accrual: Overall, about 2000 MBC patients with a HER2-negative primary tumor will have to be screened to be able to include 120 patients with HER2-positive CTCs for DETECT III (started in February 2012) and 400 patients with HER2-negative CTCs for DETECT IV (started in December 2013). So far, 751 patients have been screened for CTCs. **Methods:** Prevalence of CTCs at various time points as well as the HER2 status of CTCs will be determined using the FDA-approved CellSearch System (Veridex, USA). Survival endpoints will be estimated using the Kaplan-Meier method. Perspectives: The DETECT III trial is the first study in which treatment is based on phenotypic characteristics of CTCs. If this trial succeeds in proving efficacy of lapatinib in patients with HER2-negative primary tumor but HER2-positive CTCs, it may lead to new treatment strategies for MBC. DETECT IV complements DETECT III with regard to additional therapy indications. The innovative study concept of these clinical trials with therapy decisions being based on prevalence and molecular phenotypes of CTCs is an important step towards a more personalized cancer treatment for MBC. Clinical trial information: NCT01619111/ NCT02035813.

**TPS11133 General Poster Session (Board #414B), Sat, 1:15 PM-5:00 PM**

**Pharmacist-led lung cancer biomarker detection.** *Presenting Author: Emer Ann Sheridan, University of Huddersfield, Huddersfield, England*

**Background:** Patients at risk of lung cancer may have subclinical disease present for years before diagnosis. Exhaled breath condensate (EBC) is water vapour which contains aerosolized particles in which a large number of metabolites are detectable. Lung malignancy, inflammation and therapeutic intervention influence these biomolecules. This project aims to use EBC as a non-invasive means of detecting biomarkers, differentiating between lung malignancy, lung inflammatory disorders and the generally healthy population. In doing so, there is potential for early diagnosis of lung cancer in a public health setting. This will involve the design of a novel care pathway where pharmacists administer non-invasive breath tests to at-risk patients and flag up and distinguish early signs of malignant or inflammatory lung disease. **Methods:** A cohort of histologically confirmed lung cancer patients (both SCLC and NSCLC) a cohort of patients with inflammatory lung disease (asthma and COPD) and a control cohort of volunteers from the general population will be recruited to a proof of principle study aiming to collect breath samples. These will be profiled for mRNA expression of a range of candidate biomarkers using both custom and commercially available qRT-PCR pathway arrays. This will be extended to both genomic and proteomic analysis. A putative biomarker signature has been identified in silico using Gene Expression Omnibus and Oncomine databases. To aid differentiation between stable or progressing COPD/asthma and early signs of lung cancer, we have incorporated groups of tumour biomarkers with increased expression in lung cancer e.g., those associated with the hypoxic tumour microenvironment. This theoretical signature comprises approximately 100 genes. These genes have all been mined with a threshold of at least a two fold change and statistical significance of $P = 10^{-4}$. For this comparative study a multiple ANOVA approach will be utilised. Potentially a large number of outcomes may be considered, variable reduction techniques (e.g. principal component analysis) will be utilised to reduce the dimensionality of the study. The study will run alongside chemical analysis, working towards a highly specific, selective and combined biological and chemical signature.

**TPS11134 General Poster Session (Board #415A), Sat, 1:15 PM-5:00 PM**

**GEFCAPI 04: A phase III trial comparing a treatment oriented by a molecular analysis with CancerTYPE ID test to cisplatin-gemcitabine in patients with carcinoma of an unknown primary (CUP).** *Presenting Author: Geraldine Martineau, Clinical Research Department, Institut Gustave Roussy, Villejuif, France*

**Background:** Despite advances in tumor imaging and pathology, patients with CUP still account for about 2-3% of all cancer patients in European registries. Two randomized phase II trials: GEFCAPI01 (Culine, J Clin Oncol 2003) and GEFCAPI02 (Gross-Goupil, Eur J Cancer 2012) demonstrated that the combination of cisplatin and gemcitabine has anticancer activity and can be regarded as an acceptable comparator for new treatments. Recently, several groups have shown that molecular analysis can identify a likely primary cancer in up to 80% of patients with CUPs. This trial aims to assess whether the use of a molecular test-oriented systemic treatment improves progression-free survival (PFS) over cisplatin-gemcitabine in patients with CUPs. **Methods:** GEFCAPI04 is a European randomized, phase III study comparing a diagnostic and therapeutic strategy based on molecular analysis followed by suspected primary cancer tailored specific therapy, to an empiric strategy by cisplatin and gemcitabin (NCT01540058). It was initiated in March 2012. Eligibility criteria include: patients presenting with CUP, confirmed by histo-pathological analysis, diagnostic work-up in keeping with guidelines (Lesimple et al., 2003), good or poor prognosis CUP, CUP not belonging to a subgroup requiring a specific treatment, no previous chemotherapy. Patients are stratified by prognostic factors (performance status and serum LDH level) and center. 223 patients will be randomized 1:1 to cisplatin-gemcitabine (A) or treatment according to the result of the molecular analysis (B). The primary endpoint is PFS based on central independent review. Imaging will be undertaken every 6 weeks, in each arm. A 0.05 level two-sided log-rank test for equality of PFS curves will have 80% power to detect a 3 months difference between PFS medians (5 months in group A and 8 months in Group B, (HR=0.62). Secondary endpoints include: overall survival, objective response rate, tolerance, and economic evaluation. The study is recruiting patients and 30 patients are included. Clinical trial information: NCT01540058.

**TPS11135 General Poster Session (Board #415B), Sat, 1:15 PM-5:00 PM**

**A phase I study of the safety and activation of a cathepsin-activatable fluorescent cancer-specific probe LUM015.** *Presenting Author: Melodi Javid Whitley, Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC*

**Background:** Local recurrence is a common mode of failure for patients with cancer. Intra-operative detection of microscopic residual disease in the tumor bed could be used to decrease the risk of a positive surgical margin, reduce the rate of re-excision, and tailor adjuvant therapy. Previously, we utilized a primary mouse model of soft tissue sarcoma (STS) to develop a novel imaging system to detect cancer (*Cancer.* 2012). Because cathepsin proteases are preferentially expressed in tumors compared to normal tissue, we used cathepsin-activatable fluorescent imaging agents with a novel imaging device for intra-operative assessment of residual cancer within tumor beds of mice. We demonstrated that residual fluorescence detected in the tumor bed by the imaging system correlates with local recurrence and that image guided surgery improves outcomes for mice with positive residual fluorescence. LUM015 is a pegylated cathepsin-activated imaging agent containing a Cy5 fluorophore attached to a quencher by a polypeptide linker. Upon cleavage of the linker by cathepsin proteases, the quencher is released, allowing fluorescence to be detected. A phase I clinical trial is open at Duke to test the safety of LUM015 (NCT01626066). **Methods:** This open-label nonrandomized trial compares up to four dose cohorts of LUM015 (cohorts -1 to 3: 0.25, 0.5, 1 and 1.5 mg/kg) in order to determine a safe and recommended phase II dose of LUM015 that labels tumors in human patients. Subjects with STS or breast cancer receive LUM015 by peripheral intravenous injection 2-72 hours prior to scheduled surgical resection. Safety evaluations prior to and during the 24-hour period after injection consist of vital signs, ECG, PFTs, blood and urine studies and documentation of any adverse pharmacological activity (APA). This evaluation is repeated at 2, 7 and 14 days after study agent delivery and an end of study APA assessment occurs 30-35 days after surgery. Pharmacokinetic parameters are also determined. Correlative studies include quantitative imaging as well as histological and biochemical analyses of the resected tissues. To date, cohorts 1 and 2 (n=9 patients) have been enrolled without APA. Enrollment in cohort 3 began in January 2014. Clinical trial information: NCT01626066.

**TPS11136 General Poster Session (Board #416A), Sat, 1:15 PM-5:00 PM**

**A prospective study to compare qPCR to IHC and FISH for the detection of anaplastic lymphoma kinase (ALK) fusions in FFPE specimens from NSCLC patients (*PCRTALK*).** *Presenting Author: David Richard Hout, Insight Genetics, Inc., Nashville, TN*

**Background:** Lung cancer is the most common cause of cancer-related deaths in North America. A number of pharmaceutical firms currently have therapies that target ALK-driven lung cancers in development, with the first-in-class FDA-approved ALK inhibitor Xalkori (crizotinib, Pfizer) demonstrating excellent anti-tumor responses without significant toxicities. There is now substantial interest in ensuring the accurate identification of those NSCLC patients who harbor ALK fusions. The *ALK qPCR assay* is a quantitative real-time PCR assay that offers high throughput, 24-48 hour TAT, and easily interpretable results. We are performing a clinical diagnostic trial, PCRTALK (PCR tumor ALK), with the primary objective of this trial being to unequivocally demonstrate the performance of the *ALK qPCR assay*against current ALK testing modalities in screening FFPE lung cancer biopsy specimens. The study is recruiting multiple clinical centers throughout Canada for patient enrollment. Once PCRTALK has been completed, our goal is to accomplish the following: (1) the trial will provide clinically relevant data on which types of lung cancer biopsies (bronchoscopy, FNA, CNB, pleural fluid thoracentesis) provide sufficient tissue for the different modalities of ALK testing and report on the number of cases rejected for ALK testing by IHC and FISH due to insufficient tissue; and (2) provide therapeutic outcome data for cases with discordant ALK diagnostic results. A second arm of the study is to conduct a correlative study analyzing both matched FFPE and blood collected from NSCLC patients using various non-invasive methodologies. **Methods:** The study will proceed according to the following work flow: (1) ALK IHC (ALK IHC-5A4, Leica Biosystems) conducted by BCCA laboratories; (2) 72 individual ALK IHC 5A4-positives and 72 ALK IHC 5A4-negatives selected according to their respective IHC scores and reflexed to 3 - 5; (3) ALK FISH (Abbott Diagnostics) performed on all 144 specimens; (4) The ALK qPCR assay performed on all 144 specimens; and (5) Sanger and/or NGS to determine true status. Initial PCRTALK clinical trial data will be presented together with conclusions based on the results. Clinical trial information: NCT02010047.

## Publication-Only Abstracts

Publication-only abstracts, which are selected to be published in conjunction with the 2014 Annual Meeting, but not to be presented at the Meeting, can be found online in full-text, fully searchable versions at abstract.asco.org and JCO.org.

The publication-only abstracts are not included in the print volume, but are citable to this *Journal of Clinical Oncology* supplement. Please refer to the following example when citing publication-only abstracts:

J Clin Oncol 32, 2014 (suppl; abstr e12000)

# Errata

The Editor of the *2014 ASCO Annual Meeting Proceedings* has authorized correction of the following errors:

**Abstract 5509**

After publication of the abstract, the authors discovered an error in matching clinical data to molecular subgroups. The changes are as follows:

1. The proliferative and mesenchymal molecular subgroups have the largest improvement of PFS when treated with bevacizumab. The mesenchymal and differentiated groups showed the largest improvements in the original abstract.
2. Patients in the proliferative group who received bevacizumab had a 10-month improvement in PFS, which is statistically significant. This difference was not statistically significant in the original abstract.
3. Analysis of overall survival was added, and shows the greatest advantage in the proliferative and mesenchymal groups, similar to PFS results. OS was not included in original abstract.
4. Non-ovarian cancer cases have been removed based on centralized pathology review. All cases were included in original analysis.

**Abstract 8043**

After publication of the Proceedings Part I, it was discovered that abstract 8043 was not included in the body of the printed edition. The abstract appears below:

**E7080 (lenvatinib) in addition to best supportive care (BSC) versus BSC alone in third-line or greater nonsquamous, non-small cell lung cancer (NSCLC).** *Presenting author: Libor Havel, 3rd Medical Faculty, Charles University, Hospital Bulovka, Czech Republic*

**Background:** Lenvatinib (E7080; LEN) is an oral, tyrosine kinase inhibitor targeting VEGFR1-3, FGFR1-4, RET, KIT, and PDGFR$\beta$ with evidence of antitumor activity in a broad range of solid tumors. Currently there is an unmet medical need for treatments in third-line or greater NSCLC patients (pts). **Methods:** This study was a double-blind, placebo-controlled, multicenter, randomized Phase II study of LEN 24 mg PO once daily + BSC vs. placebo (PBO) + BSC (2:1 randomization). Pts with nonsquamous NSCLC who had failed $\geq$ 2 two systemic anticancer regimens were enrolled. Prior erlotinib or gefitinib was required for pts with known EGFR-activating mutations. The primary endpoint was overall survival (OS). Progression free survival (PFS), overall response rate (ORR), and disease control rate (DCR) were based on investigator assessment. Efficacy endpoints were estimated via Kaplan-Meier. **Results:** 135 pts enrolled in the study. Per protocol, the study was unblinded and analyzed after 90 deaths. 76% received $\geq$ 3 prior anti-cancer regimens and 85% received prior erlotinib or gefitinib (similar rates in each arm). A summary of efficacy and safety is presented by study arm (Table). In a post hoc analysis, a similar treatment effect was observed among subjects with wild-type EGFR. **Conclusions:** LEN in addition to BSC demonstrated a clinically meaningful improvement in both OS and PFS ($\sim$ 3 months) in heavily pretreated patients with NSCLC, including those who received prior EGFR inhibitors. LEN was generally well-tolerated, with an AE profile consistent with observed LEN monotherapy studies. These data warrant additional evaluation of LEN in this population.

| Median value or percentage | LEN + BSC (n=89) | PBO + BSC (n=46) | P value |
|---|---|---|---|
| OS, wks (95% CI) | 38.4 (26.57, 47.86)<br>N=58 events | 24.1 (15.29, 36.43)<br>N=37 events | p = 0.065 |
| PFS, weeks (95% CI) | 20.9 (15.86, 23.86)<br>N=73 events | 7.9 (7.43, 8.14)<br>N=45 events | p < 0.001 |
| ORR | 10.1% | 2.2% | 0.1635 |
| DCR | 42.7% | 19.6% | 0.0079 |
| Treatment duration (days) | 113 | 58 | Not compared (NC) |
| Serious adverse events (AEs) | 52% | 46% | NC |
| Grade 3/grade 4 AEs: | 69% | 50% | NC |
| Hypertension | 17% | 0% | |
| Dyspnea | 9% | 13% | |
| Pneumonia | 9% | 6.5% | |
| Study discontinuation due to AE | 24.7% | 17.4% | NC |

*All errors have been corrected in the online versions of the abstracts on JCO.org and ASCO.org. This errata is updated on a rolling basis, as needed, and is available online at http://meetinglibrary.asco.org/errata.*
