**Background:** Head and neck squamous cell carcinoma (HNSCC) is comprised of two subtypes: human papilloma virus (HPV)- and carcinogenic-associated (HPV-negative), both linked to inactivation of the TP53 pathway. We examined alterations in HPV positive (pos) and negative (neg) HNSCC to identify treatment options and elucidate differences in pathogenesis. **Methods:** Eighty HNSCC cases (24 HPV-pos and 33 HPV-neg) were profiled using a multiplatform (IHC, NGS, ISH) approach (Caris Life Sciences, Phoenix, AZ) aimed at identification of biomarkers of therapeutic drug responses. **Results:** HNSCC arising in the following anatomic sites were assessed: larynx, nasopharynx, oropharynx, oral cavity, tongue, and head and neck, NOS. HPV positivity was detected in: nasopharynx, oropharynx, tongue, and head and neck, NOS. Statistically significant differences between HPV-pos and HPV-neg HNSCC were observed for ER(20% (4/20) vs. 0% (0/31); p=0.02) and MGMT(75% (18/24) vs. 40% (13/32); p=0.02) expression (IHC). NGS detected variants in 69% (20/29) of HPV-neg, of which 90% (18/20) had TP53 mutations. 39% (7/18) had 2$^{nd}$ and 3$^{rd}$ hits in the following genes: APC, PTEN, PDGFRA, GNAQ, CDH1 and IDH1. Rare TP53 WT/HPV-neg (10% or 2/20) patients exhibited mutations in APC and PIK3CA. In HPV-pos cases NGS detected variants in 39% (9/23) including: APC, HNF1A , FBXW7, NRAS, PDGFRA, PIK3CA and PTEN. Co-occurrence of mutations included: PDGFRA, NRAS and FBXW7, and PIK3CA and PTEN. In patients with PTEN/PIK3CA mutations (both subgroups), 83%( 5/6) exhibit loss of PTEN expression indicating benefit of mTOR inhibitors. Novel therapies based on NGS data include Wnt pathway inhibitors, multi-kinase inhibitors (imatinib), MEK inhibitors and alkylating agents based on mutations in APC, PDGFRA, GNAQ/NRAS and IDH1, respectively. **Conclusions:** Common and HPV-specific biomarkers characterize HNSCC. ER over-expression indicates anti-hormonal therapies as a potential novel therapy option in HPV-pos, whereas alkylating agents may be of benefit in HPV-neg HNSCC. Novel therapies also include mTOR inhibitors based on alterations in PTEN/PIK3CA. Lower incidence of mutations in HPV-pos HNSCC indicates a need for a multi-platform approach in identifying theranostic biomarkers.

**6081 General Poster Session (Board #116), Sat, 1:15 PM-5:00 PM**

**Prediction of HNSCC recurrence by using kinetic and volumetric FDG-PET parameters.** *Presenting Author: Ronan Abgral, Nuclear Medicine department, University Hospital of Brest, Brest, France*

**Background:** Head and neck squamous cell carcinoma (HNSCC) are tumors with a high recurrence rate and a poor prognosis. Find pre-treatment indicators for predicting survival of patients is therefore a real challenge. Fluorodesoxyglucose positron emission tomography (FDG-PET) is a functional imaging technique used for initial staging of HNSCC. Its prognostic value has already been demonstrated using SUVmax but no threshold has been established to predict recurrence (4-10 within studies). New quantitative indexes such as volumetric (MTV=metabolic tumoral volume) or kinetic (RI=retention index) parameters have been recently suggested as prognostic factors of HNSCC. The aim of this study was to compare the prognostic interest of these parameters to predict HNSCC recurrence. **Methods:** Patients referred to our department to perform FDG-PET for HNSCC staging were included. Tumoral RI corresponding to the percentage variation of SUVmax was calculated by using a dual time point method. Tumoral MTV corresponding to the 3D contour around voxels that are equal or greater to 40% of SUVmax was measured by using a semi-automated workflow. ROC analysis was performed to determine best SUVmax, RI and MTV thresholds to predict recurrence. Univariate analysis was performed to test prognostic significance of these parameters. Kaplan–Meier method was used to estimate recurrence free survival (RFS) probabilities. Multivariate analysis using Cox proportional hazard model was performed. **Results:** Seventy (61M/9F) consecutive patients (62 ± 9yo) were included. ROC analysis revealed SUVmax=7.3 (AUC=0.67), RI=19.5% (AUC=0.76), and MTV=6,7ml (AUC=0.73) as best thresholds to predict recurrence. In univariate, besides age and T stage, SUVmax (p=0.001), RI (p<0.0001) and MTV (p<0.0001) were significantly correlated with RFS. In multivariate, RI (p=0.005) and MTV (p=0.022) persisted as independent predictive parameters of recurrence but not SUVmax (p=0.703). There was no significant correlation between RI and MTV value using a Pearson test (p=0.718). **Conclusions:** Kinetic and volumetric FDG-PET parameters are independent prognostic factors likely to provide complementary information for predicting recurrence in patients with HNSCC.

**6082 General Poster Session (Board #117), Sat, 1:15 PM-5:00 PM**

**Phase I trial of intratumoral therapy using HF10, an oncolytic HSV-1, demonstrates safety in HSV+/HSV- patients with refractory and superficial cancers.** *Presenting Author: Robert L. Ferris, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** HF10 is an oncolytic herpes simplex virus 1 (HSV-1) which can replicate in and destroy cancer cells by direct oncolysis and enhanced anti-tumor immunity. This Phase I dose escalation trial is investigating intratumoral HF10 injections in patients with refractory and superficial cancers. Objectives are to evaluate the safety, tolerability, recommended HF10 dose; viral replication in blood, urine, saliva and tumor biopsies; overall and local (injected lesion) antitumor activity; anti-HSV antibodies; and anti-tumor T cell reactivity, serum cytokines, and proteomics. **Methods:** InStage 1,1 intratumoral injection of HF10 was administered to a single lesion; in Stage 2, up to 4 injections (≥ 2 weeks apart) are administered per patient. Stage 1 patients were HSV-1 seropositive; Stage 2 patients are HSV-1 seropositive or seronegative. Adverse events (AEs) are evaluated according to NCI CTCAE v3.0. **Results:** As of 12/10/2013, 26 patients were enrolled and 24 were treated. Stages 1 and 2 have been completed; an expansion cohort (with patients receiving 4 HF10 injections at 1 x $10^7$ $TCID_{50}$/dose) is ongoing. Total accrual will be 28 patients. 18 patients reported AEs and 6 had HF10-related AE, including: chills (2 patients), and injection site discolorations, edema, and pain, malaise, pruritus, and hypotension (1 patient each). Clearance of HF10 from blood, saliva and urine was rapid. Despite rapid viral clearance, one patient formed ulcers at both the injected and the non-injected lesions after single injection. Importantly, the ulceration occurred only in tumor cells without affecting normal tissue. The observed AEs and viral clearance in HSV-1 seropositive and seronegative patients did not differ. **Conclusions:** Multiple intratumoral injections of HF10 are safe and well-tolerated in HSV+ and HSV- patients with refractory/superficial cancers. Related AEs include flu-like symptoms and injection site reactions that are also reported for other oncolytic viruses. Despite rapid clearance from blood, urine, and saliva, HF10 has the potential to provide continued viral antitumor activity, suggesting that HF10 could be a promising new oncolytic virus treatment. Clinical trial information: NCT01017185.

**6083 General Poster Session (Board #118), Sat, 1:15 PM-5:00 PM**

**Oropharyngeal cancer (OPC) and racial outcome disparities in squamous cell carcinoma of the head and neck (HNSCC): Ten-year experience at the University of Maryland Greenebaum Cancer Center (UMGCC).** *Presenting Author: Dan Paul Zandberg, University of Maryland Greenebaum Cancer Center, Baltimore, MD*

**Background:** Racial outcome disparities have been observed in head and neck cancer with diminished survival for black patients compared to whites. The etiology of this disparity appears to be multifactorial in origin. **Methods:** We retrospectively analyzed 1318 patients with primary HNSCC treated at the UMGCC from 2000 to 2010. **Results:** 65.9% of patients were white, 30.7% were black and 3.3% were other races. Black patients were far less likely to present with oral cavity cancer (15.6% of cases) and far more likely to present with laryngeal or hypopharyngeal cancers (47.9% and 65.6% of cases respectively). Whites were more likely to have early stage (I and II) disease, especially in the oral cavity. In the full cohort, overall survival (OS) for blacks was significantly worse than for whites (median 2.5 years vs. 4.8 years, $p<0.0001$). Multivariable Cox regression analysis showed black patients had significantly worse OS accounting for age, gender, stage, primary site, and tobacco and alcohol consumption. Black patients had worse OS in both oral cavity (medians 5.7 vs. 3.2 years, $p<0.0001$) and oropharynx (OPC) (medians 4.9 vs. 2.1 years $p<0.0001$). However, multivariable analysis showed that race was only significantly associated with survival in OPC. The difference in survival in oral cavity cancers resulted from the larger proportion of white patients with Stage I or II disease. White patients with oral cavity and OPC were more likely to have surgery as primary treatment than blacks reflecting the higher prevalence of early stage disease. There was no difference in OS between races in laryngeal or hypopharyngeal cancer with the majority of these patients presenting with locally advanced disease. **Conclusions:** We observed striking differences in site of disease, stage at presentation and survival comparing black and white patients. Survival disparity overall is driven by a large difference in OPC patients. This is consistent with previous reports of differences in the incidence of HPV in the two ethnic groups, but likely reflects other factors as well.

**6084 General Poster Session (Board #119), Sat, 1:15 PM-5:00 PM**

**Inferior local control for T2bN0 glottic carcinoma with impaired mobility treated with radiation alone: A need for more chemotherapy?** *Presenting Author: Priyanka Bhateja, Cleveland Clinic Foundation, Cleveland, OH*

**Background:** Radiation therapy monotherapy (RT) is standard for patients (pts) with T2N0 squamous cell cancer (SCC) of the glottis. The presence of impaired vocal cord mobility (T2b) is known to portend higher failure rates compared to cancers with supra/sub-glottic extension without impaired cord mobility (T2a). This study sought to compare the local control (LC) rates for these pts and also compare them to LC rates in pts with T2b-3N0-2 glottic cancer treated with concurrent chemoradiotherapy (CRT). **Methods:** In this IRB approved retrospective review, we identified pts with histologically confirmed T2-3N0-2 invasive SCC of the glottis, treated with definitive RT or CRT from 1986 to 2013 at our institution. RT (mean dose 70Gy) was delivered using conventional opposed lateral fields; elective nodal irradiation was used for the majority of pts. Chemotherapy consisted of a 96 hour infusion of cisplatin and 5-fluorouracil on weeks 1 and 5, or single agent cisplatin q3wks. LC, overall survival (OS) and disease free survival (DFS) rates were calculated by the Kaplan-Meier method and compared between the groups using the Log-Rank test. **Results:** Among the 84 pts identified, RT alone was administered to 27 pts with T2aN0 and 31 pts with T2bN0. CRT was delivered to 26 pts with T2b-3N0-2. With a median follow-up of 34 months, we observed a 3-year LC rate in the T2bN0 pts treated with RT alone of 72.5%, compared to 95% in the T2aN0 pts treated with RT ($p=0.01$) and 91% in the T2b-3N0-2 pts treated with CRT ($p=0.08$). There was no difference in OS and DFS rates between the 3 groups. There were 13 local failures, 10 of whom were successfully surgically salvaged. On univariate analysis, lower performance status ($p=0.04$) and T2b disease treated with RT alone ($p=0.02$) were the only factors that were significantly associated with inferior LC. Patient age, tumor bulk, anterior commissure involvement, nodal stage and the type of chemotherapy were not associated with LC. The rates of acute and late toxicities were higher in the CRT group. **Conclusions:** Pts with T2bN0 glottic cancer have a relatively high rate of local failure with RT alone. CRT should be considered to maximize the likelihood of treatment success.

**6085 General Poster Session (Board #120), Sat, 1:15 PM-5:00 PM**

**Racial disparities in the incidence and survival trends in women with squamous cell carcinoma of the oral tongue based on the Surveillance, Epidemiology, and End Results (SEER) analysis.** *Presenting Author: Lindsay Joseph, Rollins School of Public Health, Emory University, Atlanta, GA*

**Background:** The incidence of oral tongue cancer (OTC) in the United States is increasing in women. To better understand this phenomenon, we examined thetime trends and racial disparities in incidence and survival in this population. **Methods:** We identified 6,199 women diagnosed with OTC that were reported to the Surveillance, Epidemiology and End Results (SEER) Program from 1973 to 2010. Cases were categorized by age, race, and year of diagnosis. The incidence and survival rates were compared across metropolitan, urban and rural residential settings and several other demographic categories by calculating rate ratios (RRs) with the corresponding 95% confidence intervals (CIs). We examined temporal variations in incidence of OTC across racial groups using joinpoint analyses to evaluate changes since 1973. **Results:** Cases were predominantly white (85.5%), and 60-64 years of age. OTC incidence in white females demonstrated a statistically significant increase with 0.53 annual percentage change (APC) between 1973 and 2010. For African American (AA) females, on the other hand, the incidence has decreased by -2.79 APC since 1973. Overall incidence was higher among white women (1.30 cases per 100,000/year) compared to AA women (0.67 cases per 100,000/year). Comparisons across residential settings produced similar results wherein incidence rates among women living in metropolitan areas were significantly lower for AA females compared to white females (RR=0.51; 95% CI: 0.43-0.60). The 1-, 5- and 10-year relative survival estimates (RS: defined as observed survival among cancer patients divided by the expected survival in the general population) for all women with OTC were 85%, 63% and 53%, respectively. When stratified on race, the corresponding 1-, 5- and 10-year race specific RS estimates were 86%, 63% and 54% for white women, and 76%, 46% and 33% for AA women. **Conclusions:** The racial disparity in survival of women with oral tongue cancer is pronounced. Identifying the demographic characteristics of white women with OTC may lead to a better understanding of the causes behind the increased incidence in this group.

**6086 General Poster Session (Board #121), Sat, 1:15 PM-5:00 PM**

**Expression of tumor biomarkers in HIV-infected patients with head and neck cancer.** *Presenting Author: Hongzheng Zhang, Department of Hematology & Medical Oncology, Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA*

**Background:** Human immunodeficiency virus (HIV)-infected individuals are at increased risk for head and neck cancer (HNC). Poor survival is associated with low CD4 counts, larynx/hypopharynx site and current tobacco use. The expression of tumor biomarkers and their correlation with risk factors has not been studied in HIV+HNC. We compared a panel of tumor oncogenic (NFkB, pAKTS473, pSTAT3tyr705 and Bcl2) and inflammatory (TGF$\beta$, IL-6 and VEGF) biomarkers in tumors from patients with HIV+ vs HIV-HNC. **Methods:** 56 HIV+HNC cases were identified at 5 US tertiary care referral centers between 1991-2011. Expression of tumor biomarkers was detected on tissue microarray by immunohistochemistry using formalin-fixed paraffin-embedded surgical specimens from primary tumors matched with anatomical site in HIV-patients with HNC (N=44/group), and scored by a pathologist. Clinical information was captured in the HIV+HNC cohort only (N=29 for biomarker analysis). **Results:** In the HIV+HNC group: median age 49 (range 28-70), median CD4 counts 298 cells/$\mu$L (range 5-1038), 78% patients were current alcohol consumers, 79% current smokers, 61% receiving highly active antiretroviral therapy at time of cancer diagnosis. Median follow up was 517 days. Tumors from the HIV- cohort tended to express greater NFkB than those from HIV+ cohort ($p=0.062$). In the HIV+HNC cohort, VEGF expression was associated with advanced tumor stage ($p<0.05$) while pSTAT3 expression was associated with early stage ($p<0.05$). Regardless of HIV status, NFkB expression was positively correlated with pAKT ($r=0.753$, $p<0.001$), both were expressed at greater levels in the oral cavity than other sites ($p<0.001$ and $p=0.003$, respectively), and both lower in current alcohol drinkers ($p<0.001$) and current smokers ($p<0.05$) than in former and/or never drinkers/smokers. Multivariate analysis indicated that high pSTAT3 ($p<0.05$) and VEGF ($p=0.061$) were associated with improved overall survival and African American race ($p<0.05$) with poor prognosis. **Conclusions:** This is the first exploratory study linking tumor biomarkers with risk factors in HIV+HNC. Tumor biomarkers are differentially expressed by HIV status, alcohol and tobacco use, and are associated with overall survival.

**6087 General Poster Session (Board #122), Sat, 1:15 PM-5:00 PM**

**Nasopharyngeal carcinoma patients with new primaries.** *Presenting Author: Musa Altun, Istanbul University Oncology Institute, Istanbul, Turkey*

**Background:** Due to improvements in treatment, the importance of new primaries in nasopharyngeal carcinoma (NPC) patients is increasing. The aim of this study is to evaluate new primaries in NPC. **Methods:** NPC patients treated between 1980 and 2008 are divided according to age at diagnosis; pediatric (≤17), and adult (> 17). In each group, new primaries (NP) are classified depending on the organ, latent period, histopathology and location (in or out of the radiation field). **Results:** 97 pediatric, 709 adult were treated between 1980 and 2008. Male: female ratio of the whole group and the patients with NP are 2:1 and 3:1, respectively. Median follow-up time was 7 years. 7 (7%) pediatric, 44 (6%) adult patients had NP. All NP were confirmed histopathologically. 6 of the 7 NP detected in pediatric patients were in-field and 4 of them were sarcomas. In the adult group, 37 metachron, 3 synchronic, 5 previous tumors were observed. 35% of metachron primaries were in the irradiated area. Larynx and lung cancers were the commonest NP in the in-field and outfield primaries. Median latent period of metachron tumors was 125 months (range 11-462) (Table). 46% of NP were located in HNC region. The incidence of radiation induced sarcoma (RIS) was significantly higher in pediatrics compared with adults (4,12% vs.0,14%, p<0,005). **Conclusions:** The significantly increased incidence of RIS in pediatric NPC patients is striking. Viral or field-cancerization relationship in NP seems not as obvious as in other HNC. Physicians should be aware of NP during follow-up for early diagnosis in this group of patients.

**Molecular predictors of response to sorafenib in patients with radioactive iodine-resistant advanced thyroid cancer.** *Presenting Author: Mark Yarchoan, Department of Internal Medicine, University of Pennsylvania, Philadelphia, PA*

**Background:** Sorafenib has demonstrated significant antitumor activity in patients with advanced iodine-refractory thyroid carcinoma. In order to identify molecular predictors of response to sorafenib, we studied tumor molecular markers and clinical responses obtained from a subset of patients entered in a phase 2 study of sorafenib in advanced thyroid cancer. **Methods:** Paraffin embedded tissues sections of the most recent tumor sample from patients were immunostained (IHC) with DAB-labeled antibodies to pERK, pAKT and pS6. Protein expression was quantified using a multispectral imaging system which allows for automated tumor segmentation, and cellular and subcellular stain localization and quantitation. Using this system, the optical density of the DAB for each immunostain on a cell by cell basis is achieved along with subcellular location. Protein expression levels were correlated with objective tumor response and progression free survival for all patients. BRAFV600E genetic mutation analysis was performed on all samples. **Results:** IHC was performed for 40 patients, of whom 17 (42.5%) achieved a partial response (PR), 21 (52.5%) achieved stable disease (SD), and 2 (5%) had disease progression as a best response. There was an inverse association between nuclear pAKT expression level and achieving a partial response to sorafenib (p=0.003). Only 2/10 patients in the highest quartile of pAKT expression achieved a partial response, as compared to 7/10 patients in the lowest quartile of pAKT expression. However, nuclear pAKT expression was not predictive of time to progression. Furthermore, there was no correlation of pERK or pS6 nuclear expression and response to sorafenib. In tumor endothelial cells, expression of pERK, pAKT and pS6 was not predictive of response to sorafenib. There was no correlation between BRAFV600E mutation status and response to sorafenib across the entire cohort or within the subset of patients with papillary thyroid cancer (n=22). **Conclusions:** These results suggest that lower nuclear pAKT expression may be a positive predictive biomarker for response to sorafenib in advanced thyroid cancer, and merits further evaluation in additional clinical trials. Clinical trial information: NCT00654238.

**6089 General Poster Session (Board #124), Sat, 1:15 PM-5:00 PM**

**Effect of the addition of temsirolimus to cetuximab in cetuximab-resistant head and neck cancers: Results of the randomized PII MAESTRO study.** *Presenting Author: Apoorva Chawla, The University of Chicago Medicine and Biological Sciences, Chicago, IL*

**Background:** Patients with cetuximab resistant HNC have a median PFS of only 1.8 months (deSouza 2012). Preclinical/computational modelling suggests synergy between mTOR and EGFR, and potential to overcome resistance and aberrations in the PI3K-MTOR pathway occur in ≥30% of HNC. A previous trial of erlotinib+everolimus was terminated early due to toxicity (Bauman 2013). **Methods:** Eligibility was PS≤1, metastatic HNC with documented progression on cetuximab. Pts were randomized to temsirolimus (T) 25 mg +/-cetuximab (C) 400/250 mg/m$^2$ weekly. Primary endpoint was PFS with a target of 80 pts to detect a 2 months increase. 2$^{nd}$ endpoints were RR, OS, toxicity. **Results:** 80 pts (40 TC, 40 T) started treatment via the Univ. of Chicago, and Mayo Phase II CTEP networks. Median age was 63 yrs; 69M, 11F. Median PFS was 89 days (TC) vs 93.5 days (T), NS. Median overall survival was 205/181 days, NS. Treatment was tolerable with fatigue, skin and hematologic toxicities being common. Hyperglycemia was seen in 17/80 patients (11 TC, 6 T). Grade 3-4 toxicities included metabolic abnormalities (17/40 TC, 10/40 T), hematologic toxicity (7/40 TC, 13/40 T), infection (4/40 TC, 3/40 T), and pulmonary toxicity (2/40 TC, 2/40 T). 5 responses (1 CR, 4 PR) were observed in the TC arm (RR 12.5%) (TC) vs 1 PR (2.5%) on T arm (one-sided $P$=0.1). Of note, all TC responders had disease control from prior C treatment (response/prolonged SD) with subsequent acquired resistance. In responders the mean interval between C failure and start of trial treatment was 3.4 months (1.1 – 6.5). In TC responders, median duration of response was 7.2 months (5.1 – 15.3). Interestingly, TC responses were maintained for up to 15 months exceeding prior benefit from C in several pts. TC responders had a median PFS of 231 days. The sole T alone response was short (89 days). **Conclusions:** T+C is safe and tolerable. The addition of T to C appears to overcome acquired C resistance in 12.5% of pts despite an overall negative trial. Responses are durable and clinically meaningful in this otherwise poor prognosis population. Single agent T is ineffective. Prior benefit from cetuximab is a candidate predictive biomarker for benefit from TC. Clinical trial information: NCI 8692.

**6090 General Poster Session (Board #125), Sat, 1:15 PM-5:00 PM**

**Phase II trial of radiotherapy (RT) with concurrent cisplatin (C) plus panitumumab (pmAb) for patients (pts) with high-risk, resected head and neck cancer (HNC).** *Presenting Author: Robert L. Ferris, Department of Otolaryngology, University of Pittsburgh School of Medicine, Pittsburgh, PA*

**Background:** Treatment intensification for human papillomavirus (HPV)-negative HNC is an active area of investigation. Targeting the epidermal growth-factor receptor pathway using the monoclonal antibody pmAb with C chemoradiation was investigated in high-risk resected, primarily HPV-HNC patients. **Methods:** Eligible were pts with ECOG performance status 0-1 with pathologic stage III or IVA squamous cell carcinoma of the oral cavity, larynx, or hypopharynx, without gross residual tumor and with high-risk factors (margins <1mm, extracapsular spread (ECS), perineural/angiolymphatic invasion, or 2 or more positive lymph nodes). Postoperative treatment started within 7 weeks of surgery, consisting of standard RT (60-66 Gy, once daily fractions in 6-7 weeks) concurrent with weekly pmAb 2.5 mg/kg IV and weekly C 30 mg/m$^2$IV. Carboplatin (AUC 1.5 weekly) substitution was allowed for certain C-associated toxicities. The primary endpoint was progression-free survival (PFS). **Results:** Of 46 pts accrued, 2 did not receive pmAb, leaving 44 for analysis. Median age was 58 (range 23-81); 16% were female. Primary sites included: oral cavity (73%), larynx (20%), hypopharynx (5%), oropharynx (2%); 86% were stage IVA. Indications for adjuvant therapy included ECS (n=23), perineural invasion (n=22), and/or positive margins (n=3). The median follow-up for 32 pts without recurrence was 27 months (range 3-67). The 2-year PFS was 73% (95% CI, 61-88%) and the 2-year overall survival (OS) was 76% (95 % CI, 64-91%). 12 pts developed recurrence; 8 of them died. An additional 5 pts died from other causes. Grade 3/4 toxicities included mucositis (41%), hyponatremia (25%), leukopenia (25%), dysphagia (18%), neutropenia (21%), nausea/vomiting (14%), anorexia (11%), rash (9%), and neutropenic fever (9%). Prophylactic gastrostomy tubes were placed in 43% of patients; 18% required tube placement during or after therapy. **Conclusions:** Preliminary analysis of adjuvant treatment intensification by adding pmAb to C chemoradiation suggests promising clinical outcome for high-risk, predominantly HPV- HNC pts. Clinical trial information: NCT00798655.

**6091 General Poster Session (Board #126), Sat, 1:15 PM-5:00 PM**

**Effect of FGFR1 on epithelial-mesenchymal transition and EGFR resistance in HNC: A systems biology approach.** *Presenting Author: Damian Rieke, The University of Chicago, Chicago, IL*

**Background:** Fibroblast Growth Factor Receptor 1 (FGFR1) plays an important role in cancer and is an emerging treatment target for squamous lung cancer and other tumor types. We determined the functional implicatiosn of FGFR1 signaling using a systems biology approach. **Methods:** 120 HNSCC tumor samples from patients treated at Univ. of Chicago were analyzed. We determined copy number alterations (Nanostring, +qPCR validation), gene expression (Agilent) as well as mutations (IIlumina)and employed in-silico modeling/published gene expression signatures (GSEA) to investigate receptor kinases as well as mechanisms correlated with FGFR1 signaling. HNC TCGA data was used for validation. Secondly we performed in-vitro validation in a panel of 12 HNSCC cell lines. Viability testing was performed with PD173074, ponatinib, gefitinib, as well as combinations of these drugs. Immunoblotting was performed for MAPK and AKT pathways, Vimentin and E-Cadherin total protein. **Results:** FGFR1 copy number gain occurred in 3% or our cohort and 8% of TCGA samples and was most prominent in laryngeal tumors. Interestingly high FGFR1 expression were identified in 20% of HNSCC and highly correlated with Epithelial-to-Mesenchymal Transition (EMT) ($p<0.001$). Several additional receptor Tyrosine Kinases (RTKs) strongly correlated with EMT including PDGFRA, PDGFRB, AXL, and ACVRL1 (TGF-beta pathway). By contrast EGFR and MET expression strongly correlated with an epithelial phenotype. We identified 6 mesenchymal-like and 6 non-mesenchymal-like cell lines out of a panel of 40 cell lines. Mesenchymal cell lines were resistant to Epidermal Growth Factor Receptor-inhibition with gefitinib, but combined FGFR and EGFR inhibition showed strong synergy in these resistant cell lines. Ponatinib showed the highest level of activity, due to evidence of co-inhibition of other EMT associated kinases. **Conclusions:** FGFR1 drives the EMT phenotype in HNC, and is a valid treatment target that may help overcome EGFR resistance when used in combination.

**6092 General Poster Session (Board #127), Sat, 1:15 PM-5:00 PM**

**Impact of lymph node ratio on survival in advanced head and neck cancer: National Cancer Data Base (NCDB).** *Presenting Author: Sukamal Saha, McLaren Regional Medical Center, Michigan State University, Flint, MI*

**Background:** Lymph node ratio (LNR), the no. of positive nodes divided by no. of nodes extracted, has prognostic importance in colon and breast cancer. We aim to evaluate the role of LNR in the treatment of head and neck cancer (HNC), as its prognostic value is unknown. **Methods:** Pts from NCDB with advanced HNC (1998-2010), including laryngeal (LC) and non laryngeal cancer (NLC), were analyzed. Pts underwent surgery of the primary site with neck dissection. Only pts with complete data of age, sex, grade, TNM staging, and LNR were included. Using the median LNR of 0.1, pts were divided into two groups: GpA (LNR $<0.1$) or GpB (LNR $>0.1$). 5yr overall survival (5yr OS) was compared using K-Meier. Multivariate analysis was performed using Cox-proportional model. An adjusted hazard ratio (aHR) was calculated for pts in both groups. **Results:** Of 81, 672 pts included, a majority were Stage III (16,562) or Stage IV (44,831) with 47,510 pts having nodal metastasis. Of these, 24,206 (51%) were in GpA and 23,304 (49%) in GpB. There were 4,564 LC pts in GpA and 4,059 in GpB. The median no. of +'ve LN were 2 and 4 while the median no. of LN extracted were 40 and 21, respectively. 5yr OS for GpA and GpB was 50% vs. 33% for Stage III and 40% vs. 24% for Stage IV. There were 19.462 NLC pts in GpA and 19,245 in GpB. The median no. of +'ve LN were 1 and 3 while the median no. of LN extracted were 36 and 17, respectively. 5yr OS for GpA and GpB was 60% vs. 57% for Stage III and 53% vs. 39% for Stage IV. The aHR of pts with LNR $>0.1$ compared to LNR $<0.1$ was 1.4 (95% CI 1.36-1.43), after adjusting for other prognostic covariates (Table 1). **Conclusions:** LNR has significant impact on the survival of pts with advanced HNC. LNR of 0.1 or higher in HNC is associated with 40% increased relative risk of death.

**Characteristics of patients in GpA (LNR < 0.1) and GpB (LNR > 0.1).**

| Variables | GpA(LNR<0.1) | GpB(LNR>0.1) | P-value |
|---|---|---|---|
| No. of patients(%) | 24,206(51%) | 23,304(49%) | |
| Median age(yrs) | 58 | 59 | |
| No. of LC(%) | 4,564(53%) | 4,059(47%) | |
| Median LN extracted | 40 | 21 | <0.001 |
| Median positive LN | 2 | 4 | <0.001 |
| 5yr OS stage III | 50% | 33% | <0.001 |
| 5yr OS stage IV | 40% | 24% | <0.001 |
| No. of NLC(%) | 19,642(50.5%) | 19,245(49.5%) | |
| Median LN extracted | 36 | 17 | <0.001 |
| Median positive LN | 1 | 3 | <0.001 |
| 5yr OS stage III | 60% | 57% | <0.001 |
| 5yr OS stage IV | 53% | 39% | <0.001 |

**6093 General Poster Session (Board #128), Sat, 1:15 PM-5:00 PM**

**Phase II study of axitinib in patients with progressive, recurrent/metastatic adenoid cystic carcinoma.** *Presenting Author: Alan Loh Ho, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Recurrent/metastatic adenoid cystic carcinoma (R/M ACC) is an incurable disease with no standard treatments. >70% of ACCs highly express the oncogenic transcription factor c-myb, which drives expression of genes that activate vascular endothelial growth factor receptor (VEGFR) and c-kit pathways. Axitinib (AG-013736; Pfizer) is a potent inhibitor of VEGFR and c-kit that we hypothesized would be an effective therapeutic for R/M ACC patients. **Methods:** For this minimax two-stage phase II trial, patients with locally advanced, recurrent, and/or metastatic ACC (any primary site) not amenable to curative surgery or radiation were enrolled. Evidence of disease progression on imaging performed within 6 months of enrollment ornew/worsening disease-related symptoms was required. Patients were treated with axitinib 5 mg orally twice daily (BID); those with ≤Grade 2 axitinib-related adverse events (AEs) for two consecutive weeks and blood pressure ≤150/90 mmHg without antihypertensive medication were eligible for dose escalation up to 10 mg BID. The primary endpoint was best overall response rate (ORR) by RECIST v1.1 criteria. The objective was to detect a difference in ORR of 5% vs. 20% (with 10% one-sided type I error and 90% power); ≥1 response among the first 18 patients had to be achieved before accruing 14 more patients in the second stage. ≥4 responses out of 32 patients would be deemed promising. **Results:** 33 patients were registered and evaluable for response. One patient included in the analysis was determined to be ineligible after one dose of axitinib and replaced. 15 of 19 eligible for dose escalation had the axitinib dose increased. 22 achieved reductions in tumor size. 3 (9.1%) had confirmed PR and 25 (75.8%) stable disease (SD) as best overall response. 11 had SD for ≥ 6 months. The most common axitinib-related AEs were hypertension, fatigue, weight loss, anorexia, diarrhea, hand-foot syndrome, nausea, and oral pain. Exploratory analyses evaluating clinicopathologic correlates to response (including c-myb expression) are ongoing. **Conclusions:** The study did not meet its primary endpoint. Axitinib does appear to achieve disease-control in a subset of progressive R/M ACC patients. Clinical trial information: NCT01558661.

**6094 General Poster Session (Board #129), Sat, 1:15 PM-5:00 PM**

**Correlation of homologous recombination deficiency in head and neck cancer with sensitivity to PARP inhibition.** *Presenting Author: Jana Heitmann, The University of Chicago, Chicago, IL*

**Background:** Cancers deficient in homologous recombination (HR) exhibit synthetic lethality when treated with poly (ADP-ribose) polymerase (PARP) inhibitors and may be more sensitive to platinum based therapies. While BRCA1/2 mutations are uncommon in head and neck cancer (HNC), we hypothesized that other mechanisms of HR deficiency occur frequently. **Methods:** We employed three methods to determine homologous recombination deficiency (HRD): (1) HRD-score, (2) Large-scale chromosomal breaks (Popova et al), (3) BRCA-like CN profile (Schouten et al) using HNC TCGA and Chicago HNC Genomic cohort (CHGC) data. We furthermore screened for HR pathway mutations in both genomic cohorts. Single agent activity of three PARP inhibitors (veliparib (non-locking), olaparib and rucaparib (locking)) was evaluated in a panel of 10 HNC cell lines (colony formation, viability) and compared with a BRCA deficient breast cancer cell line. Immunofluorescent staining for γH2AX and RAD51 was performed. A gene signature of HRD deficiency was developed. **Results:** HR deficiency was present in 25% of HNC, and was largely concordant between all three methods (1. and 2. had the highest correlation), but were not related to BRCA1/2 mutations in HNC TCGA. BRCA1/2 mutations were rare (<1%) and of unclear significance. In a panel of HNC cell lines rucaparib showed the highest potency as a single agent with three cell lines exhibiting sensitivity ($IC_{50}$: 7.0$\mu$M, 10.3$\mu$M and 11.7$\mu$M), comparable or superior to a BRCA deficient breast cancer cell line ($IC_{50}$value: 8.9$\mu$M). Seven HNC cell lines were more resistant to single agent PARP inhibition. Foci formation of the HR marker RAD51 did not serve as a reliable biomarker in those cell lines, but our newly developed gene expression signature was applicable. **Conclusions:** In conclusion, we discover that HR-deficiency is present in 25% of HNC tumors, and benefit of single agent PARP inhibition is present in pre-clinical HNC models, despite the general absence of BRCA mutations in this tumor type. HRD-score is a candidate biomarker to identify patients that may benefit from PARP inhibition, including combinations with cytotoxic chemotherapies or radiation in the future.

**6095 General Poster Session (Board #130), Sat, 1:15 PM-5:00 PM**

**Prognostic value of radiographic extracapsular extension in locally advanced head and neck squamous cell cancers.** *Presenting Author: Jerry T. Liu, Icahn School of Medicine at Mount Sinai, Department of Radiation Oncology, New York, NY*

**Background:** Previous data from our institution suggests that radiographic evidence of extracapsular extension (rECE), identified on pretreatment diagnostic CT imaging, predicts for worse outcomes for oropharyngeal cancer patients undergoing radiation therapy. We sought to validate these findings in all sites of locally advanced head and neck squamous cell cancers (LAHNC). **Methods:** From our departmental database, 224 LAHNC patients with accessible pretreatment CT scans completed definitive or adjuvant radiation therapy (± induction and/or concurrent chemotherapy) from 2005-2012. Three patients died shortly after treatment. The remaining 221 patients (nasopharynx (n=19), oral cavity (n=22), oropharynx (n=126), hypopharynx (n=15), larynx (n=21), nasal cavity/sinus (n=3), and unknown primary (n=15)) were selected and all pretreatment CTs were reviewed by our head/neck radiologist for evidence of rECE. Patients were stratified by presence of rECE, age, gender, race, smoking history, ECOG performance status (PS), disease site, cT-stage, cN-stage, and treatment type. Univariate and multivariate analyses (MVA) were performed regarding impact of these factors on locoregional control (LRC), distant control (DC), progression free survival (PFS) and overall survival (OS). **Results:** With median follow-up of 30 months (range: 3-100), 126 (57%) patients had rECE and 95 (43%) did not. These groups were well-balanced for age, gender, race, smoking history, disease site, PS, treatment type, and cT-stage. Patients with rECE were more likely to have cN2-3 disease versus those without rECE (84% vs. 77%, p=0.015). Patients with rECE had worse LRC (3yr: 78% vs. 89%, p=0.032), DC (3yr: 72% vs. 89%, p=0.017), PFS (3yr: 60% vs. 73%, p=0.011), and OS (3yr: 64% vs. 80%, p=0.011). On MVA, rECE was found to independently predict for worse LRC (HR 2.59, 95%CI 1.22-5.51), DC (HR 3.28, 95%CI 1.57-6.85), PFS (HR 1.91, 95%CI 1.16-3.15), and OS (HR 2.041, 95%CI 1.15-3.63). **Conclusions:** Presence of rECE independently predicts for worse outcomes for LAHNC patients undergoing radiation therapy. Larger studies with longer follow-up are needed to determine how rECE can guide clinical management in these patients.

**6096 General Poster Session (Board #131), Sat, 1:15 PM-5:00 PM**

**A retrospective study to determine the utility of measuring E6 and E7 antibody (Ab) levels in sera as a biomarker of recurrence in patients (pts) with locally advanced (LA), human papillomavirus-positive (HPV+) oropharyngeal squamous cell carcinoma (OPSCC).** *Presenting Author: Assuntina Gesualda Sacco, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

**Background:** Approximately 20% of pts with LA, HPV+ OPSCC have poor survival outcomes. To date, there is a paucity of biomarkers to predict which pts will ultimately fail standard therapy. E6/E7 viral oncoproteins are constitutively expressed in HPV+ tumors and highly immunogenic, resulting in readily detected serum Ab. The relative absence of E6/E7 Ab in healthy controls and HPV negative tumors, coupled with cervical cancer data suggesting a correlation between E6/E7 Ab levels and prognosis, warrants evaluation in HPV+ OPSCC. **Methods:** Pts with previously untreated, LA (stage III, IV), HPV+ OPSCC receiving definitive chemoradiation from 2003-2010 were included. Baseline and longitudinal (post-treatment, at recurrence and >12 months post-treatment) serum samples were obtained from our archived repository. E6/E7 serum Ab was measured using a glutathione-*S*-transferase (GST) capture ELISA. Serial dilutions of each serum sample were performed, with area under the curve analysis calculated. E6/E7 change was quantified linearly and on a multiplicative scale using ratios of post and pre-treatment levels. **Results:** 30 of 171 (18%) pts recurred (16 distant, 6 regional, 2 local, 2 locoregional, 2 local/distant, 2 regional/distant). 22 of 30 had baseline serum; 15 had serum at recurrence. This group (R) was compared to 30 pts who remained disease-free (NR). R and NR were well-balanced except for a non-significant (NS) trend toward higher T and N stage in R. At baseline, higher T stage was associated with lower E7 levels (p=0.016), whereas higher N stage had higher E7 levels (NS). Current smokers had lower baseline E7 levels (NS). NR pts cleared more proportion E7 than R pts, p=0.0016. Current smokers had higher baseline E6 levels (NS) and cleared less E6, p=0.04. Age and gender did not affect Ab patterns. **Conclusions:** Pts who recur clear less E7 Ab after treatment. Smoking impacts E6/E7 Ab patterns. Impact of pack-year tobacco use, alcohol and marijuana use will be reported. These findings merit evaluation in a prospective clinical trial.

**TPS6097^ General Poster Session (Board #132A), Sat, 1:15 PM-5:00 PM**

**A phase I/II randomized study of Debio1143 combined with concurrent chemoradiation therapy (CCRT) in patients with locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN).** *Presenting Author: Christophe Le Tourneau, Department of Medical Oncology, Institut Curie, Paris, France*

**Background:** Inhibitors of apoptosis proteins (IAPs) are negative modulators of apoptosis which represent attractive targets to overcome resistance to cancer therapy. The small molecule Debio1143 is a potent orally-active IAP antagonist able to promote apoptosis in tumour cells by restoring caspase activity, and modulating NF-κB signalling and TNFα effects. As single agent, Debio1143 inhibits cell growth and induces apoptosis in a subset of human cancer cell lines and in multiple xenograft models of human cancer, including SCCHN. Furthermore, Debio1143 potentiates the effects of cisplatin and radiotherapy in SCCHN nonclinical models (D. Viertl et al.,Radiotherapy and Oncol 106, Suppl.1, 2013; Abstract OC-19, p. 56). Debio1143 monotherapy was well toleratedin cancer patients up to 900 mg OD, resulted in rapid and sustained cIAP1 suppression in patient peripheral blood mononuclear cells and in skin biopsies, and achieved exposures that were previously shown to be active in animal models (H. Hurwitz et al., EJC 48, Suppl.6, 2012; Abstract 76, p. 25). **Methods:** This is a phase I/II, multicentre study comprising a dose-escalation Phase I part (A) and a randomised Phase II part (B) that enrols untreated LA-SCCHN patients with T≥2, N0-3, M0 disease eligible for exclusive chemoradiation. Oropharynx cancer patients have to be HPV-negative. Standard fraction radiotherapy is delivered with a daily dose of 2Gy for 5 days per week to a total dose of 70Gy. Cisplatin is administered on Day 2 of every 21-day cycle for 3 cycles at the dose of 100 mg/m². Debio1143 is orally administered OD on days 1-14 of every 21-day cycle. The starting dose is 100 mg and will be in part A escalated by 100 mg increase using a modified continual reassessment method. Extensive PK, PD, and pharmacogenomics assessments are included. Part B is a double-blind, placebo-controlled Phase II trial in which 97 patients will be randomised to receive placebo or Debio1143 at the dose recommended in part A in combination with CCRT. Primary endpoint is locoregional control at 18 months. Dose escalation started on September 2013 and it is ongoing. Clinical trial information: NCT02022098.

**TPS6098 General Poster Session (Board #132B), Sat, 1:15 PM-5:00 PM**

**A randomized, multicenter phase III clinical trial comparing gemcitabine and cisplatin with 5-fluorouracil and cisplatin in the treatment of recurrent or metastatic nasopharyngeal carcinoma.** *Presenting Author: Li Zhang, Cancer Center of Sun Yat-Sen University, Guangzhou, China*

**Background:** Nasopharyngeal carcinoma (NPC) is highly sensitive to both radiotherapy and chemotherapy. Nowadays, the regimen of 5-Fluorouracil plus cisplatin (FP) is widely used in recurrent or metastatic (R/M) NPC patients, but the response period is usually short and the adverse reaction is frequent and badly tolerant. Several small phase II trials suggest gemcitabine plus cisplatin (GP) has promising efficacy and better tolerability. Unfortunately, there is no head to head comparison study to evaluate these two regiments in this setting. This phase III trial will evaluate the efficacy and safety of GP versus FP as first-line therapy in patients with R/M NPC. **Methods:** The population consists of R/M NPC patients that failed the radical radiotherapy or chemotherapy-naïve advanced NPC (stage IV). Eligible patients will be randomized in a 1:1 ratio to receive either GP (gemcitabine 1,000 mg/m$^2$ on days 1, 8, cisplatin 80 mg/m$^2$ on day 1, every 3 weeks) or FP regimens (5-Fluorouracil 4,000 mg/m$^2$ CIV over 96 hours, cisplatin 80 mg/m$^2$ on day 1, every 3 weeks) for 4 to 6 cycles. The primary endpoint is progression free survival (PFS). Secondary endpoints include overall survival (OS), objective response rate (ORR), safety and quality of life. According to previously reported, it was assumed that the median PFS would be 4 months in the FP group and 6 months in the GP group. To detect a hazard ratio of 0.67, and a two-sided significance level of 5%, with a power of 80%, accommodating for a maximum drop-out rate of 5%, the necessary sample size was calculated to be 198 patients per group. Therefore, the trial plans to enroll 362 patients at 21 sites in China. Thus far, 203 patients have been enrolled. Clinical trial information: NCT01528618.

**TPS6099 General Poster Session (Board #133A), Sat, 1:15 PM-5:00 PM**

**Elderly Head and Neck Cancer (ELAN) study: Personalized treatment according to geriatric assessment in patients age 70 or older: First prospective trials in patients with squamous cell cancer of the head and neck (SCCHN) unsuitable for surgery.** *Presenting Author: Joel Guigay, Gustave Roussy, Villejuif at present Centre Antoine-Lacassagne, IUFC, Nice, France*

**Background:** 30% of SCCHN occur in patients (pts) >= 70y and the main challenges in these pts are to cope with the treatment benefit/risk ratio and the tumor related symptoms. However, these pts are usually not included in trials. We developed a large prospective clinical program planed to enroll 448 pts in 3 distinct trials to improve the multidisciplinary management of elderly SCCHN pts. The main objectives of this study are to demonstrate that a geriatric evaluation is feasible in daily practice for SCCHN pts and to set new standards of care in this population. **Methods:** To be included in one of the three trials, SCCHN pts aged 70 or over, not suitable for surgery, must first be enrolled in ELAN-ONCOVAL study where they are classified as fit or unfit, using a geriatric evaluation applicable to the daily practice. Comprehensive Geriatric Assessment is optional. In curative situation, unfit pts are proposed to be enrolled in the randomized non-inferiority ELAN-RT trial, comparing standard radiotherapy (RT, 70Gy, 35 fractions, 7 weeks) and hypofractionated split course schedule (30 Gy in 10 fractions, 2 weeks stop, 25 Gy in 10 fractions, total 6 weeks). Main endpoint is the rate of patients alive with local control 6 months after end of RT. 202 pts are planned to be randomized. In first line treatment of recurrent and/or metastatic (R/M) pts: - Fit pts are proposed to be enrolled in the 2-stage phase II ELAN-FIT trial, which evaluates the cetuximab-carboplatin-5FU (EXTREME) combination in terms of efficacy (objective response at 12 weeks) and safety assessed by lack of grade>=3 toxicity and lack of loss of independence. Enrollment of 82 pts is planned. - Unfit pts are proposed to be enrolled in the efficacy randomized phase III ELAN-UNFIT trial, that compares two monotherapies (cetuximab 500 mg/m$^2$ every 2 weeks versus weekly methotrexate 40 mg/m$^2$) in terms of failure free survival (failures are progression, treatment stop, loss >= 2 points in Activities in Daily Living scale or death). 164 pts are planned to be randomized. Inclusions started on June 2013. At now 23 centers are opened. Grants: INCa PAIR Clinical trial information: NCT01884623; NCT01864850; NCT01864772.

**TPS6100 General Poster Session (Board #133B), Sat, 1:15 PM-5:00 PM**

**Multicenter, randomized, controlled, open-label study of bevacizumab combined with carboplatin and paclitaxel versus carboplatin and paclitaxel in patients with metastatic nasopharyngeal carcinoma.** *Presenting Author: Li Zhang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

**Background:** Nasopharyngeal carcinoma (NPC) is an endemic disease with a high incidence in South-East Asian. Standard chemotherapy for metastatic NPC is platinum-based regimen. Improvement the outcome of mNPC patients remains a high-unmet medical need. Vascular endothelial growth factor (VEGF) was over expressed in 67% of NPCs and correlated to higher rate of recurrence and less survival. Bevacizumab, an anti-tumor angiogenesis monoclonal antibody, precisely targets VEGF to inhibit angiogenesis for continuous tumor control. A phase II multi-institutional trial (RTOG0615) showed that bevacizumab plus chemoradiation is feasible, and might delay the progression of subclinical distant disease in NPC. We plan to initiate the first randomized study to evaluate the efficacy and safety of bevacizumab plus paclitaxel/carboplatin (TC) particularly in mNPC population. **Methods:** This is a multi-center, randomized phase II study. The primary end-point of the study was progression-free survival (PFS) based on independently assessment. Secondary end-point include overall survival (OS), response rate (ORR), disease control rate (DCR), health-related quality of life (HRQoL) and toxicity profiles. The study was designed to have 60% power to detect a 33% improvement of PFS in bevacizumab treated arms (from 6 month to 9 month) at a two-sided significance level of 5%. Based on these assumptions, a total of 80 patients are needed to observe 57 events. Eighty treatment naïve metastatic NPC patients will be randomly assigned (1:1) to receive TC plus bevacizumab or TC alone. TC consisted of carboplatin (AUC 5, iv) /paclitaxel (175 mg/kg, iv) on day 1 of each 3-week cycle for up to 6 cycles; bevacizumab (7.5 mg/kg, iv) was administered with carboplatin/paclitaxel on day 1 and maintenance after the finish of chemotherapy until disease progression or unacceptable toxicity. Recruitment will begin in March 2014. The duration of the trial will be 24 months (12 months recruitment and 12 months follow-up).

**TPS6101 General Poster Session (Board #134A), Sat, 1:15 PM-5:00 PM**

**Personalized cancer therapy for patients with metastatic medullary thyroid cancer (MTC).** *Presenting Author: Krzysztof Misiukiewicz, Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** Standard approaches in cancer research identify new therapies based on observed benefit to average populations, but without emphasis on individual patients whose responses can vary considerably. Further, targeted therapies rarely account for the genomic complexity of patient tumors; the result is poor efficacy and rapid resistance. Ideally, we would identify drugs or drug cocktails that (1) target the details of an individual's tumor and (2) account for its complexity. Models using the fruit fly Drosophila represent a potential new paradigm in cancer therapy. We have developed fly models that can include up to 10 of a patient's driver mutations; the result is an inexpensive drug screening platform to identify drug cocktails through empirical screening. As validation flies helped identify vandetinib, now approved for treatment of metastatic MTC. **Methods:** Tumor mutations identified by deep DNA and RNA sequencing of individual tumors are screened for tumor drivers, which are then incorporated into the "personal" Drosophila model and tested against a library of FDA approved drugs. Fly mortality is used as a surrogate for toxicity and increased survival to adulthood; improvements in tumor mutation-linked eye and/or wing abnormalities serve to quantify efficacy. This allows rapid and parallel screening of up to 800 drugs and subsequent drug combinations. The most efficacious and least toxic combinations are tested in xenograft models and a multidisciplinary tumor board of experts select the best therapeutic option. The objective is to demonstrate that the personalized drosophila model approach is superior to the current standard, cabozantinib, which performed best in MTC with a 27% response rate (RR) against placebo in a phase III trial but with considerable toxicity. Using the 27% RR as a benchmark, we will apply a sequential Bayesian method for 50 MTC patients enrolled to receive personalized treatment to demonstrate that this approach has greater efficacy, or at minimum, substantially similar efficacy with reduced toxicity.

**TPS6102 General Poster Session (Board #134B), Sat, 1:15 PM-5:00 PM**

**Randomized phase II trial of weekly paclitaxel, carboplatin, cetuximab (PCC) versus cetuximab, docetaxel, cisplatin, and fluorouracil (C-TPF) in previously untreated patients with locally advanced head and neck squamous cell carcinoma.** *Presenting Author: Erminia Massarelli, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background**: The use of induction chemotherapy in patients (pts) with locally advanced head and neck squamous cell carcinoma (HNSCC) remains controversial. The induction strategy has shown to reduce risk of distant metastases but also represents a vehicle for the evaluation of other clinical and molecular endpoints. The development of increasingly effective induction chemotherapy may eventually affect the efficacy of radiotherapy with an improvement in local disease control. To determine the efficacy of combining cetuximab with induction chemotherapy, we designed a randomized phase II trial in previously untreated pts with locally advanced HNSCC using two induction chemotherapy regimens that had previously demonstrated efficacy and acceptable toxicity, followed by definitive risk-appropriate local therapy, taking into consideration both tumor (T) stage at presentation as well as human papillomavirus (HPV) status. **Methods**: Pts with stage IV T0-4 N2b-2c/3 M0 measurable disease in either the T or nodal (N) site by RECIST criteria were included in the trial. Pts were randomized to receive 6-weekly cycles of paclitaxel 135 mg/m$^2$, carboplatin AUC 2 and cetuximab 400 mg/m$^2$ week 1 then 250 mg/m$^2$ weekly (PCC) or 3 cycles of every 3 weeks docetaxel 75 mg/m$^2$ on day 1, cisplatin 100 mg/m$^2$ on day 1, 5-fluorouracile (5-FU) 700 mg/m$^2$/day continuous infusion days 1-4 and cetuximab 400 mg/m$^2$ week 1 then 250 mg/m$^2$ weeks 2, 4, 5, 7, 8 (C-TPF). HPV status was required at study entrance. Primary objective was progression free survival of both regimens followed by definitive local therapy selected on the basis of stage and HPV status, compared to historical control docetaxel/cisplatin/5-FU (TPF). Secondary objectives were: overall survival, response rate, duration of locoregional control, patterns of tumor recurrence, toxicity and biomarker analysis by HPV status and outcome. The trial has accrued a total of 135 pts as of January 2014. Planned analyses beyond primary and secondary objectives include evaluation of tumor genotype and immune phenotype in correlation with HPV-status and outcome. Clinical trial information: NCT01154920.

**TPS6103 General Poster Session (Board #135A), Sat, 1:15 PM-5:00 PM**

**A phase I/II clinical trial of sorafenib in combination with cisplatin and docetaxel in patients with recurrent/metastatic squamous cell carcinoma of the head and neck (SCCHN).** *Presenting Author: Panayiotis Savvides, The James Cancer Hospital and Solove Research Institute, The Ohio State University, Columbus, OH*

**Background:** There is rapid accumulation of data pointing to a potential role of sorafenib in the setting of recurrent/metastatic SCCHN. The combination of sorafenib to a cisplatin-docetaxel doublet backbone was chosen for further development for many reasons, including that cisplatin-containing combination regimens have been associated with higher response rates when compared with carboplatin ones and cisplatin containing regimens remain the first choice for firstline treatment and taxane-cisplatin combination regimens appear to be preferable to 5FU-cisplatin combination regimens given equal efficacy and better toxicity profile. In addition, we have generated preclinical data suggesting that sorafenib enhances the antitumor effect of chemotherapy and radiation by downregulating ERCC-1 and XRCC-1 DNA repair proteins. If validated in the clinical setting, ERCC-1 downregulation by sorafenib has the potential to improve cisplatin efficacy not only in patients with SCCHN, but across multiple tumor types, as high ERCC1 expression has been associated with shortened survival outcomes in numerous primary tumors. **Methods:** A short Phase I followed by a phase II single arm clinical trial as first line in patients with recurrent/metastatic SCCHN. A total of 3-18 and 29 patients might be needed for the phase I and II portions of the trial, respectively. Correlative studies: A total of three biopsies (blood and tumor samples) will be obtained. 1) Pre-treatment biopsy; 2) Research biopsy obtained at the end of a two week period of sorafenib monotherapy; 3) Research biopsy obtained at the end of two chemotherapy cycles. Proposed correlative studies include: a) Sorafenib target proteins analysis by Immunohistochemistry (IHC) for: 1) pERK1/2 (activated form of ERK1/2); 2) ERCC-1 (DNA repair protein); 3) pVEGFR2 (activated form of VEGFR2); 4) CD31 staining (tumor angiogenesis); 5) Activated caspase-3 staining for apoptotic cells; b) ERCC-1 gene expression analysis by RT-PCR; c) VEGF and IL-6 analysis by ELISA. Clinical trial information: NCT02035527.

**Phase I trial of cetuximab, intensity modulated radiotherapy (IMRT), and the anti-CTLA-4 monoclonal antibody (mAb) ipilimumab in previously untreated, locally advanced head and neck squamous cell carcinoma (PULA HNSCC).** *Presenting Author: Julie E. Bauman, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** Concurrent therapy for PULA HNSCC using the EGFR-specific mAb cetuximab (C) plus IMRT is an accepted standard, however disease control in intermediate or high risk disease could be improved. Our recent data indicate that C induces Ab-dependent, cell-mediated cytotoxicity and cross-priming of cytotoxic T lymphocytes. However, C also induces immunosuppressive regulatory T cells (Treg) expressing the checkpoint receptor CTLA-4; Treg correlate negatively with clinical outcomes to C. We hypothesize enhanced C-induced antitumor cellular immunity and clinical activity by targeting Treg with the anti-CTLA-4 mAb ipilimumab (ipi). We are conducting a phase I study adding ipi to C-IMRT in patients (pts) with intermediate or high risk PULA HNSCC. **Methods:** Eligible pts have stage III-IVb PULA HNSCC (pharynx, larynx). "High risk" pts are HPV(-). "Intermediate risk" pts are HPV(+) and have either: 1) $\geq$ 10 pack-year tobacco and $\geq$N2 disease; or 2) T4 or N3 disease, irrespective of tobacco status. A phase I (3+3) dose escalation trial is evaluating the addition of ipi to standard concurrent C (250 $mg/m^2$weekly after loading dose) + IMRT (66-70 Gy daily fractionation over 7 weeks). See table for dose cohorts and schedule. Dose limiting toxicity (DLT) is defined as any grade 4 toxicity (except in-field radiation dermatitis or asymptomatic, correctable lab abnormality), or any toxicity which delays IMRT $\geq$ 10 fractions. The DLT observation period ends 4 weeks after completing IMRT. As of Jan 2014, 3 pts have enrolled in the first cohort, receiving ipi at 3mg/kg. The next dose tier, assuming no DLTs, will increase ipi to 10 mg/kg. In the event of DLT at 10 mg/kg, ipi dosing will de-escalate to 6 mg/kg. Extensive immune monitoring is underway using baseline tumor tissue, including characterization of tumor-infiltrating lymphocytes, and serial monitoring of circulating lymphocytes and cytokines. Clinical trial information: NCT01935921.

**Predictor: Randomized phase II study of preoperative afatinib in untreated nonmetastatic head and neck squamous cell carcinoma patients (HNSCC) aiming at identifying predictive and pharmacodynamic biomarkers of efficacy.** *Presenting Author: Christophe Le Tourneau, Department of Medical Oncology, Institut Curie, Paris, France*

**Background:** Identification of efficacy predictive biological biomarkers in HNSCC patients treated with anti-EGFR targeted therapy is still a challenge. In the recurrent/metastatic setting, sequential biopsies allowed correlating potential predictive and pharmacodynamic biomarkers with the outcome of patients treated with erlotinib (Agulnik M et al. J Clin Oncol. 2007;25:2184). Afatinib is an Erb-B family blocker that irreversibly blocks signaling from all relevant Erb-B family dimers and may overcome limitations of current EGFR-targeted treatment in HNSCC. We conduct a randomized phase II study with afatinib **Methods:** PREDICTOR is a UNICANCER sponsored multi-centre randomized phase II study of preoperative afatinib aiming at identifying predictive and pharmacodynamic biomarkers of biological activity and efficacy in untreated non-metastatic HNSCC patients. Key eligibility criteria: confirmed non-metastatic HNSCC; T2-4N0-2 tumors (except T2N0 endolaryngeal tumors); planned date of surgery allowing the patient to receive 14 to 28 days of afatinib treatment; ECOG status 0-2. Target enrolment is 60 pts. Randomization is stratified on the site of primary tumor (oropharynx versus non-oropharynx). Pts are randomized 2:1 to receive afatinib (40mg/qd) OR no treatment (control arm). Dose adjustments are permitted according to the ocurrence of drug-related AEs (reduction to 30mg/qd). The primary endpoint is to identify predictive and pharmacodynamics biomarkers.Tumor samples are collected before treatment (biopsy) and after surgery (surgical specimen). Several molecules involved in the resistance to EGFR will be analyzed through different technics (Immunohistochemistry, High throughput protein analysis, FISH, PCR sequencing and qRT-PCR). Secondary endpoints include efficacy (tumor shrinkage), pathological response, metabolic response (FDG PET/CT scan assessment) and safety. Completion of pt recruitment and data analyses are awaited. Clinical trial information: NCT01415674.

**TPS6106 General Poster Session (Board #136B), Sat, 1:15 PM-5:00 PM**

**PAZOTHYR: A randomized, multicenter, open-label, phase II study of the optimal scheme of pazopanib in radioactive iodine-refractory differentiated thyroid carcinoma (RAIR-DTC).** *Presenting Author: Christelle De La Fouchardiere, Centre Léon Bérard, Lyon, France*

**Background:** Patients with locally advanced/metastatic progressive RAIR-DTC usually have a poor prognosis and may receive tyrosine kinase inhibitors (TKI) as first line therapy. Pazopanib (P) emerged as a promising alternative in a phase II study, with high Objective Response Rates (ORR) (49%; n=18/37) and prolonged Progression-Free Survival (PFS) (mPFS = 11.7 months) (Bible et al. Lancet Oncol. 2010). However, as with other tyrosine kinase inhibitors, the toxicity profile of P leads physicians to consider dose modifications (dose reductions, temporary and/or permanent discontinuation) that may jeopardize the clinical outcome. In addition, the probability of severe toxicity and the difficulty for patients to tolerate mild to moderate events increases with the treatment duration. We decided to investigate an alternative scheme of P preserving clinical benefits for patients and their well-being. **Methods:** A randomized, multicenter, open-label phase II study is ongoing in French patients with advanced RAIR-DTC to identify the optimal treatment strategy, through a new approach. After a 6-month period of continuous P treatment following inclusion, patients with controlled disease (CR, PR or SD) are randomized between a standard strategy (daily P maintained until disease progression (PD) or unacceptable toxicity) and an experimental sequential scheme in which P is temporarily stopped every 6 cycles, and reintroduced as soon as the patient experience PD (RECIST 1.1). This sequential scheme is followed until a PD occurs under P. The primary objective of the study is to compare the two arms in terms of Time to Treatment Failure, defined as the time from randomization to permanent discontinuation of treatment due to any cause. Secondary endpoints of the study include ORR and duration of response, disease control rate, PFS and overall survival. Quality of Life Questionnaire C30 will provide precious complementary data on the potential impact of the proposed strategy on patients' quality of daily living. To date, 13 of the planned 168 patients have been enrolled and 2 patients have been randomized. Clinical trial information: NCT01813136.

**6500 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Impact of state-specific Medicaid policies on timely receipt of breast cancer surgery.** *Presenting Author: Michael T. Halpern, RTI International, Washington, DC*

**Background:** Reports have demonstrated barriers in access to and quality of care for Medicaid enrollees, including enrollees with cancer. State-specific Medicaid eligibility policies and low reimbursements for medical care services provided to enrollees with cancer may hinder receipt of high-quality cancer treatment. This study examined how eligibility and reimbursement policies affect timely receipt of breast cancer surgery among Medicaid enrollees diagnosed with breast cancer. **Methods:** The study utilized 2006-2008 Medicaid data for all women 21-64 years of age diagnosed with breast cancer and enrolled in fee-for-service Medicaid for at least 4 months. We examined the association of state-specific Medicaid breast surgery reimbursements, Medicaid income eligibility requirements, and frequency of Medicaid eligibility renewal on time from diagnosis to receipt of breast cancer surgery. Analyses used multivariate logistic regressions controlling for correlation between beneficiaries within a state. **Results:** We identified 10,968 Medicaid enrollees with breast cancer. Lower reimbursements for breast cancer surgery were associated with greater delays for breast conserving surgery, mastectomy, and all breast cancer surgery combined. Shorter time periods for Medicaid eligibility renewal were also associated with greater surgery delays. Income eligibility thresholds did not affect delays. Black, Hispanic, and blind/disabled patients had greater delays, while older patients were less likely to experience delays. **Conclusions:** Low reimbursements were associated with less timely surgery for Medicaid enrollees with breast cancer. In addition, within the Medicaid population, disparities in timeliness of surgery based on patient race, age, and eligibility category were observed. With substantial expansion of Medicaid expected as part of the Affordable Care Act, state legislators and health policy makers need to consider how reimbursements affect receipt of high quality care and develop programs to address disparities within this vulnerable population.

**6501 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Low-dose computed tomography lung cancer screening in the Medicare program: Projected clinical, resource, and budget impact.** *Presenting Author: Joshua A. Roth, Fred Hutchinson Cancer Research Center, Seattle, WA*

**Background:** Based on evidence from the National Lung Cancer Screening Trial (NLST), the U.S. Preventive Services Task Force (USPSTF) recently recommended annual low dose computed tomography (LDCT) lung cancer screening in patients age 55-80 with a 30 pack-year smoking history who currently smoke or quit in the past 15 years. Under the terms of the Affordable Care Act, Medicare will cover this screening procedure. We project the clinical, resource, and budget impact of this policy. **Methods:** We developed a model to forecast the 5-year incremental outcomes of implementing USPSTF LDCT screening recommendations vs. no screening. The model simulates a Medicare cohort consistent with 2013 enrollment and age distribution statistics. Lung cancer detection rates and stage at diagnosis were derived from the NLST. Included costs were LDCT screening/follow up, confirmatory bronchoscopy/biopsy, and stage specific lung cancer treatment (initial, continuing, terminal care). We estimated lung cancers detected, LDCT scans, and the total and per member per month (PMPM) budget impact in two scenarios: 1) complete implementation, with all eligible patients offered screening in all years, and 2) phased implementation, with an additional 20% of eligible patients offered screening each year. **Results:** In the complete and phased implementation scenarios, screening resulted in 141,000 and 101,000 more lung cancers detected (mostly Stage I), 37.5 million and 22.4 million more LDCT scans, and increased overall expenditure of $27.4 billion (PMPM $8.80) and $17.6 billion (PMPM $5.70), respectively. The most influential inputs were the proportion of eligible patients electing to undergo screening, initial treatment cost of early-stage lung cancer, and the proportion of stage IV diagnoses in the no screening strategy. **Conclusions:** Our analyses suggest that LDCT screening is will increase lung cancer diagnoses, result in a greater proportion of cases diagnosed at an early stage, and substantially increase Medicare expenditure. Forthcoming analyses will evaluate the resource demands of complete and phased screening implementation relative to existing LDCT facility and health professional supply.

**6502 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Cost-effectiveness analysis (CEA) of bevacizumab (Bev) in first- and second-line treatment of metastatic colorectal cancer (mCRC).** *Presenting Author: Daniel A. Goldstein, Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** The addition of Bev to 5-Fluorouracil (5-FU)-based chemotherapy is the standard of care for previously untreated mCRC. A recent randomized trial demonstrated a 1.4 month increase in median overall survival (OS) when Bev is continued beyond the first progression, thus making it standard practice to use Bev with 5-FU based chemotherapy in both first- and second-line. International CEAs have evaluated Bev in the 1st-line setting. The objective of this study is to determine the cost effectiveness of Bev in the 1st line setting and when continued beyond progression from the US-payer perspective. **Methods:** We developed two Markov models to compare the cost and effectiveness of 5-FU, leucovorin and oxaliplatin (FOLFOX) with or without Bev in the first-line treatment, and subsequent chemotherapy with or without Bev in the second-line treatment of mCRC. Weibull models were fitted to the published survival curves, and were used to extrapolate the cause-specific mortality and progression risks. Costs for administration and management of adverse events were based on Medicare reimbursement rates for hospital and physician services, and drug costs based on the Medicare average sale prices (all in 2013 US $). Health outcomes were measured in life years (LY) and quality-adjusted life years (QALYS). The simulated OS and progression free survival (PFS) were validated by the fitted survival models. Model robustness was addressed by univariate and probabilistic sensitivity analyses (PSA). **Results:** Using Bev in first-line therapy provided an additional 0.289 QALYs (0.412 LYs) at a cost of $69,381. The incremental cost-effectiveness ratio (ICER) was $240,195/QALY. Continuing Bev beyond progression provided an additional 0.108 QALYs (0.167 LYs) at a cost of $23,788. The ICER was $219,742/QALY. In all one way sensitivity analyses, the ICER of Bev was > $100,000/QALY. The ICER of Bev was greater than $100,000/QALY in > 99.9% of PSAs. **Conclusions:** This is the first US based CEA of Bev in mCRC. Bev provides minimal incremental benefit at high incremental cost per QALY in both the first and second-line setting. The ICER of Bev could be improved by use of an effective biomarker to select patients most likely to benefit.

**6503 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Is advanced imaging in early-stage breast cancer ever warranted? Exploring benchmarks for an ASCO Choosing Wisely quality measure.** *Presenting Author: Tian Zhang, Duke University Medical Center, Durham, NC*

**Background:** ASCO's Choosing Wisely initiative recommends reducing certain low value services, including advanced imaging in early-stage (ES) breast cancer (BC). Few have explored baseline frequency of, or documented clinical reasons for, advanced imaging in ES BC. We analyzed data at an NCI comprehensive cancer center to characterize pt scenarios in which advanced imaging was ordered. **Methods:** We analyzed all pts with ES BC from January 2010 to June 2012 at the Duke Cancer Institute (DCI). We used the Choosing Wisely criteria for ES BC (clinical Stage IIb or less) and advanced imaging (nuclear bone scan, computed tomography (CT), positron emission tomography (PET), and brain magnetic resonance imaging). We then searched an administrative database for advanced imaging performed in the Duke Health System within 60 days after diagnosis. Three independent reviewers abstracted the medical charts of 40% of cases, randomly selected, to explore reasons for image ordering. Descriptive statistics and the chi-square test were performed. **Results:** Of 1,143 ES BC cases identified, 20.6% (235 pts) had at least one advanced imaging procedure performed. Imaging type varied widely (41% CT, 22% PET, and 36% bone scans, $p<0.001$). Pts with advanced imaging were more likely hormone receptor negative, HER2-negative, younger (age$<$50), and with higher stage (Stage IIb vs. Stage IIa or less) disease (all $p<0.001$). Of the 95 abstracted cases with imaging, 62% (59 pts) were obtained for further staging, 17% to evaluate a major concurrent disease (6 oncologic, 10 non-oncologic), and 19% for exam or history findings worrisome for distant disease. 15% (9/59 pts) of images ordered for staging were abnormal. Overall, 45% (43/95 pts) of advanced imaging ordered were for a major concurrent disease, worrisome findings, or staging which ultimately revealed an abnormality. **Conclusions:** Advanced imaging is ordered in a minority of ES BC cases. When ordered, almost half of images aid in clarifying a complex clinical decision. Our data highlight the benefit of quality measures in reducing low value services, while also acknowledging that allowances for measure non-adherence are needed to promote patient-centered cancer care.

**6504 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Relationship between surgical oncologic outcomes and publically reported hospital quality measures.** *Presenting Author: Jason Dennis Wright, Columbia University College of Physicians and Surgeons, New York, NY*

**Background:** Hospital-level measures of patient satisfaction and process measures of quality are now reported publically by the Centers for Medicare and Medicaid Services. There are currently no metrics specific to cancer patients. We examined whether publically reported hospital satisfaction and quality data correlate with surgical oncologic outcomes. **Methods:** The Nationwide Inpatient Sample was utilized to identify patients with solid tumors who underwent surgical resection in 2009-2010. The hospitals in which patients were treated were then linked to: 1) publically reported measures of patient satisfaction (Hospital Consumer Assessment of Healthcare Providers and Systems, HCAHPS), 2) perioperative quality (Surgical Care Improvement Project, SCIP), and 3) mortality measures for medical conditions (risk adjusted mortality for pneumonia, MI, and CHF). The risk-adjusted hospital-level rates of morbidity and mortality were then calculated for each hospital and the means compared between the highest and lowest performing hospital quartiles for each of the measures. Data is reported as absolute reduction in risk (ARR) for each outcome. **Results:** A total of 63,197 patients treated at 448 hospitals were identified. The ARR in perioperative morbidity was 0.0020 for patients at high vs. low performing hospitals based on the overall HCHPS score of hospital satisfaction. Similarly, the ARR for mortality based on the same measure was 0.0038 for high vs. low performing centers. High performance on perioperative quality measures based on SCIP resulted in an ARR of 0.0056 for perioperative morbidity and 0.0049. Lastly hospitals with the lowest mortality for myocardial infarction, heart failure, and pneumonia and ARR for perioperative mortality of 0.0054, 0.0062, and 0.0011 compared to higher mortality hospitals for the respective conditions. **Conclusions:** Currently available measures of patient satisfaction and quality are poor predictors of outcomes for cancer patients undergoing surgery. Specific metrics for oncologic outcomes and quality are needed.

**6505 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Measuring compliance to oral antineoplastic agents: A comparison between administrative data and medical records.** *Presenting Author: Winson Y. Cheung, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** With increasing use of oral drugs in oncology, recent studies of administrative data indicate that compliance with these agents is suboptimal. Using a population-based cohort of colon cancer to test our hypothesis, our aim was to evaluate the proportion of patients deemed non-compliant that actually had a reasonable indication for not adhering to their prescribed oral systemic therapy regimen. **Methods:** Consecutive patients diagnosed with stage III colon cancer from 2008 to 2010, referred to any 1 of 5 regional cancer centers in British Columbia, and who initiated at least 1 cycle of oral adjuvant capecitabine within 12 weeks of curative resection were included. Administrative data from the provincial oncology pharmacy were analyzed to assess for non-compliance, which was defined as any prescription refill delays of >/= 1 week from the end date of the preceding cycle. Electronic medical record abstraction was conducted to examine the factors, if any, which contributed to non-compliance. We compared administrative vs. medical record data to determine the level of concordance. **Results:** We included 752 patients: median age was 70 years (IQR 35-87), 56% were men, and 86% had ECOG 0/1. Administrative data showed that 413 patients were non-compliant: 230 (56%) and 183 (44%) had 1 and >/=2 late refills, respectively. In this group, a total of 2095 cycles of capecitabine were delivered among which 688 (33%) treatment deviations occurred. No differences in baseline characteristics were observed between individuals who were compliant and those who were not (all $p>0.05$). Of the 688 prescription delays that were ascertained from administrative data, medical records demonstrated that 30 (4%) were misclassified. From the remainder, the majority were attributable to valid reasons, including: 340 (50%) toxicities necessitating time off therapy; 171 (25%) physician discretion; 23 (3%) patient refusal; and 41 (6%) travel requiring adjustment to treatment schedule. Only 83 (12%) cases were considered as true non-compliance. **Conclusions:** Using administrative data alone to measure oral oncology drug compliance without corroborating with clinical records may overestimate the degree of non-adherence.

**6506 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**MD Anderson's Oncology Expert Advisor powered by IBM Watson: A Web-based cognitive clinical decision support tool.** *Presenting Author: Koichi Takahashi, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Application of cognitive computing technology in cancer has potential to democratize expert knowledge and enable personalized evidenced based oncology care. **Methods:** We developed a web based prototype of MD Anderson's Oncology Expert Advisor (OEA), a cognitive clinical decision support tool powered by IBM Watson. The Watson technology is IBM's third generation cognitive computing system based on its unique capabilities in natural language processing and deep QA (question-answer). OEA is built with four core capabilities: 1) Patient Evaluation through interpretation of structured and unstructured clinical data to create a dynamic case summary with longitudinal view of the pertinent events 2) Treatment and Management suggestions based on patient profile weighed against consensus guidelines, relevant literature, and MD Anderson expertise, which will include approved therapies, genomic based therapies as well as automatic matching to eligibility criteria of clinical trials at MD Anderson, 3) Care Pathway Advisory that supports management of patients by alerting adverse events and/or suggesting proactive care support, and 4) Patient-oriented Research functionalities for identification of patient cohorts and generation of hypothesis. **Results:** We trained OEA by loading 400 cases of historical patient cases and assessed the accuracy of OEA treatment suggestions using MD Anderson's physicians' decisions as benchmark. False positive result was defined when OEA recommends a non-correct answer with high confidence, whereas false negative was defined when OEA recommends a correct answer with low confidence. When 200 leukemia cases were tested to assess accuracy of standard-of-care (SOC) treatment recommendation, false positive rate was 2.9%, whereas false negative rate was 0.4%. Overall accuracy of SOC treatment recommendation by OEA was 82.6%. **Conclusions:** OEA is able to generate dynamic patient case summary by interpreting structured and unstructured clinical data and suggest personalized treatment options with reasonably high accuracy. Live system evaluation of OEA is ongoing and application of OEA in clinical practice is expected to be piloted at our institution.

**6508 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Initial utilization of Oncotype DX in the Medicare population between 2005 and 2007.** *Presenting Author: Michaela Ann Dinan, Duke Clinical Research Institute, Durham, NC*

**Background:** In 2005 the Centers for Medicaid and Medicare Services approved reimbursement for the Oncotype DX (ODX) 21-gene assay in women with early stage ER-positive, node negative breast cancers to help guide recommendations for adjuvant chemotherapy. This analysis provides the first nationally representative examination of the adoption of ODX in Medicare beneficiaries with breast cancer. **Methods:** Retrospective analysis of SEER-Medicare linked data for breast cancer patients diagnosed between 2004 and 2007 was used to characterize overall utilization of ODX and identify demographic and clinical factors associated with receipt of ODX. **Results:** A total of 46,084 Medicare beneficiaries diagnosed with breast cancer in the SEER registries met study criteria. Utilization of ODX testing among newly diagnosed Medicare breast cancer patients increased from 1.2% to 5.2% among all stages and subtypes and from 1.9% to 7.5% among women with localized, ER positive, node negative disease from 2005 to 2007. As compared to patients who did not receive ODX testing, beneficiaries who received ODX testing were more likely to have higher baseline histologic grade, larger tumor sizes, and be ER and PR positive. Increasing age category (71-75, 76-80, 80 or older) and number of comorbidities (1, 2 or more) conditions were associated with a decreased odds of receiving ODX, whereas being married was associated with increased odds of receiving ODX testing in multivariable analysis (all $P<0.001$). Relative to patients with stage 1 disease, patients with stage 0, II, III, and IV disease all had decreased odds of receiving ODX (OR 0.02, 0.55, 0.04, 0.04, all $P<0.001$). We found no significant difference in regional ODX utilization. **Conclusions:** Following the approval of ODX coverage by CMS in 2005, the utilization of ODX has significantly increased. Utilization was largely limited to patients in whom testing is considered medically necessary by CMS and is supported by current guidelines, and in younger and healthier patients in whom chemotherapy would be more likely to be a clinically appropriate management option. The impact and utilization of ODX adoption on the care of breast cancer patients in the future remains an important area of health policy research.

**6509 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Discussions about clinical trials among patients with lung and colorectal cancer.** *Presenting Author: Kenneth L. Kehl, Brigham and Women's Hospital, Boston, MA*

**Background:** Clinical trials are essential for evaluating new cancer therapies, but less than 5% of adults with cancer enroll in trials. Barriers to enrollment may include patient-provider communication factors, such as lack of patient awareness or understanding about the option of participation. **Methods:** We surveyed a population- and practice-based sample of patients (or their surrogates) 3 to 6 months after diagnoses of lung or colorectal cancer. We assessed whether respondents learned that clinical trial participation might be an option, and if so, with whom they first discussed this possibility. We used multivariable logistic regression to assess the association of patient characteristics with clinical trial discussions and enrollment. **Results:** Of 7,887 respondents, 1,114 (14.1%) reported discussing clinical trial participation. Most (92.7% of participants, 75.8% of nonparticipants) learned about trials from their physicians. 287 patients (3.6% of all patients, 25.8% of trial discussants) enrolled. Among 2,173 patients who received chemotherapy for advanced (stage III/IV lung or stage IV colorectal) cancer, 25.7% discussed trials, and 7.6% (29.5% of discussants) enrolled. In adjusted analyses among all patients, discussion of clinical trials was more common among college-educated patients (OR 1.9, 95% CI 1.5-2.5 vs <high school education) and those with incomes >$60,000/year (OR 1.7, 95% CI 1.4-2.2 vs <$20,000/year), and less common among older patients (OR 0.96, 95% CI 0.95-0.97/year). These factors were not significantly associated with enrollment among patients discussing trials. Enrollment was higher among patients reporting shared vs. physician–driven decisions ($P<0.05$). **Conclusions:** In this population-based cohort, less than one-sixth of cancer patients discussed clinical trials. Discussions were more frequent in the setting of advanced disease but were still reported by a minority of patients. Older age and lower education and income levels were associated with less discussion of clinical trials but not with enrollment in trials following discussions. Strategies to broaden access to trials and facilitate patient-provider communication about participation may improve enrollment rates.

**6510 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Clinical trial subjects compared to "real world" patients: Generalizability of renal cell carcinoma trials.** *Presenting Author: Aaron Philip Mitchell, Duke Cancer Institute, Durham, NC*

**Background:** While narrow eligibility criteria improve the internal validity of clinical trials, they threaten the generalizability of study findings to real-world populations. How similar is the population of patients receiving treatment for metastatic renal cell cancer (mRCC) to subjects enrolled in pivotal trials? **Methods:** A retrospective registry of academic (Duke University Health System) and community (ACORN Network) practices was used to compare real world mRCC patients to study subjects in the landmark phase III clinical trials of the new, targeted therapies. Patients were compared to subjects who were treated with the same agent. **Results:** Of 633 patients in the registry, 438 received sunitinib, sorafenib, temsirolimus, or pazopanib; everolimus and axitinib were not included due to small patient numbers. Registry patients were a mean of 4.6 years older than clinical trial subjects ($p<0.0001$). With the exception of temsirolimus-treated patients, registry patients had poorer risk disease by MSKCC model (poor: 7.4% vs 2.9%, $p<0.0001$; favorable: 30.6% vs 43.8%, $p=0.0004$) and were more likely to have impaired functional status (ECOG >1, 8.4% vs 0.6%, $p<0.0001$). Applying the eligibility criteria described in the clinical trial manuscripts, 40.0% of patients failed inclusion criteria for the phase III clinical trial testing the drug they received (Table), 9.9% due solely to non-clear cell histology. **Conclusions:** mRCC patients in "real world" clinical practice are older and sicker than those enrolled in pivotal clinical trials. Over one third of mRCC patients would not have met eligibility criteria for the phase III clinical trial that led to approval of the agent they received. Application of clinical trial findings to dissimilar populations may result in patient harm. Research of mRCC drugs in general populations is needed to guide real world clinical practice.

**Impact of the NCI Community Cancer Centers Program (NCCCP) on clinical trial (CT) activities in a community cancer center in rural Nebraska.** *Presenting Author: Mehmet Sitki Copur, Saint Francis Cancer Treatment Center, Grand Island, NE*

**Background:** 85% of cancer patients (pts) are diagnosed/treated in the community, but only 3-5% are enrolled on CTs. Community oncologists lack adequate time, resource, infrastructure, reimbursement to engage in CTs. In July 2007, a 5-yr NCCCP contract was awarded to 16 pilot sites in diverse communities across the United States to support CTs and cancer care delivery. **Methods:** 5-yr prior and 5-yr after NCCCP, Saint Francis Cancer Center CT activities data, which included number/percent (pts) on CTs, percent underserved on CTs, number/type CTs available, staffing, collection/storage of tissue samples, organizational infrastructure/linkage to NCI designated cancer centers, availability of new cancer care services were gathered and compared. **Results:** Number/percent pts on CTs before/after NCCCP increased from 127 (5%) to 630 (23%), ($p<0.001$, Chi-square). All pts were rural Nebraskans, with 70% older than age 60. Number of available CTs increased four-fold with more prevention, quality of life, supportive care, cancer care delivery, biospecimen and treatment type trials after NCCCP. Non-treatment/treatment type trials both increased from an average 3/yr to 12/yr and 8/yr to 28/yr respectively ($p=0.012$, Wilcoxon). Average accrual per clinical trial was 13.2 before and 15.8 after NCCCP ($p=0.5$, Wilcoxon). CT staffing increased from an average of 1.2 to 3.9 FTEs ($p=0.012$, Wilcoxon). Two nurse navigators/genetic counselors, one smoking cessation counselor/outreach project coordinator were hired. Collection/storage of tissue samples increased from 24 (19%) to 330 (52%), ($p<0.001$, Chi-square). Affiliation with NCI designated Eppley Cancer Institute enhanced linkage to NCI programs. **Conclusions:** Participation in NCCCP positively impacted CT related activities with enhanced access to expanded types of CTs and cancer care services. Our data demonstrate the feasibility of implementing an expanded spectrum of CTs and programs within the rural community setting.

**The clinical trial assessment of infrastructure matrix tool (CT AIM) to improve the quality of research conduct in the community.** *Presenting Author: Eileen P. Dimond, National Cancer Institute, Rockville, MD*

**Background:** ASCO described minimum standards and exemplary attributes for CT sites to improve research quality (Zon et al *JCO* 2008, *JOP* 2011; Baer et al *JOP* 2010). Based on these attributes, the NCI Community Cancer Centers Program (NCCCP) developed and piloted the CT AIM Tool to facilitate research program improvements through self-assessment and benchmarking. The tool identified 9 attributes (see Table) each with 3 progressive levels for research sites to "score" their program from less (Level 1) to more (Level 3) exemplary CT infrastructure (e.g. Level 1- only phase 3 treatment trials open vs. Level 3 – Phase 1/2/3, cancer control and prevention trials open). **Methods:** From 2011-13, 21 NCCCP sites self assessed their CT programs annually using the tool. **Results:** See Table. **Conclusions:** Statistically significant increases ($p<0.0001$) occurred in Level 3 (more exemplary) infrastructure ratings from 2011 to 2013 across all 9 attribute categories assessed at the 21 sites. Statistically significant gains were seen in two attributes: CT Portfolio – increases in site early phase and cancer control trial implementation; CT Communication /Awareness - shifts observed from institutionally focused CT education to broader community outreach/engagement. The tool showed utility across the sites for promoting quality improvement, benchmarking research performance, progress reporting and providing metrics for communicating infrastructure needs. Use in research beyond oncology and outside the community setting is plausible. NCI Contract HHSN261200800001E.

### 6513 Poster Highlights Session (Board #1), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM

**Impact of duration of adjuvant therapy (AT) on cancer survival.** *Presenting Author: Aalok Kumar, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** Trials demonstrate that patients (pts) with specific cancers who complete AT experience better outcomes than those who do not. However, the magnitude of benefit in pts who discontinue AT early is poorly defined. Using a population-based cohort of stage III colon cancer (CC) pts, our aims were to (1) examine the rate of receiving all planned AT, (2) determine the factors associated with AT completion, and (3) explore the relationship between early AT discontinuation and survival. **Methods:** We analyzed pts diagnosed with stage III CC from 2006 to 2010 and initiated at least 1 cycle of adjuvant FOLFOX at any 1 of 5 regional cancer centers in British Columbia. Logistic regression models were constructed to determine the factors associated with AT completion, which was defined as receipt of >/= 10 cycles of FOLFOX. Kaplan-Meier methods and Cox regression that accounted for prognostic factors were used to evaluate the relationship between early AT discontinuation and disease-free (DFS) and overall survival (OS). **Results:** We identified 616 patients: median age 62 years (range 26-80), 52% men, 87% T3/4 tumors, and 40% N2 disease. Among them, 183 (30%) received < 10 and 433 (70%) underwent >/= 10 cycles. Adjusting for confounders, men and those with obstruction/perforation were more likely to discontinue AT early (OR for AT completion 0.62, 95%CI 0.43-0.89, p=0.01 and 0.55, 95%CI 0.33-0.92, p=0.02, respectively). In terms of survival, T3/4 stage, N2 disease and long post-operative recovery of >/= 1 week were correlated with worse DFS, while T4 stage and N2 disease were also associated with inferior OS. However, early discontinuation of AT did not impact DFS and OS (Table). Sensitivity analyses using different definitions for AT completion produced similar findings. **Conclusions:** Early discontinuation of adjuvant FOLFOX was not associated with significant survival differences, lending support to trials that are underway evaluating the utility of shorter durations of AT.

**Does routine symptom screening with the Edmonton Symptom Assessment System (ESAS) decrease emergency department visits in breast cancer patients undergoing adjuvant chemotherapy?** *Presenting Author: Lisa Catherine Barbera, Odette Cancer Centre, Toronto, ON, Canada*

**Background:** In 2007 the provincial cancer agency in Ontario, Canada initiated a wide scale program to screen for symptoms in the cancer population using the Edmonton Symptom Assessment Scale (ESAS). The purpose of this study is to evaluate the impact of screening with ESAS on emergency department (ED) visit rates in women with breast cancer receiving adjuvant chemotherapy (CT). **Methods:** This retrospective cohort study used linked administrative health care data from across the province of Ontario, Canada. The cohort included all women aged ≥18 who were diagnosed with stage I-III breast cancer between January 2007 and December 2009 and received adjuvant CT within 6 months of diagnosis. Using a recurrent event model to adjust for covariates, we examined the association of screening with ESAS at a clinic visit on the ED visit rate. **Results:** 8,359 women were included. Approximately one third were screened with ≥1 ESAS during their chemotherapy. The rate of ED visits was 35% lower among patients screened with ESAS compared to those not screened. For each additional ESAS assessment there was a 19% decreased rate of ED visits. **Conclusions:** Our results demonstrate that screening with ESAS is associated with decreased ED visits. To our knowledge this is the first report on the effectiveness of routinely documenting patient-reported symptoms on ED visits, in a real world setting. Adjusted model results showing relative rate (RR) of ED visits for exposure to ESAS during chemotherapy either as a dichotomous or continuous variable (also adjusted for region and number of clinic visits).

### 6515 Poster Highlights Session (Board #3), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM

**Can we accurately identify chemotherapy-related acute care visits in administrative data?** *Presenting Author: Monika K. Krzyzanowska, Division of Medical Oncology & Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Administrative data is increasingly being used to study treatment related complications that lead to acute care visits such as emergency department visits or hospitalizations (ED+H). We evaluated the accuracy of billing codes for identifying chemotherapy related acute care visits (CRVs) among women with breast cancer. **Methods:** We prospectively developed an algorithm to identify CRVs from administrative data in women receiving adjuvant chemotherapy for breast cancer in Ontario, Canada. Sensitivity (SN) and specificity (SP) were calculated for 3 scenarios: chemotherapy related ED visit, chemotherapy related H, and febrile neutropenia (FN) related visit using the chart as the gold standard. Since there is no specific billing code for FN, three different definitions of FN were considered: liberal (defined as fever or infection or neutropenia as main reason for visit), moderate (neutropenia as main reason for visit) or strict (fever or infection plus neutropenia). The population based cohort was generated by linking several health databases to identify women who had at least one ED+H during adjuvant chemotherapy for breast cancer between 2007-2009. The validation cohort consisted of 496 randomly selected cases from this cohort. **Results:** The population-based cohort consisted of 8,359 patients of whom 43.4% had at least one ED+H including 1496 women who had multiple visits resulting in 6293 unique ED+H. Of these, 73.1% were considered CRVs based on our algorithm. The algorithm performed well in identifying CRVs that included an H either from ED (SN 90%, SP 100%) or directly from home (SN 91%, SP 93%) but less well for ED visits that did not result in H (SN 65%, SP 80%). Depending on which FN algorithm was used, 4.8-24% of visits were considered FN related. The liberal FN algorithm had excellent SN regardless of whether the visit involved H (94-98%) but SP was moderate (64-80%). The strict FN algorithm had good SP (79-99%) but SN was highly variable (13-89%). The moderate FN algorithm provided the best tradeoff between SN (69-97%) and SP (83-98%). **Conclusions:** CRVs can be identified from administrative data with reasonable confidence, obviating the need for chart abstraction to evaluate chemotherapy related serious events.

### 6516 Poster Highlights Session (Board #4), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM

**Clinical outcomes of elderly patients receiving neoadjuvant chemoradiation for locally advanced rectal cancer.** *Presenting Author: Maria Jiang, University of Ottawa, Ottawa, ON, Canada*

**Background:** There are limited studies assessing the outcomes of elderly patients treated with neoadjuvant chemoradiation (nCRT) for locally advanced rectal cancer. Our aim was to assess the impact of age on clinical outcomes in a large multi-institutional database. **Methods:** Data from patients across Canada with locally advanced rectal cancer who received nCRT and had curative intent surgery from 2005 to 2012 were collected from Tom Baker Cancer Center, Cross Cancer Institute, BC Cancer Agency, Ottawa Hospital Cancer Centre and Dr. H. Bliss Murphy Cancer Centre. Age was analyzed as both a continuous and a dichotomous variable (<70 v ≥ 70 yrs) and correlated with time free of recurrence (TFR where death without recurrence is censored), disease free survival (DFS), and overall survival (OS). Multivariable analyses (MVA) controlled for sex, ECOG, circumferential resection margins, radiation dose, distance from anal verge, pre-treatment anemia, clinical stage, pathologic stage and completion of neoadjuvant chemotherapy. **Results:** A total of 1,172 patients were included with a mean age of 62 years (SE±0.33) and a mean follow-up of 3.8 yrs (SE±0.05). Among them, 295 (25%) patients were ≥ 70 years. Elderly patients were less likely to receive adjuvant chemotherapy (ACT) (57% v 77%, p<0.0001), oxaliplatin-based ACT (12% v 31%, p<0.0001). They were also less likely to complete neoadjuvant chemotherapy (76% v 86%, p<0.001) but more likely to be anemic at initiation of nCRT (42% v 31%, p=0.0004). In the MVA, elderly patients had improved TFR (HR 0.65, 95% CI 0.45 – 0.95, p = 0.02), similar DFS (HR 0.928, 95% CI 0.68 – 1.26, p = 0.63) and similar OS (HR 1.28, 95% CI 0.88 – 1.86, p =0.2) compared to younger patients. As a continuous variable, age was not significantly associated with TFR (HR 0.99, 95% CI 0.98 – 1.01, p = 0.47) or DFS (HR 1.00 95% CI 0.99 – 1.02, p =0.49). However, it was significantly associated with inferior OS (HR 1.02, 95% CI 1.00 – 1.03, p =0.04) in the MVA. **Conclusions:** Elderly patients (≥ 70 yrs) who receive nCRT followed by surgery appear to have similar cancer related outcomes compared to younger patients. Decisions regarding eligibility for nCRT and surgery should not be based on age alone.

**6517 Poster Highlights Session (Board #5), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Population-based analysis of treatment receipt in prostate cancer patients who initially pursued active surveillance (AS).** *Presenting Author: Nathan Christopher Sheets, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Active surveillance for early prostate cancer may reduce over-treatment based on publications of patients managed in clinical trials or at high volume academic centers. In these selected reports, up to 30% of AS patients receive treatment (prostatectomy, radiation, hormone therapy) within 3 years due to cancer progression or patient anxiety. However, no study has examined receipt of treatment in AS patients in the community. **Methods:** Patients diagnosed from 2004-7 in the Surveillance, Epidemiology, and End Results (SEER)-Medicare linked database with low or intermediate risk prostate cancer were included; claims were available through 2010. AS was defined as a repeat prostate biopsy between 2-24 months after diagnosis with no treatment prior to repeat biopsy. We report the proportion of AS patients who received treatment within 3 years. Logistic regression examined factors associated with treatment receipt. **Results:** 737 low-risk and 618 intermediate-risk prostate cancer patients were analyzed. At 3 years, 64% of low-risk and 76% of intermediate-risk patients received treatment (Table). On multivariate analysis, being married (odds ratio [OR]=1.45; 95% CI 1.1-1.9), later year of diagnosis (2007 vs 2004, OR=1.73; 95% CI 1.2-2.5) and intermediate risk disease (vs. low-risk, OR=2.0; 95% CI 1.5-2.5) were associated with increased odds of treatment. Older patients had lower odds of treatment (age 76-79 vs 66-69, OR=0.6; 95% CI 0.4-0.9). **Conclusions:** On a population level, two-thirds (low-risk) to three-fourths (intermediate-risk) of early prostate cancer patients who initially chose AS converted to treatment within 3 years. These rates are twice that of published studies from trials or academic centers. This information may be informative to patients and physicians in the treatment decision-making process. Studies are needed to discern the reasons for this high rate of treatment, potentially due to suboptimal patient selection for AS or anxiety.

**Treatment by 3 years in AS patients.**

**6518 Poster Highlights Session (Board #6), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Prolonged radiation duration in women with cervical cancer: A population-based analysis of associated factors and impact on survival.** *Presenting Author: Ana Isabel Tergas, Department of Obstetrics and Gynecology, Columbia University College of Physicians and Surgeons, New York, NY*

**Background:** The National Comprehensive Cancer Network recommends that radiotherapy (RT) for treatment of locally advanced cervical cancer (LACC) finish within 8 weeks (wks). Although RT duration is a proposed national quality metric, there is little data supporting this in the era of concurrent chemotherapy. We examined factors associated with prolonged RT duration and its impact on survival in women with LACC treated with primary chemoradiation. **Methods:** Women reported in the National Cancer Database with stage IB2-IVA cervical cancer from 2003-2011 who received external beam RT, brachytherapy, and chemotherapy were analyzed. RT duration was modeled dichotomously (≤ or > 8 wks) and categorically (6-8, 9-10, >10 wks). Multivariable logistic regression was used to determine factors associated with prolonged RT duration (defined as >8 wks). Impact of RT duration on survival was examined using Kaplan-Meier analysis and Cox proportional hazards models. **Results:** Of the 7,209 women identified, 3,401 (47.1%) completed RT within 8 wks; 2,159 (29.9%) and 1,649 (22.9%) completed RT in 9-10 and >10 wks, respectively. Stage, race, insurance, comorbidity, diagnosis year, facility location, and neighborhood rurality/urbanicity were associated with prolonged RT on multivariable analysis. Black women (OR 1.22; 95% CI 1.07– 1.40), Medicaid recipients (OR 1.20; 95% CI 1.06 - 1.35), and rural residents (OR 1.84; 95% CI 1.24 - 2.73) were more likely to have prolonged RT. There was no survival difference for RT duration ≤8 vs. >8 wks. However, RT duration >10 wks was associated with inferior survival times (log rank p-value 0.002). Compared to those completing RT within 8 wks, adjusted hazard ratios for death for the 9-10 wks group and the >10 wks group were 0.90 (95% CI 0.78 – 1.03) and 1.1 (95% CI 0.95 - 1.26), respectively. **Conclusions:** Sociodemographic factors are important predictors of radiotherapy duration for cervical cancer. Impact of radiation duration on survival is marginal and only seen with duration >10 wks, bringing to question its use as a quality metric. Further research is needed to support the recommendation of radiation duration to not exceed 8 weeks in the era of concurrent chemoradiation.

**6519 Poster Highlights Session (Board #7), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**The toxicity gap: Do real-life patients get hospitalized more during chemotherapy compared to trial patients?** *Presenting Author: Rebecca Michelle Prince, Princess Margaret Hospital, Toronto, ON, Canada*

**Background:** Toxicity related hospitalizations during chemotherapy are poorly reported in the literature. We sought to compare "real world" versus clinical trial rates of hospitalizations among patients with metastatic non-small cell lung cancer (mNSCLC) receiving chemotherapy. We hypothesised that hospitalization rates in real life patients would be significantly higher. **Methods:** We conducted a systematic review of Medline and EMBASE (1946-June 2013) to identify articles reporting hospitalization rates during chemotherapy in patients with cancer. Both observational studies and clinical trials were eligible. This report focuses on patients with mNSCLC receiving palliative chemotherapy as data was available for this clinical scenario in both the observational and clinical trial setting, allowing comparison. Study results were abstracted using a standardised form. Summary statistics were used to describe results and the chi-square test used to compare hospitalization rates. **Results:** The search identified 64 articles (all published after 1987), of which 19 were clinical trials and 45 were observational ("real world") studies. Nine studies examined chemotherapy in mNSCLC - four observational studies and five randomised trials. The four observational studies included 7,456 patients; three included patients on any chemotherapy while the other focused on doublet regimens. Of the five randomised trials which included 3,556 patients, three treated patients with platinum doublets and two used single agent chemotherapy. The real life cohort was older (69.2 years vs. 62 years). The aggregate hospitalization rate among real life patients was significantly higher than among trial patients (57.5% vs. 14.8%, OR=7.7, 95% CI 6.9-8.5, p-value < 0.0001). Performance status and type of chemotherapy were associated with hospitalization during chemotherapy in clinical trials. The observational studies did not report risk factors for hospitalization. **Conclusions:** Clinical trials in mNSCLC consistently report lower rates of hospitalization than real life cohorts of patients undergoing similar therapies but very few clinical trials report this information.

**6520 Poster Highlights Session (Board #8), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Comparison of results between the first and updated reports of phase III clinical trials (RCTs).** *Presenting Author: Elena Elimova, MD Anderson Cancer Center, Houston, TX*

**Background:** Updated results of RCTs may differ from those initially reported due to the longer follow-up. The primary aim of the present study is to compare efficacy and toxicity of experimental anticancer agents between the first and updated published reports of RCTs. **Methods**: Reports of RCTs evaluating systemic therapies in lung, breast, and prostate cancer, which were published between 1990 and 2010 in *JAMA*, NEJM, JCO, *Annals of Oncology*, *Lancet*, and *Lancet Oncology* were eligible. Either first or updated report had to be published in one of these major journals. Hazard ratios (HRs) of the primary and secondary time-to event outcomes and the occurrence of adverse events (AEs) were compared between the first and the corresponding updated reports of the eligible RCTs. **Results:** We included 311 initial and 64 updated reports of RCTs into our analysis. Adjuvant and metastatic trials were equally likely to be updated for efficacy outcomes (56.3% vs 43.8%; p=0.38) and 28% of the updated reports had no update on AEs. Only 30% of the first and 27% of the updated reports used overall survival (OS) for the primary outcome. Definitions of primary, secondary or both outcomes were discordant between the first and updated report in 11.3% of RCTs. When comparing reports of RCTs with the concordant primary outcomes we found that the median hazard ratio (HR) of the primary endpoint increased from 0.75 to 0.83 in updated reports (p=0.003). However, decrease in this treatment effect occurred exclusively in the early setting trials (p<0.001). Both low- and high- grade AEs occurred significantly more often in the updated reports (p=0.01) (Table). **Conclusions**: Efficacy of anticancer agents in the first reports of RCTs for early lung, breast and prostate cancer is over-estimated. Over-estimated efficacy and under-reported toxicity of anticancer agents may lead to their overly enthusiastic prescribing in the every-day clinical practice.

**Comparison of effect size and toxicity between the first and updated reports.**

**Impact of chemotherapy dose and schedule on progression and survival in metastatic breast cancer: A systematic review.** *Presenting Author: Marek S. Poniewierski, Duke University, Durham, NC*

**Background**: Metastatic breast cancer (MBC) is a responsive but heterogeneous disease with generally a poor prognosis. The clinical importance of chemotherapy dosing and schedule in this setting has been questioned. **Methods**: A systematic review of randomized control trials (RCTs) of chemotherapy in MBC was conducted via searching PubMed (1990-2013) and meetings abstracts (2010-2012). RCTs comparing regimens that utilized the same agents or those studying impact of addition of agents were eligible. Relative risks of progression and mortality were based on event rates at 6, 12, 24 months. Heterogeneity was assessed by inconsistency index $I^2$. Meta-analyses were based on fixed effects models. **Results**: Among 2626 studies identified, 70 eligible RCTs involving 15,181 patients were analyzed. Average median time to progression and overall survival were 7.5 and 19.8 months, respectively. RCTs were divided into four a priori defined groups based on trial design: higher vs lower dose intensity (DI) (n=30), addition of ≥1 agents (n=26), continuation of treatment vs observation (n=7), and sequential (A→B) vs concurrent (AB) schedule (n=7). More intense regimens were associated with reduced progression at 6 and, to a lesser extent, 12 months, as well as reduced mortality at 1 year with the greatest effect in the added drug group. At 2 years, a trend for reduced mortality was observed with the greatest reduction in sequentially treated patients (Table). **Conclusions:** Chemotherapy can be an effective treatment for MBC with results suggesting better efficacy with higher DI and multidrug regimens, with stronger early effects diminishing by 2 years. The question of optimal treatment in MBC requires additional studies.

**Relative risk and 95% confidence interval.**

| Groups | Progression 6 months | Progression 1 year | Mortality 1 year | Mortality 2 years |
|---|---|---|---|---|
| Higher vs lower DI | 0.89 (0.84-0.94) | 0.97 (0.94-1.00) | 0.94 (0.87-1.01) | 0.96 (0.92-1.01) |
| Continued tx. vs observation | 0.68 (0.61-0.76) | 0.89 (0.85-0.94) | 0.91 (0.77-1.08) | 0.93 (0.85-1.01) |
| More vs fewer agents | 0.74 (0.70-0.78) | 0.91 (0.88-0.93) | 0.86 (0.81-0.92) | 0.97 (0.94-1.01) |
| Sequential vs concurrent | 1.00 (0.85-1.19) | 0.98 (0.92-1.06) | 0.96 (0.77-1.20) | 0.88 (0.79-0.98) |

**Adoption of hypofractionated radiotherapy for early-stage invasive breast cancer after publication of randomized trials.** *Presenting Author: Ronald C. Chen, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Large randomized trials have established the non-inferiority of shorter courses of "hypofractionated" radiotherapy to the whole breast (HyRT) vs conventional courses using smaller daily doses (CRT). HyRT is more convenient and less costly, so we sought to document its uptake as randomized trial evidence accumulated. **Methods:** In SEER-Medicare, we identified 15,781 women with pT1-2, node negative breast cancer who received lumpectomy followed by external beam RT from 2004-10. Number of RT treatments was obtained from Medicare claims, and grouped into partial breast RT (PBI, ≤12 treatments), HyRT (13-24), or CRT (≥25). We evaluated patterns and correlates of HyRT receipt on bivariable and multivariable analyses. **Results:** HyRT steadily increased after 2006 (3.6%): 5.3% (2007), 9.3% (2008), 13.7% (2009-10), with corresponding decrease in CRT from 92.6% to 83.5%. HyRT was more common in older women in all T-stage subgroups (4.0-5.9% for age 66-69 vs 6.0-8.2% age 76-79 vs 11.6-13.3% for age 80+). Multivariable analysis showed increased HyRT in recent years; in patients with older age, smaller tumors (T1a-b), increased comorbidity; and in regions with higher educational levels (Table). **Conclusions:** HyRT use increased in a low-risk population-based sample of older US women with publication of randomized trials, but overall use (13.7%) of this cost-saving approach remained low.

**Logistic regression for receipt of HyRT (vs. CRT; PBI excluded).**

**A randomized, controlled study comparing NCI's original and revised informed consent templates.** *Presenting Author: Holly A Massett, National Cancer Institute, Rockville, MD*

**Background:** In 1997, the National Cancer Institute (NCI) began using a standardized template to develop Informed Consent Documents (ICD) for its clinical trials. NCI recently revised the template based on expert input from five working groups to reduce its complexity and length. We report findings from a study comparing the application of the original and the revised, concise template to a Phase 3 colon cancer treatment trial. **Methods:** Two ICDs for the same trial were compared using a randomized, controlled design. Participants were randomly assigned to Group 1 (the control) which reviewed the original ICD (O-ICD) or Group 2, which reviewed the concise ICD (C-ICD). We hypothesized that viewing the C-ICD would result in higher knowledge and satisfaction scores than viewing the O-ICD. Participants' likelihood to consider a clinical trial (CT) after seeing the ICD was assessed. Participants were adult colorectal cancer survivors who completed treatment in the past 10 years and had never taken part in a CT. Pre- and post-test responses were collected via an online survey. **Results:** The groups (O-ICD, N=72; C-ICD, N=81) did not differ on age, gender, education, income or prior CT knowledge. No group differences were found on number of knowledge items correct (O-ICD: avg=20.3/24 total; C-ICD: avg=21/24; p=.20) or satisfaction (O-ICD: avg=4.23/5.0; C-ICD: avg=4.16/5; p=.23 [1 low; 5 high]). Higher education predicted greater number correct (p=.04). Less education and more prior CT knowledge predicted higher satisfaction with the ICDs (p=.01). All respondents reported lower intentions to participate in a CT after viewing the ICDs. **Conclusions:** The C-ICD's format applied plain language principles and was shorter by two pages (11 vs. 13 pgs for O-ICD). Although the C-ICD did not prove superior, it maintained high knowledge and satisfaction scores similar to the O-ICD. This study allowed unlimited time to read the ICDs and did not carry the same emotional implication as an actual CT situation where brevity may have greater impact. Finally, education about CTs appears beneficial as those reporting prior CT knowledge had significantly increased satisfaction scores and were more likely to consider a clinical trial in the future.

**6524 Poster Highlights Session (Board #12), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**The use of health-related quality of life outcomes in oncology practice: An international study.** *Presenting Author: Julie Rouette, Queen's University, Kingston, ON, Canada*

**Background:** Although health-related quality of life (HRQL) outcomes are often reported in randomized controlled trials (RCTs), research has identified challenges to their clinical application. The current perspectives of experienced oncologists on the use of HRQL outcomes, and how these perspectives vary between countries and specialties, are unknown. **Methods:** A cross-sectional e-survey of oncologist members of the NCIC Clinical Trials Group in Canada, the UK National Cancer Research Institute Clinical Studies Groups, and the network of the Australia/NZ cancer clinical trials groups was conducted. Respondents reported their perceptions of the usefulness of HRQL outcomes, use of HRQL outcomes in clinical practice, barriers/facilitators to their use in practice, and preferences for presentation of HRQL data in RCT publications. Chi-square tests were used to compare responses between countries and specialties. **Results:** Of the 396 participating oncologists (est. r. rate: 31%), 53% were medical oncologists in Canada and the UK and 61% were radiation oncologists in Australia. HRQL outcomes were reported to be useful in all types of trials (range 76-97%), particularly non-inferiority (89%) and palliative (97%) trials. More than 50% of oncologists reported not using HRQL outcomes with the majority of their patients to guide clinical decisions. Perceived barriers were lack of time (67%) and understanding (57%), and concerns about generalizability of results (68%). Identified facilitators included a summary of clinical implications of the HRQL results in RCT publications (76%), clear description of missing data (86%) and joint publication of HRQL and clinical outcomes (96%). Use of HRQL outcomes in practice, perceived barriers/facilitators, and presentation preferences did not differ by country or specialty. **Conclusions:** Oncologists support HRQL outcomes but perceive important barriers to their use in clinical practice, regardless of their country or specialty. Publishing HRQL and clinical outcomes jointly or simultaneously in the same journal, a clear description of missing data, and a clear summary of the clinical implications of the HRQL results, may facilitate the clinical application of HRQL outcomes.

**Are new drugs more expensive than old ones? Trends in the benefit-adjusted launch prices of anticancer drugs, 1995-2013.** *Presenting Author: David H. Howard, Emory University Department of Health Policy and Management, Atlanta, GA*

**Background:** Media reports have fueled the perception that anticancer drugs' launch prices have increased over time, but these typically rely on inaccurate measures of prices, focus on a few high-profile drugs, and do not adjust for benefits. We evaluate trends in drugs' benefit-adjusted launch prices. **Methods:** We hand-collected data on 56 anticancer drugs newly approved between 1995 and 2013. We measured launch prices using Medicare reimbursement formulae for oral and IV drugs. Prices represent the cost of a course of therapy for the typical patient. We obtained information on survival benefits from phase III trials and modeling studies. We evaluated the relationship between drugs' prices, survival benefits, and approval year. We adjusted prices for inflation using the Consumer Price Index. **Results:** We find that there have been economically and statistically significant increases in launch prices over time. The price of an additional month of survival time increased by $600 per year (95% CI: $100-$1,100; p = 0.02). Our model predicts that the launch price of a drug that extends median survival by 5 months would be $37,000 in 1995. If the same drug were launched in 2010, the price would have been $84,000. Results are robust to the inclusion of controls for side effect rates, administration route, and other drug attributes. **Conclusions:** Our results confirm what many suspect: newer anticancer drugs are more expensive than older agents. We explain pricing trends using "reference price" models of demand. Physicians are reluctant to prescribe drugs with prices they perceive as unreasonable. However, perceptions of reasonableness are malleable and influenced by the prices of previously-approved drugs, giving manufacturers leeway to increase launch prices over time.

**Cost-utility analysis of routine surveillance imaging of patients in first remission after treatment for diffuse large B-cell lymphoma.** *Presenting Author: Scott F. Huntington, Division of Hematology/Oncology, University of Pennsylvania, Philadelphia, PA*

**Background:** Surveillance imaging of patients (pts) with DLBCL in first remission (CR1) remains controversial. NCCN guidelines recommend CT scans in asymptomatic pts no more often than every 6 months for 2 years post treatment. A decision-analytic Markov model was developed to evaluate follow up (f/u) strategies for pts in CR1 after rituximab-containing treatment. **Methods:** Three strategies were compared in 55 year old pt cohorts: standard f/u without routine imaging, routine f/u with biannual CT scans for 2 years, or routine f/u with biannual PET/CT for 2 years. Our transition state model used 6 month length cycles with transition probabilities and clinical utilities derived from published studies. Costs were based on the Medicare fee schedule and future cost/benefits were discounted at a rate of 3% annually. The baseline model was biased to favor imaging strategies by associating asymptomatic imaging-detected relapses with improved clinical outcome. Quality-adjusted utility, lifetime costs, and incremental cost-effectiveness ratios (ICERs) were calculated for each f/u strategy. Conclusions were tested by multi-way sensitivity analyses that varied the rate of asymptomatic relapse detection, likelihood of favorable International Prognostic Index (IPI) with asymptomatic relapse, and the impact of IPI on salvage therapy outcome. **Results:** Surveillance strategies utilizing 2 years of routine CT or PET/CT scans were associated with minimal survival benefit versus f/u without routine imaging (mean OS, routine: 261.6 mos, CT: 261.8 mos, PET/CT: 262.1 mos). The benefit of imaging-based f/u remained small after quality-of-life adjustments (CT: 0.017 QALY, PET/CT: 0.023 QALY). Costs associated with imaging based surveillance strategies are considerable and ICERs were $202,300/QALY and $312,600/QALY for CT and PET/CT strategies respectively. ICERs for imaging strategies remained >$100,000/QALY or were dominated by routine f/u in multi-way sensitivity analyses over clinically relevant ranges. **Conclusions:** Our analysis suggests surveillance imaging of asymptomatic pts in CR1 following treatment for DLBCL offers little clinical benefit at substantial economic cost.

**6527 Poster Highlights Session (Board #16), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Cost-effectiveness analysis of pharmacokinetic-guided (PK) 5-fluorouracil (5FU) when combined with leucovorin and oxaliplatin (FOLFOX) chemotherapy for metastatic colorectal cancer (mCRC).** *Presenting Author: Daniel A. Goldstein, Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Dosing chemotherapy based on body surface area (BSA) results in marked variability in inter-individual drug exposure. An immunoassay for 5FU has been developed that assists in PK-guided dose adjustments. A randomized trial showed increased overall survival (OS) and decreased toxicity with PK 5FU/Leucovorin compared to BSA 5FU/Leucovorin in patients with mCRC. Similar results were achieved in a non-randomized trial comparing PK FOLFOX with BSA FOLFOX. The objective of this study is to compare the cost effectiveness of PK FOLFOX with BSA FOLFOX in patients with mCRC. **Methods:** We developed a Markov model to evaluate the cost-effectiveness of PK FOLFOX compared with BSA FOLFOX. Published progression-free survival (PFS) and OS curves were fitted with Weibull models. Progression risks and cause-specific mortality were extrapolated from the fitted survival models. Costs for administration and management of adverse events were estimated based on Medicare reimbursement rates for hospital and physician services, and drug costs based on the Medicare average sale prices, (all in 2013 US $). Primary outcomes were incremental cost per quality adjusted life-year (QALY) gained. We performed univariate and probabilistic sensitivity analyses (PSA) to address parameter uncertainties. **Results:** PK FOLFOX provided 2.03 QALYs at a cost of $50,205 compared to BSA FOLFOX with 1.46 QALYs at a cost of $37,173. The incremental cost per QALY was $22,694/QALY. In all one-way and 99.7% of PSA, the incremental cost-effectiveness ratio of PK remained below $50,000/QALY. **Conclusions:** At a $50,000/QALY threshold, PK FOLFOX is cost-effective for mCRC. The main cost driver was the PK test ($400) that was used for 4 cycles to establish the optimal dose. The main driver of benefit was improved PFS and OS. Given the cost-effectiveness profile and OS advantage with PK FOLFOX, it should be evaluated further in comparative effectiveness studies.

**6528 Poster Highlights Session (Board #17), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Comparative health care (HC) costs and quality of care in five cancer types by physician office (PO) and hospital outpatient (HOP) settings.** *Presenting Author: Maxine Fisher, HealthCore, Inc., Wilmington, DE*

**Background:** This study compares HC costs, resource utilization (RU), and select quality of care measures in cancer pts receiving treatment (tx) in PO or HOP. **Methods:** This retrospective study used medical & pharmacy claims (1/2006 - 8/2012) from 14 US health plans to identify early breast cancer (eBC), metastatic BC (mBC), metastatic lung cancer (mLC), metastatic colorectal cancer (mCRC), and non-Hodgkin's lymphoma (NHL) or chronic lymphocytic leukemia (CLL) pts initiating IV chemotherapy (ctx) or biologic tx. Death date was confirmed by Social Security Administration Death Master File (SSDI). RU, quality measures of ctx and hospitalization 30 days prior to death & GCSF use were compared using T-test or chi-square test. Multivariate analyses assessed differences in mean annual HC costs. **Results:** 18,740 pts were identified (69% PO vs. 41% HOP) with mean age 51.6 yrs, Deyo-Charlson score of 5.37, and follow-up of 2.2 yrs. PO had higher mean outpatient visits (21.8 PO vs. 21.2 HOP), other outpatient services (50.8 PO vs. 48.5 HOP), and pharmacy claims (35.1 PO vs. 33.6 HOP), but lower inpatient hospitalizations (0.7 PO vs. 0.8 HOP) and ER visits (0.3 PO vs. 0.4 HOP) [p<0.001]. Proportion of pts using GCSF was significantly lower in HOP (PO 73.3% vs 57.2% HOP, p<0.001). There were no differences in ctx or hospitalizations 30 days prior to death. Mean (median) annual HC cost in HOP was higher than PO ($122,473 [$123,075] vs. $82,773 [82,424] p<0.001). In multivariate analyses, mean annual cost was 8.3% higher in HOP (95% CI: 6.3-10.3%) **Conclusions:** Pts receiving care in PO were associated with lower HC costs than HOP. Chart review and pt satisfaction studies are ongoing to further characterize the care received in PO and HOP settings.

**Association between CT utilization and radiation therapy at the end of life (EOL) in elderly breast and prostate cancer patients.** *Presenting Author: Michaela Ann Dinan, Duke Clinical Research Institute, Durham, NC*

**Background:** High cost imaging can inform prognosis for cancer patients and potentially de-escalate unnecessary treatment at the EOL, but it may also be associated with increased health care expenditures. We investigated the association between hospital referral region (HRR)-level utilization of CT imaging and radiation therapy at the EOL. **Methods:** Retrospective, patient-level analysis of SEER-Medicare patients who died from breast and prostate cancer between 2002 and 2007. HRR-level utilization of CT scans was categorized into tertiles for each cancer type. HRRs were assigned where patients received the majority of inpatient care during the last 6 months of life. Multivariable logistic regression models were constructed to correlate tertile of imaging use with receipt, type, and overall cost of radiation therapy. **Results:** A total of 5,980 breast and 7,538 prostate cancer patients met study criteria, of which 22.2% and 28.3% received radiation therapy in the last year of life and 3.6% and 4.4% received radiation therapy in the last 30 days, respectively. The average number of CT scans in the last 6 months of life per patient varied by HRR from 0.79 to 1.74 scans for breast and 0.80 to 1.70 for prostate cancer. Treatment within a high vs. low CT utilizing HRR for either cancer type was not associated with increased use of radiotherapy in the last year or 30 days of life. Patients undergoing radiotherapy within high CT utilizing HRRs were more likely to undergo intensity modulated radiotherapy (breast; 4% vs. < 1%; prostate 5.5% vs. 3.8%, both $\chi^2$ $P < 0.05$). Mean costs of direct radiation therapy among patients undergoing radiotherapy in the last year of life were similar across HRR imaging tertiles, and averaged $5,009 in breast and $4,501 in prostate cancer patients. In contrast, overall costs were higher in both breast ($48,705 vs. $32,438) and prostate ($46,283 vs. $32,411) cancer patients in high vs. low CT utilizing HRRs (both $P<$ 0.001). **Conclusions:** Treatment within a high CT utilizing HRR for EOL patients with breast or prostate cancer was not associated with increased utilization or costs of radiation therapy at the EOL, but was associated with significantly higher overall medical expenditures.

**6530 Poster Highlights Session (Board #19), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Patient demand for care: How much does this contribute to inappropriate tests and treatments?** *Presenting Author: Keerthi Gogineni, Hospital of the University of Pennsylvania, Philadelphia, PA*

**Background:** There are many calls for physicians to provide more cost-effective care. Physicians sometimes claim that patients demand high cost or low value tests and treatments. How frequently do patients demand medical services? **Methods:** We surveyed oncologists and nurse practioners immediately after patient encounters to determine the frequency of patient requests or demands for tests and treatments, whether the request was appropriate, whether it was granted, and why. **Results:** Of the 2050 encounters, 73.1% of patients were white with a mean age of 60. Overall 42.0% had Stage IV or refractory disease and 66.3% were undergoing active treatment; 49.5% with palliative intent. Of the 26 clinicians surveyed, 97.0% were white, 54% were female and had a median of 14 years of post-training experience. In the table below, we report the key results of this survey. Providers declined granting a patient's request 18.1% (32/177) of the time; in 84.4% (27/32) of these cases this was because the test or treatment was felt to be inappropriate or had no evidence for clinical benefit. In less than 1% of encounters (4/2050) did the provider order a test or treatment deemed inappropriate. **Conclusions:** Inappropriate patient demands for tests or treatments are very uncommon among cancer patients and probably do not drive high utilization of high cost or low value medical services.

| Survey measure | Percentage |
|---|---|
| Patient encounters with requests or demands | 8.6% (177/2050) |
| Requests or demands were inappropriate based on clinician judgment | 13.6% (24/177) |
| Requests or demands were appropriate based on clinician judgment | 79.7% (141/177) |
| Clinician complied with patient request or demand | 81.9% (145/177) |
| Clinician ordered an inappropriate test or treatment based on patient demand | 0.2% (4/2050) |

**6531 Poster Highlights Session (Board #20), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Place of readmission and outcomes after major cancer surgery.** *Presenting Author: Karyn Beth Stitzenberg, Division of Surgical Oncology and Endocrine Surgery, University of North Carolina School of Medicine, Chapel Hill, NC*

**Background:** Readmission rates after major cancer surgery are high (20-45%). Many patients are readmitted to a hospital different than where surgery was performed. We hypothesize that readmission to a different hospital is associated with poorer outcomes and higher costs. **Methods:** We used SEER-Medicare to examine 2001-6 incident cases of bladder, esophagus, lung and pancreas cancer. Claims data were used to identify any hospital readmissions during the 90-days post-discharge from the surgical admission (index hospitalization). Pearson chi-square and multiple logistic regression were used for all tumor sites together and individually to compare location of readmission based on various patient and hospital factors. Cox proportional hazard models were constructed to examine the association between the location of readmission and survival. **Results:** Of the 24,412 patients who had surgery, 6,552 (27%) were readmitted at least once, and 2,133 (33%) were initially readmitted to a hospital other than the index hospital. There were no significant differences in demographics between patients readmitted to the index vs. different hospital. Patients who had surgery at the highest volume centers were the most likely to be readmitted to a different hospital ($p<.001$ for all). Patients readmitted to a different hospital lived farther from the index hospital than those readmitted to index hospital (median 24-33 vs. 6-11 miles, $p< .001$ for all). The association with volume persisted after accounting for distance. Patients readmitted to a different hospital were more likely to be transferred to another hospital (9-10% vs. 2-3%, $p<0.05$ for all). Total 90 day costs of care differed significantly only for esophagus cancer (index $69K vs. different hosp $62K, $p=0.005$). Survival was associated with location of readmission only for bladder cancer (index hosp HR=1.22; 95% CI=1.067-1.401). **Conclusions:** From a broad perspective, initial readmission to a hospital other than the index hospital after major cancer surgery is not associated with substantially poorer long-term survival or higher costs for Medicare patients. However, more detailed studies are needed to determine the impact on fragmentation of care and other patient-level outcomes.

**6532 Poster Highlights Session (Board #21), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Oral chemotherapy performance indicators: Early results from three rounds of Quality Oncology Practice Initiative (QOPI) data.** *Presenting Author: Jessica A. Zerillo, Beth Israel Deaconess Medical Center, Boston, MA*

**Background:** While use of oral chemotherapy is becoming more and more prevalent, little is known about the quality of care patients currently receive when these agents are prescribed. Moreover, few practice-level systems are in place to ensure safe utilization of oral chemotherapy. **Methods**: We analyzed results from 151 practices that voluntarily provided data to the American Society of Clinical Oncology's (ASCO's) QOPI program on 17 test measures of oral chemotherapy administration and management in at least one of three collection periods: spring or fall 2012, or spring 2013. The 17 test measures cover three domains—treatment plan documentation, patient education, and adherence/toxicity monitoring. We defined composite scores for each of the three domains. We analyzed the individual measures and composite scores by secular trend and tested the difference in composite scores for the three domains, excluding practices that had fewer than five charts for each analysis. Additionally, we tested change in scores over time among practices that participated at least twice. **Results**: The majority of data was provided by QOPI-certified practices. Overall, mean practice scores ranged from 66-68% for treatment plan documentation, 51-57% for patient education and 75-81% for adherence/toxicity monitoring ($p<.0001$ for all collection periods). Composite scores for practices that participated more than once did not improve significantly. **Conclusions**: The collection of oral chemotherapy test measures was feasible. Practices generally scored better on adherence/toxicity monitoring compared to plan documentation and patient education. Participation in subsequent rounds was not associated with an improvement in scores. These findings highlight opportunities for improvement in care for patients taking oral chemotherapy.

**Composite measures by collection round.**

| | Spring 2012 Mean (SD) | Fall 2012 Mean (SD) | Spring 2013 Mean (SD) | Trend P value |
|---|---|---|---|---|

**6533 Poster Highlights Session (Board #22), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Decisions about cancer treatment: Matching of actual to preferred roles and patient ratings of care.** *Presenting Author: Kenneth L. Kehl, Brigham and Women's Hospital, Boston, MA*

**Background:** Shared decision-making in cancer treatment is an important aspect of high-quality care and is associated with improved outcomes. However, patients have different preferences regarding roles they want to play in treatment decisions. We assessed the association of patients' actual roles in decisions with ratings of their care and whether this association varied by preferred decision roles. **Methods:** In the Cancer Care Outcomes Research and Surveillance Consortium (CanCORS) cohort, a population- and health system-based study of lung and colorectal cancer patients, participants were surveyed about their preferred roles in treatment decisions and their actual roles in decisions about surgery, chemotherapy, and radiation. Among patients receiving treatments under consideration, we used logistic regression to assess associations between actual roles in decisions and patient-reported care quality, both overall and stratified by preferred roles, adjusting for clinical and demographic traits. **Results:** Among 8,191 decisions made by 5,170 patients treated with surgery, chemotherapy, and/or radiation, patients described 39.8% of decisions as patient-controlled, 47.1% as shared, and 13.1% as physician-controlled. Patients making these decisions more often reported preferring a shared role (58.5%) or a patient-controlled role (35.5%) than a physician-controlled decision role (6.0%). Overall, patients described excellent quality for 67.8% of treatments received. In adjusted analyses, patients reporting physician-controlled decisions were less likely to report excellent quality for each treatment than those reporting a shared role (OR 0.6, 95% CI 0.5-0.7). This association was similar regardless of preferred role (p for interaction=0.29). **Conclusions:** More active participation in treatment decisions for lung or colorectal cancer was associated with better reported care quality among patients receiving treatments under consideration. This effect did not vary by patients' preferred roles in treatment decisions. These findings underscore the importance of a shared approach to decision-making for all patients, even those who might prefer that physicians make final treatment decisions.

**6534 Poster Highlights Session (Board #23), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Medicare Part D low-income subsidy and disparities in breast cancer treatment.** *Presenting Author: Alana Biggers, Medical College of Wisconsin, Milwaukee, WI*

**Background:** Breast cancer outcomes are worse among black than white women, but the role of income and out-of-pocket costs (OOPCs) in these disparities is understudied. The Medicare D program provided medication insurance for older women and also included a low-income subsidy (LIS) which eliminated or reduced OOPCs among women with low assets and limited income (based on federal poverty level). We examined differences in adherence to HT by race/ethnicity among a Medicare D population, hypothesizing that LIS might reduce racial disparities in HT adherence. **Methods:** With data collected from a national sample of women enrolled in Medicare Parts A, B and D, we identified Medicare Part D enrollees ≥65 years diagnosed with breast cancer who underwent mastectomy or breast conserving surgery in 2006-07 and received either tamoxifen or an AI (anastrozole, letrozole, or exemestane) within one year of surgery. Non-adherence rates (medication possession rate of >0.80) were calculated by race and LIS status for each year after first fill up through December 2011. The association of race with HT adherence was examined in unadjusted Chi-square analyses and in regression models adjusted for age, comorbidity, chemotherapy use and zip code level- income and education. All models utilized GEE to account for within-patient clustering. **Results:** Among a sample of 23,299 women (50.6% age 65-74, 40.9% age 75-84), 27.2% received LIS. LIS (but not AI use) varied substantially by race, so that 20.6% of white women and 69.7% of black women received the subsidy. In the first year of therapy, differences in adherence by race were statistically significant, but small (79.3% for white, 78.1% for black and 80.9% for Hispanic). Adherence dropped during years 2-3 of the study, but reductions were much smaller among LIS recipients. Results were confirmed in adjusted models. **Conclusions:** Enrollment in the Medicare D LIS was high among black and Hispanic breast cancer patients, and disparities in adherence to breast cancer HT among these women were small and remained so over three years. Our study offers important information about the role of medication subsidies and SES in adherence, and suggests their potential to reduce the breast cancer outcomes gap by race.

**6535 Poster Highlights Session (Board #24), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Variation in hospital thromboprophylaxis rates for abdominal cancer surgery.** *Presenting Author: Robert Wallace Krell, University of Michigan, Ann Arbor, MI*

**Background:** Venous thromboembolism (VTE) remains a prominent cause of morbidity and mortality following cancer surgery. Though ASCO evidence-based guidelines recommend major cancer surgery thromboprophylaxis start before incision and continue at least 7-10 days postoperatively, the extent to which the guidelines are followed is unknown. We assessed variation in thromboprophylaxis practices for abdominal cancer surgery in a regional surgical collaborative. **Methods:** We studied abdominal resections for primary gastrointestinal, hepatopancreaticobiliary (HPB) and neuroendocrine malignancies in the Michigan Surgical Quality Collaborative from July 2012-Sep 2013 (N=1,444 patients in 52 hospitals). We obtained detailed perioperative and postoperative pharmacologic and mechanical thromboprophylaxis information for patients without documented exemptions (e.g. active bleeding, allergy). We then compared differences in procedure mix and operative complexity across hospitals based on their perioperative thromboprophylaxis rates. **Results:** Overall, 43.1% of eligible patients had perioperative pharmacologic thromboprophylaxis for abdominal cancer surgery, and 25.3% (318/1258) of the highest-risk patients had evidence of inadequate postoperative prophylaxis (under-prophylaxis either by dose or duration). Hospital perioperative thromboprophylaxis rates ranged from 0%-96.1%, and postoperative thromboprophylaxis rates ranged from 73.9%-100%. Compared to hospitals with the lowest perioperative thromboprophylaxis rates, hospitals with the highest perioperative prophylaxis rates performed more HPB procedures (24.1% vs. 5.3%) and fewer concomitant operative procedures (31.1% vs. 44.7%). Epidural use did not impact hospital pharmacologic thromboprophylaxis rates. **Conclusions:** Fewer than half of patients undergoing abdominal cancer surgery receive perioperative thromboprophylaxis, and there is wide variation in hospital thromboprophylaxis utilization despite strong evidence-based guidelines supporting its use. Identifying reasons for non-adherence to published guidelines and best practices will be important to improve outcomes in this vulnerable patient population.

**6536 Poster Highlights Session (Board #25), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Sustaining quality cancer care in the NCI Community Cancer Centers Program (NCCCP).** *Presenting Author: Kathleen M. Castro, National Cancer Institute of the National Institutes of Health, Rockville, MD*

**Background:** In 2007, the NCCCP pilot program launched with 16 sites and a goal to improve quality of care, reduce cancer disparities and increase participation in clinical trials. In 2008, NCCCP began to participate in the Commission on Cancer Rapid Quality Reporting System (RQRS). An evaluation of NCCCP in 2010 assessed changes in cancer care quality among the sites before vs. after program implementation compared to non-NCCCP hospitals during the same time period (Halpern et al. 2013). Our current analysis examines if improvements in quality were sustained. **Methods:** Conducted a retrospective analysis of patients diagnosed and receiving all or part of their initial cancer treatment at an NCCCP facility. Compared concordance rates for 6 NQF- approved quality of care measures (3 breast, 2 colon and 1 rectal) for patients diagnosed between 2006-2007 (pre-NCCCP), 2008-2010 (early NCCCP) and 2011-2013 (later NCCCP). **Results:** The sample included 17,288 breast, 6,655 colon and 569 rectal cancer patients. Patient-level concordance rates improved significantly for all 6 measures and were sustained for 5. Breast cancer measures showed the greatest improvement from pre-NCCCP and were subsequently sustained. Hormone therapy for hormone receptor positive breast cancer increased from 51% (pre) to 90% (early) to 92% (later). Radiation therapy for breast conserving surgery increased from 72% to 93% to 92%. Colon cancer measures also showed sustained improvements with adjuvant chemotherapy for stage III cancer increasing from 72% to 90% to 89%. However, adjuvant chemotherapy for stage III rectal cancer improved from baseline (83%) to early NCCCP (90%) but then returned to pre-NCCCP rates (83%) later in the program. Significant changes were also seen in disparate populations. **Conclusions:** Quality of care measures at NCCCP sites increased after program initiation, and this increase was largely sustained over time. Improvement in recording of treatment administration due to the RQRS was a factor in increasing concordance. Concurrent NCCCP activities, including a working group to improve RQRS reporting and presentations of NCCCP results to the participants, may have helped sites significantly improve and sustain quality cancer care.

**6537 Poster Highlights Session (Board #26), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Lymphadenectomy quality measure for colon cancer: Is it working?** *Presenting Author: Jennifer Leigh Paruch, Division of Research and Optimal Patient Care, American College of Surgeons, Chicago, IL*

**Background:** Endorsement of the 12 lymph node colon cancer measure has led to improvements in national performance. However, it is unknown whether hospital performance on this measure is associated with improved outcomes. The objectives of this study were to determine whether improvement on this measure impacts stage migration or survival. **Methods:** Patients in the National Cancer Data Base undergoing resection for stage I-III colon cancer (1995-2011) were identified. Three hospital improvement groups were created using change in median node count over time (< 5; 5-10; >10). Changes in the ratio of stage III patients over time were compared between groups. A hierarchical Cox model was used to assess the relationship between hospital improvement and 5 year overall survival for stage II patients. **Results:** A total of 455,155 patients from 1,047 hospitals were identified. Median hospital lymph node counts increased from 10 (IQR 8-10) to 17 (IQR 15-19) over the study period. Increase in stage III patients over time was related to hospital improvement group (1.2% for improvement <5; 3.2% for improvement 5 – 10; 4.4% for improvement > 10; p<.0001). Hospital improvement group was significantly associated with 5-year overall survival in stage II patients (improvement 5-10: HR 0.97 [0.84-0.99]; improvement >10: HR 0.95 [0.91-0.98]). **Conclusions:** Stage migration and improved stage II survival were related to degree of hospital improvement in median node count. Implementation of this quality measure at Commission on Cancer accredited facilities may have greatest impact on outcomes at centers with most improvement.

**6538 General Poster Session (Board #1), Mon, 1:15 PM-5:00 PM**

**Media reporting of practice-changing clinical trials in oncology: A North American perspective.** *Presenting Author: Peter Andrew, Department of Internal Medicine, The Ottawa Hospitals, Ottawa, ON, Canada*

**Background:** The median time interval from phase III trial completion to public availability of results is 29 months. Our primary objective was to characterize the accuracy of information regarding ASCO 2012 *Clinical Cancer Advances* (CCA, n=17) as reported by the media and Internet; important public sources during that time. **Methods:** The *first* articles referencing CCA conference material were collected from newspapers, cable news, cancer websites, and industry websites. Two investigators independently rated the completeness of information using a 15-point scoring system [media reporting score (MRS)]. Statistical analyses were by Kruskal-Wallis one-way ANOVA-by-ranks test with post hoc analysis (Statistica, Statsoft Inc., Tulsa, Oklahoma, USA). **Results:** From 163 media articles, 107 (66%) had sufficient data for analysis. Per MRS, information was most complete from industry > cancer websites > newspapers > cable news (Table; Kruskal-Wallis $H$ test = 8.52; $df$ = 3; $p<0.05$). The most commonly omitted items were: study limitations > exclusion criteria > conflict of interest > other. **Conclusions:** The media should be encouraged to use a standardized reporting template and provide access to original source information.

**6539 General Poster Session (Board #2), Mon, 1:15 PM-5:00 PM**

**A prospective comparison of times to presentation and treatment of rural and urban head and neck cancer patients in Queensland, Australia.** *Presenting Author: Zulfiquer Ali Otty, James Cook University, Townsville, Australia*

**Background:** Rate of survival from head and neck (H and N) cancer is lower among rural patients compared with their urban counterparts. This study's aim was to examine whether there was any difference between Urban (U) and rural (R) areas in the time taken to receive various aspects of H and N cancer management. **Methods:** H and N cancer patients presenting to Townsville, Cairns and Mackay hospitals were prospectively recruited from January 2009 to January 2011. The demographic factors as well as median times between 1) symptoms and first consultation, 2) symptoms and referral to specialist, 3) symptoms and visit to specialist, 4 ) symptoms and first treatment, 5) diagnosis and first treatment, 6) consultation and referral to specialist, and 7) visit to specialist and treatment, were collected. Fisher's, Kruskal-Wallis and Mann-Whitney tests were used to compare the two groups. **Results:** Out of the total of 158 patients , 62 % were living in urban and 37.3 % were living in rural areas. According to univariate analysis, there was significant difference in median time between diagnosis and first treatment between U and R areas (p=0.015). Indigenous patients had significant delays from diagnosis to first treatment (p=0.013), and visit to a specialist and treatment (p=0.031), compared to non-indigenous patients. According to multivariate analysis, there was significant delay in time between symptoms and first treatment in low-income compared to high-income population (P =0.03) and in patients with lower level of education compared to those with higher level of education ( P=0.04). There was significant delay in time between diagnosis and treatment for patients living in R area compared to those living in U area (P=0.028). The time between first consultation and referral to a specialist and time between visit to specialist and treatment was significantly longer in patients living in R areas compared to U area ( P=0.025 and P=0.003). **Conclusions:** There are delays in various aspects of head and neck cancer management depending on remoteness of residence and socio-economic factors. Improvement in management pathways for rural patients may improve their survival rates from H and N cancer.

**6540 General Poster Session (Board #3), Mon, 1:15 PM-5:00 PM**

**Relationships among financial distress, emotional symptoms, and overall distress in insured cancer patients.** *Presenting Author: Yu-Ning Wong, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Cancer care can be a financial burden, even among those with insurance. Overall Distress (OvDis) in cancer patients (pts) may be caused by many factors including Emotional Symptoms (EmSx). We examined the degree to which Financial Distress (FinDis) affected both OvDis and EmSx. **Methods:** We surveyed pts from medical oncology clinics about demographics, clinical information and the InCharge Financial Distress/Financial Well-Being Scale (range 1-10, lower scores indicating greater FinDis). Overall distress (OvDis) was measured using the NCCN distress thermometer (DT) (range 0-10, higher scores worse). As part of the DT, pts also responded to a list of symptoms including EmSx(i.e. depression, anxiety). We used linear regression and ANOVA to investigate potential pathways linking FinDis, EmSx and OvDis. Accrual is ongoing. **Results:** Of 60 pts recruited, median age was 64 years (34-85), 53% were male, 32% were working, 28% had self reported annual income >$100,000, 100% were insured, 69% had prior chemotherapy. 60% had clinically relevant DT scores ≥ 4 (median 5, 0-10), 58% reported at least one EmSx. The most common EmSx were worry(44%) and nervousness (34%). Median FinDis score was 6.5 (1-10). Evaluating the impact of each separately, FinDis and EmSx explain 30% and 39.6% of the variability in among OvDis scores respectively. After accounting for EmSx, FinDis explained 10.1% of the variability in OvDis (full model $R^2$=0.497). Conversely, after accounting for FinDis, EmSx accounted for 19.75% of the variability in OvDis. Using linear regression, a 1 unit increase in FinDis was associated with a 0.79 unit worsening in DT (p<0.001). After adding EmSx, a 1 unit increase FinDis was associated with a 0.51 worsening in DT (p=0.002). The attenuation of the FinDis effect due to EmSx was significant (p=0.003). **Conclusions:** Even among this group of affluent pts seen at a tertiary referral center, OvDis, FinDis, and EmSx were common and inter-related. Even among pts who are insured, FinDis may play a profound role on both EmSx and OvDis. Focused interventions that help pts navigate insurance obstacles and address other financial concerns may help to reduce FinDis and EmSx and thus in turn reduce OvDis among cancer pts.

**6541 General Poster Session (Board #4), Mon, 1:15 PM-5:00 PM**

**Impact of care at NCI comprehensive cancer centers (NCICCC) on cancer outcome: Results from a population-based study.** *Presenting Author: Julie Anna Wolfson, City of Hope, Duarte, CA*

**Background:** Despite advances in therapy and supportive care, prognosis for certain cancers remains poor. Rigorous processes ensure quality of research, clinical care and education at NCICCC. However, impact of site of care on survival and access to NCICCC for vulnerable subpopulations (race/ethnicity, payor) remains unstudied. **Methods:** We constructed a population-based cohort of 53,618 patients diagnosed between 22y - 65y with adult-onset cancers and reported to LA County cancer registry between 1998 - 2008. Geographic Information Systems (ArcGIS) was used for geospatial analysis. **Results:** Across multiple diagnoses, patients at NCICCC showed superior 5y overall survival (OS) as compared to those at community sites (breast [n=31,770]: 89% vs. 86%, p<0.01; lung [n=10,855]: 28% vs. 17%, p<0.01; hepatobiliary [n=4,296]: 34% vs. 19%, p<0.01; gastric [n=2,678] 32% vs. 22%, p<0.01; pancreas [n=2,326]: 13% vs. 6%, p<0.01; oral [n=1,838]: 68% vs. 59%, p=0.01). Adjusting for clinical (age, stage, gender) and sociodemographic (race/ ethnicity, payor, socioeconomic status [SES]) characteristics, multivariable Cox regression revealed an increased risk of mortality in patients receiving care at non-NCICCC sites: Breast: hazard ratio (HR)=1.2, p<0.01; Lung: HR=1.5, p<0.01; Hepatobiliary: HR=1.4, p<0.01; Gastric: HR=1.4, p<0.01; Pancreas (n=2,326), HR=1.5, p<0.01; Oral: HR=1.3, p=0.05. Overall 7% of patients were seen at NCICCC (range 4-16%, p<0.01). Multivariable logistic regression adjusting for clinical characteristics revealed that low SES (OR range across diagnoses: 0.4-0.5, p<0.01), public (OR 0.4-0.9, p<0.03) or no (OR 0.1-0.7, p<0.04) insurance, African-American race (OR 0.4-0.6, p<0.03) or Hispanic ethnicity (OR 0.5-0.7, p<0.02), and residing > 9 miles from nearest NCICCC (OR 0.5-0.9, p<0.01) decreased likelihood of care at NCICCC. **Conclusions:** Population-based data reveal superior OS among adult-onset cancer patients receiving care at NCICCC. Patients without private insurance, from low SES, African-American and Hispanic backgrounds or living more than 9 miles from an NCICCC, are less likely to use NCICCC. Barriers to care at NCICCC are currently being explored.

**6542 General Poster Session (Board #5), Mon, 1:15 PM-5:00 PM**

**Effect of pre-existing mental health comorbidities (MHC) on stage and timeliness of care of solid tumors in Veterans Affairs Connecticut Healthcare System (VACHS).** *Presenting Author: Roxanne Jimmy Wadia, Yale-New Haven Hospital, New Haven, CT*

**Background:** Axis I MHC affects approximately 18% and 30% of the adult US and VA population, respectively. There are limited and conflicting data on the impact of MHC on stage and timeliness of cancer care. The purpose of this study was to compare stage and timeliness of care in colorectal (CR), urothelial (UR) and head/neck (HN) cancers among Veterans with and without MHC. **Methods:** After IRB approval, we reviewed charts of Veterans with CR, UR and HN cancers diagnosed at VACHS between 2008 and 2011. Pts were identified via the cancer registry. NCCN guidelines were used to define standard of care. MHC was defined as an Axis I diagnosis treated in the year prior to the cancer diagnosis. Three time intervals were calculated: initial cancer symptom to presentation to a provider (TSP); provider to tissue diagnosis (TPD); and diagnosis to initiation of treatment (TDT). Data was analyzed using Chi-square, Fisher's Exact and non-parametric Wilcoxon rank sum tests as appropriate, using SAS. **Results:** We reviewed 412 charts including 174 pts with UR, 155 with CR and 83 with HN cancers. Of our pts, 36.6% (151) had Axis I MHC, 18.7% (77) had alcohol abuse/dependence, and 5% (21) had illicit drug abuse/dependence. In regard to staging, 221 (45%), 171 (41.5%) and 96 (23.3%) had Stage 0-1, stage II-III, and stage IV cancer. Diagnosis and treatment delays of at least 2 weeks were found in 73 pts (17.7%) and 63 (15.3%), respectively. In addition, 61 pts (14.8%) chose not to accept the standard of care. We found no difference between pts with or without MHC in stage distribution, symptomatic disease at presentation, diagnostic or treatment delays, or deviation from standard of care. Furthermore, there were no significant difference in the three measures of timeliness of care (TSP, TPD and TDT) between pts with and without MHC. **Conclusions:** Stage at diagnosis of CR, UR and HN cancers in VACHS did not differ between pts with and without Axis I MHC. The presence of MHC did not result in delays in care. Our data provides reassurance that within a healthcare system that provides integrated, comprehensive medical and psychiatric care, pts with Axis I MHC do not experience significant delays in cancer care.

**6543 General Poster Session (Board #6), Mon, 1:15 PM-5:00 PM**

**Accrual of adolescents and young adults with cancer to eligible clinical trials: A report from the NCIC Clinical Trials Group (NCIC-CTG).** *Presenting Author: Lesleigh S. Abbott, NCIC Clinical Trials Group, Kingston, ON, Canada*

**Background:** Improvement in 5-year survival among adolescents and young adults with cancer (AYAWC) has not kept pace with gains made in other age groups. Further, in the United States, 40-70% of children younger than 15 years old are enrolled onto National Cancer Institute clinical trials while less than 2% of 20-29 year old participated (Burke et al. 2007; Bleyer et al. 2002; 2006). We hypothesized that AYAWC were also underrepresented on clinical trials performed through the NCIC CTG, a predominantly adult oncology group. **Methods:** For this analysis, we defined AYAWC as 15-29 years old. All relevant trials from 2003-2013 were reviewed. Canadian cancer incidence was obtained from the Canadian Cancer Statistics (CCS) registry, deriving the mean annual incidence from data collected over a three year period (Statistics Canada, 2005-2007). We assessed the ratio of the number of AYA enrolled in NCIC CTG trials over the average annual numbers of new cases of the cancers in the AYA population in Canada and the ratio of the total numbers of patients on the NCIC CTG trials over average new cases of the cancer. **Results:** A total of 24,044 patients were enrolled on NCIC CTG trials, including 159 AYAWC (0.66%), while AYAWC represented 1.6% of incident cases from 2005-2007. The table indicates a selection of key AYA cancers; however, the total represents all cancer types included in this study. **Conclusions:** Overall AYA patients are more than 2-fold under-represented in current adult clinical trials; however, certain cancer types such as colorectal, breast and non-Hodgkin lymphoma have better than expected accrual as compared to incidence data.

**6544 General Poster Session (Board #7), Mon, 1:15 PM-5:00 PM**

**Exclusion of patients with prior cancers from clinical trials: Is this justified?** *Presenting Author: Noelia Tarazona, The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

**Background:** Strict eligibility criteria are necessary for clinical trials to maintain patient (pt) safety and scientific validity. However exclusion of pt populations leads to impaired generalizability of results. As survival in gastrointestinal (GI) cancer relates mainly to the GI malignancy, we hypothesised that previous unrelated cancers do not impact on pt survival and are not a rational reason to exclude pts from trials. **Methods:** Pts were identified for this retrospective observational study from the electronic patient record at the Royal Marsden Hospital, UK. Eligibility criteria included age ≥ 18 years, diagnosis of colorectal (CRC), gastric, pancreatic or hepatocellular cancer, and treated with chemotherapy from 1/1/2006 – 31/12/2006. Chart review was performed and pt age, gender, GI cancer stage, prior cancer stage, clinical trial availability/eligibility, and dates of cancer recurrence, death and last follow up were identified. Overall (OS) and GI cancer specific survival (SS) were estimated using the Kaplan Meier method and compared by the log-rank test for pts with/without prior cancer. **Results:** 701 pts were identified. Most GI cancers were CRC (74%) and stage III (41%) or IV (38%) at diagnosis. 58 pts (8%) had a prior cancer; commonly breast (26%), prostate (19%), colon (9%), or melanoma (7%) and most were stage I (52%) or II (27%). 299 (65%) pts had GI cancer recurrence, 8 (14%) pts had relapse of a prior cancer. Median follow up was 84 months (m): 505 (72%) pts have died, 172 (25%) are alive with no cancer and 24 (3%) pts are alive with cancer. 477 (95%) died of GI cancer, 2 (0.3%) of their prior cancer and 16 (3%) from other causes. 492 (70%) of all pts had an available trial but of pts with a prior cancer who had an available trial 30% were ineligible due to the previous cancer. OS and GI cancer SS were comparable for pts with/without a prior cancer at 45.9 versus 40.6 m, p=0.93 and 49.2 versus 41.2 m, p=0.74, respectively. **Conclusions:** Survival for pts with a GI cancer requiring chemotherapy relates to the GI cancer and rarely a prior cancer. As there is no statistically significant difference in OS and GI cancer specific survival between pts with and without prior cancer, these pts should not be excluded from clinical trial participation.

**6545 General Poster Session (Board #8), Mon, 1:15 PM-5:00 PM**

**Barriers to insurance coverage of next-generation tumor sequencing by U.S. payers.** *Presenting Author: Julia Rachel Trosman, Center for Business Models in Healthcare, Chicago, IL*

**Background:** Next-generation tumor sequencing (NGTS) panels, which include tens to hundreds of targets of varying clinical significance applicable across cancers, are crossing from research to clinical practice, but are not formally covered by U.S. payers. Lack of consistent coverage policy may impact access and adoption. Our study aimed to identify considerations used by payers for NGTS coverage decisions. **Methods:** We conducted semi-structured interviews with senior executives of 7 large national and 3 regional plans in the U.S., covering >125 million members. We used the framework approach of qualitative research for thematic analyses. **Results:** Most payers (80%) believe NGTS has a potential to transform cancer care, but all (100%) report barriers to coverage. (1) 70% of payers view NGTS as a 'bundle" of cancer markers, vs. comprehensive tumor characterization, and thus may evaluate evidence for one target and one cancer type at a time. Sufficient evidence for all targets included in an NGTS panel may be required for a positive coverage decision. (2) 80% of payers may predicate coverage policy for NGTS not only on validity of included targets, but also on outcomes from therapies informed by NGTS, with 30% requiring Phase 3 evidence for each new marker / drug indication. (3) 70% of payers note that NGTS converges clinical care and research by interrogating both established and novel targets, and thus does not fit the coverage framework separating "medically necessary" vs "experimental / investigational". Therefore, payers may not cover panels that include novel targets. However, 40% also note health reform requirements to cover trials for terminal conditions and may use NGTS as a means for complying with this requirement. (4) Payers cite challenges in assessing accuracy and value of bioinformatics required to implement NGTS. 70% do not believe that bioinformatics should be reimbursed. **Conclusions:** Next-generation tumor sequencing does not fit the current payer coverage and evidence framework and thus faces potential barriers to access. The entry of this rapidly evolving technology into clinical practice requires ongoing dialogue among payers, providers, and policy-makers to develop an innovative roadmap to coverage and reimbursement.

**6546 General Poster Session (Board #9), Mon, 1:15 PM-5:00 PM**

**A national survey of breast cancer screening in rural America.** *Presenting Author: Jeffrey M. Peppercorn, Duke Cancer Institute, Durham, NC*

**Background:** Breast cancer screening leads to improved survival yet disparities among rural women persist. The impact of inconsistent mammography guidelines on attitudes and utilization is unknown. **Methods:** We conducted a national self-administered survey of 2,000 randomly selected women between ages 40 and 65 insured by the National Rural Electric Cooperative Association (as utility workers or family members). A study-specific survey assessed mammography use, knowledge and attitudes about screening, awareness of guidelines, and correlation between knowledge, attitudes and screening. **Results:** 1,581 women responded (response rate 79%). 41% were age 40-49, 58% age 50-65. 74% were rural, 18% suburban, and 8% urban. 98% agreed that mammograms find cancer early and improve chance of cure. Only 19% believed that mammograms may lead to unneeded biopsies and 4% to unsafe radiation. 54% thought annual mammography was recommended for women 40-49, 22% biennial, 17% that expert views vary, 2% screening not recommended, and 5% unsure. Non-rural women were more likely to believe annual screening is recommended (64% vs. 51%, $p = 0.0002$). For women over 50, 66% believed annual screening was recommended, 14% biennial, 11% expert views vary, and 9% unsure. While only 9% reported confusion over guidelines, few reported practices consistent with U.S. Preventative Services Task Force (USPTF) recommendations. Among women < 50, 46% report annual screening, 32% biennial, and 23% rare/never. Among women > 50, 63% reported annual screening, 25% biennial, and 13% rare/never. Among younger women, belief that annual screening was recommended correlated with reported annual screening, (70% vs. 20%, $p < 0.0001$). Younger women who reported understanding current guidelines were also more likely to report annual screening (51% vs. 33%, $p = 0.0003$) and less likely to report rare/never screening (18% vs. 34%, $p = 0.0002$). Among women over 50, those reporting confusion over guidelines were twice as likely to report rare/never screening vs. those reporting understanding (18% vs. 9%, $p = 0.0004$) **Conclusions:** Perceptions of recommendations and confusion over guidelines correlate with screening behavior suggesting a need for expert consensus to inform appropriate utilization.

**6547 General Poster Session (Board #10), Mon, 1:15 PM-5:00 PM**

**A targeted intervention to improve awareness to molecular testing in NSCLC.** *Presenting Author: Alona Zer, Princess Margaret Cancer Center, Toronto, ON, Canada*

**Background:** Molecular testing is now standard of care to guide treatment selection in advanced NSCLC. Population-based implementation of testing remains a challenge in Ontario'spublic healthcare system, with ~37% of eligible samples undergoing testing and~12% insufficient for testing. We developed an intervention to improve understanding among Ontario specialists of the importance of molecular testing and appropriate diagnostic sampling in NSCLC. **Methods:** Based on IASLC guidelines for molecular testing in NSCLC, leaders in lung pathology, respirology, interventional radiology and thoracic surgery identified key messages for each specialty regarding molecular testing and diagnostic sampling in lung cancer. Specialty-specific educational programs (delivered by a multidisciplinary team) were developed and administered at provincial and national specialty meetings. Participants were assessed on their knowledge of targeted therapy, molecular testing and sample requirements **Results:** Ten educational programs were administered across the country targeting pathologists, thoracic surgeons, respirologists, interventional radiologists, medical and radiation oncologists. 210 pre- and 188 post-intervention surveys were completed.Baseline results demonstrated significant uncertainty: 30% were unsure regarding tissue handling techniques to ensure successful molecular testing, 20% chose an incorrect technique. Half were unfamiliar with how to initiate *EGFR* and *ALK*testing, and 17% were uncertain of whom to test. After the intervention, specialist knowledge increased regardingtissue handling techniques (OR=3.01, p<0.0001), appropriate fixation (OR=2.48,p<0.0001), and the level of uncertainty decreased from 30% to 3% (p<0.0001). Participants understood the importance of initiating testing as soon as possible rather than deferring to the medical oncologist (p<0.0001), and to send samples even if unsure they met technicalrequirements (OR=4.63,p<0.0001). **Conclusions:** Significant knowledge gaps existabout molecular testing in NSCLC among specialists that diagnose the disease. Specialist education significantly improves knowledge and awareness about molecular testing and its importance in NSCLC.

**6548 General Poster Session (Board #11), Mon, 1:15 PM-5:00 PM**

***BRCA1/BRCA2* (*BRCA*) testing in young women with breast cancer: Patterns, motivations, and implications for treatment decisions.** *Presenting Author: Shoshana M. Rosenberg, Harvard School of Public Health, Boston, MA*

**Background:** While BRCA testing is recommended for women diagnosed with breast cancer before age 50, little is known about decisions surrounding testing in young patients. **Methods:** As part of an ongoing cohort study, we surveyed 765 women diagnosed with breast cancer at age ≤ 40 about their experience with BRCA testing at approximately 1 year after diagnosis. We used Chi-square tests to evaluate differences in how genetic information was used to make treatment decisions among women who 1) tested positive 2) tested negative 3) were not tested. Among untested women, we assessed whether 1) genetic risk was discussed with a provider 2) reasons why they were not tested. **Results:** 655/765 (86%) of women reported undergoing BRCA testing by 1 year from diagnosis. 31% (232/746) said that knowledge/concern about genetic risk influenced treatment decisions. Among these women (Table), 87% of mutation carriers, 50% of non-carriers, and 45% of untested women chose bilateral mastectomy; fewer women reported that adjuvant treatment decisions were influenced by genetic risk concern. Among untested women, 32% (35/110) had not discussed the possibility that they might have a mutation with their doctor. The top 5 reasons cited for not testing were: patient perceived risk low (25%), doctor perceived risk low (24%), not a priority (18%), insurance/work (14%), financial (11%). 39% were thinking of testing in the future. **Conclusions:** >10% of women with breast cancer ≤ 40 were not tested for a BRCA mutation within a year of diagnosis. Among these women, 1/3 did not discuss genetic risk with their doctor. Given that knowledge/concern about genetic risk influences surgical decisions and can affect systemic therapy trial eligibility, all young breast cancer patients should have access to adequate genetic counseling and testing if desired.

**Genetic concerns influenced use/choice of treatment in the following ways.**

| (N=232) | BRCA+ N=71 N (%) | BRCA- N=139 N (%) | Not tested N=22 N (%) | p |
|---|---|---|---|---|
| Mastectomy instead of lumpectomy | 3 (4) | 14 (10) | 7 (32) | 0.001 |
| Bilateral mastectomy | 62 (87) | 70 (50) | 10 (45) | <0.0001 |
| Salpingo-Oophorectomies | 37 (52) | 6 (4) | 2 (9) | <0.0001 |
| Endocrine therapy | 12 (17) | 28 (20) | 4 (18) | 0.78 |
| Chemotherapy | 14 (20) | 17 (12) | 3 (14) | 0.35 |

**6549 General Poster Session (Board #12), Mon, 1:15 PM-5:00 PM**

**Burnout among Canadian oncologists and oncology residents.** *Presenting Author: Thao Phuong Nguyen, Tom Baker Cancer Centre, Calgary, AB, Canada*

**Background:** The objective of this study was to evaluate characteristics associated with burnout in Canadian oncologists and oncology resident physicians (ORP). **Methods:** Canadian medical oncologists (MO), radiation oncologists (RO) and ORP were asked to complete a self-administered survey which included: a validated single-item measure of burnout, questions regarding personal and professional characteristics, impact of work-related stress on family life and an exploration of the oncologists' support network. A similar survey was sent to spouses to determine the spouse's perception of oncologist burnout **Results:** A total of 307 oncologists and ORP completed the survey (median age 47, including 45% MO, 43% RO, 12% ORP). The response rate was 31%. The prevalence of high burnout in each group was: 20% MO, 14% RO, and 20% ORP. Overall, 61% MO and 37% RO reported a high work-overload, 25% MO and 22% RO had high work-family conflict, and 11% MO and 14% RO had family-work conflict. Regarding career satisfaction, 15% MO and 16% RO regreted their decision to become a physician, 23% MO and 29% RO considered leaving their current province, 17% MO and 20% RO considered leaving oncology as a career altogether. The concordance rate for burnout between physicians and spouses was 77.6% (kappa = 0.32). On multivariable analysis, factors associated with burnout included female gender, less exercise, less alcohol consumption and lower level of co-worker support. Factors included in the multi-variable analysis that were not associated with burnout include: age, number of cancer sites covered, spousal support, as well as time allocated to patient care and doing work tasks at home. **Conclusions:** Across Canada, one in five oncologists reported having high burnout. This is a lower rate than previously reported. Predictors of burnout in Canadian oncologists are different compared to a recently reported study of medical oncologists in the United States.

| Multivariable analysis predictors | OR | P-value |
|---|---|---|
| Female | 2.409 | 0.0277 |
| Exercise (several times/ week min.) | 0.324 | 0.0045 |
| Alcohol (4 drinks/week versus less) | 0.333 | 0.019 |
| Coworker support (more versus less) | 0.946 | 0.0305 |

**6550 General Poster Session (Board #13), Mon, 1:15 PM-5:00 PM**

**Do special access programs facilitate off-label prescribing? The experience of enzalutamide in prostate cancer.** *Presenting Author: Nimira S. Alimohamed, Department of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** There is limited data on prescribing patterns during special access programs. Enzalutamide, a novel oral anti-androgen, improves overall survival in patients with metastatic castration resistant prostate cancer (mCRPC). In the post-docetaxel setting, enzalutamide was Health Canada approved in May 2013 and publically funded in Ontario in December 2013. In the pre-docetaxel setting, data demonstrating benefit of enzalutamide (PREVAIL study) was only recently released and it is yet to be approved in this setting. Enzalutamide was provided free of charge by the manufacturer as part of a patient assistance program from June-December 2013. To understand factors influencing decision to offer enzalutamide in this program, we surveyed treating oncologists. **Methods:** Following ethics approval, oncologists at our institution prescribing enzalutamide completed an anonymous paper or electronic survey asking questions about the patient's disease characteristics, prior treatments, and reasons for prescribing enzalutamide. **Results:** Of 193 patients enrolled, surveys were completed on all 155 patients prescribed enzalutamide by oncologists. The majority of patients had metastatic CRPC (92%), while a minority had non-metastatic CRPC (8%); 95% had progressive disease at initiation while 5% did not. Pre-docetaxel prescribing occurred in 65% of cases; with 54% of those being after PREVAIL data was released. The primary reasons for prescribing enzalutamide were data supporting its use (50%) and its availability at no charge (35%). Enzalutamide was felt to be the best choice or as good as other options by 82%; 11% stated enzalutamide would be the next line of treatment but only at the time of further disease progression; 7% stated enzalutamide would not be their next line of treatment and only prescribed it because of the program. **Conclusions:** During this patient access program, off-label use of enzalutamide was seen, perhaps because it is a well-tolerated hormonal agent, which may delay the need for chemotherapy. This study demonstrates that funding and accessibility issues impact prescribing practices.

**6551 General Poster Session (Board #14), Mon, 1:15 PM-5:00 PM**

**Choosing a cancer surgeon: Analyzing factors in patient decision making using a best-worst scaling methodology.** *Presenting Author: Aslam Ejaz, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Surgeon experience has been shown to influence outcomes for many types of cancer. The attributes and factors that patients utilize when selecting a hospital or surgeon for cancer treatment remain poorly defined. **Methods:** All patients with a cancer diagnosis seeking treatment at a surgical clinic at Johns Hopkins Hospital were asked to participate. A survey utilizing a best-worst scaling methodology was constructed to elicit the importance of various factors when selecting a cancer surgeon. Attributes were chosen based on an extensive review of the literature and a pre-test analysis. Attributes were grouped into four categories: surgeon reputation, surgeon qualifications, hospital-related and non-clinical factors. **Results:** 194 patients with a cancer diagnosis participated in the study (80.8% response rate). Median age was 62 years (IQR: 51.5, 70). Patients had a variety of primary tumor diagnoses with the most common being hepatobiliary (N=35, 18.1%) and breast (N=31, 16.1%). Among the attributes, patients placed the highest value on physician qualifications and hospital-related factors. Specifically, surgeon case-specific experience (coefficient: 2.52, SE 0.06) and the receipt of specialized training experience (coefficient: 2.28, SE 0.06) ranked highest (both $P<0.001$). Among hospital-related factors, hospital case-specific volume (coefficient: 1.31, SE 0.06; $P<0.001$) was most important. The lowest rated factors were parking availability (coefficient: -2.80, SE 0.064) and home-to-clinic distance (coefficient: -2.09, SE 0.06) (both $P<0.001$). The majority of patients reported their ideal surgeon to have at least 6 years of experience (N=153, 86.0%) and to have performed their specific procedure at least 50 times (N=144, 76.6%). After stratifying patients by education level and state of residence, the ranking of factors remained unchanged. **Conclusions:** Patients consider several factors when choosing a cancer surgeon. Surgeon qualifications and hospital-related factors appear to be most influential in their decision. Easier and more widespread dissemination of surgeon and hospital cancer data such as case volume may be useful for patients in the future.

**6552 General Poster Session (Board #15), Mon, 1:15 PM-5:00 PM**

**Why is it so difficult to enroll patients in clinical trials?** *Presenting Author: Norma Kanarek, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Nationwide, approximately 3% of patients participate in therapeutic clinical trials. It is presumed that patient education and navigation will increase enrollment. For these interventions to work, a clear understanding of the reasons patients do not enroll is needed. Employing our enrollment framework (Kanarek et al, 2012), we set out to define, at one comprehensive cancer center, the reasons new cancer patients fail to enroll onto clinical trials. **Methods:** Medical Oncology records from a consecutive series of new breast, non-small cell lung (NSCLC), pancreas and prostate cancer patients were abstracted. Abstraction was based on seven framework sequential steps: 1) trial availability, 2) trial eligibility, 3) physician triage 4) physician-patient discussion, 5) patient's interest, 6) consent, and 7) enrollment. Each step depends on the prior step (e.g. if there were no trial available then eligibility for a trial could not be considered). Reasons noted for failing any step were summarized. **Results:** Between 2012 and 2013, records from 688 patients were reviewed. Clinical trial enrollment varied: 5% NSCLC, 12% pancreas and prostate, and 17% breast. The 4 most common reasons for non-enrollment were: no trial available or patient did not meet eligibility (36-55%); standard treatment was recommended or preferred (6-23%); distance from the cancer center (1-22%); and lost to clinical follow-up or patient chose to receive care elsewhere (5-14%). Combined, these 4 reasons eliminate 64% of breast, 83% of pancreas, 84% of prostate and 89% of NSCLC patients from trial participation. About half of the remaining patients enrolled onto clinical trials. **Conclusions:** Our study suggests that these 4 common reasons for clinical trial non-participation may need to be addressed to increase clinical trial percentages.

Patient distribution n(%).

| | n | No available trial w/eligibility | Distance | Sth tx recomm./ preferred | Lost to follow up/ care elsewhere | Total not available (4 reasons) | Remaining available | Enrolled on to clinical trials |
|---|---|---|---|---|---|---|---|---|
| Breast | 293 | 106 (36) | 13 (4) | 39 (13) | 29 (10) | 187 (64) | 106 (36) | 50 (17) |
| Lung | 154 | 78 (51) | 2 (1) | 36 (23) | 21 (14) | 137 (89) | 17 (11) | 8 (5) |
| Pancreas | 147 | 81 (55) | 24 (16) | 9 (6) | 8 (5) | 122 (83) | 25 (17) | 17 (12) |
| Prostate | 94 | 43 (46) | 21 (22) | 9 (10) | 6 (6) | 79 (84) | 15 (16) | 11 (12) |

**6553 General Poster Session (Board #16), Mon, 1:15 PM-5:00 PM**

**The cost of thromboembolic events in French hospitalized patients with breast or prostate cancer.** *Presenting Author: Isabelle Borget, Institut Gustave Roussy, Villejuif, France*

**Background:** Cancer is associated with a high risk of venous thromboembolism. We aimed to determine the number of stays and the cost of hospital management of thromboembolic events (TEEs) occurring in patients with breast cancer (BC) or prostate cancer (PC). **Methods:** The French national hospital database (PMSI) was analysed in order to identify patients whose BC or PC was diagnosed in 2010 and who were hospitalized for a TEE at least once during the following two years. The numbers of stays induced by a TEE, and the corresponding number of patients hospitalized, were determined using the disease-specific ICD-10 codes. Associated hospital costs were estimated from the perspective of the third-party payer, using the French official tariffs. **Results:** We identified 62,365 patients with BC and 45,551 patients with PC; in each group, 1,271 (2.0%) and 997 (2.2%), respectively, were hospitalized for a TEE or had a TEE during their hospital stay. During the 2 years of follow-up of these 2,268 patients, 346 (15.3%) were hospitalized for a TEE recurrence. In total, 1,604 stays for BC patients and 1,210 stays for PC patients were analyzed. In BC patients, the mean cost per stay amounted to €3,302 and €2,916 for first event and recurrence, respectively, and in PC patients, €3,611 and €3,363 for first event and recurrence, respectively. In patients who had at least one recurrence, mean hospitalization cost per patient was €5,545 and €5,692 in BC and PC, respectively. Over a 2-year period, the total cost of hospital stays induced by TEEs reached €1.98 million and €1.43 million for BC and PC, respectively. **Conclusions:** The burden of TEE in cancer patients is high; costs would be reduced by decreasing the occurrence of thromboembolic complications in this at-risk population. Better prevention and follow-up measures may reduce recurrence and TEE costs.

**Cost of hospital stays for patients with BC or PC and TEE.**

| | First event | Recurrence | Total |
|---|---|---|---|
| **Breast cancer** | | | |
| **Mean cost/stay** | €3,302 | €2,916 | €3,261 |
| **Total cost** | €1,789,615 | €186,620 | €1,976,235 |
| **Prostate cancer** | | | |
| **Mean cost/stay** | €3,611 | €3,363 | €3,584 |
| **Total cost** | €1,278,397 | €147,959 | €1,426,357 |

**6554 General Poster Session (Board #17), Mon, 1:15 PM-5:00 PM**

**Physician communication on cost of cancer care under the Affordable Care Act.** *Presenting Author: Laura LaNiel Tenner, Melvin and Bren Simon Cancer Center, Indianapolis, IN*

**Background:** The steeply rising cost of cancer care in the United States adversely impacts the economy as well as patient emotional well-being and financial stability. The aim of this study was to assess U.S,oncologists' attitudes and perceptions about the cost of cancer care in the wake of ACA implementation. **Methods:** From June through August 2013, a survey instrument was emailed to practicing oncologists in 50 states. Survey items included assessments of self-reported practices concerning communication of cost of therapy as well as influences of the ACA. Other survey items assessed oncologists' perceptions of cost effectiveness data. **Results:** The electronic survey response rate was 16% with respondents from 35 states. Respondents were more likely to strongly or somewhat agree that it was important to discuss out-of-pocket costs [OPC] (89%) and healthcare system costs [HSC] (66%) with patients, $p<0.0001$. 70% reported that OPC of therapy influence their treatment decisions. 60% agreed that OPC and HSC of cancer treatments were likely or extremely likely to have a larger effect on their decisions regarding which cancer treatments to recommend to patients in the future under the ACA. While 4% agreed the government should play a role in determining the value of a cancer therapy, 53% of respondents thought that government price controls for cancer drugs were needed. A large majority agreed that physician education on the use of cost-effectiveness data (91%) and communicating cost of therapies with patients (85%) was needed. **Conclusions:** U.S. oncologists reported that they desire more cost and comparative effectiveness research as well as more education on how to communicate with patients about costs of therapy. Respondents perceived that both OPC and HSC will play a larger role in their cancer treatment decisions over the next five years, and that they will need to increase their communication with patients about both OPC costs as well as HSC. Respondents appeared divided on the topic of government intervention on pharmaceutical price controls and unified in their resolve to maintain control of decisions on the value of therapy.

**6556 General Poster Session (Board #19), Mon, 1:15 PM-5:00 PM**

**A cost-effectiveness analysis evaluating allogeneic hematopoietic cell transplantation (AHCT) versus consolidation chemotherapy for the treatment of acute myeloid leukemia (AML) in first complete remission.** *Presenting Author: Abby Statler, Cleveland Clinic Taussig Cancer Institute, Case Western Reserve University, Shaker Heights, OH*

**Background:** The objective of this study was to determine which treatment strategy for AML in first complete remission (CR) is more cost-effective: consolidation chemo or AHCT. **Methods:** Simple decision analyses were performed for the cost and the effectiveness of each strategy; the cost-effectiveness was subsequently compared using incremental cost-effectiveness analysis. The population modeled included AML pts $<$ 60 years old in first CR. The majority of the outcome data pulled from the literature included pts with unfavorable cytogenetics (poor/intermediate risk AML). The analyses assumed a 5-year time horizon and assessed medical costs and health benefits, which were measured in quality adjusted life years (QALYs). Costs and QALYs were discounted 3% per year. Sensitivity analyses were performed on the probabilities, costs, and utilities. **Results:** Chemo was the more effective (2.67 vs. 1.79 QALYs; 3.04 vs. 2.15 5 year overall survival) and less expensive ($163,391 vs. $182,018) strategy. Chemo was cost-saving compared to AHCT, i.e. it was both more effective and less expensive. The Sensitivity analyses did not change the results. Exploratory sensitivity analyses did however demonstrate if the probability of dying from AHCT was the same as chemo and the probability of relapsing after AHCT was $\leq$ .17, AHCT would dominate the chemo strategy. **Conclusions:** The chemo strategy was more effective because its QALY and OS outcomes were superior to AHCT. The contribution of the Quality-of Life (QoL) outcomes depreciated the effectiveness (i.e. QALYs) of each strategy almost equally (chemo: 0.37 vs. AHCT: 0.36). This finding demonstrates although the overall QALYs were greater in the chemo strategy, the contribution of the QoL outcomes were virtually the same for both strategies. As the clinical effectiveness of AHCT improves over time, the QoL outcomes will become more influential. In the future, if the improvement in AHCT efficacy is coupled with a meaningful increase in the AHCT QoL outcomes, AHCT could become the more cost-effective treatment strategy.

**6557 General Poster Session (Board #20), Mon, 1:15 PM-5:00 PM**

**Developing a predictive model for cancer clinical trial accrual.** *Presenting Author: Wendy R. Tate, The University of Arizona Cancer Center, Tucson, AZ*

**Background:** With increasing cost to conduct clinical trials, it is imperative to select trials rationally for local activation. We sought to create a predictive model with an outcome of anticipated accrual that can be used when considering a prospective clinical trial. **Methods:** This retrospective cohort study used 5.8 years of registry data to predict clinical trial accrual at our center. A negative binomial regression model was employed using variables known pre-study. These were abstracted from the OnCore clinical trial management system (Forte Systems, Madison, WI) and clinicaltrials-.gov. Statistical significance was set a priori to 0.05. Normality and collinearity of independent variables and model fit were assessed. Variables modified an effect if the beta coefficient of the other independent variable changed by $>$10%. Accrual was predicted for the studies used to build the model. **Results:** The model included 207 trials with complete information. Mean accrual was 7.3 per trial ($\pm$18.4) and 55 (26.6%) trials did not succeed in accruing subjects locally. In univariate analysis, use of an investigational drug, local disease management team (DMT), number of national sites, use of local IRB, number of total months open nationally, months of accrual already completed, and overall proposed national enrollment were significantly associated with accrual. In multivariate analysis, DMT, proposed national enrollment, number of sites, use of local IRB, number of total months open, and the number of months already opened were significantly and independently associated with accrual. The full model was statistically significant (P$<$0.001), demonstrating these variables' contribution to protocol accrual. Accrual was predicted at 94% of the actual value and maintained predictive value at multiple cutoff values. **Conclusions:** We identified key factors, both nationally and locally, associated with the accrual of subjects to a therapeutic clinical trial at our site. This model can aid in deciding whether a study is likely to accrue a desirable number of subjects. We plan to prospectively validate the model. If valid, this model would provide a quick and valuable metric in assessing trial success as well as planning resource allocation and estimating costs.

**6558 General Poster Session (Board #21), Mon, 1:15 PM-5:00 PM**

**How much is the pharmaceutical industry's cost of capital for clinical research of novel drugs?** *Presenting Author: Henry Jacob Conter, University of Western Ontario, London, ON, Canada*

**Background:** Attracting private research investment to fund clinical trials in rare tumor types can be difficult. This is compounded by the inability of investors to directly invest in higher-risk trials, lack of interest in by large pharmaceutical companies, and a lack of understanding of what return on investment would be acceptable. **Methods:** A project finance model was created. The owner of the desired compound would license it to a special investment vehicle (SIV). The SIV would purchase the license from the holder by raising cash through a repurchase agreement with a financial institution in exchange for zero-coupon (Z-) bonds issued by the SIV. The financial institution could short sell the bonds to investors. Bond holders could hold the debt or purchase credit default swaps (CDS) to hedge risk. The Merton Model was employed to value the debt and calculate the yield per dollar of future revenue. Published clinical trial phase transition probabilities were used to estimate success. The hazard for failure was calculated from the time from phase I initiation (extracted from clinicaltrials.gov) to FDA approval, assuming an 80% failure rate, for all novel drugs approved since 2000. **Results:** Phase transition probabilities were 76.8%, 59.4%, and 57.1% for phase I-II, phase II-III, and phase III-FDA approval, respectively. After completion of pre-clinical work, the value of the compound would be $0.24. The value of the license could either be $0 or $0.31, $0.31 or $0.49, $0.49 or $0.74 at the end of phase I, II, or III trials, when adjusted for inflation. If the face value of debt was equal to the initial value of the compound, the z-bond would yield 20.7%, 8.2% and 13.6% annually with continuous compounding for phase I, II, and III, trials. A minimum equity of 29.3%, 19.7%, and 37% would need to be raised in addition to the debt financing to purchase the license for phase I, II, and III trials, respectively. For the 28 drugs approved, the mean approval time was 6.5 years (range 3.2-10.9). A perfectly hedged CDS would cost $0.84. **Conclusions:** Project financing techniques allow for a quantitative determination of the cost of capital for different stages of drug development. This financial structure could be employed to finance trials for rare tumors.

**6559 General Poster Session (Board #22), Mon, 1:15 PM-5:00 PM**

**Does cancer treatment-related financial distress worsen over time?** *Presenting Author: Lena Van Nimwegen, Duke University School of Medicine, Durham, NC*

**Background:** Patients with cancer are at risk for experiencing financial distress. Prior studies have indicated that objective financial burden follows trends associated with treatment course. However, little is known about whether patients' subjective financial distress follows similar trends during the course of their treatment. The ability to predict risk of financial distress in relation to time on treatment may facilitate timing of interventions to alleviate financial distress. **Methods:** This was a cross-sectional study of insured adults with solid tumors on anticancer therapy for $\geq$1 month. Consecutive patients were surveyed, in person, at a referral center and 3 rural oncology clinics. Participants were asked about financial distress (via a validated measure) and out-of-pocket costs. Medical records were reviewed for disease and treatment data. We used the Spearman Rank Correlation Coefficient test and multivariable logistic regression to assess the correlation between months on treatment and financial distress. **Results:** 300 participants (86% response rate) had a median age of 60 years (range 27-91). 79% had incurable cancer. 56% had private insurance. Median income was $60,000/yr. Median OOP costs were $592/mo. The median FD score (7.4 out of 10, SD 2.5) corresponded to moderate FD with 16% reporting high/overwhelming FD. The median time on treatment was 4.6 months (range 1-156 months). Treatment duration was not correlated with financial distress (p=0.89). In adjusted analyses, having curable disease (p=0.02) was associated with higher odds of experiencing high/overwhelming financial distress. **Conclusions:** Severity of cancer treatment-related financial distress did not correlate with time on treatment. However, patient and disease characteristics may predict risk of financial distress. Consistent with prior studies, patients receiving curative treatment might be at higher risk of experiencing financial distress possibly due to higher costs incurred in the initial period following diagnosis. Sociodemographic characteristics might be useful for targeting early interventions in patients who are at risk for treatment-related financial distress.

**6560 General Poster Session (Board #23), Mon, 1:15 PM-5:00 PM**

**Estimation of drug cost avoidance (DCA) and pathology cost avoidance (PCA) through participation in NCIC clinical trials group (NCIC-CTG) phase III clinical trials in Canada.** *Presenting Author: Patricia A. Tang, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

**Background:** Cost avoidance (CA) occurs when, due to the provision of a drug therapy (DCA) or a pathology test (PCA) via trial participation, payment for standard treatment or testing is not required. The aim of this study was to estimate the total DCA and PCA for Canadian patients (pts) enrolled in NCIC-CTG conducted phase 3 trials. **Methods:** Phase 3 trials that had completed accrual and resulted in DCA or PCA were identified. PCA was calculated based on the number of pts screened and test cost. DCA was estimated based on pts randomized, protocol dosing regimen, drug cost, median dose intensity and median duration of therapy. If this information was incomplete, assumptions were made based on published literature. Costs for Canadian pts accrued are presented in Canadian dollars. No adjustment was made for inflation. **Results:** From 1999-2011, 4 trials resulted in PCA (1,479 pts) and 17 trials resulted in DCA (3195 pts). Total PCA was estimated at $4,194,849, which included testing for KRAS ($141,058), microsatellite instability ($18,600), and 21-gene recurrence score ($4,035,191). Total DCA was estimated at $27,935,957, of which targeted therapy comprised 42.6% of DCA (5 trials). The combined PCA and DCA was $32,130,806. **Conclusions:** Over the time period studied, these NCIC-CTG trials resulted in total CA (PCA and DCA) of approximately $7514/pt. Although not all trials lead to CA, these savings should be taken account when considering the financial impact of conducting clinical research.

| Trial (drug with CA) | Mean DCA per pt ($) | Total DCA for trial ($) |

**6561 General Poster Session (Board #24), Mon, 1:15 PM-5:00 PM**

**Physician experience and attitudes toward addressing the cost of cancer care.** *Presenting Author: Ivy Altomare, Duke University Medical Center, Durham, NC*

**Background:** ASCO recommends that patient-physician treatment discussions include addressing costs of cancer care; when and how these conversations should optimally take place is unclear. We sought to determine contemporary attitudes of US cancer physicians toward discussing treatment costs as a part of medical decision-making. **Methods:** A 15-question, self-administered, anonymous, electronic survey was distributed to US ASCO physician members after conducting 10 pilot interviews to improve usability and face validity. Differences in answers among groups were compared using simple logistic regression with 2-sided p-values. **Results:** 333 of 2290 physicians responded (RR=15%; 35% medical oncologists, 35% radiation oncologists, and 31% surgeons; 45% academic, 55% community practice). Overall, 67% agreed that doctors should discuss costs of care with patients; 33% disagreed. 60% reported addressing costs frequently/always and 40% rarely/never in their own practice. Medical oncologists were more likely than radiation or surgical oncologists to discuss costs with patients (OR 3.14 and 3.75, p$\leq$.00001). Compared to community physicians, academic physicians were less likely to discuss costs (OR 0.41, p=.00012), and felt less prepared for such discussions (OR 0.492, p=.005), but were more likely to consider costs to the patient (OR 2.68, p=.02) and to society (OR 1.822, p=.02) when planning treatment. Physicians who reported frequent discussions were significantly more likely to prioritize treatments in terms of cost, have a sense of their patients' financial well-being, feel their patients were well-informed about costs and believe doctors should explain both out of pocket and societal costs of care to their patients. Surgeons were most likely to refer patients to financial counselors (p=.01). The most common reported barriers were lack of resources to guide cost discussions (58%) and lack of time (44%). **Conclusions:** Though a majority of oncology physicians believe it is important to discuss costs of care, practice is inconsistent and there is no consensus on when and how to discuss costs. There is a need to define the goals and content of cost discussions and to address perceived barriers that limit this aspect of quality cancer care.

**6562 General Poster Session (Board #25), Mon, 1:15 PM-5:00 PM**

**Cancer cost evaluation in chemotherapy (chemo)-naive patients (pts) treated under a payer-sponsored pathway program.** *Presenting Author: Bruce A. Feinberg, Cardinal Health Specialty Solutions, Dublin, OH*

**Background:** US cancer costs are projected to increase to over $173 billion in 2020. Clinical pathways can help curb rising costs by reducing unnecessary and costly treatment variation while improving pt outcomes. Initial treatment may have the greatest pathway impact as it influences pt outcomes and subsequent care. We evaluated cost savings of a payer-sponsored pathway program for pts with cancer receiving first chemo intervention. **Methods:** A large payer for the Mid-Atlantic region of the US collaborated with its community oncology provider network to create a 3-year pathway program, managed by Cardinal Health, for chemo-naïve pts. Using claims data, 3 years of chemo and supportive care drug use were evaluated to establish a baseline cost trend for pts with breast cancer (BC), colorectal cancer (CRC), and lung cancer. Using this baseline as historical control, pts who started first-line treatment in pathway year 1 were included in the analysis. All drug costs were standardized to average sales price effective in the last quarter of the program year. Although voluntary, participating physicians received financial incentives for additional work required to manage the program. **Results:** The pathway cohort consisted of 453 pts; historic control cohorts for years 1-3 consisted of 362, 325, and 387 pts, respectively. Arms were well balanced; 24% were diagnosed with CRC in the study arm vs 26% in the control arm; 45% vs 44% for BC, and 31% vs 30% for lung cancer, respectively. Savings relative to projected cost/pt/year for pathway cohorts were $21,106 for CRC and $2,964 for lung cancer. For BC, cost increased $9,271. Overall mean cost/pt, adjusted for trastuzumab use (29% study vs 21% control), decreased 5% ($1,698 pt/yr) for an aggregate savings of $750,436. **Conclusions:** Voluntary pathway participation can lower drug cost of common malignancies even in first-line treatment. The approach of limiting pathway inclusion to chemo-naive pts will provide the greatest clarity of pathway impact throughout the duration of illness. This is our third report of reduced cancer care cost despite enhanced physician reimbursement. We believe the body of evidence dispels concerns about reproducibility of pathways benefits.

**6563 General Poster Session (Board #26), Mon, 1:15 PM-5:00 PM**

**Patients and physicians can discuss the actual costs of cancer treatment with high interest and little conflict.** *Presenting Author: Ronan Joseph Kelly, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** As one solution to reducing costs and medical bankruptcies, experts such as the Institute of Medicine and ASCO have suggested patients and physicians should discuss the cost of care before doing the treatment. Whether these discussions are possible in an oncology setting, and their effects on the doctor-patient relationship are not known. We could find no published study of actual patients reviewing their costs in real time with their oncologist. **Methods:** We used the National Comprehensive Cancer Network (NCCN) Guidelines and the eviti Advisor platform to show patients with metastatic breast, lung, or colorectal cancer the costs associated with their treatment options during an oncology consultation. We measured provider attitudes and assessed patient satisfaction when the consultations included the costs of expected care. **Results:** We approached 107 patients: 96 (90%) enrolled in the study, 3 (3%) asked if they could be interviewed at a later date, and only 8 (7%) did not want to participate. Only 5/18 oncologists (28%) felt comfortable discussing costs, and only 1/18 (6%) regularly asked patients about financial difficulties. The majority of patients (80%) wanted cost information, and 84% reported that these conversations would be even more important if their co-pays were to increase. In total, 72% of patients responded that no health care professional has ever discussed costs with them. The majority of patients (80%) had no negative feelings to hearing cost information, and did not think it added conflict to the patient-physician relationship. **Conclusions:** In an era of rising co-pays, the great majority of cancer patients want cost of treatment discussions, especially if they have increased personal financial responsibility. These conversations do not lead to negative feelings in the great majority of patients. Additional training to prepare clinicians for how to discuss costs with their patients is needed.

**6564 General Poster Session (Board #27), Mon, 1:15 PM-5:00 PM**

**Staging in early breast cancer: Help or hindrance?** *Presenting Author: Naera Waters, Medical Oncology Department, Auckland City Hospital, Auckland, New Zealand*

**Background:** In 2012, ASCO identified staging CT, radionuclide or PET scans for asymptomatic, low risk breast cancer pts as one of the 5 big money wasters in oncology, due to a lack of demonstrated benefit and the potential harm of a false positive diagnosis. We assessed the frequency of staging CT and bone scans in asymptomatic pts with early breast cancer, whether metastases were conclusively detected, and the impact of inconclusive results. **Methods:** 664 consecutive pts with breast cancer referred to the Auckland Regional Cancer and Blood Service between 1 Nov 2010 and 25 Oct 2013 were identified from a prospectively collated referral database. 273 pts were excluded for locally recurrent or metastatic disease, symptoms requiring investigation, or neoadjuvant therapy. Age, LN status, tumour type and grade, receptor and HER2 status and results of staging and follow up scans were recorded in 391 women. **Results:** 81/330 (25%) pts with <4 nodes involved (N0/1) had staging CT, bone scan or both. Metastatic breast cancer (MBC) was found in 2/81(2%) and staging was negative in 51%. 38(47%) pts had radiological abnormalities of uncertain importance. Follow up scans showed 2/38 of these abnormalities were MBC, and 2 lung cancer (1 early stage, 1 metastatic), (total metastatic 3/38=8%). 59/61(97%) pts with >4 nodes (N2+) had staging. MBC was identified in 2 pts (3%), 1 of whom also had early stage lung cancer. 33 (56%) pts had indeterminate radiological findings, of which 5 (15%) were later confirmed to be MBC. Staging was negative in 41%. Up to 5 follow up scans per pt and 1-24 mo were required to clarify indeterminate findings **Conclusions:** Staging investigations modified adjuvant treatment plans in only 4/140 (3%) pts who were found to have MBC. 11% of women with indeterminate lesions on staging were later shown to have either metastatic breast (n=7) or metastatic lung cancer (n=1) underscoring the importance of continuing adjuvant therapy where uncertainty exists. Indeterminate results were frequent, imply the possibility of incurable cancer, and required up to 24 mo and 5 extra scans before pts could be reassured. This causes great uncertainty and distress for pts and consumes limited healthcare resources. The harms and benefits of staging in early breast cancer should be carefully weighed.

**6565 General Poster Session (Board #28), Mon, 1:15 PM-5:00 PM**

**Cost-effectiveness of alternative adjuvant bisphosphonate regimens in postmenopausal women with early breast cancer.** *Presenting Author: Katherine Elizabeth Reeder-Hayes, Lineberger Comprehensive Cancer Center, Chapel Hill, NC*

**Background:** The benefit of bisphosphonate drugs in adjuvant breast cancer care has been a topic of clinical debate. A recently presented meta-analysis of clinical trials by Coleman et al (2013) suggested recurrence and survival gains from adding bisphosphonates to the adjuvant treatment of post-menopausal women, but the most efficacious bisphosphonate dose and schedule has not been defined. Our study assessed the cost-effectiveness of bisphosphonate regimens available in the United States based on available clinical trials and meta-analysis data. **Methods:** We used a decision tree model to assess costs and benefits of the following regimens: no treatment, alendronate (A) 70 mg/week, low dose ibandronate (I) 150 mg/month, high dose I 50 mg/day, low dose zoledronic acid (Z) 4 mg/6 months, or high dose Z (six doses in the first 6 months, eight doses in the next 24 months and five doses in the final 30 months). All regimens except high dose Z were continued for three years. The model followed a simulated cohort of 100,000 post-menopausal women with non-metastatic breast cancer over ten years. Using a payer perspective, we considered direct medical costs and quality of life effects of initial treatment, distant recurrence, and complications of bisphosphonate therapy. The primary outcome was cost per quality-adjusted life year (QALY). We performed one-way and probabilistic sensitivity analyses to assess the robustness of results to variations in parameter estimates. **Results:** In the base-case model, A and low dose I were cost-saving compared to no therapy, while low dose Z was cost-effective with an incremental cost-effectiveness ratio (ICER) of $10,317/QALY gained. More intensive regimens including high dose I and high dose Z were not cost-effective at a willingness-to-pay threshold of $50,000/QALY gained. **Conclusions:** The cost-effectiveness of adjuvant bisphosphonate therapy in this patient population varies considerably depending on the choice of regimen. Until further evidence is available regarding the comparative benefit of differing regimens used in clinical trials, clinicians seeking to integrate bisphosphonates into adjuvant breast cancer care should consider lower dose regimens.

**6566 General Poster Session (Board #29), Mon, 1:15 PM-5:00 PM**

**Impact of prior cancer on eligibility for lung cancer clinical trials.** *Presenting Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Fewer than 3% of adult oncology patients in the U.S. enroll onto clinical studies. Stringent eligibility criteria are a key factor limiting accrual. Among these, the assumption that a prior cancer diagnosis could interfere with study conduct or outcomes results in frequent exclusion of subjects with a prior cancer. We determined the prevalence and characteristics of prior cancer-related exclusion criteria in lung cancer clinical trials, and estimated their impact on study accrual. **Methods:** We reviewed lung cancer clinical trials sponsored or endorsed by the Eastern Oncology Cooperative Group, 1986-2013, for exclusion criteria related to a prior cancer diagnosis. We assessed the association between trial characteristics and prior cancer exclusion using chi-square analysis. We estimated prevalence of prior primary cancer diagnoses among lung cancer patients using Surveillance Epidemiology and End Results (SEER)-Medicare linked data. We applied these figures to trial accrual goals to estimate the percent and absolute number of patients excluded. **Results:** Fifty-one clinical trials were included. Trial accrual ranged 10-1500 patients (mean 290; total 14,785). Forty trials (78%) excluded patients with a prior cancer diagnosis as follows: any prior (16%), diagnosed within 5 years (39%), diagnosed within 2 or 3 years (7%), or active cancer (16%). Eighty-nine percent of trials with survival as a primary endpoint and 70% of trials with non-survival primary endpoints excluded patients with prior cancer ($P$=0.12). In SEER-Medicare data (N=210,509), rate of prior cancer diagnosis ranged 14-24% according to lung cancer stage and histology; 56% of prior cancers were diagnosed ≤5 years before the lung cancer diagnosis. Across trials, the estimated number and proportion of patients excluded due to prior cancer ranged from 0 to 207 (0-18%). **Conclusions:** A substantial proportion of patients are reflexively excluded from lung cancer clinical trials due to prior cancer. This inclusion criterion is applied widely across studies, including more than two-thirds of trials with non-survival endpoints. More research is needed to understand the basis and ramifications of this standard exclusion policy.

**6567 General Poster Session (Board #30), Mon, 1:15 PM-5:00 PM**

**Asian and non-Asian disparities in outcomes of head and neck cancer (HNC).** *Presenting Author: Jason D. Kim, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** Racial differences in cancer outcomes are frequently observed for specific tumor types, including nasopharyngeal cancers, but prior research has mainly focused on disparities between Black and White races. Our aim was to evaluate the impact of Asian and non-Asian races on overall survival (OS) in a large population-based cohort of HNC. **Methods:** All patients diagnosed with non-nasopharyngeal HNC from 2001 to 2010 and referred to any 1 of 5 regional comprehensive cancer centers in British Columbia, Canada were reviewed. Using specialized software (Onomap, Inc.) that recognized common and distinctive surnames based on race, patients were classified as Asians vs. non-Asians. Using Kaplan-Meier methods and Cox regression, we examined the relationship between race and OS while controlling for confounders that consisted of additional socio-demographics and other tumor and treatment-related characteristics. **Results:** We identified a total of 3,036 patients: median age was 64 years (range 20-100), 74% were men, 32% were ECOG 0/1, and 7% and 93% were Asian and non-Asian, respectively. Comparing baseline characteristics between racial groups, Asians tended to exhibit worse prognostic features in that they had poorer functional status (ECOG 2+, 29% vs. 23%, p=0.07) and were more frequently affected by larger tumors (>4 cm, 33% vs 21%, p=0.02) and by oral cavity cancers (38% vs. 25%, p<0.001) than non-Asians. With respect to treatment, Asians were less likely to receive multimodality therapy than non-Asians (90% vs. 95%, p=0.02). Upon adjusting for prognostic factors, multivariate models showed that non-Asians actually had significantly higher odds of death when compared to Asians (HR 2.46, 95%CI 1.25-4.87, p=0.009). Advanced age, worse ECOG, greater tumor size, and lack of treatment also correlated with inferior OS. **Conclusions:** In addition to the racial differences reported in the literature for nasopharyngeal carcinoma, we observed variations in non-nasopharyngeal HNC outcomes between Asians and non-Asians. Despite worse prognostic features and less treatment, Asians exhibited better survival than non-Asians, suggesting a potential difference in tumor biology, pharmacogenetics, or predisposition to HPV exposure.

**6568 General Poster Session (Board #31), Mon, 1:15 PM-5:00 PM**

**Socioeconomic status and lifestyle behaviors in cancer survivors.** *Presenting Author: Hiten Naik, Ontario Cancer Institute, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Socioeconomic disparities in cancer survival exist even in universal healthcare systems. These disparities may be explained in part by lifestyle behaviors such as smoking and physical activity (PA). We evaluated the associations between socioeconomic variables and changes in smoking and PA after diagnosis in Ontario cancer survivors. **Methods:** 1,252 adult cancer survivors across diverse disease sites were surveyed about their smoking and exercise habits. Using multivariate logistic regression models, we evaluated the association of income, occupation, and education with each behavior, after adjusting for clinicodemographic and pathological covariates. **Results:** Cancer survivors were surveyed at a median of 26 months after diagnosis. 16% had breast cancers, 12% gastrointestinal, 26% gynecological/genitourinary, 14% head and neck, 6% lung and 19% hematologic. 15% reported being smokers at diagnosis; 45% reported being physically inactive; after diagnosis, 56% had quit smoking and 18% increased their PA. Survivors with a lower education level were more likely to be current smokers (p<0.0001) and less likely to quit if they were smoking at diagnosis (p=0.02). Similarly, patients with less education were more likely to be physically inactive currently (p<0.0001), and less likely to improve if they were inactive when they were diagnosed (p=0.004). In contrast, household income and occupation were not associated with current engagement or changes in these behaviours. Population-based marginalization indices confirmed that factors related to education level were significantly associated with smoking cessation (p<0.05). **Conclusions:** Cancer survivors with lower educational levels were more likely to have at baseline, and maintain, after diagnosis, unhealthy lifestyle behaviors. Targeting at-risk survivors by education level should be evaluated as a strategy in cancer survivorship programs.

**6569 General Poster Session (Board #32), Mon, 1:15 PM-5:00 PM**

**Impact of patient navigation on women with cervical abnormalities.** *Presenting Author: Electra D. Paskett, The Ohio State University Comprehensive Cancer Center - Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, Columbus, OH*

**Background:** Almost 40% of women with cervical abnormalities fail to return for timely and proper follow-up care with higher rates among minority/underserved populations. As part of the Patient Navigation Research Program (PNRP), we examined the effect of patient navigation (PN), vs usual care on timely follow-up for women with cervical abnormalities. **Methods:** Cervical patients from 4 PNRP sites were divided into low- and high-risk sets and analyzed separately. Low-risk patients (n=2,088) were those who enrolled with an initial pap finding of ASCUS with a positive high-risk HPV serotype, atypical glandular cells or LGSIL. High-risk patients were those who enrolled with an initial finding of HGSIL (n=229). A dichotomous outcome of resolution within 180 days was used for the low-risk set, and resolution by 60 days for the high-risk, consistent with guidelines. A logistic mixed-effects regression model was used to evaluate the intervention effect using a random effect for arm within institution. A backwards selection process was used for multivariable model building considering the impact of each predictor on the intervention effect. **Results:** The final multivariable model for resolution within 180 days for the low-risk cases included arm, age, race and an interaction between race and arm. Patients aged 30+ years showed an increased odds of resolution as compared to those under 30, regardless of arm (Table). The PN arm showed an improvement in the odds of resolution across all racial groups, but significant positive effects were observed in non-English speaking Hispanics (p=0.0002). **Conclusions:** Patients with low-risk lesions showed a benefit from PN with a significantly increased odds of resolution within 180 days for non-English speaking Hispanics. At-risk populations can particularly benefit from PN programs. Clinical trial information: NCT01569672 NCT00613275.

**Multivariable model estimated ORs (95% CI) for resolved within 180 days for low-risk patients.**

| Predictor | Comparison | OR for resolved within 180 days (95% CI) | p-value |
|---|---|---|---|
| Age | 30-39 vs. <30 | 1.74 ( 1.32, 2.30) | <.0001 |
| | 40+ vs. <30 | 1.65 ( 1.20, 2.25) | 0.002 |
| Race by arm | Black: PN vs. control | 1.41 ( 0.69, 2.88) | NS |
| | White: PN vs. control | 1.58 ( 0.78, 3.17) | NS |
| | Hisp-Eng: PN vs. control | 2.02 ( 0.95, 4.32) | 0.07 |
| | Hisp-NonEng: PN vs. control | 5.88 ( 2.81, 12.29) | 0.0002 |

**6570 General Poster Session (Board #33), Mon, 1:15 PM-5:00 PM**

**Urban and rural differences in outcomes of head and neck cancer (HNC).** *Presenting Author: Tian Yang Darren Liu, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** Management of HNC is becoming more specialized where effective treatments frequently require multidisciplinary and multimodality care. Concerns exist that access to such complex care may be suboptimal for marginalized subsets of the population. Our aim was to examine for potential urban and rural disparities in HNC outcomes within a population-based single payer healthcare system. **Methods:** All patients diagnosed with HNC from 2001 to 2010 and referred to any 1 of 5 regional comprehensive cancer centers in British Columbia, Canada were reviewed. Based on census data, patients were classified into 4 categories: 1) rural 2) small urban 3) moderate urban and 4) large urban areas. Kaplan Meier methods and Cox regression were used to correlate site of residence with overall survival (OS), controlling for prognostic factors that included socio-demographics and other tumor and treatment-related characteristics. **Results:** A total of 3,036 patients were included: median age was 64 years, 74% were men, and 32% were ECOG 0/1. The majority resided in large urban areas (55%) followed by rural (22%), moderate urban (13%), and small urban (10%). There were no clinically significant differences in baseline characteristics across the 4 groups. In multivariate-adjusted models, advanced age >/= 65 years (HR 1.58, 95%CI 1.21-2.06, p<0.001), ECOG 2+ (HR 4.20, 95%CI 2.41-4.93, p<0.001), and lack of multimodality treatment (HR 2.88, 95%CI 1.72-4.81, p<0.001) correlated with inferior OS, but site of residence did not (Table). In subgroup analyses that stratified by type of treatment (radiation, chemotherapy, and/or surgery) and anatomic location of HNC (oral cavity, oropharynx, larynx, hypopharynx, nasopharynx), OS remained similar irrespective of urban or rural residence. **Conclusions:** Urban-rural differences in outcomes were not observed. The centralization of HNC management in this large population-based cohort represents an appropriate model of care for cancers in which multimodality treatments are increasingly complex and where disparities in access may be prevalent.

| Residence | HR for death | 95%CI | P-value |
|---|---|---|---|
| **Rural** | 1.0 | -- | -- |
| **Small urban** | 1.27 | 0.77-2.10 | 0.35 |
| **Moderate urban** | 0.84 | 0.52-1.37 | 0.49 |
| **Large urban** | 1.19 | 0.80-1.56 | 0.51 |

**6571 General Poster Session (Board #34), Mon, 1:15 PM-5:00 PM**

**Bridges to care: Results from a novel cancer outreach initiative.** *Presenting Author: Christopher S. Lathan, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Disparities in incidence and mortality for ethnic minorities have been described for a multitude of cancers, yet few interventions have been established in underserved areas. This study, started in 2012, describes preliminary results from a collaboration between a Federally Qualified Health Center (FQHC), in Roxbury, Massachusetts, and Dana-Farber Cancer Institute. The intervention is based on a co-location model with medical oncologists evaluating patients on site at the FQHC. Services include screening, diagnosis, survivorship, and if needed expedited evaluation and treatment at Dana-Farber. **Methods:** Pre-intervention clinical data on incident cancer cases was collected from the FQHC over a 2 year period and compared to intervention data, which included demographics, total number of patients with a cancer diagnosis, percentage of patients on clinical trial, and our outcome of interest: median time from presentation to resolution.(MTR) Non-parametric analyses of the effect of demographics on the primary outcome was performed. 160 patients were evaluated at the outreach facility over a two year period, with 84 patients having a cancer diagnosis. 94 patients were consented into a prospective research cohort, the basis of this analysis. **Results:** 40 patients with cancer were diagnosed at the FQHC from 2009-2011 before the intervention. The MTR for all cancers was 32.5 days. From 2012-2013, 160 patients were evaluated via the outreach initiative. The majority of the patients were African American (81%), with a median age 55. Of the 94 research cohort patients, 60% were women, 53% had a cancer diagnosis. (N=50), and 50% of the patients on active treatment were on a clinical trial. The MTR for patients seen via the intervention, was 11.5. Race, language, and insurance all had no significant effect on MTR. **Conclusions:** Compared to historical data, preliminary analysis of the clinical outreach initiative showed an increase in cancer diagnoses, favorable reduction in time to resolution, and high clinical trial enrollment. A future prospective case control analysis is planned, but initial observational data is encouraging.

**6572 General Poster Session (Board #35), Mon, 1:15 PM-5:00 PM**

**Patterns of hospice use for metastatic cancer in the American Indian/Alaska Native and non-Hispanic white populations.** *Presenting Author: Stacey Shiovitz, University of Washington, Seattle, WA*

**Background**: Hospice care should be available to all individuals with terminal cancer, regardless of race or ethnicity. Little is known about end-of-life care for American Indian/Alaska Native (AI/AN) persons with cancer. Accordingly, the aim of this study was to compare the use of hospice care between AI/AN individuals with non-Hispanic Whites (NHW) with metastatic cancer. **Methods**: Using the linked Surveillance, Epidemiology and End Results (SEER)-Medicare database, we identified AI/AN and NHW who were diagnosed with distant-stage breast, prostate, lung, colorectal, stomach, or ovarian cancer from 2001 to 2008 and had Medicare claims records through 12/31/09. Among individuals who died during the study period and were enrolled in Medicare until death, we evaluated the proportion with hospice initiation. Among hospice initiators, we also assessed late utilization of hospice, defined as enrollment <7 days prior to death. Logistic regression models were used to compare the AI/AN and NHW patients. **Results**: Compared to NHW (n=70,990), AI/AN (n=370) with metastatic cancer were younger (74.6 v. 76.2 yr, p<0.001), but had similar gender distribution (male: 52 v. 48%, p=0.2) and Klabunde co-morbidity scores at diagnosis (0.37 v. 0.36, p=0.75). Rural residence was similar, but AI/AN had lower reported income (p<0.001) and proportion who were married (p<0.001). Among patients who died, enrollment in hospice was lower for AI/AN (46%) compared to NHW (58%), with AI/AN race associated with a significantly lower odds of hospice enrollment (OR 0.72, 95% CI 0.57-0.91, p=0.01). However, late enrollment on hospice was not significantly different between AI/AN and NHW (28 v. 34%; OR 0.87, 95% CI 0.60-1.26, p=0.45). Male gender, higher Klabunde score, and certain SEER catchment areas were also associated with lower hospice enrollment (all p<0.001). **Conclusions**: AI/AN metastatic cancer patients were less likely than NHW patients to use hospice services. However, the proportion with late utilization of these services was similar. It is unclear if decreased utilization of hospice in AI/AN terminal cancer patients is due to decreased access to hospice or differences in beliefs about end-of-life care.

**6573 General Poster Session (Board #36), Mon, 1:15 PM-5:00 PM**

**The association between American Indian/Alaska Native race and time to treatment initiation for nonmetastatic breast, colorectal, and lung cancer patients in Medicare.** *Presenting Author: Scott V. Adams, Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle, WA*

**Background:** Early initiation of treatment following a cancer diagnosis is associated with better patient outcomes. Therefore, we compared time to treatment initiation in American Indian/Alaska Native (AIAN) vs. non-Hispanic White (NHW) cancer patients, with the goal of identifying a modifiable factor to improve survival among AIAN cancer patients. **Methods:** We used Surveillance, Epidemiology, and End Results (SEER) registry data linked to Medicare claims to identify new cases of colorectal, lung, or female breast cancer who were: 1) diagnosed from 2001-2007 with local or regional stage disease, 2) residing in a SEER catchment area, 3) enrolled in Medicare A and B at diagnosis, 4) ≥65 years old, and 5) AIAN or NHW. Cancer diagnosis date was obtained from SEER; the date of first surgical, chemotherapeutic, or radiation treatment was ascertained from Medicare claims. We used Cox regression models to estimate adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) comparing the rate of treatment initiation during the 6 months following diagnosis between AIAN and NHW patients, stratified by cancer site and stage. Model covariates were age, sex, diagnosis year, marital status, rural residence, and pre-diagnosis Klabunde comorbidity score. **Results:** 146,877 NHW and 522 AIAN patients were diagnosed with local or regional breast, colorectal, or lung cancer over the study period. Compared to NHWs, AIANs were younger (mean age 75.0 vs. 76.2y), more likely to live in rural areas (37% vs. 22%), and had higher co-morbidity scores (mean Klabunde 0.43 vs. 0.36). The rate of treatment initiation during the 6 months following diagnosis was lower in AIAN compared to NHW patients diagnosed with breast (HR=0.85, CI: 0.72-0.99), colorectal (HR=0.74, CI: 0.63-0.87), or lung (HR=0.82, CI: 0.67-1.00) cancer. **Conclusions:** Our results suggest that despite equal Medicare insurance coverage, AIANs may experience delays in treatment initiation compared to otherwise similar NHWs. Decreasing the time to treatment initiation may improve survival rates for AIAN cancer patients, who currently have among the lowest five-year survival rates of any racial group.

**6574 General Poster Session (Board #37), Mon, 1:15 PM-5:00 PM**

**Impact of race on outcome of stage II colon cancer subjects not receiving adjuvant therapy.** *Presenting Author: Amy L. Cleveland, University of Arkansas for Medical Sciences, Little Rock, AR*

**Background:** The etiology of racial disparity in colorectal cancer outcome has been controversial. Higher mortality rates (per 100,000/yr.) of 31.4 in African Americans [AA] compared to 21.4 in Caucasians [C] could be due to biology or treatment-related variables. Access to care within the Veterans Affairs [VA] health system is similar for all veterans. The outcome of subjects with stage II colon cancer treated with surgery alone in the VA system was investigated in order to evaluate the possibility of difference in tumor biology rather than patient and treatment related variables. **Methods:** A retrospective study of recurrence and overall survival [OS] comparing AA vs. C was conducted using data from the VA health system's 10-institution database (VISN-16) from 10/1/1996 to 3/31/2010 adjusted for age, gender, T-stage, and number of lymph nodes (LN) resected at the time of surgery. None of the subjects received adjuvant therapy. Patient characteristics were analyzed via chi-square tests. OS was analyzed using Kaplan-Meier methods. **Results:** There were 226 deaths among 513 subjects during 2,645.4 total years of follow-up. Median OS was 9.9 years in AA versus 7.9 years in C (log-rank p=0.22). Age, gender, T stage, and number of lymph nodes were balanced between races (see table). **Conclusions:** There was no difference in OS of AA compared to C with stage II colon cancer subjects treated with surgery alone. The two groups had no statistical difference in stage, median age, gender, lymph node resection or T stage. These results indicate that the difference in the outcome of AA and C with colon cancer may not be due to tumor biology.

| Variable | | African American | Caucasian | p Value |
|---|---|---|---|---|
| N=513 | | 135 (26%) | 378 (74%) | |
| Median age (range) in years | | 71 (40-91) | 71 (44-87) | 0.98 |
| ≥12 lymph nodes excised | | 69 (49%) | 175 (46%) | 0.57 |
| T stage | T1 | 1 (0.7%) | 5 (1.3%) | 0.83 |
| | T2 | 3 (2.2%) | 7 (1.8%) | |
| | T3 | 60 (44%) | 182 (48%) | |
| | T4 | 69 (51%) | 180 (48%) | |
| Gender | | 97.0% male | 97.9% male | 0.82 |
| Recurrence | | 18/120 (15%) | 37/346 (11%) | 0.21 |
| Median overall survival (years) | | 9.94 | 7.91 | 0.22 |

**6575 General Poster Session (Board #38), Mon, 1:15 PM-5:00 PM**

**Low area-level socioeconomic status and breast cancer biologic features in a diverse population-based sample.** *Presenting Author: Jennifer J. Griggs, University of Michigan, Ann Arbor, MI*

**Background:** The purpose of this study was to investigate the association between area-level socioeconomic status (SES) and breast cancer biology controlling for demographic factors and comorbid conditions in a diverse population-based sample. **Methods:** We enrolled women with Stages I – III breast cancer reported to the Los Angeles County and Detroit Tri-County Surveillance, Epidemiology and End Results (SEER) registries between 1998 and 2004. Black women and Latinas were over-sampled. Census block-level SES was assigned using a validated composite of six variables from the 2000 Census and then divided into quartiles. Clinical and pathology data from medical records supplemented SEER registry data. Bivariate and multivariate analyses investigated relationships between SES and tumor grade, hormone receptor status, triple-negative status, and lymphovascular invasion (LVI) controlling for race/ethnicity, obesity status, diabetes, hypertension, and menopausal status. **Results:** The sample included 1,931 women (988 non-Hispanic whites, 611 blacks, and 332 Hispanics). In bivariate analyses, lower SES was associated with higher grade ($p < 0.001$), higher rates of LVI ($p = 0.007$), and hormone receptor-negative disease ($p < 0.001$). In multivariate analyses, area-level SES was significantly associated with Grade 3 disease (OR 1.86, 95% CI 1.11 – 3.09 for the lowest SES quartile), hormone receptor-negative disease (OR 1.96, 95% CI 1.11 – 3.46 for the lowest quartile, p value for trend 0.02). SES was also significantly associated with triple-negative disease (OR 4.93, 95% CI 1.37 – 17.82 for the lowest quartile, p value for trend 0.01). Black race was not associated with tumor biologic features with the exception of hormone receptor -negative disease (OR 2.11, 95% CI 1.41 – 3.18). **Conclusions:** In this population-based study, low area-level SES was independently associated with unfavorable tumor biology. Environmental factors, the allostatic load caused by chronic stress, and lifestyle behaviors may contribute to the poorer breast cancer-specific outcomes associated with lower SES.

**6576 General Poster Session (Board #39), Mon, 1:15 PM-5:00 PM**

**Disparities in breast cancer surgery: The lingering effect of race.** *Presenting Author: Vanessa Sheppard, Georgetown University, Washington, DC*

**Background:** Stage migration may be associated with delays in surgical breast cancer treatment >90 days. Although it is not recommended to have a 3-month span from diagnosis to definitive surgical management, there are no precise guidelines that establish a model time interval. This study investigates racial disparities in time to receiving first surgical treatment (i.e. surgical delay) in breast cancer patients. **Methods:** A cohort study of 290 insured Black (56%) and White (44%) women with primary breast cancer participated in telephone interviews that gathered data on psychosocial (e.g., self-efficacy) and healthcare factors (e.g., communication, barriers). Clinical data were abstracted from medical records. Time to surgical delay was defined as the time in days between diagnosis and definitive surgical treatment. We also considered 60-day and delay outcomes. We used unadjusted hazard ratios to examine univariate relationships between delay outcomes and covariates. Cox proportional hazard models were used for multivariate analyses. **Results:** Median time to surgery was 41 days and was higher in Blacks (m=47 days) compared to Whites (m=33 days) (p= .001). Considering the 90-day outcome, Black women had greater delay to surgery than White women after covariates adjustment (HR= 1.7; 95% CI: 1.2 to 2.3). Women reporting internet use (vs. not) and those with breast conserving surgery (vs. mastectomy) had greater delay to surgery (p<. 01) after adjustment. **Conclusions:** Prolonged delays to definitive breast cancer surgery persist among Black women. Most notably, racial differences persisted for the 90-day interval that has been associated with poorer outcomes. Interventions to address delay in Black patients are needed.

**6577 General Poster Session (Board #40), Mon, 1:15 PM-5:00 PM**

**Impact of location to repeat mobile mammography utilization trends: 10-year analysis of a comprehensive urban cancer center.** *Presenting Author: Elizabeth Carloss Riley, University of Louisville, School of Medicine, Louisville, KY*

**Background:** Mobile Mammography Units (MMU) are a model of community outreach through targeted locations. The purpose of this study was to analyze the association between MMU utilization and screening location in the largest county in Kentucky. **Methods:** From January 2001- December 2010, 48,324 screening mammograms were performed with 21,587 unique subjects. Locations were divided into three categories: Corporate, Partnership Clinics (public health clinics) and Partnership Community (local events.) Utilization was defined as once, twice or more than 3 times in a 10 year period. The *p*-values were computed using the Pearson Chi-square test. The comparison with a *p*-value $< 0.05$ was considered statistically significant. **Results:** Partnership Clinic accounted for the majority of encounters (40.6%) and was most likely to repeat twice (19.1%) or 3 or more times (30.2%) in a 10 year period. Partnership Community accounted for the least at 24% and was least likely to utilize the van repeatedly (p=<.001.) The majority of screens occurred only once in a 10 year period regardless of location. **Conclusions:** To our knowledge this is the largest database of MMU reported in the literature. We previously reported on race and insurance status as predictors of repeat utilization. The current dataset suggests women referred from the Partnership Clinic (Public Health Clinics) are most likely to repeat utilize the van which would be consistent with the intended purpose of the MMU as these patients are most likely to be uninsured or underinsured. Partnership Community are the least likely to repeat utilize however further analysis is needed to determine whether consistency of offered location from year to year could impact these trends as the Community group locations may be less consistent annually. Analysis of the trends of utilization of MMU based on location has implications for funding and outreach.

| | Total N= 21857 | 1 screen N=11816 | 2 screens N=3983 | >/= 3 screens N=6058 | P value <.001 |
|---|---|---|---|---|---|
| Corporate (%) | 7741 (35.4) | 4223 (54.6) | 1385 (17.9) | 2133 (27.6) | |
| Partnership clinic (%) | 8874 (40.6) | 4499 (50.7) | 1694 (19.1) | 2681 (30.2) | |
| Partnership community (%) | 5242 (24.0) | 3094 (59.0) | 904 (17.2) | 1244 (23.7) | |

**6578 General Poster Session (Board #41), Mon, 1:15 PM-5:00 PM**

**Misconceptions in colorectal cancer among a community-based population and CRC screening adherence.** *Presenting Author: Thomas Guerrero, Internal Medicine Residency Program, Memorial Hospital of RI, W Alpert Medical School, Brown University, Pawtucket, RI*

**Background:** Colorectal cancer (CRC) screening rates among Latinos are lower than those of non-Latinos. Prior research suggests that a higher proportion of Latinos have erroneous understandings of cancer and many have misperceptions about cancer that may negatively impact their preventive behavior. The goal of this study was to estimate the prevalence of previously identified CRC misconceptions among a sample of primary care patients. **Methods:** Cross-sectional survey of primary care primary care patients with an oversampling of Spanish-speaking patients. The survey included items specifically developed to assess participants' knowledge regarding previously identified misconceptions of CRC risk factors: (1) constipation increases risk of developing CRC, (2) constipation increases the risk of developing polyps, (3) polyps consist of excess cholesterol, and (4) rectal sex increases the risk of developing CRC. Individual misconceptions and a composite misconception score were calculated based on these items and compared across race, ethnicity, and language of survey respondent (English vs. Spanish). **Results:** Of 1,600 surveys mailed, the response rate was 41.1% with 346 responding in English and 311 responding in Spanish. Mean age for the sample was 59 years, 60% of respondents were female, and 40% had less than high school education. For each individual misconception item, Spanish-speaking Latinos had rates of endorsing the misconception that were nearly twice those of non-Latinos: 76% vs. 38% for constipation increases risk of developing CRC; 63% vs. 32% for constipation increases the risk of developing polyps: 20% vs. 9% for polyps consist of excess cholesterol; and 38% vs. 21% for rectal sex increases the risk of developing CRC ($p<0.001$ for all comparisons). Ninety percent of Latino respondents vs. 64% of non-Latino respondents endorsed 2 or more misconceptions. **Conclusions:** In this sample of primary care patients, Latinos are more likely to hold misconceptions about CRC risk. While it is uncertain whether these beliefs negatively impact actual screening rates, it provides an opportunity for education.

**6579 General Poster Session (Board #42), Mon, 1:15 PM-5:00 PM**

**Disparities in age-related incidence of colon and rectal cancer in the United States, 1975-2010.** *Presenting Author: Christina Edwards Bailey, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The overall incidence of colorectal cancer (CRC) has been decreasing since 1998, but there has been an apparent rise in the incidence of CRC in young adults. The primary aim of this study was to evaluate age-related disparities in secular trends in CRC incidence in the United States. **Methods:** A retrospective cohort study was performed using the Surveillance, Epidemiology, and End Results (SEER) registry. All patients diagnosed with colon or rectal cancer from 1975 to 2010 was queried. SEER*Stat (version 8.04, National Cancer Institute) was used to obtain the annual cancer incidence rates, annual percent change (APC), and corresponding p-values for the secular trends. **Results:** Overall age-adjusted CRC incidence decreased by 0.92% between 1975 and 2010. There has been a steady decline in the incidence of CRC in patients age 50 years or older, but the opposite trend has been observed in patients 20 to 34 years of age. The APC for patients with localized, regional, and distant colon cancer at diagnosis in the 20 to 34 year age group was 1.10 (95% CI 0.28 to 1.93; P=0.01), 0.91 (95% CI 0.23 to 1.61; P=0.01) and 1.81 (95% CI 0.88 to 2.75; P<0.001). The APC for patients with localized, regional and distant rectal cancer in the 20 to 34 year age group was 4.03 (95% CI 3.02 to 5.05; P<0.001), 3.05 (95% CI 1.95 to 4.17; P<0.001) and 2.66 (95% CI 1.33 to 3.99; P<0.001). Based on current trends, in 2030 the incidence rate for colon and rectal cancer will increase by 90% and 124.2% respectively for patients 20 to 34 years of age while decreasing by 37.8% and 34.3% for patients 50 to 75 years of age. **Conclusions:** There has been a significant increase in the incidence of CRC diagnosed in patients aged 20 to 34, with a decline in older patients. Further studies are needed to determine the cause for these trends and identify potential preventive and early detection strategies.

**Percent change of APC-based predicted incidence rate of colon and rectal cancer by age compared to incidence rate in 2010.**

| | Colon | | Rectal | |
|---|---|---|---|---|
| **Age group** | **2020** | **2030** | **2020** | **2030** |
| **20-34** | 37.8% | 90.0% | 49.7% | 124.2% |
| **35-49** | 13.0% | 27.7% | 20.8% | 46.0% |
| **50-75** | -21.2% | -37.8% | -19.0% | -34.3% |
| **>75** | -25.5% | -44.5% | -30.3% | -51.5% |

**6580 General Poster Session (Board #43), Mon, 1:15 PM-5:00 PM**

**Use of the 21-gene recurrence score assay (RS) and chemotherapy (CT) across health care (HC) systems.** *Presenting Author: Anosheh Afghahi, Stanford University School of Medicine, Stanford, CA*

**Background:** The Onco*type* DX (Genomic Health, Redwood City, CA; GHI) RS estimates 10-yr risk of distant recurrence and CT benefit in patients (pts) with ER+, early-stage breast cancer (EBC). After 10 yrs of RS use, variability across HC settings is poorly understood. **Methods:** Patient-level clinical data from electronic medical records (EMR) of Stanford University (HC-U) and Palo Alto Medical Foundation, a community practice (HC-C) in the same catchment area, were linked with demographic data from the California Cancer Registry. RS results were obtained from GHI. Multivariable analysis, adjusted for patient age, year of diagnosis, race/ethnicity, institution, stage, nodal status, grade and histology, was used to identify factors associated with use of RS and CT. **Results:** 3,584 EBC pts met RS indications (Stage I-II, ER+, HER2-negative). RS use was only 10.4% (373 pts, 95% confidence interval [CI] 9.5-11.5%), increasing over time (2010-2011 vs. 2005-2007: odds ratio [OR] 3.03, CI 2.23-4.10). On multivariable analysis, based on subjects with complete data, factors inversely associated with RS use were high grade (vs. low: OR 0.66, CI 0.44-0.99), involved nodes (vs. none: 0.17, 0.11-0.27) and age <40 (vs. 50-64: 0.37, 0.20-0.70) or ≥65 (0.24, 0.18-0.34). Low RS results were usually associated with less (vs. no RS: 0.39, 0.25-0.59), and high results with more (7.96, 2.49-25.5) CT use. However, the 638 (17.8%) pts seen in both HC systems more often had RS (vs. HC-U only: 3.72, 2.77-5.01), and received more CT (1.51, 1.17-1.95). **Conclusions:** In 2 HC systems, CT use usually followed RS guidance. Although lower than expected, RS use rose over time, perhaps a sign of clinicians' growing familiarity with RS. By contrast, the 17.8% of pts treated in both HC systems used more CT across all RS risk groups, suggesting less guidance by RS and over-utilization of care. These results may inform efforts to reduce unwarranted variability and optimize value.

**6581 General Poster Session (Board #44), Mon, 1:15 PM-5:00 PM**

**Current quality gaps in rectal cancer pathology reports.** *Presenting Author: Zaid M. Abdelsattar, University of Michigan, Ann Arbor, MI*

**Background:** High-quality pathology reporting is important for optimal management of rectal cancer (RC). To this end, several quality measures have been clinically validated or endorsed by the National Quality Forum (NQF). In this multi-institutional study, we assess the adherence to these measures and explore pathologists' perspectives. **Methods:** Seven quality measures (4 NQF endorsed) were assessed for adherence at 10 community and academic hospitals from 2007 to 2012 via trained data abstractor chart review. Measures included documentation of T stage, N stage and histologic grade; ≥12 lymph nodes; measurement of distal and radial margin; and grading of total mesorectal excision (TME) quality. Open-ended phone surveys were conducted with pathologists from six hospitals to identify differences in practice and barriers to improved practice. **Results:** A total of 333 patients underwent radical RC surgery. Adherence to all measures varied by hospital (Table). For example, only 75% of cases (range by hospital 64-100%) had ≥12 lymph nodes examined and the median number was 15 (range by hospital 13-34). Surveys revealed that pathologists would not find it burdensome to increase requirements for nodes or margin measurements; however, there were greater barriers to TME grading. Although all pathologists aim to retrieve ≥12 nodes, their methods vary and 33% routinely use defatting solutions. TME quality reporting is uncommon. 83% of pathologists were familiar with this measure; however, half of those were not comfortable reporting it to the surgeon. When asked about facilitators of best practices, pathologists emphasized: 1) comprehensive checklists, 2) pathology assistants, and 3) better communication with surgeons. **Conclusions:** Hospitals vary on the quality of RC pathology reporting, indicating significant room for improvement. Based on pathologist surveys, quality improvement interventions might include peer mentoring of node retrieval methods and strategies for better communication with cancer surgeons.

**Adherence to pathology quality measures.**

| Quality measure | Overall adherence, % | Range by hospital, % |
|---|---|---|
| **T stage** | 94 | 74 – 100 |
| **N stage** | 93 | 74 – 100 |
| **Grade** | 78 | 29 – 100 |
| **≥12 nodes** | 75 | 64 – 100 |
| **Radial margin** | 57 | 11 – 95 |
| **Distal margin** | 89 | 62 – 100 |
| **TME quality** | 12 | 0 – 69 |

**6582 General Poster Session (Board #45), Mon, 1:15 PM-5:00 PM**

**Survival of U.S. Medicare patients with advanced non-small cell lung cancer by line of therapy.** *Presenting Author: John R. Penrod, Bristol-Myers Squibb, Princeton, NJ*

**Background:** Prior real-world (RW) studies of advanced non-small cell lung cancer (adv NSCLC) have described overall survival (OS) from diagnosis (Dx) for all patients (pts) as well as separately by whether chemotherapy was received. More recently, innovations in systemic anti-cancer treatment (SATx) have expanded to include oral targeted agents. Current RW data on OS of advanced pts in the US are limited, particularly by line of therapy (LOT). In this study, we use data from a recent cohort of SEER-Medicare pts to examine OS from adv NSCLC Dx for all pts and separately by SATx status. For treated pts, we also describe OS from initiation of each LOT. **Methods:** Fee-for-service pts aged ≥66 enrolled in Medicare Parts A/B/D with an incident Dx of adv NSCLC (Stage IIIB/IV) during 2007–9 were identified in the SEER-Medicare linked database. OS follow-up was available through 12/31/2011. We examined demographic and clinical characteristics, including histology, and the receipt of SATx (chemotherapy, tyrosine kinase inhibitors, or monoclonal antibodies). We performed descriptive and Kaplan Meier (KM) analysis of OS from adv NSCLC Dx for all pts and separately by receipt of SATx. KM OS analysis by LOT was performed from date of treatment initiation. **Results:** Of 7,080 eligible pts, 26% had squamous, 51% had nonsquamous, and 24% had not otherwise specified histology; 28% of pts were Stage IIIB and 72% were Stage IV. Overall, 44% of pts received SATx. For all pts, median OS from Dx was 4.9 months, and 1- and 2-year OS rates were 23% and 7%, respectively (Table). Median OS from adv NSCLC Dx was 2.8 months for pts not receiving SATx and 9 months for pts receiving SATx ($P<.0001$). From initiation of each LOT, OS declined with each successive line, with median OS of 6.6, 5.9, and 5.3 months for 1L, 2L, and 3L, respectively. **Conclusions:** Despite advances in SATx for adv NSCLC, more than half of RW pts do not receive such treatment and outcomes for both treated and untreated pts remain poor, with fewer than 10% of pts alive at 2 years following Dx or initiation of SATx.

**OS of adv NSCLC pts.**

| | N (%) | Median OS (months) | 1-yr OS, % | 2-yr OS, % |
|---|---|---|---|---|
| **All pts** | 7,080 (100) | 4.9 | 23 | 7 |
| **SATx (from adv Dx)** | | | | |
| **Yes** | 3,131 (44) | 9.0 | 37 | 11 |
| **No** | 3,949 (56) | 2.8 | 11 | 3 |
| **LOT** | | | | |
| **1L** | 3,113 (44) | 6.6 | 28 | 8 |
| **2L** | 1,320 (19) | 5.9 | 25 | 7 |
| **3L** | 535 (8) | 5.3 | 21 | 5 |

**6583 General Poster Session (Board #46), Mon, 1:15 PM-5:00 PM**

**Influence of age on incident diabetes (DM) and cardiovascular disease (CVD) among prostate cancer survivors receiving androgen deprivation therapy (ADT).** *Presenting Author: Alicia Katherine Morgans, Vanderbilt University Medical Center, Nashville, TN*

**Background:** ADT has been associated with increased risk of developing DM and CVD, though this is controversial, particularly for CVD. We prospectively assessed the relationship between ADT and incident DM and CVD in the Prostate Cancer Outcomes Study (PCOS), a population-based cohort of prostate cancer survivors followed longitudinally for 15 years from diagnosis. **Methods:** We identified men in the PCOS with non-metastatic prostate cancer diagnosed from 1994-1995 and followed through 2009-2010. We used multivariable logistic regression models to compare groups receiving short-term ADT (<2 years), prolonged ADT (≥2 years) and no ADT to assess the relationship between ADT exposure and subsequent diagnoses of DM and CVD (determined by patient report and cause of death data). We evaluated the effects of age at diagnosis, race, stage, and comorbidity on the development of DM and CVD. **Results:** Among 3,526 men with comorbidity and treatment data, 2985 men without baseline DM and 3,112 men without baseline CVD constituted the DM and CVD cohorts, respectively. Regardless of duration of ADT exposure, there was not an increased risk of DM or CVD in men younger than 70 at diagnosis. Compared to no ADT exposure, prolonged ADT was associated with an increased risk of DM and CVD that increased steadily over age 76 at diagnosis for DM (OR 2.11 at age 74, 95% CI 1.02 – 4.36; OR 2.65 at age 80, 95% CI 1.09 – 6.47) and age 74 at diagnosis for CVD (OR 1.89 at age 74, 95% CI 1.02 - 3.49; OR 3.19 at age 80, 95% 1.25 – 8.17). Increasing comorbidity burden modified risk of DM and CVD (for ≥ 3 comorbidities versus no comorbidities; for DM, OR 4.25, 95% CI 2.3 - 7.9; and for CVD, OR 8.1, 95% CI 4.3 -15.5 P<0.001). **Conclusions:** The relationship between ADT and development of CVD and DM may be dependent upon age at diagnosis in addition to length of ADT administration, with longer ADT exposure predominantly increasing risk among older men only. Men with greater comorbid burden had increased risk of developing DM and CVD. Younger men with few comorbidities may not have an increased risk of developing DM or CVD despite treatment with ADT.

**6584 General Poster Session (Board #47), Mon, 1:15 PM-5:00 PM**

**Reporting quality of abstracts in cancer clinical trials.** *Presenting Author: Shanthi Sivendran, Hematology/Oncology Medical Specialists, Lancaster General Health, Lancaster, PA*

**Background:** Detailed and transparent abstracts are critical for assessing clinical trials. For some practitioners, access to full text manuscripts may be limited due to financial, language, and information technology considerations. In 2007, the Consolidated Standards of Reporting Trials (CONSORT) group generated an extension statement with recommendations regarding the minimum elements that should be included in an abstract. The degree to which these recommendations are adhered to in oncology publications has not been previously evaluated. **Methods:** A review of citations from PubMed, Medline, and Embase published between Jan 1, 2009 and December 31, 2011, identified randomized, controlled, phase III trials in metastatic solid malignancies. Abstracts were assessed for the 18 elements recommended in the CONSORT extension statement for abstracts; a completeness score (range, 0 to 18) was calculated by adding the number of elements reported. **Results:** 175 eligible publications with data for 96,125 patients were included in this analysis. The median completeness score was nine (range, three to 17). 67% of the abstracts also had a full text available for review through open access. The median completeness score of abstracts with available full text on open access (nine; range, four to 14) was similar to those full texts that were not available (10; range, three to 17). Of the 18 abstract elements, the items that were least frequently reported included - description of the trial design (18%), the method by which participants were allocated to interventions (14%), use of blinding (22%), whether the trial is ongoing (23%), registration and name of trial (25%) and the funding source (19%). Although 46% of publications included the number of participants randomized to each group only 26% of publications included the number of patients analyzed. **Conclusions:** Cancer clinical trial abstracts typically report only half of the reporting elements recommended by the CONSORT group. Further, there is significant heterogeneity in the quality of reporting. Inclusion of the CONSORT elements may allow for better interpretation and application of clinical information.

**6585 General Poster Session (Board #48), Mon, 1:15 PM-5:00 PM**

**Factors associated with loss of employment among metastatic patients.** *Presenting Author: Amye Tevaarwerk, University of Wisconsin Carbone Cancer Center, Madison, WI*

**Background:** Up to a third of those diagnosed with cancer do not return to work. Metastatic patients seem particularly vulnerable, but few data exist. We examined employment outcomes for working age metastatic patients on EZ202 (a symptom-based study conducted through ECOG) to understand metastatic employment patterns, and potentially modifiable factors associated with employment loss. **Methods:** E2Z02 prospectively enrolled cancer patients irrespective of therapy or stage. Employment was assessed by questionnaire: "Has your employment status changed due to illness?" [Answer = Yes/No] and "What is your current employment status?" [Answer = full-time; part-time; not in the workforce]. We excluded patients >65 years and without metastatic cancer. Factors associated with employment group (no longer working vs. stably employed) were evaluated using logistic regression. Variables examined included cancer type (breast, prostate, colon, lung), therapy status (none, hormone, all other treatment), gender, age (≤ 45, >45-55, >55-65), race/ethnicity (non-Hispanic white, all other), metastatic sites (none, bone/soft tissue, visceral, other, >2 sites), ECOG performance status (0-1, 2-4) and symptom interference on the MD Anderson Symptom Inventory (none-mild, moderate-severe). Factors with p-value <0.10 on the univariable analysis were further fitted into the multivariable model. **Results:** 3,106 analyzable patients accrued between 3/06 and 5/08; 668 metastatic patients had employment data. 236 of 668 (35%) worked full or part-time; 154 of 236 (65%) reported working without any change. Among patients no longer working, 302 of 432 (70%) reported change as being due to illness. PS, race/ethnicity, therapy status, and symptom interference were significantly associated with no longer working in multivariable analysis (respectively, p=0.0007, 0.03, 0.03, 0.0008). **Conclusions:** Working age metastatic patients often remain employed. Worse ECOG performance status and higher symptom interference were more likely among patients no longer working while hormone therapy and non-Hispanic white race were more likely among those stably working. These factors should be considered when counseling metastatic patients about continued employment. Clinical trial information: NCT00303914.

**6586 General Poster Session (Board #49), Mon, 1:15 PM-5:00 PM**

**Impact of National Cancer Institute (NCI)-mandated scientific review on protocol development and content.** *Presenting Author: Ning Ning, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** The National Cancer Institute (NCI) requirement that all clinical trials involving cancer patients at NCI-designated cancer centers undergo a scientific review in addition to Institutional Review Board (IRB) review is unique among medical specialties. We evaluated the impact of this process. **Methods:** We collected data on oncology clinical trials undergoing full board review by the UT Southwestern Protocol Review and Monitoring Committee (PRMC) 2009-2013. We analyzed associations between trial characteristics, PRMC decisions, protocol changes requested, and protocol changes implemented using Chi-square testing, Fisher's exact testing, and logistic regression. **Results:** The analysis included 226 trials. Initial PRMC decisions were: approve (40%), approve pending response (52%), defer (7%), and disapprove (1%). Final PRMC decision was approve for 96% of trials. The PRMC requested a total of 270 changes (range 0-17 per protocol). Number of requested changes per protocol was associated with trial type (mean 0.7 for industry-sponsored versus 3.0 for investigator-initiated; $P<0.001$) and study year (mean 0.7 in 2009 versus 2.4 in 2013; $P=0.03$). Requested protocol changes included design (53%), intervention (24%), evidence-background-rationale (14%), and population (11%). Compared to those for industry-sponsored trials, PRMC requested changes for investigator-initiated trials were more likely to be implemented (91% versus 83%; $P=0.08$). A pronounced difference was noted for requested changes related to trial design: among 154 industry-sponsored trials, 28 changes to study design were requested (average 0.2 per trial), of which 29% were implemented; among 52 investigator-initiated trials, 39 changes to study design were requested (average 0.8 per trial), of which 90% were implemented. **Conclusions:** The NCI-mandated scientific review of cancer clinical trials appears to have a substantial impact on investigator-initiated protocols, but the effect on industry-sponsored protocols is less clear. Given heightened interest in the quality and timeliness of oncology clinical trials, further research into this process is warranted.

**6587 General Poster Session (Board #50), Mon, 1:15 PM-5:00 PM**

**Looking beyond the first cycle in phase I cancer clinical trials.** *Presenting Author: Shing Mirn Lee, Columbia University, New York, NY*

**Background:** Phase I cancer trials use toxicity data from the first cycle to define dose limiting toxicity and guide dose escalation. Since doses are assigned only after outcomes for previous patients are observed, a short assessment period allows for more realistic time-frames to complete studies when using conventional methods to determine the maximum tolerated dose. However, in phase II and III clinical trials, toxicities are generally summarized for the entire treatment period into a maximal toxicity grade. **Methods:** Toxicity data from two phase II lung cancer trials conducted by the Southwest Oncology Group were obtained. Toxicities were graded for each cycle of treatment up to six cycles. The percentage and severity of toxicities in cycle 1 are compared to the maximal toxicity across all cycles. Moreover, summarizing toxicities by patient, the percentage of patients with dose limiting toxicities using data cycle 1 versus all cycles are compared. **Results:** For the first study, 779 toxicities were reported for 57 patients and summarized into 610 maximal toxicities. Out of the 610 maximal toxicities, 28% were not reported in cycle 1. Among the 442 maximal toxicities that were present in cycle 1, 9% worsened in a later cycle. Using data from cycle 1 yielded 7 dose limiting toxicities (12%); across all cycles, the dose limiting toxicity rate was 47% (27/57). The second study had a higher number of toxicities and of greater severity. There were 3510 toxicities coming from 115 patients. These yielded 1655 maximal toxicities. 46% were not reported in cycle 1. Among the 901 toxicities that were present in cycle 1, 18% worsened in a later cycle. Using data from cycle 1 yielded 60 dose limiting toxicities (52%); across all cycles, the dose limiting toxicity rate was 90% (103/115). **Conclusions:** Given the substantial amount of under reporting observed, further research is warranted to compare toxicity data from cycle 1 alone versus all cycles in a prospective manner. If discrepancy exists, the time-to-event continual reassessment method, a model-based design for estimating the maximum tolerated dose, can be used since it allows for inclusion of late-onset toxicities during dose escalation and uninterrupted patient recruitment due to toxicity assessment.

**6588 General Poster Session (Board #51), Mon, 1:15 PM-5:00 PM**

**The risks of debilitating falls (DFs) in patients (pts) with cancer: The Manitoba experience.** *Presenting Author: Joel Roger Gingerich, CancerCare Manitoba, Winnipeg, MB, Canada*

**Background:** Falls and fall-related injuries are significant pt safety challenges. We sought to identify if cancer pts were at greater risk of DFs. **Methods:** Using a retrospective population-based study design, we linked the Manitoba Cancer Registry with health care use records from Manitoba, Canada. Our study cohort consists of all adult community-dwelling pts with a first cancer diagnosis between April 1, 2003 and March 31, 2008, matched by age and gender to three cancer-free controls. DFs were defined as falls requiring hospitalization (ICD billing codes) between the time of cancer diagnosis and Dec 31, 2009. Regression models using death as a competing risk were used to compare DFs separately for those <65, 65-79 and 80+. Each model was adjusted for individual year of age, sex, medication use, neighborhood income, previous falls and co-morbidities. Results were expressed using sub-hazard ratios (SHR). **Results:** 27,164 cancer pts were matched to 83,928 controls; 50% of the overall cohort was female, with a median age of 68 years. For each group, the median length of follow-up ranged from 1.6 and 3.7 years and decreased with age. DFs occurred in 866 cancer pts (3.2%) vs. 2883 (3.4%) controls. Without adjustment, short-term (<1 year) DF risk was greater in cancer versus control pts (Table 1). For all pts except those 80+ this increased risk was explained by study covariates. Adjusted long-term (>1 year) DF rates were statistically lower in cancer pts 65+ years old vs. controls. The SHRs for death in cancer pts compared to controls during <1 and >1 years were: <65, 104.4 and 20.6 (p<.001); 65-79, 41.2 and 7.7 (p<.001); 80+, 26.6 and 3.7 (p<.001). **Conclusions:** In this population-based study, cancer pts were at increased risk of DFs compared to matched controls during the 1st year after diagnosis. The risk disappeared after adjusting for confounding factors except in those > 80. After 1 year of follow-up, cancer pts no longer had a higher risk of falls in part due to their higher risk of death.

**6589 General Poster Session (Board #52), Mon, 1:15 PM-5:00 PM**

**Medical oncology patient readmissions: Are they preventable?** *Presenting Author: Andrew S. Epstein, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** As part of the Affordable Care Act, Centers for Medicare and Medicaid Services has initiated programs for certain non-cancer index admissions aimed to improve patient care and reduce costs, via preventing readmissions (defined as an admission within 30 days of a discharge). Readmissions for cancer patients have not been extensively evaluated, and might or might not be reasonably preventable. We therefore examined readmissions of patients on an inpatient service of a comprehensive cancer center. **Methods:** An institutional electronic database was queried to identify patients with a readmission and for demographics and other data related to the readmissions of patients to the Gastrointestinal (GI) Oncology service of Memorial Sloan Kettering Cancer Center (MSKCC). Of these, 50 patients were randomly selected for manual review to assess reasons for index admission and readmission, nature of index admission discharge plan, and whether readmission was preventable (defined pre-study as likely preventable by either prolongation of the index admission or a foreseeable, and accomplishable change in an agreed upon index admission discharge plan). **Results:** Between September 1, 2008 and March 1, 2013, 3,995 patients with GI cancers had an index admission to the MSKCC GI Oncology Service, of whom 876 (22%) had at least one readmission. Index admission discharge plans for these 876 index admissions were as follows: home without supportive services (64%), home with supportive services (32%), rehab facility (2%), home hospice (1%), or long term care facility (1%). From the 50 manually-reviewed cases, the most common diagnosis categories for either index admission or readmission were infection, pain, or GI issues. For each readmission, the diagnosis was different from the index admission diagnosis in 64% of the cases. Disagreement between the care team and patient/family about index admission discharge plan was documented in 10% of cases. One case (2%) was preventable. **Conclusions:** Readmissions in this population are common and reflect high disease burden. Our data suggest that readmissions in the population studied do not overall represent lapses in care or discharge management during the index admission and are not reasonably preventable.

**6590 General Poster Session (Board #53), Mon, 1:15 PM-5:00 PM**

**Evaluating the utility of baseline cardiac function assessment in early-stage breast cancer treatment.** *Presenting Author: Sandy R. Truong, Harvard Medical School, Boston, MA*

**Background:** Cardiotoxicity is a rare complication of anthracycline or trastuzumab-based therapy for patients with early-stage breast cancer. Screening echocardiogram (ECHO) and radionuclide ventriculogram (RVG) are often performed prior to administration of these agents to evaluate cardiac function. Only limited evidence for the clinical utility of these screening tests is available. We sought to determine the role of baseline cardiac imaging in treatment planning in asymptomatic patients without prior cardiac problems. **Methods:** Early-stage breast cancer patients diagnosed from 2006 to 2011 (n=1067) with a baseline ECHO/RVG were identified in a single institution prospective registry. Chart review was performed to obtain pre- and post-ECHO/RVG treatment plans, baseline ECHO/RVG results, and cardiac risk factors. A total of 600 patients had available medical records, as well as no prior chemotherapy, radiation therapy, or cardiac history or complaints. ECHO/RVG abnormalities were defined as ejection fraction (EF) <55%, valvular disease, left ventricular hypertrophy, and diastolic dysfunction. **Results:** Among 600 eligible patients, average age was 48 (range 23-80); 79% of treatment plans included anthracycline, 34% included trastuzumab, 16% both. Abnormal ECHO/RVG results were observed in 13 of the 600 patients (2.2%, 1.2%-3.7%), including 9 with baseline EF <55%. There were no detected changes in treatment plans (e.g., switching to a less cardiotoxic agent) in any of these patients, although 2 were recommended to undergo more frequent cardiac function monitoring in follow-up. There were no statistically significant differences in age, race, menopausal status, smoking history, alcohol use, BMI, or medical comorbidities (hypertension, diabetes, or hyperlipidemia) between patients with abnormal and normal ECHO/RVG results. **Conclusions:** Baseline screening ECHO/RVG rarely yields an abnormality that prompts change in anthracycline and/or trastuzumab-based treatment plan. Further investigation should include determination of the utility of baseline screening ECHO/RVG among patients who develop cardiac problems during or following breast cancer treatment.

**6591 General Poster Session (Board #54), Mon, 1:15 PM-5:00 PM**

**What is the extent of the AYA gap for young adults with cancer?** *Presenting Author: Julie Anna Wolfson, City of Hope, Duarte, CA*

**Background:** Poorer outcome is documented among AYA (15-39y at diagnosis [dx]) with cancer as compared to younger (<15y) or older (40-65y) patients with similar dx, coining the term AYA Gap. While this phenomenon has been examined in cancers spanning the age spectrum, those typical in young adults (YA: 22-39y) remain unstudied. **Methods:** We constructed a population-based cohort of 67,292 patients dxed between 22y - 65y with adult-onset cancers and reported to LA County's cancer (ca) registry from 1998 - 2008 (YA 22-39y: n=5,801; adults 40-65y: n=61,491). Multivariate Cox regression stratified by disease and adjusted for clinical characteristics (stage, gender, race/ ethnicity) compared outcome between age groups. Analysis of variance compared change in 3y overall survival (OS) over time between age groups; interaction between age/dx year was examined for statistical significance (p<0.05). **Results:** Outcome by age group is shown in Table: YA with breast ca had poor outcome compared to adults. YA with lung, hepatobiliary, gastric, colorectal ca had superior outcome. There was no difference in mortality in oral or cervical ca. For patients with lung, hepatobiliary and gastric ca, change in 3y OS over time differed significantly (p=0.05) between YA (saw no improvement) and adults (there was improvement); 3y OS over time did not differ significantly (P>.05) between YA and adults with breast or colorectal ca (both saw survival improvements) as well as oral or cervical ca (neither saw change over time). **Conclusions:** YA with breast ca demonstrate inferior outcome compared with adults. Furthermore, there appears to be no improvement over time for YA with lung, hepatobiliary and gastric ca, while adult patients with similar dx demonstrate improvement in outcome. Thus YA with breast, lung, hepatobiliary and gastric ca constitute a vulnerable population vis a vis their adult counterparts, and need to be studied.

**Likelihood of mortality [22-39y vs. 40-65y: Adjusted for stage, gender, race/ethnicity].**

| Primary diagnosis | HR | CI | P value |
|---|---|---|---|
| **Breast (n=31,767)** | 1.2 | 1.1-1.3 | <.0001 |
| **Hepatobiliary (n=4,194)** | .7 | .6-.9 | .0004 |
| **Lung (n=10,848)** | .8 | .7-1.0 | .02 |
| **Colorectal (n=12,301)** | .8 | .7-1.0 | .005 |
| **Gastric (n=2,667)** | .8 | .7-.9 | .003 |
| **Cervix (n=3,691)** | .9 | .8-1.0 | .1 |
| **Oral (n=1,824)** | 1.0 | .7-1.3 | .9 |

**6592 General Poster Session (Board #55), Mon, 1:15 PM-5:00 PM**

**Utilizing nomogram-predicted outcomes as the control group in randomized clinical trials.** *Presenting Author: Arielle C. Lutterman, Emory University School of Medicine, Atlanta, GA*

**Background:** Phase III randomized clinical trials require a large study population to demonstrate improved outcomes. Validated nomograms exist that predict survival outcomes for cancer patients. Nomogram-predicted outcomes for a study population could be used as a virtual control group, obviating the need for a live control group. To test this hypothesis, we used data from CLB 9344, a randomized study demonstrating a benefit of adjuvant paclitaxel in breast cancer. **Methods:** The nomogram developed by Michaelson (http://cancer.lifemath.net) was used to create a virtual control group matching the 1570 paclitaxel treated participants from 9,344. This virtual control group was compared to observed data to determine whether paclitaxel improved survival over that predicted for AC alone. Cumulative deaths were compared with the cumulative hazard (expected deaths) using a one-sample log-rank test. Sample size estimates were calculated for deaths and total study population needed for 80% power, with a type I error of 0.05. **Results:** See Table. A statistically significant mortality benefit favoring the experimental group emerged by year 7. By year 15, cumulative hazard is significantly higher than the observed number of deaths, indicating paclitaxel improves survival over standard of care. **Conclusions:** These results validate the use of existing nomograms as a virtual control group in clinical trials, allowing for smaller, faster, statistically valid Phase III studies. The lack of a live control group together with tighter prediction of expected outcomes for the participants suggest sample sizes could be reduced by 50-80%.

**Nomogram-predicted survival with AC and observed survival with AC + T.**

| **15** | <0.001 | 623 | 849.14 | 0.46 | 0.57 |

**6593 General Poster Session (Board #56), Mon, 1:15 PM-5:00 PM**

**Experimental fertility preservation (FP) interventions in prepubertal (PP) boys with cancer: A report on preferences of teenage cancer survivors, parents, and providers.** *Presenting Author: Abha A. Gupta, Hospital for Sick Children, University of Toronto, Toronto, ON, Canada*

**Background:** Risk of infertility from cancer therapy is a source of great distress for young cancer survivors. FP can be a challenge in PP boys who are unable to produce bankable sperm through ejaculation. We sought to determine factors influencing patient, parental and provider preferences for testicular biopsy (TBx) even though the utility of PP tissue for FP remains experimental. **Methods:** Oncology providers, parents, and teenage cancer survivors were recruited from 3 pediatric centers in Canada. During participant surveys, a hypothetical decision was made between TBx and no TBx. Top factors influencing decisions were identified and willingness to accept complications, costs, risk of infertility, and chance of technology developing were used to measure strength of preference for TBx. Multiple regression was used to associate predictors with TBx desirability scores (under risk of infertility condition). **Results:** The proportion of respondents who preferred TBx (vs no TBx) were: 110/153 (72%) parents, 22/30 (73%) providers, and 52/77 (67%) cancer survivors. The top ranked factor influencing decisions for all groups was risk of infertility. For those that chose biopsy, a switch to no TBx occurred at very low chance technology developed (median 9%), highest cost point (median $500/year), and low risk of infertility (median 9.5%). Providers would accept much lower level of complications from TBx (median 21%), compared to parents (41%) and survivors (100%). Child age, type of cancer, ethnicity, or hospital were not significant factors associated with preference for TBx, but parents who reported a higher income were more likely to prefer TBx (p=.05). Some providers would not present TBx in cases of lower risk of infertility and poor prognosis. In contrast, parents (96%) and survivors (89%) wanted information on TBx before treatment began to ensure they had choice; no matter the factors of the case. **Conclusions:** Parents, survivors, and providers strongly favor TBx. Parental income was the only predictor of preferences under the risk of infertility condition. Addressing the costs associated with FP should remain an important focus of advocates for FP.

**6594 General Poster Session (Board #57), Mon, 1:15 PM-5:00 PM**

**Comparison of RCC surveillance guidelines: Competing tradeoffs.** *Presenting Author: Tracey Lynn Krupski, University of Virginia, Charlottesville, VA*

**Background:** Renal cell carcinoma (RCC) is now detected at earlier stages than in the past due to increased use of abdominal imaging for unrelated medical conditions. Three organizations offer differing guidelines for surveillance imaging strategies following partial nephrectomy (PN). We hypothesized that published surveillance patterns would have previously unrecognized sizable differences in intensity, cost, and radiation exposure and real world experience would not adhere to guidelines. **Methods:** Cost ($2,012) and radiation exposure in millisieverts (mSv) were compared between the following surveillance guidelines:American Urological Association (AUA), Canadian Urology Association (CUA), and the European Association of Urology (EAU). These were stratified into low-risk and high-risk based on tumor characteristics and compared to patients undergoing PN for RCC at the from 2009-2010. The intensity, cost, and estimated radiation exposure were calculated for each subject. We used the Welch's t-test to test for significant differences in cost and radiation exposure between the low-risk and high-risk groups. **Results:** The median cost of low risk surveillance from least expensive to most expensive is as follows: CUA ($481), EAU ($928) and AUA ($1,320). For high risk surveillance, least expensive was CUA ($543), EAU ($1,447) and AUA ($2,621). Radiation exposure was least for the CUA guidelines (low and high risk was 16.2 and 16.4 mSv ) and highest for the AUA guidelines at ( low and high risk was 48mSv and 92). The EUA guideline exposures were 23 mSv and 46mSv for low and high risk respectively. For comparison with a real world subset, 43/63 patients undergoing PN had complete records. We identified wide variability in intensity, frequency, and modality of surveillance imaging. These were not correlated to risk category or guidelines. **Conclusions:** Published surveillance strategies for RCC following PN differ greatly in terms of cost and radiation dose. Practicing clinicians do not seem to stratify patients by tumor-risk category as recommended by the published guidelines. It is important for clinicians to adopt standardized surveillance strategies that limit unnecessary cost and radiation exposure.

**6595 General Poster Session (Board #58), Mon, 1:15 PM-5:00 PM**

**Biomarker testing and time-to-treatment decision in patients with advanced non-small cell lung cancer.** *Presenting Author: Charles Henry Lim, University of Toronto, Toronto, ON, Canada*

**Background:** Testing for tumour biomarkers including *EGFR* mutation and *ALK* rearrangement has become standard in the management of advanced non-small cell lung cancer (NSCLC). At our institution, *EGFR* testing became routine in March 2010 and *ALK* testing in April 2012. We assessed the prevalence and timing of biomarker testing for advanced NSCLC patients and whether testing affected the timeliness of treatment decisions. **Methods:** We conducted a retrospective chart review of patients with advanced NSCLC referred to the Princess Margaret Cancer Center from April 1, 2010 to March 31, 2013. A random sample of one fourth of patients referred was chosen using a random numbers generator. **Results:** Of 278 patients reviewed, 136 (49%) had biomarker testing performed. Of these, 29% had documented *EGFR* mutations and 2% *ALK* rearrangement. Patients tested for biomarkers were more likely to be female (50% vs. 34%, $p=0.006$), Asian (22% vs. 9%, $p=0.008$) and non-smokers (41% vs. 8%, $p<0.0001$). Of 137 patients with newly diagnosed non-squamous NSCLC, 96 (69%) had biomarker testing performed and 16 (12%) had results available at the time of initial oncology consultation. There was a non-significant trend towards shorter mean time from consultation to treatment decision (29 vs. 42 days, $p=0.42$) and mean time to treatment start (38 vs. 50 days, $p=0.46$) for patients with results available at initial consultation compared to those without. Reflex testing resulted in 84% of samples undergoing testing compared to 59% if clinician-initiated, and a non-significantly shorter mean time for results (53 vs. 84 days, $p=0.34$). 10% of patients did not have adequate tissue for biomarker analysis at the time of first consultation; 56% of these went on to have repeat biopsy for molecular testing. Of those with an *EGFR* mutation, 16% started chemotherapy prior to results becoming available to the clinician. **Conclusions:** Awaiting biomarker test results can increase wait times to treatment decisions for patients with advanced NSCLC. This may be improved by incorporating reflex biomarker testing into diagnostic algorithms for NSCLC at the level of the pathologist, and further education of specialists involved in obtaining diagnostic cancer specimens.

**6596 General Poster Session (Board #59), Mon, 1:15 PM-5:00 PM**

**Staging imaging for metastatic disease in patients with early-stage breast cancer: What do physicians think of the ASCO top-5 recommendation?** *Presenting Author: Demetrios Simos, Division of Medical Oncology, The Ottawa Hospital Cancer Center, University of Ottawa & The Ottawa Hospital Research Institute, Ottawa, ON, Canada*

**Background:** In 2012, ASCO's inaugural "Top 5" list recommended against the routine use of imaging to look for metastases in asymptomatic women with early breast stage cancer. Despite this recommendation being in close agreement with published guidelines, staging imaging is frequently over-utilized. The objective of this study was to determine physicians views on the ASCO "Top 5" and guidelines pertaining to staging imaging for metastatic disease. **Methods:** A questionnaire was developed and circulated electronically using a modified Dillman technique to Canadian medical, radiation, and surgical oncologists. **Results:** The questionnaire was completed by 173 physicians (26% response rate). 82% indicated awareness of at least one published guideline on this issue. 60% indicated that they had read the ASCO recommendation and of those, 81% agreed with it. 24% indicated that the ASCO recommendation has influenced them to order less staging imaging. The percentage of respondents who would seldom order imaging for stage 1, 2 and 3 disease was 88%, 37% and 2% respectively. >95% of physicians identified a suspicious history, physical exam, and inflammatory breast cancer as important factors to be taken into consideration when deciding whether or not imaging should be done. The majority did not feel patient demand, fear of litigation or ease of access to imaging were important indications for imaging. **Conclusions:** Despite awareness of and general agreement with the staging imaging recommendations of the ASCO "Top 5" for early breast cancer, most physicians who treat breast cancer patients have not reduced their use of perioperative imaging. Disease stage, clinical evaluation, and tumour biology were identified as the most important factors influencing their decision of whether to do or not do staging imaging. Alternative strategies, beyond simply publishing recommendations, are therefore required if there is to be a sustained change in physician behaviour.

**6597 General Poster Session (Board #60), Mon, 1:15 PM-5:00 PM**

**A rank-based randomized phase II design when the phase III design is based on overall survival (OS).** *Presenting Author: William Leonard Mietlowski, Novartis Oncology, East Hanover, NJ*

**Background:** Gan (2013) reported that approximately 27% of 120 randomized phase III trials with a primary endpoint of OS had statistically significant outcomes. Ratain (2005) suggests that the low phase III success rate in Oncology may stem from a low positive predictive value (PPV) in phase II trials. There were four 2012 publications that independently reported that the components of tumor assessment were independent predictors of OS. Consequently, we proposed a rank-based (RB) (Lachin 1992) randomized phase II design that differentially weights the risk of death by the type and time of disease progression and the percentage change in tumor burden and compared this design with one based on progression-free survival (PFS). **Methods:** We chose CONFIRM-2, a randomized phase III trial in second-line colorectal cancer comparing chemotherapy±PTK787 as a negative OS trial ($n=855$, hazard ratio (HR)=1.00). In the absence of a database for a positive phase III trial based on OS, we constructed two positive-OS phase III trials by oversampling long-term survivors from the CONFIRM-2 database (P1: OS HR=0.75, PFS HR=0.85 and P2: OS HR=0.74, PFS HR=0.72). We simulated 2500 phase II trials ($n=150$, 80% power based on a one-sided test at the 10% significance level, after 110 events, when PFS is mature) from each of the three phase III trials. We compared the specificity, sensitivity, PPV and negative predictive value (NPV) of the RB method with PFS. **Results:** See Table. **Conclusions:** We show that the rank based method may have a substantial increase in specificity and PPV for OS compared to PFS. This may reflect the ability of the components of the tumor measurement process to predict OS since a lack of effect on OS would imply a lack of effect on the components (i.e. very good specificity and PPV). The comparison of sensitivity and NPV appears to depend on the PFS HR. Further studies with other tumor types and treatment modalities are warranted. Clinical trial information: NCT00056446.

| | | Operating characteristic | | | |
|---|---|---|---|---|---|
| **Positive OS trial** | **Design** | **Specificity** | **Sensitivity** | **PPV *** | **NPV*** |

**6598 General Poster Session (Board #61), Mon, 1:15 PM-5:00 PM**

**Impact of weekend admission on hospital length of stay and organ failure in pediatric leukemia patients at free-standing U.S. children's hospitals.** *Presenting Author: Elizabeth K. Goodman, The Children's Hospital of Philadelphia, Philadelphia, PA*

**Background:** In adult leukemia patients, weekend admission is associated with increased inpatient mortality. We used a U.S. cohort of pediatric leukemia patients to evaluate the impact of weekend admission on clinical outcomes in index leukemia admission. **Methods:** The Pediatric Health Information System (PHIS) database was used to assemble a retrospective cohort of children with newly diagnosed ALL or AML identified from 43 freestanding children's hospitals between January 1, 1999 to December 31, 2011. Index admissions were dichotomized as 'weekend' (Saturday or Sunday) and 'weekday'. Admission mortality, length of stay, time to chemotherapy, and organ system failure were compared between weekday and weekend admissions. Bivariate analyses were performed using Chi-square and Student's *t* tests. Adjusted analyses were performed using logistic regression. **Results:** 10,720 ALL patients and 1,323 AML patients were identified; 2,009 patients (16.7%) were admitted on weekends. Weekend admissions had a significantly higher proportion of young, non-white, and publically-insured patients. Patients receiving ICU-level resources within the first 2 days of admission represented a higher percentage of total weekend admissions although the absolute numbers of these severely ill patients was constant. Patients admitted on the weekend did not have an increased index admission mortality (OR 0.96, 95% CI 0.57-1.61 %); however, they had significantly increased length of stay (1.38 day increase, $p<.001$), time to chemotherapy (0.36 day increase, $p<.001$), and risk of respiratory failure (OR 1.47, 95% CI 1.16-1.71) after adjusting for demographics, severity of illness, and hospital level factors. **Conclusions:** While newly diagnosed children with leukemia admitted on weekends do not have higher index admission mortality, they have an increased length of stay, time to chemotherapy, and rate of respiratory failure. A higher proportion of patients are severely ill at presentation. Optimizing weekend resources may reduce hospital length of stay across all weekend admissions and ensure the availability of comprehensive care for those weekend admissions with higher acuity.

**6599 General Poster Session (Board #62), Mon, 1:15 PM-5:00 PM**

**Conditional survival in melanoma and thyroid cancer patients.** *Presenting Author: Megan Rist Haymart, University of Michigan, Ann Arbor, MI*

**Background:** Melanoma and thyroid cancer are two increasingly common malignancies. Although likelihood of survival from both cancers can vary by disease severity, it isn't known how patients' life expectancy changes the further they are from time of diagnosis. **Methods:** Using Surveillance, Epidemiology, End Results (SEER) data we selected patients diagnosed with melanoma (N=95,041) or well-differentiated thyroid cancer (N=43,392) between 1998 - 2005. Patients were followed for up to 12 years. Cox regression provided estimates of disease-specific survival by SEER stage and age, which we then transformed to estimate conditional five year survival. **Results:** Patients with localized melanoma and thyroid cancer have an excellent five year survival at time of diagnosis and for subsequent years. For both regional melanoma and thyroid cancer there is an age gradient with improved conditional survival in melanoma patients over time. For distant melanoma, the initial five year survival is poor but improves rapidly whereas the improvement is gradual with distant thyroid cancer. There is an age effect for disease-specific survival for both cancers, but it persists across all stages for thyroid cancer: for local disease [hazard ratio for age 70-79 versus <30 is 26.6 (95% confidence interval is 8.08-164)], for regional disease [59.4 (30.1-140)], and for distant disease [54.5 (20.7-221)]. For melanoma, the age effect is smaller and only present for local disease [3.79 (3.01-4.84)] and regional disease [2.36 (1.93-2.91)]. **Conclusions:** The likelihood of continued survival in a patient with melanoma or thyroid cancer differs based on age and how long the patient has already survived. Understanding the five year conditional survival of these cancers can help patients and physicians with their treatment plans.

**6600 General Poster Session (Board #63), Mon, 1:15 PM-5:00 PM**

**Clinical utility of tumor measurement (TM)-based metrics in phase II (P2) to predict phase III (P3) overall survival (OS) outcomes using the RECIST 1.1 database.** *Presenting Author: Sumithra J. Mandrekar, Mayo Clinic, Rochester, MN*

**Background:** While many alternative TM-based metrics to RECIST tumor response (TR) have been proposed, none have replaced TR in practice. The abilities of TR and previously proposed TM-based metrics to predict OS was assessed using simulation studies. **Methods:** 2,000 randomized P2 trials of 90 to 160 patients were resampled from 2 (lung) negative (-ve) (each with 2 active treatment arms) and 2 (colorectal) positive (+ve) P3 trials for OS. Cox models (landmarked at 12 weeks (w)), adjusted for baseline tumor size (mm) were fit to each P2 trial – Model 1: slope1 (baseline to 6w, mm/w), slope2 (6w to 12w, mm/w) and linear spline terms for +ve slope1 and slope2; Model 2: %change1(%change/w), %change2 (%change/w) and linear spline terms for +ve %change1 and %change2; Model 3: best TR within 12w. The +ve (-ve) predictive value (PPV/NPV), defined as the probability (Pr) of a +ve (-ve) phase II trial (using model predicted risk score differences, 1-sided p=0.20) yielding a +ve (-ve) P3 trial outcome (OS benefit associated with treatment), was calculated across the 2000 P2 trials for a given P3 trial for a range of false +ve (-ve) rates (FPR (FNR)) and Pr(+ve/-ve P3 trial). **Results:** Compared to TR, the slope and %change P2 models had lower OS prediction error for all P3 trials and better PPV/NPV for all but one P3 trial; however the absolute differences in PPV/NPV/prediction errors were negligible. **Conclusions:** TR has similar PPV/NPV as the continuous TM-based metrics, and should not necessarily be replaced. Acknowledgement: CA167326.

**A virtual consult service to optimize clinical trial participation in patients with metastatic breast cancer.** *Presenting Author: Karen Anne Cadoo, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** With an increasing complexity and number of endocrine, molecularly-targeted and immunotherapeutic clinical trial and standard-of-care therapies available for patients with metastatic breast cancer (MBC), rapidly identifying appropriate options is a challenge for physicians. We designed and piloted an email-based virtual consult system to facilitate matching of patients to appropriate studies. **Methods:** We assembled eligibility criteria and slot availability for 10 therapeutic Phase Ib/II clinical trials in the Breast Cancer Medicine Service at a tertiary referral center. Service physicians emailed patient details to a centralized address, one of three consulting fellows reviewed the patient's chart and responded within 24 hours with a ranked list of relevant studies. **Results:** 56 unique consults were received in 4 months. Median age was 56 (21-83), median ECOG performance status 0 (0-3). Reflecting the trials available, the majority (96%) of patients had estrogen receptor positive, human epidermal growth factor receptor 2 (HER2) negative disease. Mutational analysis of PIK3CA, AKT and HER2 was available for 35 tumors (62.5%); 21 had an actionable mutation, all of these tumors harbored *PIK3CA* mutations, one had a concurrent *AKT* mutation. 44/56 patients (79%) were eligible for at least one trial, of which 24 (55%) are enrolled onto or waitlisted for a specific study. Of the 20 eligible patients who did not pursue a trial, reasons included: the attending recommended alternate therapy with cause (9, 45%) patient declined (4, 20%), trial slot was unavailable (2, 10%), or unknown (5, 25%). 12 patients (21%) were ineligible due to site of progressive disease, second active malignancy, number of prior therapies or declining performance status. **Conclusions:** This virtual consult system is a potential strategy to assist physicians in identifying clinical trial options for patients. This process can be performed by supervised non-professional personnel with defined criteria, which will be the next phase of the pilot, incorporating prespecified metrics to ascertain the benefit.

**6602 General Poster Session (Board #65), Mon, 1:15 PM-5:00 PM**

**Improving cancer clinical trial accrual in Ontario, Canada: The clinical trials infrastructure fund (CTIF) experience.** *Presenting Author: Lesleigh S. Abbott, NCIC Clinical Trials Group, Kingston, ON, Canada*

**Background:** Participation in clinical trials is essential to evaluating safety and efficacy of emerging cancer therapies. To improve trial activities in the province of Ontario, Canada, the CTIF was established in 2002 and operationalized from 2004-2008 by the Ontario Cancer Research Network (OCRN), Ontario Institute for Cancer Research's (OICR) predecessor and funded by the Ontario government. The goals were to double trial recruitment from the baseline of 2001 and have self-sustaining trial units over 4 years. **Methods:** Beginning in 2004, the CTIF awards were issued in 3 phases – phase 1: 14 adult cancer centers, phase 2: 9 community hospitals, phase 3: 5 pediatric cancer centers. Per case funding (PCF) provided was $3300/patient; $4000/patient to community hospitals. The total program cost was $12.9 Million/3 years. Participating sites reported recruitment to academic and industry trials and shared 11% of additional industry trial funding over 5 years back to OCRN/OICR. The number of patients accrued was divided by the number of patients treated at sites to calculate the percentage of cancer patients accrued to clinical trials. **Results:** Trial recruitment and personnel increased during the years of the CTIF peaking in 2007. Trial increase was most marked for larger adult cancer centers. Successful sites maintained an average of 40% industry trials within their clinical trials portfolio and had a clinical trials manager with business experience. **Conclusions:** Providing additional PCF improved clinical trials accrual in Ontario, particularly in larger cancer centers that could rapidly expand their trial activities and personnel, but the effect was not sustained. Defining the best business model(s) and trial portfolio for trial units requires further elucidation.

**6603 General Poster Session (Board #66), Mon, 1:15 PM-5:00 PM**

**The clinical oncology treatment plan and summary implementation guide: An interoperable HL7 document standard to improve the quality of cancer care.** *Presenting Author: Jeremy Warner, Vanderbilt University Medical Center, Nashville, TN*

**Background:** Cancer care is interdisciplinary and longitudinal, and increasingly depends on seamless electronic transmission of clinical data. Accurate health information exchange, using structured and unambiguous data elements, is critical for coordination of care across all phases of the cancer journey. However, sharing data across multiple clinical practices remains difficult due to lack of standardization and general incompatibility between electronic health records. There is a growing need for well-designed, oncology-specific interoperability standards. Thus, ASCO is developing standards to improve the quality of cancer care. **Methods:** ASCO volunteers formed a Standards Work Group (SWG), and ASCO engaged an independent consulting firm for technical work. The SWG adapted ASCO's Breast Cancer Adjuvant Treatment Plan and Summary, originally developed as a paper-based form, for translation to an interoperable standard. The standard was developed using Health Level Seven International (HL7) Clinical Document Architecture (CDA), an ANSI-recognized standard in broad use. This required extensive input from medical and surgical oncologists, ASCO staff, and the consultants in order to define and disambiguate clinical concepts. Several concepts not represented in the Systematized Nomenclature of Medicine, Clinical Terms were added by the National Library of Medicine. **Results:** The HL7 Implementation Guide for CDA, Release 2: Clinical Oncology Treatment Plan and Summary, DSTU Release 1 (COTPS) was successfully balloted in May 2013 and published in late 2013. Several organizations have already expressed interest in the standard; the Athena Breast Health Network of five University of California sites has begun trial implementation. **Conclusions:** The COTPS is the first oncology-specific standard approved through the HL7 balloting process. Experience gained through trial implementation will continue to inform future work by the SWG. Oncology standards will improve quality by allowing efficient transmission of reliable, meaningful, and up-to-date clinical data between providers, patients, quality improvement initiatives, and registries.

**6604 General Poster Session (Board #67), Mon, 1:15 PM-5:00 PM**

**Febrile neutropenia and mortality in patients with breast cancer, lung cancer, and non-Hodgkin lymphoma.** *Presenting Author: Aniket A Kawatkar, Kaiser Permanente Southern California, Pasadena, CA*

**Background:** Chemotherapy-induced febrile neutropenia (FN) contributes considerably to morbidity and mortality. This retrospective cohort analysis evaluated FN incidence and mortality in patients with breast cancer, lung cancer, and non-Hodgkin lymphoma (NHL) identified in the Kaiser Permanente Southern California (KPSC) Cancer Registry. **Methods:** Adults age ≥18 years with newly diagnosed breast cancer, lung cancer, or NHL who initiated myelosuppressive chemotherapy between January 1, 2000 and December 31, 2009 were included. Patients who had undergone bone marrow/stem cell or solid organ transplantation, had white blood cell diseases within 6 months of starting chemotherapy, or received prior chemotherapy in the 12 months immediately preceding their cancer diagnosis were excluded. Each cycle within the first course of chemotherapy was identified, as were FN events (per ICD-9 codes for neutropenia and/or fever) and deaths (any cause). Patients were followed until the end of study (60 days after last treatment) for no more than 9 cycles. Data were included for all KPSC medical centers within the Southern California region. Outcomes stratified by cancer type and time period are shown below. **Results:** Overall, 12,086 patients across the 3 tumor types were identified (mean age [SD], 59.7 [11.8] years; females, 77.9%; Caucasians, 69.9%; Hispanic, 18.2%). Patient-level rates of FN and mortality are shown in the Table. **Conclusions:** This study found variation in the rate of chemotherapy-induced FN and mortality by cancer type and time period among patients with lung cancer, breast cancer, or NHL identified in the KPSC Cancer Registry. Differences across time periods may reflect changes in cancer treatment and FN management.

| | Breast | Lung | NHL |
|---|---|---|---|
| FN, n/N (%) | | | |
| Overall | 814/7268 (11.2) | 682/3730 (18.3) | 321/1088 (29.5) |
| 2000–2005* | 387/4615 (8.4) | 366/2160 (16.9) | 205/689 (29.8) |
| 2006–2009* | 429/2848 (15.1) | 317/1654 (19.2) | 118/433 (27.3) |
| Deaths (any cause) among patients with FN events, n/N (%) | | | |
| Overall | 14/814 (1.7) | 99/682 (14.5) | 21/321(6.5) |
| 2000–2005* | 8/387 (2.1) | 46/366 (12.6) | 17/205 (8.3) |
| 2006–2009* | 6/429 (1.4) | 53/317 (16.7) | 4/118 (3.4) |

* Some patients with multiple FN events may have been counted in both time periods.

**6605 General Poster Session (Board #68), Mon, 1:15 PM-5:00 PM**

**Trends in the quality of preventive care before and after prostate cancer diagnosis.** *Presenting Author: Lauren P. Wallner, Kaiser Permanente Southern California, Pasadena, CA*

**Background:** Most men diagnosed with prostate cancer will die from other causes, making preventive care for comorbid diseases of aging critical. However, concerns exist that the diagnosis often focuses subsequent care on prostate-related issues rather than overall health. Therefore, we examined the use of preventive services before and after diagnosis among men with prostate cancer and compared it to non-cancer controls. **Methods:** 15,631 men enrolled in Kaiser Permanente Southern California who were newly diagnosed with prostate cancer from 2002 through 2008 were matched 1:1 to non-cancer controls on age, race and timing of PSA test. They were passively followed through electronic medical records to determine the use of preventive services, including screening for colorectal cancer (CRC) (colonoscopy and/or fecal occult blood tests), tests for diabetes (glucose and hemoglobin A1c (HbA1c)) and heart disease (lipid panel test) and vaccinations (influenza and pneumococcal) in the 5 years before and diagnosis (or index date for controls). Rates of use were calculated for cases and controls separately and compared using Poisson regression. **Results:** CRC screening rates were 3-fold greater after diagnosis compared to before and were equivalent across group (Relative Rate (RR): 2.97, 95%CI: 2.89-3.05). The rates of lipid testing were similar before and after diagnosis, but increased an additional 10% in cases relative to controls after diagnosis (RR: 1.10, 95%CI: 1.14-1.25). HbA1c rates were lower among cases when compared to controls both before and after diagnosis (RR: 0.73, 95%CI: 0.72-0.74). Rates of glucose testing increased 25% more in the cases after diagnosis relative to the controls (RR: 1.25, 1.23-1.27), with the highest rate in the first 6 months after diagnosis. Influenza vaccination rates increased 24% after diagnosis in both groups (RR: 1.24, 95%CI: 1.22-1.26). **Conclusions:** Our results suggest that in this system, once diagnosed with prostate cancer, no less attention is paid to general preventive care. The increased use of preventive services may be the result of an integrated care model, further supporting the importance of the provider and system in the delivery of high quality survivorship care.

**6606 General Poster Session (Board #69), Mon, 1:15 PM-5:00 PM**

**Treatment decision making in advanced cancer: Communication about patient values and preferences.** *Presenting Author: Hanneke W.M. Van Laarhoven, Department of Medical Oncology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

**Background:** Medical decision making profoundly influences the quality of life of advanced cancer patients and, hence, strongly depends on patients' values and preferences. This observational study examines the type of values and preferences patients express in treatment decision consultations and how medical oncologists invite and react to such expressions. **Methods:** Advanced cancer patients for whom undergoing systemic treatment is medically not self-evident were identified. Patients (n = 43) were included when they met with a medical oncologist (n = 13) for the first time or to evaluate current treatment. Either one or two consultations were taped (total n = 64). Verbatim transcripts were analysed using MAXqda10 software. Independent coders identified and categorised patient expressions of values or preferences. Oncologists' utterances preceding or following such expressions were coded. **Results:** Preliminary analysis (n = 20; 31%) shows that patient expressions of values and preferences were more frequent in first consultations (M =7) than in evaluation consultations (M = 2). Expressions often concerned (54%) either a general goal, a wish to receive treatment or an evaluation of a treatment option. One third of expressions (37%) were qualified as patient-initiated. Two thirds (63%) were qualified as oncologist-invited, triggered by e.g., a direct question, a referral to the importance of patients' preferences or a treatment advice. Half of oncologists' responses qualified as space reducing (51%), i.e., not responding or by providing information. Responses qualified as space providing (39%) were probe questioning, checking, reflecting or providing an alternative perspective. A minority of oncologist responses qualified as solving (10%), including offering advice or consideration time. Sequences (30%) instead of isolated patient expressions (70%) often occurred when oncologists gave space providing responses. **Conclusions:** Shared decision making in advanced cancer can be improved by teaching oncologists to invite and provide space to patient expressions of values and preferences. Particularly when evaluating current treatment, patients' values and preferences should be put on the agenda.

**6608 General Poster Session (Board #71), Mon, 1:15 PM-5:00 PM**

**Trends and safety of image-guided percutaneous pleural biopsies in cancer patients.** *Presenting Author: Melissa Kate Accordino, Columbia University College of Physicians and Surgeons, New York, NY*

**Background:** Image-guided percutaneous pleural needle biopsy (IGPPB) is an important tool in the diagnosis and management of cancer patients. Complications of IGPPB include pneumothorax and chest tube placement. Small, single institution studies report rates of pneumothorax between 8-60% and subsequent chest tube in 6-53%. We performed a population-based analysis to evaluate patterns of use, complication rates, and cost associated with IGPPB. **Methods:** The Premier Perspective database was used to identify cancer patients with at least 1 claim for IGPPB from 2006-2012. Perspective is a fee-supported database created to measure resource utilization and quality from >600 US hospitals. Patients with a pneumothorax were defined by claims within 1 month of IGPPB; rates of hospitalization, chest tube placement and hospital length of stay (LOS) after pneumothorax were analyzed. Multivariable analysis was performed to further examine patient, insurance and hospital characteristics associated with biopsy setting (outpatient vs. inpatient). Pleural biopsy volume and procedure-associated costs over time were evaluated. **Results:** We identified 59,796 cancer patients who received ≥1 IGPPB, 32,474 (54.3%) in outpatients and 27,322 (45.7%) in inpatients. Characteristics associated with outpatient IGPPB included: younger age, white race, less comorbidity, tumor type, commercial insurance and larger hospitals ($p<0.01$). Of patients who received outpatient IGPPB, 3,835 (11.8%) developed a pneumothorax, 749 (19.5%, 2.3% of total) were hospitalized and 140 (3.7%, 0.4% of total) required chest tube. Among patients who received IGPPB as an inpatient, 5,638 (20.6%) developed a pneumothorax and, of those, 2,321 (41.2%, 20.4% total) required chest tube. LOS was similar for patients hospitalized after outpatient IGPPB (median 6, mean 7.9) compared to inpatient IGPPB (median 6, mean 8.7). Over time, IGPPB volume increased by 33%, patient costs rose by 53% and outpatient costs rose by 16%. **Conclusions:** We have shown that in a large population-based sample the use of IGPPB has increased substantially. While pneumothorax was frequent in outpatients, the rate of hospitalization and chest tube placement was small.

**6609 General Poster Session (Board #72), Mon, 1:15 PM-5:00 PM**

**The association of treatment breaks with survival in metastatic cancer.** *Presenting Author: Kuan Rui (Sean) Tan, The University of British Columbia, Vancouver, BC, Canada*

**Background:** As outcomes for specific metastatic cancers continue to improve, the concept of treatment to disease progression must be tempered by the potential for cumulative toxicities of ongoing therapy. Early research suggests that treatment holidays or "breaks" may provide improved quality of life without significantly compromising outcomes, but data are inconsistent. Using a population-based cohort of metastatic colorectal cancer (mCRC) patients to test this hypothesis, our aim was to determine the impact of treatment breaks on overall survival (OS). **Methods:** Patients diagnosed with mCRC from 2008 to 2010 and who initiated palliative systemic therapy at any 1 of 5 regional cancer centers in British Columbia were reviewed. Treatment breaks were defined as any intervals of >/= 4 weeks without receipt of any systemic therapy. The number and average length of breaks were characterized for first (1L) and second (2L) line therapy. Using Cox regression that controlled for confounders that included number of lines of therapy and total duration of therapy, we examined for the effect of treatment breaks on OS. **Results:** In total, 946 patients were identified: median age 64 (IQR 55-72) years, 521 (55%) were men, and 624 (66%) had colon cancer. The median number of treatments received in 1L and 2L therapy were 9 (IQR 4-13) and 7 (IQR 4-12) cycles, respectively. Treatment breaks were prevalent with 223 (24%), 76 (8%) and 55 (6%) patients in the cohort experiencing 1, 2 and >/=3 breaks, respectively. The median length of breaks varied depending on the line of therapy: 49 (IQR 36-99) days for 1L and 56 (IQR 38-100) days for 2L. There were no differences in baseline patient and tumor characteristics between subjects who underwent breaks and those who did not (all p>0.05). On multivariate analyses that adjusted for prognostic factors, patients who received more and longer treatment gaps did not experience worse OS (Table) **Conclusions:** This study suggests that treatment breaks from systemic therapy in carefully selected patients with mCRC do not compromise outcomes.

| Total number of breaks | HR for death | p-value | Median duration of breaks (days) | HR for death | p-value |
|---|---|---|---|---|---|
| None | 1.0 | <0.001 | 0 | 1.0 | <0.001 |
| 1 | 0.72 | | 1 to 30 | 0.79 | |
| 2 | 0.62 | | 31 to 60 | 0.58 | |
| 3+ | 0.46 | | 61 to 90 | 0.30 | |

**6610 General Poster Session (Board #73), Mon, 1:15 PM-5:00 PM**

**Influence of extent of lymphadenectomy on survival for localized non-small cell lung cancer.** *Presenting Author: Daniel Jacob Becker, Mount Sinai St. Luke's Hospital, Mount Sinai Roosevelt Hospital, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** Several studies suggest that more extensive lymph node dissection during surgery for localized non-small cell lung cancer (NSCLC) is associated with better prognosis. Given recent changes in therapy we sought to update previous analyses and include patients with higher stage, pathologically node negative (N0) disease. We further sought to identify clinical and demographic predictors of more extensive lymphadenectomy. **Methods:** We reviewed the SEER records of patients with N0 NSCLC, stage I-III diagnosed 2000-2010, who underwent lobectomy or pneumonectomy, with removal of > 1 lymph node (LN). We used the Cox proportional hazards model to examine the relationship between the number of LN examined and lung cancer specific survival (LCSS). We used linear and logistic regression to examine the relationship between clinical/demographic variables and number of LN removed. **Results:** We identified 34,233 patients with N0 NSCLC, treated with lobectomy/pneumonectomy between 2000 and 2010. The patients were 55.5% malewith medianage of 68;78.9% stage I, 7.9% stage II and 13% stage III. The median number of LN sampled was 7 (IQR 4-12). More LN resected at surgery were associated with improved OS and LCSS. Compared to patients with 1-3 LN resected, the hazard ratios for LCSS were 0.90 (CI 0.85-0.95) for 4-6 LN resected, 0.86 (CI 0.80-0.91) for 7-9 LN, 0.84 (CI 0.79-0.91) for 10-12 LN, 0.85 (CI 0.78-0.92) for 13-15 LN and 0.80 (CI 0.75-0.86) for > 16 LN resected. After controlling for age, gender, race, ethnicity, grade, stage, year of diagnosis and registry, little additional benefit was seen for resection of >7-9 LN. Older patients (age 70-80, OR 0.91), black race (OR 0.79), female (OR 0.90) and Hispanics (OR 0.81), were less likely to have > 7 LN resected. Patients diagnosed in 2005 and after (OR 1.15 - 1.62) were more likely to have > 7 LN resected. We also noted significant heterogeneity of LN resected by registry. **Conclusions:** In a current cohort of patients who had curative intent surgery for N0 NSCLC, the number of lymph nodes resected is strongly associated with LCSS. We propose that resection of 7 lymph nodes is feasible and may be considered a minimally acceptable number of nodes to be removed at curative resection of localized NSCLC.

**6611 General Poster Session (Board #74), Mon, 1:15 PM-5:00 PM**

**The impact of PET-CT on staging, management, and prognostication of small-cell lung cancer.** *Presenting Author: Alona Zer, Princess Margaret Cancer Center, Toronto, ON, Canada*

**Background:** Although frequently used, there is no randomized data assessing the role of PET CT in the staging process of SCLC patients, or its impact on patients' management. We aimed to review the utility of PET-CT in patients diagnosed with SCLC in a single tertiary medical center. **Methods:** All patients diagnosed with SCLC for 5 consecutive years were included, either staged by PET-CT or not. We retrieved clinical data, staging procedures, PET parameters (SUVmax and TLG) progression free survival (PFS) and Overall Survival (OS). In the group of patients who underwent PET CT during initial evaluation, re-assessment staging was performed by two independent radiologists: one according to PET-CT findings, and the other according to chest, abdomen and pelvic contrast-enhanced CT scan findings (with bone scan results if available) and blinded to the PET results. **Results:** 108 patients were identified. 2 patients were excluded from the analysis for lack pathology or staging procedure data and 10 patients were excluded since their PET imaging was not accessible. Out of 96 patients, 54 had a PET-CT done as part of their staging procedure. PET-staged patients had significantly less staging procedures (including FDG-PET scan, CT scans, MRIs, Bone Scans, BMBs) done than non-PET-staged patients (24% underwent 3-4 staging procedures versus 62%, p=0.04). PET altered management in 19 patients (35%), with 13 patients with suspected metastatic disease, who benefited from down-staging by PET. Treatment was delayed in PET-staged patients by 4 days; 30 vs 26 days from diagnostic procedure to treatment (p=0.04). High TLG level predicted poorer survival (HR=3.38, p=0.007). **Conclusions:** PET-CT adds to SCLC patients' management by reducing the amount of staging procedures and possibly down staging patients who otherwise would have been treated for palliative intent. In the setup of a public health system, waiting for the PET to be done and reported could result in treatment delay. TLG appears to be a new promising prognostic biomarker in small cell lung tumors. Prospective randomized trials are warranted to properly evaluate sensitivity, specificity and influence on management.

**6612 General Poster Session (Board #75), Mon, 1:15 PM-5:00 PM**

**Measurement of urinary incontinence after prostate surgery from data-mining electronic health records (EHR).** *Presenting Author: Tina Hernandez-Boussard, Stanford School of Medicine, Stanford, CA*

**Background:** National initiatives to develop quality metrics emphasize the need to include patient-centered outcomes, yet rely on manual chart abstraction or administrative data. Chart abstraction is expensive and labor intensive, while administrative data are incomplete. We sought to use EHR to examine post-operative urinary incontinence (PO-UI) as a patient-centered outcome, as this is prevalent in prostate cancer patients (reported ranges are 10% to 40%) yet rarely recorded in administrative data. **Methods:** We included patients who underwent prostatectomy at the Stanford Cancer Institute (SCI), 1995 - 2013. We processed clinician-generated encounter notes from EHRs using a validated text-mining workflow to measure PO-UI (PloS one. 2013;8(5):e63499). Our analysis included coded data (ICD-9-CM and CPT codes) as well as term-mentions extracted from unstructured clinicians' notes. **Results:** We identified 5,353 patients who underwent prostatectomy; 43.8% open, 7.2% robot-assisted, 7.7% laparoscopic, and 41.3% were other, which includes codes that do not distinguish between robotic and laparoscopic procedures. 37.1% of our patients, treated prior to EHR implementation, were without an EHR note. UI was identified pre-surgery in 6.99% of patients and post-surgery in 9.66% of patients. Using only coded data, rates dropped to 0.24% pre-surgical and 0.21% post-surgical. In patients with an EHR clinical note (3,367 patients, 62.9%), PO-UI was identified in 22.6% of patients; 19.7% open, 12.7% robot-assisted, 21.5% laparoscopic, and 29.5% other surgeries (p<0.0001). 47% of all PO- UI were identified within 60 days of surgery. 20.8% of patients had documentation of no PO-UI. 44.2% of patients had pre-operative discussion of PO-UI documented as a possible complication. **Conclusions:** Using EHR to identify quality metrics is feasible, efficient and can capture patient-centered outcomes. Our results indicate that patient-centric events are not always coded in EHR and therefore not entered into administrative datasets; thus escaping quality assessment. Using EHRs for quality assessment promotes meaningful use of health information technology and allows quality measurement to move into the Big Data era.

**6613 General Poster Session (Board #76), Mon, 1:15 PM-5:00 PM**

**Improved access to tobacco cessation services for cancer patients using a statewide collaborative approach.** *Presenting Author: Jane Alcyne Severson, Michigan Oncology Quality Consortium, Ann Arbor, MI*

**Background:** The Michigan Oncology Quality Consortium (MOQC) collaborated with the Michigan Department of Community Health (MDCH) and Michigan Cancer Consortium (MCC) to implement a statewide Tobacco Cessation Demonstration Project to improve cancer patients' access to tobacco cessation services. **Methods:** Beginning in fall 2012, MOQC, MDCH, and MCC implemented a program to refer all cancer patients who use tobacco to the Michigan Tobacco Quitline. Referred patients were provided free counseling services and nicotine replacement therapy. A lean problem solving approach was deployed that included standard workflows, scripts, and visual management tools to support frontline staff in identifying all cancer patients who use tobacco and referring them to the Quitline. Eighteen oncology practices (63 physicians) participated in 3 learning sessions during which the following were provided: education by subject matter experts, data management and lean tools, and sharing of barriers and successes. **Results:** Between May and December of 2013, a total of 694 cancer patients were referred for cessation support and at least 1 contact attempt was made for 686 patients. A total of 308 patients (45%) were successfully contacted by the Quitline, only 3% were ineligible to participate, and 26% declined participation. Whereas total Michigan Quitline referrals increased by an average of 40% each month in this period, non-MOQC referrals decreased from 140 per month in May to 95 per month in December. In contrast, MOQC cancer patient referrals increased from 62 per month to 80-123 per month in the subsequent months representing an average of 43% of all Michigan Quitline referrals. Tobacco assessment rates for cancer patients were maintained above 95%, and an average of 61% of eligible cancer patients were referred to the Quitline, a four-fold increase from the baseline referral rate of 15%. **Conclusions:** Increasing access to dedicated statewide resources and providing oncology practices with lean resources including standardized workflows improves the tobacco cessation referral rate for oncology patients. Improvements in referral rates may significantly increase participation in dedicated tobacco cessation programs.

**6614 General Poster Session (Board #77), Mon, 1:15 PM-5:00 PM**

**Prevalence of prescribing errors resulting in administration of incorrect dosages of antineoplastic treatment.** *Presenting Author: Thea Otto Mattsson, University of Southern Denmark, Odense, Denmark*

**Background:** The prevalence of non-intercepted prescribing errors and the impact of computerized order entry systems (CPOE) in preventing such errors are not known. Our objective was to evaluate both prevalence and severity of non-intercepted prescription dose errors as well as the impact of a CPOE system on these in a setting of adult cancer patients. **Methods:** A prospective observational case control study in two clinical oncology units. One institution used a parallel CPOE system with no connection to the electronic patient chart data, while the other used paper based prescription forms. All standard prescriptions from both institutions were included and reviewed. Doses were recalculated according to the guidelines of each of the institutions using the patient data as documented in the chart, on the paper based form or in the CPOE system at the time of prescription. A non-intercepted prescription dose error was defined as ≥ 10% difference between the administered and the recalculated dose. Main outcome measures were prevalence and severity of prescription errors using validated harm categories. **Results:** Data were collected from November 1, 2012 til January 31, 2013. A total of 5,767 physician prescriptions were evaluated. 2,677 from the institution using CPOE and 3090 from the institution with paper based prescription forms. Crude analysis showed an overall risk of a prescription dose error of 1.73 per 100 prescriptions. CPOE resulted in 1.60 and paper based prescription forms in 1.84 errors per 100 prescriptions. OR = 0.87 (95%CI 0.59-1.29, P=0.49). Furthermore, no significant difference between institutions in severity of errors was observed. **Conclusions:** Non-intercepted prescribing dose errors are relatively common in clinical oncology units. Non integrated CPOE systems without decision support do not seem to significantly reduce the risk of prescription errors or affect severity of errors. Based on the results of this study strategies to prevent future prescription errors are highly warranted.

**6615 General Poster Session (Board #78), Mon, 1:15 PM-5:00 PM**

**Can we identify patients at risk for discordance in preferred and actual role in cancer treatment decision making?** *Presenting Author: Leah L. Zullig, Health Services Research and Development, Durham VA Medical Center, Durham, NC*

**Background:** Assuring treatment-related decision-making aligns with patients' preferences is a critical component of quality care. Yet often patients' preferred and actual treatment-related decision-making roles are discordant (i.e., patients may play a more or less active role in decision-making than was preferred). We examined whether patient characteristics predict discordant treatment decision-making roles. **Methods:** We surveyed adults receiving anti-cancer therapy. First, patients were asked to state their preferred role: to make treatment decisions with little or no input from their oncologists; to let their oncologists make the decision for them; or to engage in shared decision-making. Second, patients were asked about their actual role: the role they played when treatment decisions were actually made, using the same categories. A dichotomized variable measured discordance between preferred and actual decision-making roles. Multivariable regression examined the association between characteristics (age, gender, race, education, income, financial distress, employment, insurance, marital status, treatment intent, time on treatment, income, quality of life, out-of-pocket costs) and decision-making role discordance. **Results:** Of 300 respondents (86% response), 12% preferred to make decisions with little or no input, 7% preferred their doctor to make decisions, 25% preferred their doctor to make decisions after considering their input, and (55%) preferred shared decision-making between patients and their oncologists. The most common discrepancy was patients preferred a shared decision, but in actuality doctors made the decision after considering patients' opinion (5%). 81% reported decision making consistent with preferences. None of the examined patient characteristics were associated with decision-making role discordance. **Conclusions:** There was relatively little discordance between preferred and actual decision-making style.Readily identifiable patient characteristics were not associated with role discordance. Therefore, it may be important for clinicians to simply ask patients what role they would prefer to play in cancer treatment decision-making.

**6616 General Poster Session (Board #79), Mon, 1:15 PM-5:00 PM**

**Which formats for communicating patient-reported outcomes (PROs) work best?** *Presenting Author: Michael Donald Brundage, Queen's University, Kingston, ON, Canada*

**Background:** PROs provide patients' perspectives on health conditions and treatments. Both group-level PRO data (eg, clinical trial results) and individual-level PRO data (eg, charted symptoms) can inform clinical care. How to optimally present PROs to assist comprehension and use is unclear. **Methods:** We purposively sampled cancer patients (by cancer type, care setting, and education) and clinicians (by specialty and practice setting). Participants were randomized to evaluate either 6 formats for group-level data or 4 formats for individual-level data. For each format (eg, bar charts, line graphs), participants answered 2 questions testing comprehension and rated ease of understanding and usefulness (0 least-10 most). In follow-up qualitative interviews, participants described their interpretations of the formats and reported presentation elements that aided/hindered understanding. **Results:** We recruited 49 patients (median age 65, 44% <college graduate) and 20 clinicians (median age 42). Participants evaluating group-level formats rated line graphs highest for ease of understanding and usefulness (patients: median 8.0 and 8.0, respectively; clinicians: median 9.0 and 8.5, respectively). Accuracy of interpretation across formats ranged from 38%-100% for patients and 56%-100% for clinicians. The group-level qualitative data suggested clinicians value confidence intervals, normed scores, and p-values, but patients find this information confusing. Participants evaluating individual-level formats also rated line graphs highest for ease of understanding and usefulness (patients: median 8.0 and 8.0, respectively; clinicians: median 8.5 and 9.0, respectively). Accuracy of interpretation across formats ranged from 64%-96% for patients and 90%-100% for clinicians. The individual-level qualitative data suggested reference scores for comparison and highlighting issues requiring clinical attention are helpful. **Conclusions:** Participants preferred line graphs of trends over time for both group-level and individual-level PRO data. Given the variation in interpretation accuracy across formats, results regarding aspects that were helpful and confusing can inform best practices for presenting PRO data.

**6617 General Poster Session (Board #80), Mon, 1:15 PM-5:00 PM**

**NCI pilot intervention program to assist accrual for challenging late-phase clinical trials.** *Presenting Author: Andrea Denicoff, National Cancer Institute, Rockville, MD*

**Background:** Since 2010, the National Cancer Institute (NCI) has taken substantial efforts to compress the timelines for protocol review and trial activation (Abrams, JNCI, 2013). In 2012, NCI's Cancer Therapy Evaluation Program (CTEP) began a pilot in collaboration with NCI Cooperative Groups (CG) to support accrual to Phase 2-3 treatment trials identified as potentially challenging or at risk for insufficient accrual (Korn, JCO, 2010). Pilot program findings are reported. **Methods:** CG trials were identified for the pilot if accrual concerns were raised during the concept or protocol review or were at risk of not meeting CTEP's slow accrual guidelines after activation. In collaboration with CG study teams, each trial underwent the following evaluation and analyses: accrual feasibility/challenges; site activation data; tailored interventions to address challenges, track and report accrual changes. **Results:** To date, 18 trials are in the pilot (10 identified pre-activation, 8 post-activation). Nine received interventions and 9 are in process. Interventions included: trial-specific materials, outreach to investigators/sites, survey data to guide amendments, social media outreach. Accrual data are available for 5 trial interventions. Quarterly accrual rates (QAR) increased for all 4 post-activation trials: Trial 1 now exceeds projected QAR (18 patients) by 6% (pre-intervention=10; post=19); Trial 2 exceeds projected QAR (72 pts) by 6% (pre=52; post=76); projected QAR for Trial 3 (36 pts) and Trial 4 (84 pts) remain below goals but QAR did improve(Trial 3: pre=5, post=29; Trial 4: pre=44, post=63). The lone pre-activation trial (Trial 5) is 61% below its projected QAR (102) 2 yrs after activating. **Conclusions:** Improved QARs for 4 of 5 trials. No intervention appears generally applicable and most trials require very specific interventions. Monitoring of trials will continue as interventions are implemented. CTEP plans to expand the pilot to support the new NCI National Clinical Trials Network (NCTN) and Early Therapeutic Clinical Trials Network (ET-CTN) and assist both early and late phase trials with accrual challenges. The effect of future interventions will be continually assessed.

**6618 General Poster Session (Board #81), Mon, 1:15 PM-5:00 PM**

**Next steps for IBM Watson Oncology: Scalability to additional malignancies.** *Presenting Author: Andrew S. Epstein, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** We reported on the development of IBM Watson Oncology, a cognitive computing system designed to inform clinical decision making. The initial prototype demonstrated results (Bach, Proc ASCO 2013) in lung cancers, including the complexities of natural language processing. Here, we report the experience scaling the tool to additional cancers using an alternative method of attribute collection. **Methods:** Memorial Sloan Kettering and IBM's continued collaboration now includes the creation of electronic decision support prototypes for colon, rectal, bladder, pancreatic, kidney, ovarian, cervical and endometrial cancers. To date, each prototype has been created with IBM Watson and trained by Memorial Sloan Kettering physicians by identifying key attributes common to all cancers (e.g., stage, age) and specific to individual cancers (e.g., high risk features for stage II colon cancer), manually entering attribute and candidate treatment answer combinations, and ranking treatments as preferred, acceptable, or not recommended. Precision, defined as [(correct preferred treatments)/(correct preferred treatments + false positives (incorrect preferred treatments) + false negatives (missing preferred treatments))], was measured for each prototype. **Results:** To date, each cancer prototype has been created with dozens of training cases and candidate treatment answers. Average precision, retesting with the same training data, has improved from 5% to nearly 100% depending on the cancer type. Table 1 is provided as a descriptive summary and not a statement of statistical significance. **Conclusions:** IBM Watson Oncology's training is scalable to additional cancers and today covers the majority of solid tumors, including breast and lung. Future steps include using additional machine learning features and training cases to improve precision, testing using blind cases, and using natural language processing to automatically extract clinical attributes from electronic medical records.

**Average precision (%) by disease site.**

| | First run | Middle run | Latest run |

**6619 General Poster Session (Board #82), Mon, 1:15 PM-5:00 PM**

**Impact of recent clinical trials on the use of chemotherapy for resectable non-small cell lung cancer in the United States.** *Presenting Author: Ravi Rajaram, Center for Healthcare Studies, Institute of Public Health and Medicine, Feinberg School of Medicine, Northwestern University, Chicago, IL*

**Background:** Multiple clinical trials have demonstrated chemotherapy combined with surgery improves survival in many patients with non-small cell lung cancer (NSCLC). Per NCCN Guidelines, for selected stage IB and II-IIIA patients there is level 2B and 1 evidence for use of chemotherapy, respectively. We sought to (1) evaluate changes in chemotherapy utilization in surgically treated NSCLC over time and (2) to identify factors predictive of chemotherapy administration in this population. **Methods:** Patients who had surgery for AJCC seventh edition stage IB-IIIA NSCLC (2002-2011) were identified from the National Cancer Data Base. Administration of chemotherapy (neoadjuvant or adjuvant) was assessed over time. Hierarchical regression models were developed to assess patient, hospital, and tumor characteristics predicting chemotherapy utilization separately for IB and II-IIIA tumors. **Results:** Overall, 112,049 patients had resection for stage IB-IIIA NSCLC. In 55,016 patients with stage IB disease, chemotherapy use increased from 5.3% to 15.1%, with adjuvant therapy specifically increasing from 2.4% to 14.4% (both $p < 0.01$). On multivariable analysis, stage IB patients were less likely to receive chemotherapy if they were older, treated at an academic or NCI center (vs. community), had more comorbidities, or had lower grade tumors (all $p \leq 0.01$). In 57,033 patients with stage II-IIIA disease, chemotherapy administration also significantly increased from 29.3% to 58.4%, with adjuvant therapy increasing from 18.0% to 43.4% (both $p < 0.01$). Predictors of decreased chemotherapy use in stage II-IIIA patients included increasing age, non-private insurance status, non-NCI academic treating facility, increased comorbidities, squamous histology, lower grade tumors, or sublobar resection (all $p < 0.04$). Stage IIIA (vs. IIA) disease (OR 2.82, 95% CI 2.56-3.11) was predictive of increased chemotherapy delivery. **Conclusions:** In patients with resected stage IB-IIIA NSCLC, use of chemotherapy has substantially increased since 2002. However, while many providers have adopted evidence-based recommendations into their practice, sizeable treatment gaps persist and are areas for targeted quality improvement.

**6620 General Poster Session (Board #83), Mon, 1:15 PM-5:00 PM**

**HIV and predictors of advanced cancer at presentation: Uganda.** *Presenting Author: Manoj Menon, Fred Hutchinson Cancer Research Center, Seattle, WA*

**Background:** The HIV epidemic has contributed to the increasing incidence of cancer in sub-Saharan Africa (SSA), where most patients with cancer present at an advanced stage. However, improved access to HIV care and treatment centers in SSA may facilitate earlier diagnosis of cancer among HIV+ patients. To test this hypothesis, we characterized the stage of cancer and evaluated predictors of advanced stage at presentation among patients in Uganda. **Methods:** We conducted a retrospective analysis of adult patients who presented for care at 1 of 2 tertiary care sites in Kampala, Uganda with any of 5 specific cancers between 2003 and 2010. Demographic, clinical and laboratory data were abstracted from the medical record along with the outcome measure of advanced stage of disease (clinical stage 3 or 4). We utilized bivariate analyses to identify measures with $p<0.20$ for inclusion in a multivariate logistic regression model. **Results:** We analyzed 802 patients with the following cancers: cervical (39%), breast (27%), NHL (17%), esophageal (9%) and HL (8%). Nearly 80% presented at an advanced stage and 34% had HIV infection. The median age was 44 years. Over 90% of patients were symptomatic and the median duration of symptoms prior to presentation was 5 months. The median hemoglobin (hgb) level at presentation was 11.1g/dl (IQR 4.4 g/dl). In bivariate analyses of all cancer types, higher hgb, fewer symptoms, shorter symptom duration, younger age and HIV infection were associated with less advanced cancer. The association between HIV infection and less advanced stage of cancer was significant at $p<0.01$ for only the AIDS-defining cancers (i.e. cervical cancer and NHL). In the multivariate model, HIV+ patients were less likely ($p=0.01$) to present at an advanced stage, as were patients with higher hgb ($p=0.03$) and fewer symptoms ($p<0.01$). **Conclusions:** Patients with limited access to primary care may present with advanced cancer due to a delay in diagnosis. However, patients with HIV now have better access to clinical care. Utilization of this growing infrastructure to increase cancer screening and referral is promising and deserves continued support, as the prognosis of HIV+ patients with advanced cancer is characterized by poor survival, even in resource-abundant regions.

**6621 General Poster Session (Board #84), Mon, 1:15 PM-5:00 PM**

**Relationship between type of therapeutic intervention and funding source in randomized clinical trials (RCTs) in oncology.** *Presenting Author: Fernando Costa Santini, Hospital Sirio Libanes, Sao Paulo, Brazil*

**Background:** Pharmaceutical companies play an important role in drug development and approval in an environment where performing RCTs has become increasingly costly and complex. However, myriad questions about the impact of surgical and radiotherapy interventions equally require adequate hypothesis testing in RCTs. A potential lack of funding for non-drug related RCTs may lead to important gaps in clinical knowledge. **Methods:** We searched PubMed for all RCTs published between 01/2009 and 12/2013 in breast, prostatic, lung and colorectal cancers. All articles published in this period were manually screened for eligibility. We included only RCTs with clinical endpoints such as TTP, PFS, OS and response rate. Two investigators independently selected phase 2 and phase 3 RCTs with at least 50 patients published in English. We classified eligible trials according to the type of intervention (drugs, radiotherapy or surgery) and the stated funding source (industry versus nonprofit). **Results:** We retrieved 4,416 RCTs studies of which 709 (16%) were eligible. 578 (82%) of the RCTs evaluated drugs, 74 (10%) radiotherapy and 57 (8%) surgery. There was a significantly greater number of RCTs evaluating radiotherapy or surgery performed in colorectal and prostatic cancers compared to lung and breast. Overall, 470/709 (66%) RCTs were funded entirely or partially by industry (pharmaceutical and device companies) and 239/709 (34%) by nonprofit organizations (government, academic centers or foundations). There was a significant association between source of funding and type of intervention: 448/578 RCTs (77,5%) evaluating drugs were funded by industry, in comparison to only 22/131 (17%) of surgical and radiotherapy RCTs ($p<0.0001$). **Conclusions:** The vast majority of RCTs in oncology relates to drug development and is being funded by industry, while 83% of RCTs evaluating surgical or radiotherapy related questions are not industry funded. Even though drug development is of paramount importance, the extent to which clinically relevant issues are not being properly addressed by RCTs, at least in part due to lack of funding, should be considered and further evaluated.

**6622 General Poster Session (Board #85), Mon, 1:15 PM-5:00 PM**

**Permanent stoma use in rectal cancer surgery in Canada: A population-based analysis.** *Presenting Author: Geoffrey A. Porter, Canadian Partnership Against Cancer, Toronto, ON, Canada*

**Background:** Sphincter preservation is important for many patients with rectal cancer; avoidance of a permanent stoma (either colostomy or ileostomy) is a well-accepted quality indicator of rectal cancer care. This study describes, at a population level, the frequency of permanent stoma (PS) use in rectal cancer surgery in Canada. In addition, this study examines potential disparities in PS use related to income, geography and immigration status. **Methods:** Patients undergoing resection for primary adenocarcinoma of the rectum in Canada during fiscal years 2007/08-2011/12 with a valid postal code were included; procedure codes from the discharge abstract database were used to categorize surgery as involving either a permanent stoma (PS), temporary stoma (TS) or no stoma (NS). Income for urban Canada was categorized according to neighbourhood income quintile, and immigration density represented the percentage of immigrant/non-permanent populations living in a dissemination area based on census information. Geography was examined according to province of residence, statistical area classification (SAC) of urban/rural, and travel time (in minutes) to nearest hospital **Results:** Among the 10,559 patients undergoing rectal cancer resection, 3,895 (36.9 %) underwent a PS, 3,501 (33.2 %) a TS, and 3,163 (30.0%) had NS. Significant variation in PS rates was identified among 9 Canadian provinces (range 35.1%- 51.4%; $p<0.0001$). The table below shows increased rates of PS among patients living in rural/remote areas, low income neighbourhoods, and those with longer travel time to hospital. Lower rates of PS were seen among patients residing in areas of higher immigration density. **Conclusions**: Significant variation exists in the use of PS for rectal cancer in Canada, particularly related to geography. Better understanding of root causes of such variation will be important to guide targeted initiatives aimed at optimizing the quality of rectal cancer care at a population level.

**6623 General Poster Session (Board #86), Mon, 1:15 PM-5:00 PM**

**Standardized criteria for required palliative care consultation on the solid tumor oncology service.** *Presenting Author: Kerin Adelson, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** Studies have shown that for patients with advanced cancer, integration of Palliative Care (PC) is associated with improved symptom control, clearer understanding of prognosis, lower utilization of health care resources, and increased hospice use. The 2012 ASCO guidelines call for incorporation of PC for any patient with metastatic cancer and/or high symptom burden. Despite a top-rated PC division at Mount Sinai, our Solid Tumor (ST) Division utilized PC and hospice less than other centers. Our inpatient ST service demonstrated poor quality metrics. Our 2011-2012 UHC statistics were: mortality index, 1.35 (target <1), 30-day readmission rate, 21.7%, (target < 10.3%) and length of stay (LOS) index, 1.23 (target <1). We hypothesized that implementing standardized criteria for PC consultation would improve these metrics. **Methods:** During this 3-month pilot, criteria for PC consultation included patients with one or more of the following: stage IV disease, Stage III lung or pancreatic cancer, hospitalization within prior 30 days, >7 day hospitalization, uncontrolled symptoms (pain, nausea, dyspnea, delirium, distress). We looked at two baseline groups for comparison: 1) patients who met eligibility in a six week period prior to the intervention 2) For UHC index data, we used the hospital dashboard average over a 1-year period prior to the intervention. Primary outcomes were: hospice utilization, ST mortality index, 30-day readmission rate and LOS. **Results:** Comparing group 1 to the pilot group, palliative care consultation doubled from 41% to 82%, 30-day readmission decreased from 36% to 17% ($p = 0.022$), and hospice utilization increased from 14% to 25% ($p = 0.146$). UHC data (Group 2 vs. Pilot) showed: mortality index improved (1.35 to 0.59) and 30-day readmission rates decreased (21.7% to 13.5%, $p = 0.026$). LOS was unchanged (1.23 to 1.25). **Conclusions:** Mandating palliative care consults for patients at the highest risk for in hospital death and readmission improved hospice utilization, 30-day readmission, oncology service mortality and adherence with ASCO guidelines. Mount Sinai has funded an extra palliative care team; use of these criteria have become our standard of care.

**6624 General Poster Session (Board #87), Mon, 1:15 PM-5:00 PM**

**Development of a new oncology quality metric: The rate of evidence-based adherence.** *Presenting Author: Kerin B. Adelson, Division of Hematology and Medical Oncology, The Tisch Cancer Institute, Mount Sinai School of Medicine, New York, NY*

**Background:** The degree to which electronic health records enhance the quality of patient care depends on how the system is used to monitor and improve practice. In planning the transition to Epic's electronic chemotherapy ordering platform, we saw an opportunity to increase evidence-based practice. **Methods:** Our Chemotherapy Council vetted more than 600 electronic protocols based entirely on published clinical trials and NCCN guidelines; modifications made to these protocols represent a divergence from clinical evidence. We examined the number of times the chemotherapy section of a protocol was modified before the first cycle to avoid counting dose modifications made for toxicities. To get the rate for the cancer center we calculated the # of discrete times all protocols were used (denominator) and the number of times all protocols were modified (numerator). We subtracted the ratio from 1 to reflect the proportion of protocols that were not modified. This ratio serves as a new quality metric – the Rate of Evidence-Based Adherence (REBA). $REBA_{institution} = 1$ - Total # of modifications prior to first cycle for each protocol / Total # of uses of all protocols. Additionally, REBA can be used to examine disease group rates ($REBA_{group}$), individual provider rates ($REBA_{provider}$) and rates for individual protocols ($REBA_{protocol}$). Institutions that have implemented evidence-based clinical pathways have strived for 80% (.80) adherence. We set this as our REBA benchmark. **Results:** The $REBA_{institution}$ was .86, higher than our pre-defined goal ($p<0.001$). There was wide variation in the $REBA_{group}$ (range 0.50-0.95). The $REBA_{protocol}$ identified two protocols (rates of .33 and .42 respectively) that were dose reduced the majority of the time. In the example of our Breast Group, the $REBA_{provider}$, ranged from (.78 to .97) reflecting differing practice among 4 physicians. **Conclusions:** The REBA can identify faculty and disease groups who underutilize clinical evidence, facilitating feedback for quality improvement. The $REBA_{protocol}$ is a useful tool to identify specific chemotherapy templates that may need modification. The REBA is a powerful electronic tool, which can be utilized to monitor and enhance the rate of evidence-based practice in oncology.

**6625 General Poster Session (Board #88), Mon, 1:15 PM-5:00 PM**

**Associations among socioeconomic status (SES), patterns of care and outcomes in breast cancer (BC) patients (pts) in a universal health care system: Ontario's experience.** *Presenting Author: Alexander Kumachev, University of Toronto, Toronto, ON, Canada*

**Background:** The Canadian health care system was designed to provide equitable access to equivalent standards of care. We aim to examine if BC pts with different SES received different care and had different overall survival (OS) in Ontario, Canada's largest province. **Methods:** Female pts diagnosed with BC between 2003-2009 were identified from the Ontario Cancer Registry and linked to databases related to physician claims, hospital and emergency visits and provincial funding programs to ascertain demographics, cancer stage (CS), comorbidities, mammography use, surgery type, adjuvant chemotherapy (chemo), radiation (RT), and vital statistics. SES was defined as neighbourhood income by postal code attained from Statistics Canada and divided into income quintiles (Q1-Q5; Q5=highest). Univariate and multivariable analyses were used to examine the association between i) SES and mammogram screening and BC treatments, and ii) SES and OS. **Results:** 34,446 BC pts with CS available were identified. 76.0% were > 50 years old. The proportion of CS I, II, III and IV were, 41.4, 38.8, 14.9, & 4.9%, respectively. Screening mammograms (1-5 years prior to diagnosis) rates were significantly higher with higher SES (Q5 = 50.1% and Q1=41.7% (OR = 1.43, 95% CI: 1.32-1.56, $p<0.0001$)) for pts age >55. Pts with higher SES were more likely to be diagnosed at an earlier CS ($p<0.0001$, Q5=44.3% & Q1=37.7% were diagnosed with CS (OR = 1.31, 1.23-1.41)). Pts with higher SES were more likely to receive adjuvant chemo ($p<0.0001$, Q5 vs. Q1 OR = 1.18, 1.10-1.26) and RT ($p<0.0001$, Q5 vs. Q1 OR = 1.24, 1.15-1.33). There were no obvious differences in adjuvant trastuzumab (T-mab) use ($p=0.62$), breast conserving surgery ($p=0.057$) and time between surgery and adjuvant chemo ($p=0.15$) based on SES. The 5 year OS rates for Q1-Q5 were 80.0, 81.0, 82.2, 83.9 & 85.7%, respectively ($p<0.0001$). After adjusting for age, CS, comorbidities, rural residence, use of adjuvant chemo, T-mab, RT and surgery type, higher SES remained associated with better OS ($p=0.0017$). **Conclusions:** Higher SES is associated with more use of screening and treatments, and better OS in BC pts in a universal health care system.

**6626 General Poster Session (Board #89), Mon, 1:15 PM-5:00 PM**

**Practice of venous thromboembolism (VTE) prophylaxis in hospitalized cancer patients at a comprehensive cancer center.** *Presenting Author: Maria Alma Rodriguez, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background**: VTE prophylaxis measures are endorsed by the National Quality Forum in alignment with quality indicators from the Centers for Medicare and Medicaid Services. Accordingly, documentation of VTE risk, prophylaxis measures, and contraindications are recommended for hospitalized patients. To standardize practice we embedded a VTE risk assessment and prophylaxis module into admission and post-surgical order sets (OS), starting August 15, 2011. **Methods**: A retrospective study of 9,065 cancer patients (≥18 years) admitted to The University of Texas MD Anderson Cancer Center between June 01, 2013, through September 30, 2013**.** Pharmacological prophylaxis was executed with low-molecular-weight heparin or unfractionated heparin. Mechanical prophylaxis was executed with graduated compression stockings and/or sequential compression devices. *Chi*-square testing was used to determine the association between categorical variables. **Results**: 7,366 (81%) of all hospital admissions had documented VTE risk assessment and prophylaxis through the standardized VTE module. Before implementation of the new OS, only 40% of eligible patients received an order for VTE prophylaxis**.** The majority of patients were designated high or moderate risk (91.1%). Patients with high risk were more likely to receive pharmacological prophylaxis than those with moderate risk (74.1% vs. 38.2%, $P<0.01$). The most frequent contraindications to pharmacological prophylaxis were major surgery with risk of bleeding and thrombocytopenia. Results are shown in Table. **Conclusions**: Most patients received VTE prophylaxis based on VTE risk levels presented in a standardized OS. Because there is limited information in the clinical literature about the impact of VTE prophylaxis on outcomes among cancer patients, we plan to monitor and analyze anticoagulation-related outcomes as well as mortality and morbidity related to thrombosis and bleeding in this cohort of patients.

**VTE risk assessment and prophylaxis (n=7,366).**

| | | % of prophylaxis | | |
|---|---|---|---|---|
| VTE risk level | No (%) | Pharmacological | Pharmacological contraindication | Mechanical |
| High | 1,021 (13.9%) | 74.1 | 20.1 | 99.7 |
| Moderate | 5,689 (77.2%) | 38.2 | 56.3 | 35.4 |
| Low | 656 ( 8.9%) | N/A | N/A | 97.6 |

**6627 General Poster Session (Board #90), Mon, 1:15 PM-5:00 PM**

**An electronic prompt prior to myelosuppressive therapy to improve hepatitis B virus screening.** *Presenting Author: Jordan J. Feld, University Health Network, University of Toronto, Toronto, ON, Canada*

**Background:** Hepatitis B virus (HBV) reactivation is a potentially fatal and yet preventable complication of myelosuppressive therapy. However, HBV screening rates have been low despite the recommendation from the Centre of Disease Control (CDC) to screen all patients prior to myelosuppressive therapy. We evaluated the effectiveness of an electronic prompt on HBV screening rates. **Methods:** An electronic prompt was established in Nov 2010 at a large academic oncology centre in Toronto (study centre). The electronic prompt reminded ordering physicians to order HBV surface antigen (HBsAg) at the time of booking a new patient's first chemotherapy electronically. For physicians who agreed, HBsAg was automatically ordered. The prompt was not implemented at another large academic oncology centre in Toronto (control centre). Both centres received the same educational rounds in Nov 2010. The primary endpoint was the rate of HBV screening. Actual HBV screening rates were determined in both centres both prior to the intervention (Nov 2009 to Oct 2010) and during the intervention (Nov 2010 to Oct 2011). Multivariable logistic regression with random effects was conducted to assess the effect of the electronic prompt adjusting for potential confounders and clustering of patients by physicians. **Results:** 6,116 patients received first chemotherapy during the study period (2,095 study centre, 4,021 control center). In the pre-prompt period, the screening rate was 17% in the study centre and 25% in the control centre. In the prompt period, the screening rate increased to 61% in the study centre and was unchanged at 25% in the control centre. The overall screening rate for patients with hematological (heme) malignancies was higher (62.3% vs. 20.4% in non-heme patients, $p<0.0001$). After adjusting for study period, centres and heme malignancies, the electronic prompt improved the HBV screening rate significantly (odds ratio 11.0, 95% CI 8.3-14.7, $p<0.0001$), which remained significant adjusting for clustering of patients by physicians ($p<0.0001$). **Conclusions:** An electronic prompt increased the rate of HBV screening, however screening rates remained relatively low. Educational rounds did not appear to improve the HBV screening rate.

**6628 General Poster Session (Board #91), Mon, 1:15 PM-5:00 PM**

**Coordinating cancer care: What organizations do to deliver high-quality breast cancer care.** *Presenting Author: Nina A. Bickell, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** Hospitals are reorganizing how they coordinate care. Little is known about how cancer care is effectively coordinated particularly for patients at high risk of underuse. **Methods:** We interviewed 75 key informants (48 clinical; 14 administrative; 11 clerical; 2 other) from 9 inner-city safety net hospitals with a high proportion of minority breast cancer patients. We used fuzzy set Qualitative Comparative Analysis focusing on defined coordination approaches, calibrating each approach between 0 and 1 based on sites' coordination processes and assessed their relationship to adjuvant underuse. **Results:** Five organizational factors appear salient to coordinating adjuvant breast cancer care: 1) better performing sites had someone designated to track and re-contact *no-shows*; 2) *handoffs* include exchange of clinical information (drs speaking directly to drs) as well as clerical transfer of responsibility (clerks scheduling appointments); 3) *organizational attention to clinic patients:* some sites separated private & clinic patients tolerating hectic, understaffed clinics; 4) all high quality sites had *integrated Electronic Medical Records* - doctors could see patients' tests and treatments across specialties; 5) organizations with a *culture of patient-centeredness* worked for their patients, not vice-versa. **Conclusions:** Organizational factors can affect care coordination & cancer care quality. Higher quality sites had a fully integrated EMR, were better at tracking no shows, managing handoffs, paying attention to clinic patients & fostering a patient-centered culture. As care coordination across sites and specialties is encouraged by federal law and regulation, specialty care silos and rigid communication systems still pose barriers to change. Improving organizational factors may increase appropriate delivery of adjuvant breast cancer therapies, particularly for vulnerable women.

**6629 General Poster Session (Board #92), Mon, 1:15 PM-5:00 PM**

**An international survey of health care providers involved in the management of cancer patients exposed to cardiotoxic therapies.** *Presenting Author: Susan Faye Dent, The Ottawa Hospital Cancer Center, University of Ottawa, Ottawa, ON, Canada*

**Background:** Targeted agents used in cancer therapy may negatively impact cardiovascular health. There is increasing interest by health care providers (HCPs) in developing multidisciplinary approaches to manage these patients (pts). The objective of this international survey was to gain better understanding of current knowledge and practice patterns among HCPs involved in the management of cancer pts exposed to potentially cardiotoxic drugs. **Methods:** HCPs involved in the management of cardiac disease in cancer pts were surveyed using email lists from the Canadian Association of Medical Oncologists, Canadian Cardiovascular Society, Canadian Cardiac Oncology Network and International CardiOncology Society. The survey consisted of 14 questions related to cancer treatment-induced cardiotoxicity. Canadian HCP's were asked to comment on treatment strategies for 3 case scenarios. Descriptive data was collected and summarized. **Results:** 393 survey responses were received (response rate of 25%). The majority of respondents were cardiologists (47%, 185/393), or medical oncologists (40%, 158/393). 55% of respondents were in academic practice (212/383). The majority agreed that cardiac issues are important to cancer pts (97%, 381/393); 94% felt that the diagnosis of cardiac disease had an impact on cancer prognosis (349/383), and 77% agreed that chemotherapy or radiation is an important risk factor for cardiac disease (301/393). Only 36% of respondents felt there is an accepted definition of cardiotoxicity (109/383). 78% of respondents felt cardiac medications are protective during active cancer treatment (307/393), however only 51% would consider prescribing these medications upfront in cancer pts (199/393). While the majority of Canadian HCP's ($n=77$) agreed on pt care strategies, there was marked discrepancy in the cardiac management of metastatic breast cancer pts with asymptomatic heart failure. **Conclusions:** There is a high level of concern for cardiac safety among HCP's regarding active cancer therapy for pts; however, there is a lack of consensus on the definition of cardiotoxicity and uncertainty remains for optimal management in this new field of cancer care.

**6630 General Poster Session (Board #93), Mon, 1:15 PM-5:00 PM**

**Combining survival and toxicity effect sizes from clinical trials into an interpretable, quality-adjusted survival effect size estimate of treatment efficacy.** *Presenting Author: Jeff A. Sloan, Mayo Clinic, Rochester, MN*

**Background:** How can a clinician combine survival and toxicity data to interpet treatment benefit? Quality adjusted life years (QALYs) attempts to account for both the quality and quantity of life lived but interpretation and power considerations are barriers to implementation. We developed a new method by extending the ½ standard deviation approach to assessing clinical significance to combine survival and toxicity clinical trial data into a single quality-adjusted survival effect size (QASES). **Methods:** QASES is a weighted combination of the survival and toxicity effect sizes based on differences in survival and toxicity using the ½ standard deviation method. We demonstrate the QASES method on 20 exemplary oncology clinical trials involving brain, breast, colorectal, lung, melanoma and pancreatic tumors. One example is a phase III clinical trial carried out by the North Central Cancer Treatment Group, NCCTG 89-20-52 (Alliance), which randomized patients to once-daily thoracic radiotherapy (ODTRT) versus twice-daily treatment of thoracic radiotherapy (TDRT) for the treatment of lung cancer. **Results:** The ODTRT (TDRT) arms had non-significantly different median survival times of 22 (20) months.($p=0.49$) but strikingly different toxicity rates of 39% (54%), ($p<.05$). The combined QASES of 0.18 standard deviations is equivalent to a significant 5.7 months advantage in quality-adjusted survival for the ODRT arm over the TDRT treatment arm (22 (16.3) months, $p<0.05$). Similar results will be presented for the four possible case combinations of significant/non-significant differences in survival and toxicity data using 20 completed clinical trials including the CLEOPATRA and FLAGS trials. **Conclusions:** The QASES approach allows for an intuitively appealing and mathematically simple and robust approach to combining survival and toxicity data. Clinicians can use QASES to interpret and communicate the findings of oncology clinical trials to patients by weighing both the survival and toxicity information into a single quality-adjusted estimate of survival.

**6631 General Poster Session (Board #94), Mon, 1:15 PM-5:00 PM**

**Abnormal screening mammogram follow-up: Improving time and timeliness benchmarks.** *Presenting Author: Seyed S. Pairawan, Loma Linda University School of Medicine, Loma Linda, CA*

**Background:** Abnormal screening mammograms cause significant patient distress. Current benchmarks for timeliness of care for additional imaging after abnormal screening assess the time interval from screening to initial follow-up imaging. We sought to investigate the overall length of time required for imaging resolution after abnormal screening mammogram. **Methods:** We performed a retrospective review of women undergoing screening mammograms during a two month period at a tertiary-care institution. The main outcome measure was calendar days (d) between dates of screening mammogram and imaging resolution (final additional imaging or percutaneous biopsy). **Results:** From 1,133 sequential screening mammograms, 237 (20.9%) patients required at least one recall study. Median patient age was 55 years (28-92). Of patients requiring call back exams, 68.7% required only one recall; however, 23.6% required two; 6.3% required three; 0.8 % required four; and 0.04% required five. The overall median time for resolution of abnormal screening mammogram was 22 d (range 0-405). The time for resolution was significantly longer for women with a prior history of breast cancer than those without (35.5 d vs. 21 d, p=0.04), and in women with mass lesions compared to those with calcifications or a focal asymmetry (34 d vs. 22 d and 20 d, respectively, p=0.01). Time to resolution for patients requiring one recall was 14 d, two recalls was 42.5 d, three recalls was 49 d, four recalls was 68 d, and five recalls was 203 d (p<0.0001). There was no significant difference in time to resolution of abnormal screening mammogram based on patient age, race/ethnicity, BMI, insurance type, breast density, or individual radiologist. **Conclusions:** While most patients with abnormal mammograms had a single call back and resolution of imaging findings within two weeks of screening, a significant proportion of women required more prolonged imaging follow up. Patients with a history of breast cancer and those who present with mass lesions should be targeted for quality improvement. Benchmarks evaluating the overall time required for resolution of imaging findings may better represent the patient experience.

**6632 General Poster Session (Board #95), Mon, 1:15 PM-5:00 PM**

**Defining quality and value in a prospective study of an emergency department (ED) febrile neutropenia pathway (FNP).** *Presenting Author: Michael Kenneth Keng, Leukemia Program, Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH*

**Background:** Febrile neutropenia (FN) is an oncologic emergency and delays in antibiotic (ABX) administration lead to worse outcomes. We instituted a FNP in the Cleveland Clinic (CC) ED to reduce ABX delays. **Methods:** This is a prospective study comparing ED FNP patients (pts) (06/12-06/13) to historical (H) pts (02/10-05/12) and direct admit (DA) FN pts (06/12-06/13). Interventions included: providing pts with FN ID cards, recognizing FN as a distinct chief complaint, revising ED triage level for FN, creating ED-specific electronic FN order sets, administering ABX prior to return of neutrophil count, and relocating all FN ABX to ED automated drug dispensing machines. The primary goal of the FNP was empiric broad-spectrum ABX administration within 90 minutes of ED presentation. Group comparisons were made using the chi-square and Kruskal-Wallis tests, as appropriate. **Results:** In total, 276 consecutive FN episodes in 217 FNP pts occurred during the 12 month study period, 107 episodes in 87 pts and 114 episodes in 101 pts in the H and DA cohort respectively. All ED FN pts were triaged and treated using the ED FNP, but use of the specific FN order set was variable: episodes were classified as treated per order set (n=103) or not (n=173). In addition to hospital stay, the ED FNP improved all identifiable metrics (all p <.0005), depicted in Table 1. Other factors increasing hospital stay were primary hematologic malignancy and degree of neutropenia (p <.05). **Conclusions:** The CC ED FNP is a significant quality initiative, and was able to demonstrate value by decreasing time to ABX administration and length of hospital stay compared to both H and DA controls in cancer pts presenting to the ED with fever. ICU admission rate and ICU length of stay were also decreased. Usage of the ED FNP FN order set further improved these metrics.

| | ED FNP | | | H | DA | p value |

**6633 General Poster Session (Board #96), Mon, 1:15 PM-5:00 PM**

**Risk of hematologic malignancies following radiation treatment for well-differentiated thyroid cancer in the United States over 37 years.** *Presenting Author: Surbhi Sidana, Department of Internal Medicine, Cleveland Clinic Foundation, Cleveland, OH*

**Background:** Radiation therapy (XRT) including radioisotopes (RI), radioactive implants (RAI) and external beam radiation (EBRT) are commonly used for treatment of well differentiated thyroid malignancies (WDTMs) – papillary and follicular. We investigated the risk of all secondary hematologic malignancies (SHMs) in a population-based cohort of patients (pts) with WDTMs treated with XRT. **Methods:** Surveillance, Epidemiology, and End Results (SEER) 17 registries were queried to identify a cohort of 52,121 adult pts with WDTM as the first primary cancer between 1/1973 and 12/2010 who had adequate follow up. To determine the risk of development of SHM at least one year after the diagnosis of WDTM, pts who received XRT were compared to those who did not. SHMs included leukemias, lymphomas and Multiple Myeloma (MM). Fine and Gray competing risk regression analysis was performed with SHM as a time-dependent endpoint and death from any cause, development of non-hematologic malignancy as the competing events. Hazard ratios (HR) with 95% confidence intervals (CIs) are reported. **Results:** The median age at WDTM diagnosis was 45 (range 18 - 100) years (yrs); most pts were Caucasian (82.4%); female (77%). 45% of patients were treated with XRT; of them 85% received RI or RAI, 4.9% received EBRT, 16.9% both and in 9.3% details were not specified. In total, 371 pts developed SHM after a median interval of 7.6 yrs (range 1- 37.2) from WDTM diagnosis: 178 pts developed lymphoma [Non-Hodgkin's Lymphoma (n=163); Hodgkin's Disease (n=15)]; 124 pts developed leukemia [Acute Myeloid Leukemia (n=44); Chronic Lymphocytic Leukemia (n=34); Chronic Myeloid Leukemia (n=23)] and 68 developed MM. In multivariate analysis, XRT was associated with an increased risk of developing SHM vs. no XRT (HR=1.27; CI, 1.01 – 1.60, p=0.038). Among the XRT modalities, RAI or RI were associated with 32% increased risk (HR=1.32; CI, 1.02 – 1.71, p=0.037) vs. no XRT. Age (HR=1.39, p<0.0001), male gender (HR=1.39, p=0.004) and papillary histology (HR=1.43, p=0.044) were additional risk factors. **Conclusions:** XRT increases the risk for developing SHM by 27% in pts with WDTM, which is mainly attributable to 32% increased risk with RAI/RI.

**6634 General Poster Session (Board #97), Mon, 1:15 PM-5:00 PM**

**Implementation of a written chemotherapy consent form with explicit goals of treatment in a university center.** *Presenting Author: Brendan F. Curley, Mary Babb Randolph Cancer Center at West Virginia University, Morgantown, WV*

**Background:** The American Society of Clinical Oncology (ASCO) has stated that consent to treatment with chemotherapy is an important part of the delivery of quality cancer care. Best practices dictate that consent conversations should be well documented in the patient record. Discussion of goals of treatment can be difficult for physicians and patients, however research has shown that patients often mistakenly believe that therapy with palliative intent is in fact curative. The implementation of a written consent form with goals of care in an academic practice has not been studied. **Methods:** As part of the inaugural ASCO Quality Training Program, a quality improvement project that focuses on the implementation of a written chemotherapy consent with incorporated goals of treatment was designed and implemented. Chemotherapy consent documentation and goals of therapy were retrospectively collected on all patients receiving a new line of chemotherapy. The written chemotherapy consent form was implemented on July 1, 2013; patient data was collected for the duration of 2013, and divided into pre and post intervention data. Patients on clinical trials were excluded from analysis, as written consent is required on protocol. **Results:** Data was collected from 546 patients, with 224 in the pre-intervention group and 322 in the post-intervention group. Documentation of chemotherapy consent decreased from 63% to 52% (p =0.011) when written consent was required. However, documentation of goals of care improved dramatically with 95% of patients having explicit goals of care documented with written chemotherapy consent, compared to 48% of those that consented orally (p<0.0001). **Conclusions:** Implementation of written consent that is reviewed and signed by the patient may initially reduce compliance with the consent process when compared to documenting an oral consent in the patient's chart. However, written consent appears to drastically improve documentation of treatment goals.

**6635 General Poster Session (Board #98), Mon, 1:15 PM-5:00 PM**

**Impact of pretreatment variables on overall survival of patients with stage IV NSCLC: An analysis of the Veterans Affairs Central Cancer Registry.** *Presenting Author: Danielle M. File, Medical College of Wisconsin, Milwaukee, WI*

**Background:** The aim of this study was to utilize a large database of patients treated in the VA to identify prognostic factors that influence survival in patients with stage IV NSCLC. **Methods:** Patients diagnosed with stage IV NSCLC from 2001 to 2008 who received chemotherapy within 4 months of diagnosis were identified using the VA Central Cancer Registry. We augmented the VACCR database with data regarding clinical variables, comorbid conditions and vital signs from several VA databases. The 2009 Area Resource File was used to identify area level surrogates for socioeconomic status. Multivariate analysis was performed using a standard Cox proportional hazard model with a stepwise selection procedure with a p value of 0.25 to enter the model and a p value of 0.10 to remain in the model. **Results:** We identified 20,172 individuals with metastatic NSCLC during the study time period; 4,352 patients met our inclusion criteria. The median overall survival (OS) was 8.1 months with 32% alive at one year and 11% alive at two years, which mirrors what was found in the landmark ECOG 1594 study. In a multivariate analysis prior hospitalizations (HR 1.09, 95% CI 1.05-1.13), a higher percentage of weight loss (HR 1.02, 95% CI 1.02-1.03), chronic kidney disease (HR 1.14, 95% CI 1.03-1.59), baseline anemia (HR 1.21, 95% CI 1.11-1.32), thrombocytopenia (HR 1.49, 95% CI 1.05-2.11) and hypoalbuminemia (HR 1.46, 95% CI 1.34-1.59) were all independently associated with decreased survival. The OS for stage IV NSCLC in patients with pretreatment Hgb $<$12g/dl was 6.5 versus 9.2 months in patients with Hgb $>$12g/dl. A pretreatment albumin of $<$3.5g/dl was associated with a 6 month OS compared to a 10.2 months if albumin was $>$3.5g/dl. The OS of patients with a GFR $<$60ml/hr was 7.7 versus 8.0 months in those with a GFR $>$60ml/hr. Presence of a platelet count of $<$100,000 was associated with a OS of 3.7 months compared to 8.0 months in those with a higher platelet count. **Conclusions:** The outcomes of patients treated with a platinum doublet within the VA system mirror those reported in clinical trials. Several pretreatment factors present at the time of initial treatment can be used to determine prognosis in patients with NSCLC.

**6636 General Poster Session (Board #99), Mon, 1:15 PM-5:00 PM**

**Outcomes of in-hospital cardiopulmonary resuscitation in patients with metastatic cancer.** *Presenting Author: Touqir Zahra, Massachusetts General Hospital, Boston, MA*

**Background:** Patients with metastatic cancer are increasingly availing the use of palliative care services. However, most of them also enroll in clinical trials of novel chemotherapeutic agents. The occurrence of an episode of cardiopulmonary resuscitation (CPR) while these patients are hospitalized may significantly affect their performance status and subsequent treatment. The data with regards to outcome of CPR in patients with metastatic disease is very limited. **Methods:** Using the Healthcare Cost and Utilization Project – California State Inpatient database 2005-2011, patients undergoing in hospital CPR were identified using appropriate ICD-9-CM. Chi square test and Wilcoxon rank test were used to compare discrete and continuous variables respectively. Significance was defined as p value set at $<$0.05. Bonferroni's correction was applied for multiple comparisons. **Results:** There were 110,581 patients who underwent CPR from 2005 to 2011. Of these 5828 (5.3%) had metastatic cancer. After adjusting for age, the odds of mortality were 3.64 times higher (95% confidence interval 1.99-6.67) when compared to those without any cancer. Age was not associated with better outcomes in those with metastatic cancer undergoing CPR. The outcomes of patients who underwent CPR are shown below (see Table). **Conclusions:** The resource utilization in patients who underwent CPR is similar regardless of metastatic disease. The mortality however, is significantly higher in those with metastatic disease. Patients with metastatic cancer may benefit from early palliative care services if they undergo CPR and their functional status significantly deteriorates during hospitalization.

**6637 General Poster Session (Board #100), Mon, 1:15 PM-5:00 PM**

**Enhancing pathway adherence in a quality initiative for breast cancer.** *Presenting Author: Johnathan M. Lancaster, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Clinical pathways are associated with improved outcomes and reduced health care costs. However, physician adherence to clinical pathways remains a challenge for cancer centers across the country. Moffitt Cancer Center (MCC) has developed and implemented clinical pathways across disease-focused programs. We performed a series of measurements of adherence to evidence-based clinical pathways, which included subsequent educational feedback on performance. **Methods:** Using Clinical Performance and Value (CPV®) vignettes, a validated *in silico*simulation measurement tool, we evaluated breast cancer clinical pathway adherence every 4 months. 18 providers completed two BC cases each at months 1, 5 and 9. For each case completed, an overall CPV score was generated with scores calculated as a percentage of the items that the physician correctly completed against all necessary elements of care for that case. Clinicians then received confidential individualized feedback for each case, with quantitative feedback benchmarked to their peers and qualitative individual feedback with suggestions on how they could improve pathway adherence. **Results:** At baseline, measurement revealed wide variance levels of adherence to pathways across the clinician cohort. With serial measurement and feedback, mean CPV scores increased significantly from 55.4% at round 1 to 68.8% at round 3 (p $<$0.01). Particular categories of pathway compliance also improved after the three rounds. Chemotherapy pathway compliance increased from 40% to 65%; appropriate diagnostic work up from 31 to 93% and surgery pathway compliance from 69% to 86%. **Conclusions:** We found that adherence to clinical pathways can be improved with a serial measurement and feedback tool. Future studies will link these changes to utilization and costs. Consistent feedback at the individual and group level engages and aligns providers around pathways and common practice standards.

**Breast pathway adherence improvement over time, by treatment category.**

| **Hormonal** | 79% | 64% | 100% |

**TPS6638 General Poster Session (Board #101A), Mon, 1:15 PM-5:00 PM**

**Simone-simulation in medical oncology education: Part I—Pilot feasibility study.** *Presenting Author: Shelly Sud, Division of Medical Oncology, The Ottawa Hospital Cancer Centre, Department of Medicine, University of Ottawa, Ottawa, ON, Canada*

**Background:** Advances in medical oncology therapeutics have led to increasingly challenging cancer scenarios (CCS), including an expanding spectrum of treatment side effects and chronic cancer complications. There is no defined curriculum addressing CCS management. Simulation based training with debriefing (SBTD) is an educational method utilizing a virtual medium to mimic clinical scenarios. We hypothesize that SBTD, as an educational tool, is better than traditional didactic teaching of CCS management. This unique study tests the feasibility of high-fidelity SBTD in medical oncology education. We eventually aim to develop a national standardized oncology SBTD curriculum to train oncologists in CCS management **Methods:** With ethics approval, a curriculum highlighting CCS topics was created. Three clinical scenarios were developed and programmed using the high-fidelity SimMan mannequin. Scenarios last 10 minutes, and participants' decisions determine the course of the scenario. Participants are recruited from medical oncology and internal medicine. After receiving the curriculum, participant demographics are collected and they are randomized 1:1 to intervention Arm A or B. Both arms perform three simulation scenarios. After scenario #1, all participants take a quiz testing CCS-relevant knowledge. Then, Arm A receives an expert-facilitated debriefing; Arm B receives a didactic lecture covering CCS management. The next day all participants perform simulation and quiz #2, with simulation and quiz #3 planned for 8 weeks later. Each simulation is videotaped for two independent reviewers to grade performance using the validated Ottawa Crisis Resource Management Global Rating Scale. Beyond feasibility, outcomes include change in performance and quiz scores, and participants' satisfaction with educational method as assessed by questionnaire after simulation #2-3. Differences between the three simulation scores in both arms will be calculated, and assessed using independent t-test. At this time, eleven participants have been enrolled and all participants have completed two simulations. Data will be analyzed after the third simulation.

**TPS6639 General Poster Session (Board #101B), Mon, 1:15 PM-5:00 PM**

**Prospective survey on patient satisfaction and quality-of-life impact concerning the administration of fentanyl pectin nasal spray for breakthrough pain in cancer: Qualipec study.** *Presenting Author: Ignacio Delgado, Hospital Infanta Cristina, Badajoz, Spain*

**Background:** Previous clinical trials have confirmed the efficacy and safety of fentanyl pectin nasal spray (PFNS), as a rapid analgesic agent in cases of Breakthrough pain in cancer (BTPc), characterized by intermittent episodes of intense pain of limited duration. Here we present two QUALIPEC studies aimed to assess patient satisfaction after early administration and dose titration of PFNS for BTPc. The surveys intend to describe patients' quality of life improvement along the four week observational period and the effects of PFNS treatment on their everyday activities. Concurrently, they expect to analyze the clinicians' therapeutic management in real practice. **Methods:** These are two multicenter, open-label, prospective, observational studies conducted in different hospitals in France and Spain. The current numbers of enrolled patients are 253 and 42 patients, for France and Spain, respectively. Major eligibility criteria were patients over 18 that were taking at least 60 mg/day morphine (or equivalent) for chronic background pain in cancer. The BTPc diagnosis was evaluated through patient medical interrogation and/or visual analog scale (VAS). Patients started PFNS treatment during the inclusion visit. The first criterion for prescribing PFNS treatment was the BTPc intensity, associated with the daily number and/or duration of the episodes. Patients initially entered a dose-titration training phase which was primarily done during the first treatment prescription and evaluated during the following medical consultation. The primary objective was the measurement of early treatment satisfaction after PFNS titration. Also additional quality of life criteria were evaluated and the effect on daily activities. Clinical trial information: NCT01693328 (France) and NCT01698645 (Spain).

**7002 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Randomized multicenter phase II trial of timed-sequential therapy with flavopiridol (alvocidib), cytarabine, and mitoxantrone (FLAM) versus "7+3" for adults with newly diagnosed acute myeloid leukemia (AML).** *Presenting Author: Joshua F. Zeidner, The Johns Hopkins Hospital and The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background**: Serial studies have demonstrated that induction therapy with flavopiridol (50 mg/m$^2$ days 1-3), a multi-serine-threonine cyclin-dependent kinase inhibitor, followed by cytarabine (667 mg/m$^2$/days 6-8) and mitoxantrone (40 mg/m$^2$ day 9) yields complete remission (CR) rates of nearly 70% in pts with newly diagnosed, poor-risk AML. This trial compares "FLAM" with 7+3 in newly diagnosed AML pts. **Methods**: Between May 2011-July 2013, 165 (FLAM, n=109; 7+3, n=56) newly diagnosed AML pts (18-70 years) with non-favorable cytogenetics were randomized 2:1 to receive FLAM or 7+3 (cytarabine 100 mg/m$^2$/day, daunorubicin 90 mg/m$^2$) across 10 institutions. Randomization was stratified by age, secondary AML and leukocyte count. Pts with residual leukemia on day 14 received 5+2 on the 7+3 arm, whereas pts treated with FLAM were not retreated on day 14. The primary endpoint was to compare CR rates between 1 cycle of FLAM and 1 cycle of 7+3. Secondary endpoints were safety, CR rates after 1 cycle of FLAM vs 7+3 + 5+2, overall survival (OS), and disease-free survival (DFS). **Results**: The majority of pts on both arms had at least 1 poor-risk feature, excluding age (FLAM=77%, 7+3=68%). FLAM resulted in higher CR rates compared to 7+3 (70% vs 46%, p=0.003), though this difference was less when compared to 7+3 + 5+2 (70% vs 57%, p=0.08). FLAM also produced higher CR rates in pts with secondary AML (60% vs 35%, p=0.05), pts with >1 poor-risk feature (61% vs 34%, p=0.01), pts without poor-risk features (100% vs 72%, p=0.009), and pts <60 years (79% vs 52%, p=0.02). Relapse rates as of this analysis were similar (FLAM: 36% vs 7+3: 38%). Toxicities were similar between both arms, including grade >3 toxicities, early treatment-related mortality, and time to count recovery. **Conclusions**: FLAM induction results in significantly higher CR rates compared with 7+3 without increased toxicity. FLAM appears to be more active than 7+3 in pts <60 years of age and those with poor-risk features. Although follow-up is too early to assess OS and DFS, these results are promising and a phase 3 comparison of FLAM vs 7+3 is being explored. Clinical trial information: NCT01349972.

**7003 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Efficacy of HSV-TK$^+$ suicide gene donor lymphocytes after haploidentical transplantation (haplo-HSCT): Preliminary results of randomized TK008 study.** *Presenting Author: Fabio Ciceri, Hematology and BMT Unit, Department of Onco-Hematology, San Raffaele Hospital, Milan, Italy*

**Background:** Haploidentical family donors represent the ideal solution to offer for every patient with high risk leukemia the potential cure of hematopoietic stem cell transplantation. Extensive application of haplo-HSCT is limited by high rate of late transplant related mortality (TRM) and relapse associated with the inadequate immune reconstitution (IR) due to ex vivo T cell depletion or in vivo post-transplant cyclophosphamide administration for severe graft-vs-host disease (GvHD) prevention. **Methods:** In a haplo-HSCT phase III trial (TK008, NCT00914628), we infuse donor lymphocytes genetically engineered to express the suicide gene herpes simplex thymidine kinase (TK cells) to induce early IR after a T cell depleted graft. Key inclusion criteria are acute leukemia at high risk in patients lacking an HLA-matched donor. Control arms include T cell depleted or post HSCT cyclophosphamide haplo-HSCT. We enrolled 25 patients in 8 centres in Europe and US; 17 were assigned to experimental arm, 15/17 were in complete remission at HSCT. Hypothesis testing: 1-year disease free survival (DFS) 30% (control) vs 52% (TK arm). **Results:** Results are presented only for patients enrolled in the experimental arm at November 2013 last follow-up. TK cells were given to 13 patients; IR was obtained in 9/13 patients after a median of 2 TK cell monthly infusions; median time from last infusion to IR (CD3$^+$>100/$\mu$L) was 28 days (95% CI 24-41). Six pts developed GvHD (2 grade I, 2 grade II and 2 grade III) that was always abrogated by suicide gene induction; no progression from acute to chronic GvHD and no GvHD-related death occurred. IR obtained with TK cell infusion correlated with rapid development of a wide T cell repertoire and detection of high frequencies of T-cells specific for opportunistic pathogens. At a median follow-up of 473 days, by ITT analysis, 1-year overall survival is 89% (+ 10), DFS and immunosuppression-free survival is 80% (+ 10), 1-year TRM is 11% and relapse incidence is 8%. **Conclusions:** Preliminary results of this ongoing phase III trial confirm safety and potential benefit in improving survival of the T-cell gene transfer technology integrated with T cell depleted haplo-HSCT. Clinical trial information: NCT00914628.

**7004 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Haplo+cord transplantation: Neutrophil and platelet recovery and long-term survival compared to double umbilical cord blood (UCB) transplantation—A case-cohort analysis.** *Presenting Author: Koen Van Besien, Weill Cornell Medical College, New York, NY*

**Background:** Double UCB (dUCB) SCT can result in long-term survival and low rates of chronic GVHD. Limitations are delayed engraftment and early TRM. We previously reported that co-infusion of CD34-selected SCT from a haplo-identical relative, with a single UCB graft (haplo+cord ) results in rapid count recovery and durable engraftment from the UCB graft. In the current study we compared the outcomes of haplo+cord to dUCB transplantation. **Methods:** As of October 2013, 99 pts have been treated with haplo+cord at two institutions. Their outcomes were compared with those of 737 adults undergoing dUCB during the same period and reported to CIBMTR. Haplo-cord pts were older, more of minority descent, and had higher risk disease. Haplo+cord cases were matched to 4 dUCB controls based on age, gender, race, disease type, disease stage pre-transplant, KPS and year of transplant. The final control group had 344 pts. Despite matching, a higher percentage of haplo+cord pts had high-risk disease, (44% vs 34%, p=0.06). **Results:** In multivariate analysis, engraftment of neutrophils and platelets was faster after haplo+cord than after dUCB SCT. By day 30, 91% of haplo-cord pts had neutrophil recovery (median 12 d) and 53% had platelet recovery (median 24 d) vs 72% (median 21 d) and 6% (median 45 d) of dUCB respectively (P<0.0001). Haplo+cord survival was superior at all time points (Table). At 4 years, 43% of haplo+cord pts were alive vs 21% of dUCB (p=0.0053). **Conclusions:** Haplo+cord results in much faster engraftment than dUCB transplantation. The trend toward improved survival, that becomes more significant with prolonged follow up, justifies further prospective studies.

**7005^ Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Confirmatory open-label, single-arm, multicenter phase 2 study of the BiTE antibody blinatumomab in patients (pts) with relapsed/refractory B-precursor acute lymphoblastic leukemia (r/r ALL).** *Presenting Author: Max S. Topp, Medizinische Klinik und Poliklinik II, Universitätsklinikum Würzburg, Würzburg, Germany*

**Background:** Blinatumomab, an investigational bispecific T-cell engaging (BiTE) antibody that directs cytotoxic T-cells to CD19-expressing target cells, has shown antileukemia activity in an exploratory study in adult r/r B-precursor ALL. We evaluated blinatumomab efficacy and toxicity in a large confirmatory phase 2 study. **Methods:** Pts (≥18 yrs) with Ph-negative r/r ALL (refractory; 1$^{st}$ relapse <12 mo; relapse post HSCT <12 mo; ≥2$^{nd}$salvage) were eligible. Blinatumomab was given by continuous IV infusion (4 wks on/2 wks off) for up to 5 cycles (cycle 1 only: 9 $\mu$g/d days 1-7; then 28 $\mu$g/d). The primary endpoint was complete remission (CR) or CR with partial hematological recovery (CRh*) within the first 2 cycles. **Results:** 189 pts were enrolled and received blinatumomab for a median (range) of 2 (1–5) cycles. Median age was 39 (18–79) yrs. As of Jan 2014 (primary analysis in Feb 2014), 43% of pts achieved CR/CRh*; 80% of responses occurred within cycle 1. CRs/CRh* were seen in all subgroups (Table). Regardless of causality, the most frequent adverse events (AEs) were pyrexia (59%), headache (35%) and febrile neutropenia (29%). The most frequent gr ≥3 AEs were febrile neutropenia (26%), anemia (15%) and neutropenia (15%); 2% had gr ≥3 cytokine release syndrome. The most common gr ≥3 nervous system disorders were headache (4%), encephalopathy (3%) and ataxia (2%). 3 (2%) pts had gr 5 AEs considered treatment-related (sepsis, n=2; candida infection, n=1). **Conclusions:** This large phase 2 study confirmed the antileukemia activity of single-agent blinatumomab in a difficult-to-treat population with r/r ALL. Clinical trial information: NCT01466179.

**7007 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Phase 2 trial of GS-9973, a selective Syk inhibitor, in chronic lymphocytic leukemia (CLL).** *Presenting Author: Jeff Porter Sharman, Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, OR*

**Background:** Spleen tyrosine kinase (Syk) is a mediator of B-cell receptor signaling in normal and transformed B-cells. GS-9973 is an orally bioavailable, selective inhibitor of Syk (Kd 7.6 nM, no other kinase $<$ 100 nM). **Methods:** This Phase 2 trial enrolled 44 subjects with CLL treated with GS-9973 800 mg BID. Tumor imaging occurred at weeks 8, 16, 24 and then every 12. Response was independently evaluated according to Hallek 2008 as modified by Cheson 2012. GS-9973 plasma levels were obtained concurrently with plasma chemo/cytokine levels and phospho flow analysis of circulating leukemic cells. **Results:** 27 subjects are still on treatment (Rx) for a median of 22 weeks. Median age was 73 (range 51 - 89), 66% were male. The median number of prior Rx regimens was 3 (range 1-8). Prior Rxs included anti-CD20 antibodies (95%), alkylating agents (86%; bendamustine 64%) and fludarabine (68%); 9 subjects had 17p deletions/TP53 mutations and 17 had other poor prognosis mutations/deletions. Results: 41 subjects were treated for at least 8 weeks and had $\geq$ 1 efficacy assessment. Per investigator, 40 (91%) subjects experienced reduced tumor bulk; 28 (64%) achieved a decrease of $\geq$ 50%. Results of the independent response assessments are pending and will be presented. GS-9973 was generally well tolerated. Rx emergent adverse events occurring in $\geq$ 10% of subjects are listed in the Table. Reversible Grade 3 or 4 ALT/AST elevations occurred in 2 (4.5%) subjects. 2 subjects died while on study: 1 from progressive disease, 1 from sepsis. The mean absolute lymphocyte count increased from 46,410 to 68,850/uL by day 8 and then declined; in 38 paired samples, mean leukemic cell pSyk MdFI levels decreased from 222 (D1) to 186 (D8). **Conclusions:** GS-9973 given on this dose and schedule was generally well tolerated and demonstrated substantial activity in subjects with CLL, including those with poor prognostic features. Clinical trial information: NCT01799889.

**Randomized comparison of ibrutinib versus ofatumumab in relapsed or refractory (R/R) chronic lymphocytic leukemia/small lymphocytic lymphoma: Results from the phase III RESONATE trial.** *Presenting Author: John C. Byrd, The Ohio State University, Columbus, OH*

**The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 31, 2014, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2014, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.**

**7009 Poster Highlights Session (Board #1), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase 1b/2 study evaluating activity and tolerability of the BTK inhibitor ibrutinib in combination with ofatumumab in patients with chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) and related diseases.** *Presenting Author: Samantha Mary Jaglowski, The Ohio State University, Columbus, OH*

**Background:** Ibrutinib (Ib), an oral covalent BTK inhibitor, has significant activity in relapsed/refractory (R/R) CLL. Adding ofatumumab (O), an anti-CD20 antibody, to chemotherapy in CLL can improve response and progression free survival (PFS). Here, Ib was given with O in 3 different administration sequences. **Methods:** Patients (pts) with R/R CLL/SLL, PLL or Richter's transformation (RT) after $\geq$2 prior therapies including a purine analog were treated with 420 mg Ib daily and 300/2000 mg O (8 x weekly/then 4 x monthly) in 28-day cycles until progressive disease (PD). Group (G) 1 had 1 cycle of Ib monotherapy, then O was added. G2 started O on Day (D) 1/Cycle (C) 1 and Ib on D2/C1. G3 had 2 cycles of O monotherapy, then Ib was added on D1/C3. **Results:** 71 pts (27, 20, 24 in G1, 2, 3) were enrolled. Median age was 64 y; 61% had Rai stage III/IV; 65 pts had CLL, 1 SLL, 2 PLL and 3 RT; 75% had lymph nodes $\geq$5 cm; 44% had del(17p); 31% had del(11q). The most frequent AEs were diarrhea (68%), infusion-related reaction (IRR, 45%), peripheral sensory neuropathy (42%) and stomatitis (37%). In all, 61% had $\geq$1 AE $\geq$grade (g) 3; most common g 3-4 AE was neutropenia in 17%. 39% had SAEs including: 1 pt in G2 with $\geq$g 3 IRR; 6 pts with AEs leading to Ib discontinuation; 9 pts died within 30 days of last dose and 2 within f/u period. Overall response rate in CLL/SLL was 100% in G1, 79% in G2, and 71% in G3. 2 additional pts achieved a partial response with lymphocytosis. 4 pts in G3 progressed before starting Ib. At study end, 52/58 responders (90%) remained progression-free with f/u of 16, 12 and 11 months for G1, 2 and 3, respectively. Three RT pts had disease control followed by PD on Day 471, 168, and 137. At 12 months, PFS was 89%, 85%, and 90% in G1, 2 and 3, respectively; 76% continued on Ib in a long-term extension study; 2 pts had a transplant. **Conclusions:** Ib combined with O is well tolerated and highly active (83% ORR) in pts with R/R CLL/SLL in all 3 dosing sequences investigated. Because of these compelling results, randomized trials evaluating anti-CD20 antibodies in combination with Ib with a PFS endpoint are ongoing. Clinical trial information: NCT01217749.

**7010 Poster Highlights Session (Board #2), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Association of disease progression on ibrutinib therapy with the acquisition of resistance mutations: A single-center experience of 267 patients.** *Presenting Author: Jennifer Ann Woyach, The Ohio State University, Columbus, OH*

**Background:** The Bruton's Tyrosine Kinase (BTK) inhibitor ibrutinib (I) is very effective in chronic lymphocytic leukemia (CLL), with progression free survival of 76% at 26 months (mo) for patients (pts) with relapsed disease (Byrd J et al, NEJM 2013). We evaluated pts treated with I to explore features associated with progressive disease (PD) and subsequent outcomes. **Methods:** 267 pts from The Ohio State University Comprehensive Cancer Center participating in 3 previously reported Institutional Review Board approved trials of I were included; 196 pts received single agent I and 71 received I plus ofatumumab. A subset of pts with PD had Ion Torrent deep sequencing (DS) performed on peripheral blood at baseline and relapse. **Results:** With a median follow-up of 16 mo ($<$1 mo-42 mo), 201 pts remain on I, and 66 have discontinued due to PD (24), infection (22), toxicity (8), transplant (4), or other (8). PD includes Richter's transformation (RT; n=16) or progressive CLL(n=8). RT tended to occur early, with 10 pts transforming prior to 12 mo of I. CLL progression tended to occur later, with 1 pt relapsing prior to 12 mo of I. 9 RT pts have died, with 6 deaths occurring within 1 mo without further therapy. Of pts with CLL PD, only 3 of 8 have died at day 25, 142, and 180 after going off study. 3 patients have survived $>$1 year after PD. 6 pts with CLL PD received further therapy $<$2 mo post PD, most in $\leq$ 2 weeks. DS on 4 pts with RT revealed 2 with mutations in BTK and 2 without mutations in BTK or PLC$\gamma$2. DS on 6 pts with CLL PD revealed BTK or PLC$\gamma$2 mutations in all. 1 pt had both BTK C481S and 3 mutations of PLC$\gamma$2, 2 had BTK C481S (1 previously reported; Chang B et al, ASCO 2013), 1 had BTK C481F, and 1 had PLC$\gamma$2 R665W (previously reported). An additional 2 pts who have relapsed outside of these studies both have BTK C481S. **Conclusions:** This single institution experience with I confirms it to be a well tolerated and effective therapy. Patients with PD require therapy quickly due to rapid disease progression. These DS confirm initial reports associating mutations in BTK and PLC$\gamma$2 with PD, and require further study in larger populations.

**7011^ Poster Highlights Session (Board #3), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Efficacy of idelalisib in CLL subpopulations harboring del(17p) and other adverse prognostic factors: Results from a phase 3, randomized, double-blind, placebo-controlled trial.** *Presenting Author: Jeff Porter Sharman, Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, OR*

**Background:** Idelalisib (IDELA) is a potent and selective inhibitor of PI3K$\delta$, which is critical for activation, proliferation and survival of B cells and their homing and retention in lymphoid tissues. An unmet need exists for effective therapies in patients with CLL positive for del(17p) and other adverse prognostic factors. This report describes the efficacy of IDELA in combination with rituximab (R) in such high-risk relapsed patients. **Methods:** Samples for del(17p), del(11q), TP53mut, IGHVmut, ZAP70 and CD38 expression, and $\beta$2-microglobulin were collected prospectively and tested using standard methods. Patients were stratified based on presence of del(17p) and/or TP53mut, and on IGHV mutational status. The endpoints evaluated in the high-risk subpopulations in the preplanned 1st interim analysis include progression-free-survival (PFS) and overall response rate (ORR). The primary study analysis was reported in NEJM 2014. **Results:** IDELA+R retained robust efficacy across all high-risk subpopulations (see Table). Importantly, IDELA+R achieved 76.5% ORR and PFS HR 0.13 in the highest risk patients who were positive for both del(17p) and TP53mut, compared to 80.4% ORR and PFS HR 0.17 in those who had neither present. **Conclusions:** These results confirm the retained robust efficacy of IDELA in high-risk CLL subpopulations and support IDELA as a potentially important novel treatment for patients with CLL positive for del(17p) and other adverse prognostic factors. Clinical trial information: NCT01539512.

**Second interim analysis of a phase 3 study evaluating idelalisib and rituximab for relapsed CLL.** *Presenting Author: Steven E. Coutre, Stanford Cancer Center, Stanford University School of Medicine, Stanford, CA*

**Background:** Idelalisib (IDELA), an oral inhibitor of PI3K$\delta$, is highly active in heavily pretreated patients with CLL as single agent or combined with rituximab (R) as demonstrated in Phase 1 trials. **Methods:** A Phase 3 study evaluated IDELA+R vs placebo (PBO)+R in pts with CLL requiring therapy after progression <24 mos since completion of last therapy and considered unfit to receive cytotoxic therapy. Primary endpoint PFS was assessed by IRC and standard criteria (Hallek 2008/2012, Cheson 2012). After progression, pts could enroll into a blinded extension study to receive IDELA at 150 mg BID (prior PBO+R) or 300 mg BID (prior IDELA+R). The first interim analysis (Furman et al, 2014) led to a decision of early stop for overwhelming efficacy. **Results:** 220 pts (110/group) with median age of 71 yrs (78% ≥65 yrs), median time since diagnosis of 8.5 yrs, and median number of 3 prior therapies (range: 1-12) were randomized. 44% of pts had del17p/*TP53* mutation, 84% had unmutated *IGHV*. Table 1 summarizes efficacy and safety. **Conclusions:** Similar to the first interim analysis, IDELA+R demonstrated significant improvement in PFS, ORR, and LNR compared to control, with acceptable safety. OS of pts on IDELA+R remains superior, including pts that crossed over into the extension study. Clinical trial information: NCT01539512.

**ABT-199 (GDC-0199) combined with rituximab (R) in patients (pts) with relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL): Interim results of a phase 1b study.** *Presenting Author: Shuo Ma, Northwestern University Medical School, Chicago, IL*

**Background:** ABT-199 is a selective, orally bioavailable Bcl-2 antagonist that induces rapid apoptosis of CLL cells and > 80% response rate as monotherapy in pts with R/R CLL. R synergizes with ABT-199 in preclinical models of CD20+ve lymphoid cancers. **Methods:** Objectives were to assess safety, pharmacokinetics (PK) and preliminary efficacy of ABT-199 + R and to determine a recommended phase 2 dose. Daily ABT-199 began at 50mg (modified to 20mg), with weekly increases to a final cohort dose (200-600mg). R was then initially dosed at 375 mg/m$^2$ then 500mg/m$^2$ monthly for 6 months (cohort 1-2 had 8 doses) with daily ABT-199 until progressive disease (PD). **Results:** As of Jan 17, 2014, 37 pts were enrolled in 5 cohorts (median age 68, 14/23 F/M) with a median time on study: 4.8 (range 0 - 15.2) months, median number of prior therapies: 2 (range 1 - 5); 9 pts were fludarabine-refractory, 9 R-refractory, and 9 had del(17p). Six pts discontinued: 4 due to PD (3 Richter's transformation, 1 CLL), 1 withdrew consent (WC), 1 due to fatal hyperkalemia in the setting of tumor lysis syndrome (TLS) at 1st dose (50mg). The most common treatment-emergent adverse events (AEs, >25% pts) were neutropenia (43%), nausea (38%), diarrhea (30%). The most common grade 3/4 AEs were neutropenia (43%), thrombocytopenia (16%), and anemia (11%). Two dose limiting toxicities occurred with ABT-199 + R: thrombocytopenia (300mg/375mg/m$^2$) and hemophagocytic syndrome (300mg/500mg/m$^2$). Preliminary PK data suggest a negligible effect of R on ABT-199 exposure. Of 18 pts who have completed combination therapy or discontinued prior to completion, 7 (39%) achieved CR/CRi and 7 (39%) PR, 2PD, 1WC, 1 fatal event. Minimal Residual Disease (MRD) was quantified locally in 6/7 CR pts: 5 pts were MRD negative. Of the 19 yet to complete combination therapy, 4 have confirmed PR, 9 have unconfirmed PR, and 6 are not yet evaluable. **Conclusions:** To date, the addition of R to ABT-199 has identified no new toxicities. The combination is active in R/R CLL with a substantial CR rate. A fatal episode of TLS occurred during the ABT-199 lead-in period; with dosing modifications and increased monitoring no further TLS events occurred. Clinical trial information: NCT01682616.

**7014 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Independent evaluation of ibrutinib efficacy 3 years post-initiation of monotherapy in patients with chronic lymphocytic leukemia/small lymphocytic leukemia including deletion 17p disease.** *Presenting Author: Susan Mary O'Brien, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** CLL/SLL is generally very responsive to chemoimmunotherapy. However, relapses occur and resistance develops. In particular, del(17p) is associated with poor outcomes using all currently available treatments. Effective targeted therapies are needed. Ibrutinib, a first-in-class covalent inhibitor of Bruton tyrosine kinase, showed single-agent activity and mild toxicity in treatment-naïve (TN) (Lancet Oncology 2013) and relapsed/refractory (R/R) CLL (NEJM 2013) in the phase 1b/2 study (PCYC-1102). We present independent assessment of efficacy data 3 years following initiation of therapy to confirm and further characterize the durability of response. **Methods:** Analyses are based upon all patients (pts) treated from first dose on PCYC-1102 until data cut-off on the long-term follow-up study PCYC-1103. Patients received 420 or 840 mg ibrutinib daily. Best overall response rate (ORR) was assessed using iwCLL criteria. **Results:** Of 132 CLL/SLL (31 TN, 101 R/R) pts evaluated, the median age was 68 years (range, 37–84), with 61% aged ≥ 65 years; 36 (27.3%) pts (2 TN, 34 R/R) had del(17p) and 36 (27.3%) had del(11q). R/R pts including 34 with Del(17p) had a median of 4 (range, 1–12) prior therapies. The updated ORR (by independent review) was 78.0% for all-treated pts (83.9% TN-, 76.2% R/R and 55.9% for those R/R with del(17p)). Additionally, 5 R/R pts, 2 with del(17p), had a best response of PR with lymphocytosis. Median DOR was not reached for all-treated pts, and was 25.0 months (range, 4.8–34.3) in pts with del(17p). Median time on study was 29.4 months (range, 0.7–38.1) for all-treated pts, and 27.3 months (range, 0.9–37.5) for R/R pts with del(17p). More pts receiving prior therapy experienced serious or ≥ Grade 3 adverse events that decreased after 1 year on treatment. No new safety signals were observed in long-term follow-up; 64% of pts remain on treatment with ibrutinib. **Conclusions:** Single-agent ibrutinib showed durable responses in pts with TN or R/R CLL/SLL including those with del(17p), as independently confirmed with 3 years of follow-up.

**7015 Poster Highlights Session (Board #7), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**ABT-199 (GDC-0199) in relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL) and small lymphocytic lymphoma (SLL): High complete-response rate and durable disease control.** *Presenting Author: John Francis Seymour, Peter MacCallum Cancer Center, Melbourne, Australia*

**Background:** Overexpression of Bcl-2 in relapsed CLL/SLL is associated with dysregulated apoptosis and chemoresistance. ABT-199 is an orally bioavailable, selective Bcl-2 inhibitor that triggers apoptosis of CLL cells in vitro and in vivo, making it a promising agent for the treatment of patients (pts) with CLL/SLL. **Methods:** The primary objectives of this phase I study were to evaluate the safety and pharmacokinetics (PK) and to determine the maximum tolerated dose and a recommended phase 2 dose (RPTD) of ABT-199. A secondary objective was to assess preliminary efficacy. Following early events of tumor lysis syndrome (TLS), a weekly ramp-up period to the final cohort dose (150 – 1200 mg) was implemented. Pts are now being enrolled in the safety expansion (SE) cohort. A ramp-up period with weekly dose increases occurred from 20, 50, 100, 200 mg to the final RPTD of 400 mg. **Results:** As of 12/04/2013, 84 pts (11 in SE) were enrolled with a median time on study of 14.7 (range, 0.5-29.3) months. 23 (27%) pts had del(17p) and 48 (57%) had fludarabine (F)-refractory CLL. Most common AEs were diarrhea (37%), nausea (36%), neutropenia (35%), upper respiratory tract infection (29%), and fatigue (27%). Grade 3/4 AEs (≥3 pts) were neutropenia (32%), anemia (8%), TLS (8% including 1 G5), and febrile neutropenia, thrombocytopenia, hyperglycemia, and hypokalemia (6% each). 28 have discontinued: 18 for progressive disease, 8 for AEs, and 2 for other reasons. The objective response rate (ORR) was 79% (CR/CRi 22%) with a median duration of response (DOR) of 20.5 months [95% CI; 13.8, 20.5] for the 63 pts evaluable for efficacy. At 12 months, 91% of CR and 65% of PR pts remain progression free. The ORR was 78% for del(17p) and 79% for F-refractory CLL. Of the 14 CR/CRi pts, 9 were evaluated in local labs for minimal residual disease (MRD); 5 were negative and 4 of these were F-refractory. **Conclusions:** ABT-199 induces a high rate of response in pts with R/R CLL, including those with del(17p) and F-refractory disease. Responses are durable, especially in the 22% achieving CR/CRi, with several of these high risk pts achieving MRD negativity. Enrollment in the SE cohort is continuing. Clinical trial information: NCT01328626.

**7016 Poster Highlights Session (Board #8), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**BK virus as a predictor of chronic kidney disease in hematopoietic stem cell recipients.** *Presenting Author: Ala Abudayyeh, Section of Nephrology, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Nephropathy from BK virus (BKV) infection is an evolving challenge in hematopoietic stem cell transplantation (HSCT) recipients. In contrast to kidney transplantation, where there are screening protocols for early detection and prevention of symptomatic BKV nephropathy, there is no such guideline in HSCT. We hypothesized that BKV infection is a marker of poor renal outcomes in the HSCT survivor population. **Methods:** We analyzed all engrafted patients undergoing first allogeneic HSCT at MD Anderson Cancer Center between January 2004 and December 2012, with normal kidney function at the time of HSCT. We evaluated the renal outcome and factors impacting poor renal outcome in these patients. BKV positivity was defined as BKV detection in urine by PCR testing. Renal outcome was determined as the time between HSCT to chronic kidney disease (CKD), defined by constant decrease of 25% or more in estimated glomerular filtration rate (eGFR) compare to the baseline at the time of transplant. **Results:** In a total of 2,477 SCT patients, BK viruria was manifested in 25% (n=629) of the patients. Conditioning regimen consisted of a myeloablative in 1,275 (52%), reduce intensity in 697 (28%), and non-myeloablative in 498 patients (20%). The source of stem-cells was peripheral blood in 1,575 (64%), bone marrow in 697 (28%), and cord blood in 205 (8%). In multivariate analysis, with the adjustment of age, gender, acute GVHD, chronic GVHD, preparative conditioning regimen, graft source, and tacrolimus serum level, BKV viruria showed significant association with renal outcome (Hazard Ratio (HR) (95% confidence interval (CI) = 1.706 (1.483, 1.964), P-Value <0 .0001). Additionally, BK viral load showed significant association with CKD (HR (95% CI) = 1.023 (1.017, 1.029) for one-fold increase, P-Value <0 .0001). **Conclusions:** To the best of our knowledge, this is the first study to identify BKV as a strong independent predictor of long-term renal outcome following HSCT. This study shed more light about the differences and similarities of BKV infection in HSCT and kidney transplant survivors and helps to formulate plans for more effective future prevention and treatment.

**7017 Poster Highlights Session (Board #9), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Haploidentical transplantation (HaploSCT) with post-transplant cyclophosphamide (PTCy) and melphalan-based conditioning: A retrospective analysis of the first 100 patients treated at MD Anderson Cancer Center.** *Presenting Author: Piyanuch Kongtim, Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Outcomes of HaploSCT have recently improved with the use of post-transplantation cyclophosphamide (PTCy). Here we report results of the first 100 pts treated at our institution between 9/2009-7/2013. **Methods:** Diseases were: AML/MDS 54 (36 had high-risk cytogenetics), lymphoma/CLL 17 (12 not in remission at transplant), ALL 12 (11 beyond first remission), CML 12 (all progressed to accelerated/blast phase), other 5 pts. The median age was 45 years (range 19-67). The conditioning regimen included melphalan (100-140 mg/m$^2$), fludarabine (160 mg/m$^2$) +/- thiotepa (5-10 mg/kg). GVHD prophylaxis consisted of PTCy 50mg/kg on day +3 and +4, tacrolimus and mycophenolate. All but 4 pts received a bone marrow graft. 23 pts had previous allogeneic (11) or autologous (12) SCT and 42 pts were not in remission at transplant. **Results:** The median follow-up was 18 months (range 2-48). 94 pts had neutrophil engraftment (median 18 days). Three-year PFS of the entire cohort was 43.3% (44.6% for 1$^{st}$ SCT and 32.7% for 2$^{nd}$ SCT). The cumulative incidence (CI) of relapse and treatment-related mortality (TRM) at 3 years were 38.4% and 25.4% for 1$^{st}$ SCT; 61.8% and 10% for 2$^{nd}$ SCT, respectively. CI of aGVHD was 45% (grade 2-4 30%, grade 3-4 10%) and cGVHD was 15% (extensive cGVHD 8%). Transplant outcomes by disease type are summarized in Table1. In multivariate analysis, factors associated with worse outcomes were lack of remission at SCT (HR 1.73, 95%CI 1.02-3.03, p=0.04) and the development of aGVHD grade 3-4 (HR 2.6, 95%CI 1.08-6.26, p=0.033). **Conclusions:** HaploSCT with melphalan-based conditioning and PTCy is well tolerated with low TRM and outcomes comparable with matched transplantation. Prospective studies comparing HaploSCT with matched transplants are needed.

**Transplant outcomes by disease type.**

| Outcomes (%) | Myeloid malignancies in CR (N=40) | Lymphoid malignancies (N=17) | ALL (N=12) |
|---|---|---|---|
| 3-year PFS | 56.5 | 62.3 | 44.4 |

**Outcomes after second allogeneic hematopoietic stem cell transplantation: A single-center experience.** *Presenting Author: Waseem Touma, Washington University School of Medicine in St. Louis, St. Louis, MO*

**Background**: Relapse and graft failure continue to be major challenges after allogeneic hematopoietic stem cell transplantation (alloHSCT). There is no standard treatment for either condition and a 2$^{nd}$ alloHSCT is often considered. **Methods**: Here we report outcomes of 77 patients who underwent 2$^{nd}$ alloHSCT at Washington University School of Medicine between 1997 and 2012. Univariate survival analyses (Kaplan–Meier log-rank test) were performed to investigate factors affecting disease–free survival (DFS) and overall survival (OS). **Results**: The median age was 44 years (19–70). Acute leukemias (ALL and AML) and myelodysplastic syndromes accounted for 82% of the cases. Indications for 2$^{nd}$ alloHSCT were mostly disease relapse (78%) and graft failure (16%). Median time between the two transplants was 330 days (15–3835). 49% of patients underwent 2$^{nd}$ alloHSCT with active disease and 57% underwent myeloablative conditioning. The grafts were mostly from matched unrelated donors and matched siblings (52% and 38%, respectively). The original donor was used in 38% of the 2$^{nd}$ transplants and 34% of the recipient-donor pairs were gender mismatched. OS at 1 and 5 years were 31% and 14%, respectively [median 162 days (5–5966)]. Factors prolonging OS were: acute graft versus host disease (aGVHD) (p=0.007), chronic GVHD (cGVHD) (p=0.027), disease status not active at the time of transplant (p=0.003) [median survival 316 days vs. 129 days], period between the two transplants more than 2 years (p=0.045), and post transplant STR above 95% (p=0.0004). Choosing the same donor as in the 1$^{st}$ transplant improved the OS if that donor was gender mismatched from the recipient (p=0.021). DFS at 1 and 5 years were 46% and 35%, respectively [median 106 days (5–5966)]. Factors prolonging the DFS were cGVHD (p=0.024) and disease remission at the time of 2$^{nd}$ transplant (p=0.0008). The incidences of aGVHD and cGVHD were 39% and 32%, respectively. **Conclusions**: This single center experience suggests that performing a 2$^{nd}$ alloHSCT on patients with active disease has very poor outcomes. OS is improved when there is long remission following initial alloHSCT. Choosing the same donor can improve OS if the recipient and donor are gender mismatched.

**7019 Poster Highlights Session (Board #11), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Inotuzumab ozogamicin (IO) in combination with low-intensity chemotherapy as front-line therapy for older patients (pts) and as salvage therapy for adult with R/R acute lymphoblastic leukemia (ALL).** *Presenting Author: Elias Jabbour, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Outcome of older pts with ALL and those with R/R disease is poor. Addition of IO to effective low-intensity chemotherapy might improve outcome. IO is a CD22 monoclonal antibody bound to a toxin, calecheamicin, and has shown single-agent activity in R/R ALL. **Methods:** Pts ≥60 years (yrs) with newly-diagnosed ALL and pts ≥18 yrs with R/R disease were eligible. Chemotherapy was low intensity and referred to as mini-hyper-CVD (cyclophosphamide and dexamethasone at 50% dose reduction, no anthracycline, methotrexate at 75% dose reduction, cytarabine at 0.5 g/m$^2$ x 4 doses). Rituximab and IT chemotherapy were given for first 4 courses. IO was given on Day 3 of each of the first 4 courses. The first 6 pts received 1.3 mg/m$^2$ for course 1 and 0.8 mg/m$^2$ for subsequent cycles; pt 7 onwards received 1.8 mg/m$^2$ for course 1 and 1.3 mg/m$^2$ for subsequent cycles. **Results:** 44 pts were treated so far (Table). Grade 3-4 non-hematological toxicity included increased LFTs in 5 (11%): VOD in 1 (2%). 10 pts (23%) were switched early to maintenance due to thrombocytopenia and infectious complications. Of the 20 pts with de novo ALL, 16 (80%) are alive:14 (70%) in CR from 1 to 25 mos, 2 relapsed after 12 and 3 mos; and 4 died, 3 in CR (sepsis in 2, gun shot in 1) and 1 did not achieve CR and died 2 mos later after receiving a salvage regimen. At the last follow-up, 17 of the 24 pts (71%) with R/R ALL are alive:15 (63%) in response from 1 to 10 mos, 2 relapsed after 1 and 2 mos; and 7 died: 4 early death within 3 weeks, and 3 from resistant disease. **Conclusions:** IO + low-intensity mini-hyper-CVD is safe and shows very encouraging results (95% ORR) in the frontline setting in older pts with ALL and as a salvage approach (75% ORR). These results appear to be better than those achieved with a chemotherapy only approach and may become the new standard of care. Clinical trial information: NCT01371630.

**Phase I trial of autologous CD19-targeted CAR-modified t cells as consolidation after purine analog-based first-line therapy in patients with previously untreated CLL.** *Presenting Author: Jae Hong Park, Leukemia Service, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** In order to address the previously recognized limitation of autologous T cells modified to express chimeric antigen receptor (CAR) targeting CD19 in patients (pts) with chemotherapy refractory and relapsed CLL (Brentjens RJ et al., Blood 2011), we designed a phase I trial wherein CLL pts with residual disease following the first-line chemotherapy will receive the CD19-targeted CAR$^+$ T cells as a consolidative therapy. **Methods:** Pts with CLL who have achieved either partial (PR) or complete response (CR) with detectable minimal residual disease (MRD) to the first-line therapy consisting of 6 cycles of pentostatin, cyclophosphamide and rituximab (PCR) were enrolled. Autologous T cells were transduced with a retroviral vector encoding the anti-CD19 scFv linked to CD28 co-stimulatory and CD3$\zeta$ signaling domains (19-28z). Pts received cyclophosphamide conditioning therapy followed by 3 escalating doses of CAR$^+$ T cells. Response was assessed at 3 months according to the NCI-WG criteria. **Results:** 7 pts have received the CAR$^+$ T cells in 3 dose cohorts (3x10$^6$ - 3x10$^7$ CAR$^+$ T cells/kg). 6 pts had unmutated IgHV and 2 pts had del11q. All 7 pts achieved PR following the PCR chemotherapy. 4 pts had palpable lymphadenopathy (1 pt with bulky lymph nodes) prior to the T cell infusion. Median follow-up was 11 months (range, 3 – 17 mos). No DLT was observed. Mild and self-limiting cytokine release syndrome (CRS) was observed in 3 pts, and there was a positive correlation between the development of CRS and the CAR$^+$ T cell persistence. 1 pt achieved CR; 2 pts achieved CR in the bone marrow (1 MRD negative CR) but had progressive disease in lymph node only; 3 pts achieved PR; and 1 pt had progressive disease but this pt had rapidly rising ALC at the time of T cell infusion. **Conclusions:** Autologous CD19-targeted CAR$^+$ T cells appear to be safe and have promising anti-tumor efficacy in pts with high-risk CLL undergoing first-line chemoimmunotherapy. Our findings suggest that the CD19-targeted CAR$^+$ T cells are more effective in eradicating disease in the marrow versus lymph nodes, and further studies are being conducted to better understand the mechanism of resistance. Clinical trial information: NCT01416974.

**7021 Poster Highlights Session (Board #13), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Efficacy and safety of imatinib in CML over 10 years.** *Presenting Author: RÃ¼diger Hehlmann, III. Medizinische Universitätsklinik, Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany*

**Background:** Tyrosine kinase inhibitors (TKI) have changed the natural course of CML. With the advent of 2nd generation TKI and the now available choice of drugs, safety issues have gained interest. **Methods:** We have used 1,551 patients of the randomized CML-Study IV for a long-term safety and efficacy evaluation of imatinib. Adverse drug reactions (ADR) were reported at each follow-up visit, coded and graded according to the NCI CTC AE list. Molecular analysis for residual BCR-ABL transcripts was adjusted by the international scale. **Results:** 1,501 patients have received imatinib and were evaluable. Median age at diagnosis was 53 years, 88% were EUTOS low risk. At the last evaluation (04/11/2013) 1,003 patients still received imatinib, 164 have died, 275 have been switched to a 2nd generation TKI, 106 have been transplanted (numbers in part overlapping). The longest observation time was 11.5 years, the median observation time 6.5 years. Efficacy: 10-year progression-free and overall survival probabilities were 81% and 84%, respectively. 10-year cumulative response rates reached 89% for MMR, 81% for MR$^4$, 74% for MR$^{4.5}$ and 63% for MR$^5$. Safety: In 1,018 out of 1,375 patients (74%) non-hematologic ADR were reported during imatinib treatment, in 193 grade 3/4 ADR (14%); 8-year probabilities (all grades) were: fluid overload or edema 41 (36–46)%, gastrointestinal 38 (34–43)%, myalgia or arthralgia 25 (21–29)%, rash 20 (17–24)%, musculoskeletal 17 (13–22)%, fatigue 17 (13–20)%, neurological 11 (8–13)%, and flu-like 10 (8–13)%. Probability profiles over time have been generated for each ADR. In 5 patients peripheral arterial occlusive disease grade 2 or 3 was reported, but none could be clearly assigned to imatinib. A definite association between any ADR and death was not found. Most patients had their first ADR during the first three years with decreasing frequency later on. **Conclusions:** Given that no imatinib-related death was recorded and that grade 3/4 ADR could typically be symptomatically improved and tolerated we consider imatinib a safe, comparably well tolerated TKI even after prolonged treatment. After 10 years imatinib continues to be an excellent choice for the treatment of CML in most patients. Clinical trial information: NCT00055874.

**7022^ Poster Highlights Session (Board #14), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase 1b, dose-finding study of ruxolitinib plus panobinostat in patients with myelofibrosis.** *Presenting Author: Florian Heidel, Otto von Guericke University of Magdeburg, Magdeburg, Germany*

**Background:** Myelofibrosis (MF) is a myeloproliferative neoplasm characterized by dysregulation of the Janus kinase (JAK) pathway resulting in bone marrow fibrosis, splenomegaly, and debilitating symptoms. Ruxolitinib (RUX) is a potent JAK1/JAK2 inhibitor that decreased spleen volume, improved symptoms, and prolonged survival in phase 3 studies. Panobinostat (PAN) is a potent pan-deacetylase inhibitor (DACi) that has shown splenomegaly reduction and improvement of marrow fibrosis in phase 1/2 studies. RUX and PAN demonstrated synergistic anti-MF activity in preclinical studies. Here, we present the updated results of a phase 1b study of the combination of RUX and PAN in MF patients (pts). **Methods:** Eligible pts had intermediate-1, -2, or high-risk MF by International Prognostic Scoring System criteria with palpable splenomegaly. Pts received RUX (5-15 mg) twice daily, every day (BID) and PAN (10-25 mg) once daily, 3 times a week (TIW; days 2, 4, and 6), every other week (QOW) in a 28-day cycle. The primary objective was determination of the recommended phase 2 dose (RP2D) and/or maximum tolerated dose (MTD). Dose escalation was guided by a Bayesian logistic regression model with overdose control based on cycle 1 dose-limiting toxicities (DLTs) and other safety results. Additional pts were enrolled and treated at the RP2D in the expansion phase. **Results:** A total of 48 pts were enrolled (38 escalation phase and 10 expansion phase). Preliminary RP2D was identified at RUX 15 mg BID/PAN 25 mg TIW/QOW. Grade 3/4 adverse events (AEs) included anemia (42%), thrombocytopenia (21%), abdominal pain (8%), and diarrhea (8%) in the escalation phase and anemia (20%) and asthenia (10%) in the expansion phase. Preliminary activity in the dose escalation phase was demonstrated by a ≥ 50% decrease in palpable spleen length at any time in 76% of pts and 50% of patients demonstrating a 100% (non-palpable spleen) response. In the expansion phase, all 4 evaluable pts demonstrated a best spleen response of 100% (non-palpable spleen). **Conclusions:** The combination of RUX and PAN has a tolerable safety profile and encouraging efficacy as demonstrated by spleen responses. Additional safety and efficacy data from the expansion phase will be presented. Clinical trial information: NCT01433445.

**7023 Poster Highlights Session (Board #15), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**EPIC: A phase III trial of ponatinib (PON) versus imatinib (IM) in patients (pts) with newly diagnosed CP-CML.** *Presenting Author: Jeffrey Howard Lipton, Princess Margaret Hospital, Toronto, ON, Canada*

**Background:** PON is a potent oral TKI active against native and mutated forms of BCR-ABL, including T315I. The ph 2 PACE study demonstrated that PON is highly active in heavily pretreated Ph+ leukemia pts. **Methods:** EPIC was an international, Ph 3 trial of PON (45 mg QD) vs IM (400 mg QD) in newly diagnosed CP-CML pts, with randomization stratified by Sokal risk score. The primary endpoint was major molecular response (MMR) rate at 1 yr. On 18 Oct 2013,EPIC was terminated due to accumulating vascular events in long-term follow-up of the PACE trial. Data as of 7 Oct 2013 are presented, median follow-up 3 (0.03-12) m. **Results:** At the time of analysis, 306 were randomized. Baseline characteristics were balanced for PON vs IM; median age 55 vs 52 yrs, 17% vs 16% high Sokal risk score, 62% vs 66% received prior hydroxyurea. Data on 267 treated pts were available (133 PON; 134 IM). 77% PON and 84% IM pts were ongoing; 14 PON and 6 IM pts D/C, (D/C due to AE; 9 PON pts [most common: thrombocytopenia and rash] and 1 IM pt). Response rates are in the table (evaluable pts). Most common (≥25%) all grade (G) AEs were PON: rash (36%), abdominal pain (32%), headache (31%), lipase increased (26%), myalgia (26%); IM: nausea (32%), muscle spasms (31%). 11% PON and 2% IM had G 3/4 thrombocytopenia; 3% PON and 8% IM had G 3/4 neutropenia. Serious AEs (SAEs) occurring in ≥3 PON pts were: pancreatitis (5 pts), atrial fibrillation (3), thrombocytopenia (3); no individual SAEs occurred in ≥3 IM pts. 9 (7%) PON and 5 (4%) IM pts experienced vascular occlusive events (SAEs: 6 PON, 1 IM). Updated data will be presented. **Conclusions:** While PON demonstrated early activity in frontline CP-CML, EPIC was terminated as its objectives could not be met with PON dose reductions implemented mid-trial due to safety observations in PACE. Further investigation of PON safety is warranted. PON remains an important treatment option for pretreated CML and Ph+ ALL pts in whom the need and benefit outweigh the risk. Clinical trial information: NCT01650805.

**Ten-year follow up of patients with newly diagnosed chronic myeloid leukemia in chronic phase treated with 400 mg or 800 mg of imatinib daily.** *Presenting Author: Koji Sasaki, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The tyrosine kinase inhibitor imatinib is standard therapy for patients with chronic myeloid leukemia in chronic phase (CML-CP). It has been suggested that higher-dose imatinib (HD-IM) may offer faster and deeper responses. The purpose of this study was to assess long-term follow-up data of patients treated with HD-IM (minimum follow-up 8 years). **Methods:** Patients with newly diagnosed CML-CP received daily imatinib 400 mg (IM400; 70 patients) or 800 mg (IM800; 201 patients) in consecutive clinical trials. Patients were assessed for cytogenetic and molecular response, overall survival (OS), event-free survival (EFS), transformation-free survival (TFS), and failure-free survival (FFS). **Results:** The 271 patients' median follow-up time was 118 months. The median age was 48.3 years (range, 15.1-84.8 years). Sokal risk scores, rates of best response, FFS, TFS, EFS, and OS are given in Table 1. The response rates at 3, 6, and 12 months in IM800 patients were significantly higher than those of the IM400 patients. The overall MMR4.5 and MMR rates of the IM800 patients were significantly higher than those of the IM400 patients. The IM800 patients also had significantly higher 10-y EFS and 10-y TFS, with small, non-significant trends for 10-y OS and 10-y FFS. **Conclusions:** IM800 patients tended to have better response rates than IM400 patients, particularly for MR4.5. This translates into better EFS but not OS.

**Effect of continued imatinib (IM) in pts with detectable BCR-ABL after ≥ 2 years on study on deep molecular responses (MR): 36-month update from ENESTcmr.** *Presenting Author: Nelson Spector, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

**Background**: With 24 mo f/u, ENESTcmr demonstrated higher rates of stable, deep MRs with nilotinib (NIL) vs IM in pts on long-term (≥ 2 y) IM with residual disease. Here, we present 36-mo results, including crossover from IM to NIL after 2 y on study. **Methods**: Pts with Philadelphia chromosome–positive CML-CP (N = 207) with complete cytogenetic response but detectable BCR-ABL (by RQ-PCR with a sensitivity of ≥ 4.5 logs) after ≥ 2 y on IM were randomized to NIL 400 mg twice daily (BID; n = 104) or IM 400 or 600 mg once daily (QD; n = 103). Crossover from IM to NIL was allowed for pts with detectable BCR-ABL after 24 mo, treatment failure, or confirmed (≥ 2 consecutive assessments) loss of response at any time. **Results**: Significantly more pts achieved $MR^{4.5}$ by 36 mo with NIL (Table). Median time to $MR^{4.5}$ was 24 mo in the NIL arm and not reached in the IM arm with 36 mo f/u. 46 of 103 (45%) pts randomized to IM crossed over to NIL. When accounting only for responses up to crossover, 47% and 24% of pts on NIL and IM, respectively, achieved $MR^{4.5}$ ($P = .0003$). At 24 mo, 52 pts on NIL and 78 pts on IM had detectable disease; 4/52 who continued NIL, 0/35 who continued IM, and 11/43 who crossed over from IM to NIL achieved undetectable BCR-ABL by 36 mo. The rate of $MR^{4.5}$ appeared higher in pts randomized to NIL (33% by 1 y in pts without $MR^{4.5}$ at baseline [BL]) than in pts who crossed over to NIL (21%) with similar follow-up. Adverse event profile was similar to the 12 mo report. **Conclusions**: By 36 mo, significantly more pts achieved $MR^{4.5}$ by switching to NIL vs remaining on IM and median time to $MR^{4.5}$ was accelerated by more than 1 y in the NIL arm. Pts with detectable disease who crossed over from IM to NIL after 24 mo were able to achieve deep MRs by 36 mo on study, whereas no pts who remained on IM achieved undetectable BCR-ABL. Delaying switching from IM to the more potent BCR-ABL inhibitor NIL does not increase the proportion of pts achieving deep MR. Clinical trial information: CAMN107A2405.

| | NIL 400 mg BID (n = 98) | IM 400 or 600 mg QD (n = 96) | *P* Value |

| $MR^{4.5}$ in pts without $MR^{4.5}$ at BL (intention to treat analysis) | n (%) | n (%) | |
| By 12 mo | 32 (33) | 13 (14) | 0.0020 |
| By 24 mo | 42 (43) | 20 (21) | 0.0006 |
| By 36 mo | 46 (47) | 32 (33) | 0.0453 |
| By 36 mo, excluding pts who crossed over to NIL | 46 (47) | 23 (24) | 0.0003 |

**7026 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Results of a prospective, randomized, open-label phase 3 study of ruxolitinib (RUX) in polycythemia vera (PV) patients resistant to or intolerant of hydroxyurea (HU): the RESPONSE trial** *Presenting Author: Srdan Verstovsek, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** PV is a myeloproliferative neoplasm characterized by increased erythrocytosis, disease-related symptom burden (eg, pruritus), and risk of vascular events (thrombosis and/or hemorrhage). Maintaining hematocrit (HCT) control is a key therapeutic goal. RESPONSE is the first phase 3 study to evaluate a JAK inhibitor (RUX) in treating PV. **Methods:** Phlebotomy (PBT)-dependent patients (pts) with splenomegaly (> 450 $cm^3$) and HU resistance/intolerance were randomized 1:1 to RUX 10 mg bid or best available therapy (BAT). The primary endpoint was the proportion of pts who achieved both HCT control without PBT from wk 8 to 32 (with ≤ 1 PBT from wk 0 to 8) and a ≥ 35% reduction in spleen volume (SV) from baseline (BL) by MRI at wk 32. Key secondary endpoints included the proportion of pts who maintained the primary response at wk 48 and the proportion of pts who achieved complete hematologic response (CHR) at wk 32. Other endpoints were duration of response, symptom improvement by MPN-SAF diary, and safety. BAT-treated pts could cross over to RUX from wk 32. The primary analysis occurred when all pts reached wk 48 or discontinued. **Results:** 110 and 112 pts were randomized to RUX and BAT, respectively (median exposure: RUX, 81 wk; BAT, 34 wk); 17 (15%) RUX and 108 (96%) BAT pts discontinued randomized treatment (96 crossed over to RUX). The primary endpoint was achieved in 21% of RUX vs 1% of BAT pts ($P < .0001$); 91% of RUX pts maintained their response at wk 48. Overall, 77% of RUX pts met ≥ 1 component of the primary endpoint: 60% of RUX and 20% of BAT pts achieved HCT control without PBT; 38% of RUX and 1% of BAT pts achieved a ≥ 35% SV reduction (median BL SV, 1195 $cm^3$ in RUX and 1322 $cm^3$ in BAT pts). CHR was achieved in 24% and 9% of RUX and BAT pts ($P = .003$); 49% vs 5% had a ≥ 50% improvement in MPN-SAF 14-item total symptom score at wk 32. During the first 32 wk, grade 3/4 anemia or thrombocytopenia occurred in 1.8% and 5.5% of RUX pts, respectively, vs 0% and 3.6% of BAT pts; thromboembolic events occurred in 1 RUX and 6 BAT pts. **Conclusion:** RUX was well tolerated and superior to BAT in controlling HCT without PBT and reducing SV. RUX was also effective in improving PV-associated symptoms. Clinical trial information: NCT01243944.

**7027 Poster Highlights Session (Board #19), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Clinical activity of Crenolanib in patients with D835 mutant FLT3-positive relapsed/refractory acute myeloid leukemia (AML).** *Presenting Author: Robert Collins, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Development of D835 is a common mechanism of resistance to most FLT3 inhibitors. Crenolanib, a type I FLT3 tyrosine kinase inhibitor, has *in vitro* activity against FLT3 ITD and FLT3 D835. Crenolanib trials in relapsed/refractory FLT3 mutant AML (FLT3 ITD, FLT3 D835, FLT3 ITD/D835) are ongoing (NCT01522469, NCT01657682). **Methods:** Clinical data on the first 19 patients (7M, 12F) with a median age of 47 years (21-81) are currently available. 6 patients were refractory and 7 had relapsed within 6 months of induction therapy. 4 had undergone prior allogeneic transplants. 11/19 had progressed after exposure to ≥1 prior FLT3 TKI (8 Sorafenib, 7 AC220, 2 PLX3397, 1 PKC412,). 3 had received 2 or more prior FLT3 TKIs. Initially, crenolanib was given at a fixed dose of 100 mg PO TID but the dose was subsequently individualized to 200 mg/m$^2$/d given in 3 divided doses. **Results:** Crenolanib had a $T_{max}$ of 1.5-2 hours and a $T_{1/2}$ of 8-9 hours. Median day 15 trough levels (from 11 patients) ranged from 136 -785 nM (median 473nM). Commonly observed side effects included nausea and vomiting and transaminase elevations (primarily grade 1, 2). No patient had to go off study due to toxicity. One patient each required crenolanib dose reduction to 80mg TID due to grade 3 nausea or transaminitis, respectively. No QT prolongations on EKG were observed in any patient. 18 patients are currently evaluable for response. 1 patient achieved a rapid molecular and clinical CR with full count recovery. 2 patients achieved a CR with incomplete count recovery (CRi). An additional 4 patients had a partial response. 4 patients were bridged to transplant. **Conclusions:** Crenolanib is a FLT3 TKI that is showing preliminary clinical activity in a heavily pretreated population with both FLT3 D835 and compound FLT3 ITD/D835 mutant AML. Importantly, crenolanib is also the first agent to demonstrate clinical activity in patients refractory to other FLT3 TKIs via the major clinical resistance mechanism. Trials of crenolanib in newly diagnosed as well as first relapsed AML patients, are being initiated. Clinical trial information: NCT 01522469, NCT01657682.

| Patient No. | N=18 |
|---|---|
| CR/CRi | 3 (17%) |
| Partial Response | 4 (22%) |
| Blast Response | 2 (11%) |
| Overall Response | 9 (50%) |
| Patients bridged to transplant | 4 (22%) |

**7028 Poster Highlights Session (Board #20), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase I study of the mitochondrial metabolism inhibitor CPI-613 in combination with high-dose ara-C (HDAC) and mitoxantrone for relapsed or refractory acute myeloid leukemia (AML).** *Presenting Author: Timothy S. Pardee, Comprehensive Cancer Center of Wake Forest University, Winston-Salem, NC*

**Background:** Altered metabolism is an emerging hallmark of cancer and a possible therapeutic target. CPI-613 is a first in class agent that targets mitochondrial metabolism.This trial was designed to determine the maximum tolerated dose, safety, and efficacy of CPI-613 given in combination with HDAC and mitoxantrone in patients with relapsed or refractory AML. **Methods:** CPI-613 was given daily on days 1 through 5 starting at a dose of 500 mg/m$^2$. Beginning on day 3, HDAC at 3,000 mg/m$^2$ (or 1,500 mg/m$^2$ for age ≥60) was given every 12 hours for 5 doses and mitoxantrone at 6 mg/m$^2$ was given daily for 3 doses. The CPI-613 dose was escalated to 2250 mg/m$^2$. If residual disease was present on day 14 re-induction with the same or a three day abbreviated course could be given. Patients who achieved a complete remission (CR) or CR with incomplete count recovery (CRi) could receive additional consolidation cycles. **Results:** A total of 24 patients were enrolled. The median age was 58 (range 21-76). Four patients had refractory disease and six received two or more previous lines of therapy. In patients with relapsed disease the median duration of CR1 was 7.5 months. Cytogenetics were poor risk in 13 patients, intermediate in 8 and good in 3. The response rate was 54% (11CR+2CRi). In patients ≥60 years old the CR/CRi rate was 55% (6/11). In patients with poor risk cytogenetics the CR/CRi rate was 53% (7/13). In a historical cohort of patients treated with HDAC, mitoxantrone and asparaginase, only 25% (4/16) of patients with poor risk cytogenetics achieved a CR/CRi. Five patients (21%) died on or before day 30. Two patients with circulating blasts had blood samples taken before and after CPI-613 infusion. Samples from a patient who cleared her marrow demonstrated robust phosphorylation of adenosine monophosphate-activated protein kinase (AMPK) consistent with depletion of ATP. This phosphorylation was not seen in a patient with persistent disease. **Conclusions:** CPI-613 in combination with HDAC and mitoxantrone is a promising salvage regimen, especially in older patients and those with high risk disease. Induction of AMPK phosphorylation may serve as a predictor of response. Clinical trial information: NCT01768897.

**7029 Poster Highlights Session (Board #21), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase I study of Debio1143 (AT406) in combination with daunorubicin (D) and cytarabine (C) in patients with poor-risk acute myeloid leukemia (AML).** *Presenting Author: John F. DiPersio, Washington University School of Medicine in St. Louis, St. Louis, MO*

**Background:** Treatment of AML remains difficult due to the development of treatment resistance. Inhibitors of apoptosis proteins (IAPs) are key negative modulators of apoptosis which represent attractive targets to overcome resistance to chemotherapy. The small molecule Debio 1143 (formerly AT-406) is an orally-active IAP antagonist able to promote apoptosis by restoring caspase activity and modulating the nuclear factor kappa-B signalling in multiple preclinical models, alone and/or in combination with chemotherapy. **Methods:** This multi-center, dose escalation study aimed to evaluate tolerability, pharmacokinetics (PK), pharmacodynamics, and efficacy of Debio 1143 when given along with D and C to poor-risk patients with AML during the induction cycle. Sequential patient cohorts received 100, 200, 300, or 400 mg of oral Debio 1143 on treatment days 1-5. **Results:** Twenty-nine patients were enrolled of whom 23 completed the study. Most common adverse events of any grade deemed related to the treatment were nausea (31% of patients), diarrhoea (14%), and febrile neutropenia (14%). 3 patients had dose-limiting toxicities: a G3/4 reversible ALT/AST elevation at 100mg, a G3 mucositis resulted in electrolyte abnormalities and cardiac arrhythmia at 200 mg, and a neutropenic fever and G4 heart failure at 400 mg. The maximum tolerated dose was not reached. Exposure was highly variable and increase exceeded dose-proportionality but no accumulation over 5 days was observed. $T_{max}$ was reached in about 2h and $T_{1/2}$ was about 6h at day 1. PK of D and C were rather homogeneous among Debio 1143 dose groups. Debio 1143-induced degradation of cIAP-1 was detectable in CD34/CD117+ cells already at the lower dose. A total of 13 (47%) patients achieved complete remission, the majority in the 100 mg dose cohort. Of these, 8 (62%) relapsed still within the study period. Responders more frequently showed plasma increases of tumor necrosis factor alpha and IL-8 after the first dose of Debio 1143. **Conclusions:** Debio 1143 at doses up to 400 mg/day showed good tolerability and can be safely combined with D and C. The efficacy data are inconclusive but warrant further studies in subsets of patients with AML. Clinical trial information: NCT01265199.

**7030 Poster Highlights Session (Board #22), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**First results of a phase 2 study using a 10-day subcutaneous (SC) regimen of the novel hypomethylating agent (HMA) SGI-110 for the treatment of relapsed/refractory acute myeloid leukemia (r/r AML).** *Presenting Author: Elizabeth A. Griffiths, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** SGI-110 is a novel HMA administered as a small volume injection which results in extended decitabine exposure. We previously reported an Overall Complete Remission (OCR=CR+CRi+CRp) rate of 16% in 50 patients with r/r AML using SGI-110 daily x 5 regimen with either 60 or 90 mg/m2/d (Kantarjian et al, 2013). We report here the first results of the daily x 10 Q 28 days regimen using 60 mg/m2/d. **Methods:** Patients with AML who relapsed or progressed following prior treatment were enrolled. There was no limit on the number of prior treatment regimens, total WBC, or blast %. The primary endpoint was OCR using modified IWG 2003 criteria. Secondary efficacy endpoints included duration of response, and Overall Survival. Safety was assessed using the CTCAE Version 4. After 2-4 cycles, investigators were allowed to consolidate with daily x 5 at 60 mg/m2/d regimen until progression. **Results:** The study completed enrolment with 53 patients treated. Patients had a median age of 57 years (range 29-82), 51% were male, 83% had ECOG PS of 0-1, and 17% had ECOG PS 2. Median number of prior regimens was 2 (range 1-7); 13% of patients had prior HMA treatment. The primary efficacy endpoint of OCR was reported in 16 patients (7 CR, 6 CRi, and 3 CRp) or an OCR rate of 30% (95% CI: 18.3%, 44.3%). Seven patients are still on treatment. 30-day and 60-day mortality were 1.9% and 11.3% respectively. Of 162 total number of cycles given at the data cutoff, 149 (92%) were given using the 10-day regimen and 13 (8%) were given using the daily x 5 consolidation. The most common drug-related Grade ≥3 AEs were: anaemia and thrombocytopenia (19% each), neutropenia and febrile neutropenia (5.7% each). **Conclusions:** SGI-110 given as a daily x 10 SC regimen at a dose of 60 mg/m2/d was clinically active in heavily pretreated population of r/r AML with an acceptable safety profile. The results appear to compare favorably with our previously reported complete remission response rate in a similar patient population using the daily x 5 regimen at doses of 60 or 90 mg/m2/d. These results warrant further investigation of this regimen for the treatment of r/r AML. Clinical trial information: NCT01261312.

**7031 Poster Highlights Session (Board #23), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase II trial of cladribine and low-dose AraC alternating with decitabine in older patients with AML.** *Presenting Author: Tapan M. Kadia, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Treatment of AML in older patients (pts) is often complicated by poor tolerance to high dose chemotherapy and resistant disease. Lower intensity approaches employing more active combinations are needed. Cladribine works synergistically with araC and has been shown to improve survival when combined with standard-dose araC. **Methods:** We investigated the combination of cladribine and low-dose araC (LDAC) alternating with decitabine in pts aged > 60. Pts with adequate organ function and newly diagnosed AML (except APL) and high risk MDS were eligible. Induction was cladribine 5 mg/m$^2$ IV over 30 min on d 1-5 followed by araC 20mg SQ BID on d 1-10. Consolidation was 2 cycles of cladribine 5 mg/m$^2$ IV over 30 minutes on d 1-3 + araC 20 mg SQ BID on d 1-10 alternating with 2 cycles of decitabine 20 mg/m$^2$on d 1-5, for a max of 18 cycles. **Results:** 59 pts have been enrolled with a median age of 69 yrs (range, 49-85), including 28 pts (47%) ≥ age 70 (Table). 29 pts (49%) had secondary or therapy related AML, 10 pts (17%) had therapy for an antecedent heme disorder, and 4 pts (7%) had a concurrent active 2nd malignancy while on study. Of the 55 pts evaluable for response, there were 32 CR (58%), 3 CRp (5%), and 2 PR (4%) for an overall response rate of 67%. With a median followup of 4+ months, median OS and median CR duration have not been reached. The 1-year OS estimate is 55%. The regimen was very well tolerated, with 0% 4-week mortality. There were no treatment-related grade 3/4 non-heme adverse events (AEs). Most common non-heme AEs were elevated bilirubin, constipation, nausea/vomiting, mucositis, diarrhea and rash. **Conclusions:** The low intensity program of cladribine+LDAC alternating with decitabine is a highly effective, well-tolerated, ambulatory regimen for older pts, including those with unfavorable-risk features. Clinical trial information: NCT01515527.

**A phase 1 dose-escalation study of the oral selective inhibitor of nuclear export (SINE) KPT-330 (selinexor) in patients (pts) with relapsed/refractory acute myeloid leukemia (AML).** *Presenting Author: Karen W. L. Yee, Princess Margaret Cancer Center, Toronto, ON, Canada*

**Background:** KPT-330 (Selinexor) is a slowly reversible XPO1 inhibitor that forces the nuclear retention and activation of >10 tumor suppressor proteins (TSP) including NPM1c, reduces cMYC and BCLx, and induces AML cell death while sparing normal hematopoietic cells. **Methods:** Oral KPT-330 was given at 8-10 doses per 28-day cycle. Elevation in leukocyte XPO1 mRNA following XPO1 inhibition was a pharmacodynamic (PDn) marker for KPT-330 activity. Pharmacokinetic (PK) analyses were performed. Appetite stimulants and anti-emetics were given as part of supportive care. **Results:** 48 pts (24 M / 24 F; median age 68 yrs; ECOG PS 0/1: 11/37; pts were heavily pretreated with median 3 prior regimens (range of 1-7). Pts received KPT-330 across 5 dose levels (16.8 - 55 mg/m$^2$). There have been no DLTs. Cycle 1 grade 3/4 non-DLT adverse events (AEs) in >1 pt included: fatigue (8%), thrombocytopenia (8%), neutropenia (8%), and nausea (4%). The most common Cycle 1 grade 1/2 AEs were diarrhea (35%), anorexia (33%), nausea (29%), and fatigue (25%). Prolonged administration (>4 months) of KPT-330 was feasible and there were no drug-associated deaths. PK and PDn analyses showed dose-dependent increases in $C_{max}$ / $AUC_{0\text{-}inf}$ ($T_{1/2}$ ~6 hrs) and increases in XPO1 mRNA. Higher doses of KPT-330 were associated with greater reductions in blast counts, which were also observed across different AML subtypes. 16 pts did not complete cycle 1 and were therefore not evaluable for response. Responses in 32 evaluable pts were: complete response (CR) with full hematological recovery: 4 pts (12%), marrow CR (CRm): 1 pt (3%), CR without hematological recovery: 1 pt (3%), duration of CR/CRi/CRm 6-13 weeks; Morphological leukemia free state: 1 pt (3%), Partial Response (PR) 2 pts (6%). Twelve (37%) of the remaining pts have experienced stable disease for > 30 days, and 11 (34%) have had progressive disease. **Conclusions:** KPT-330 treatment can be given over months and induce remissions in pts with heavily pretreated AML. A randomized study of KPT-330 vs available agents in chemotherapy-ineligible relapsed AML is being initiated. Clinical trial information: NCT01607892.

**7033 Poster Highlights Session (Board #25), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Mobilization and elimination of FLT3-ITD$^+$ acute myelogenous leukemia (AML) stem/progenitor cells by plerixafor, G-CSF, and sorafenib: Phase I trial results in relapsed/refractory AML patients.** *Presenting Author: Michael Andreeff, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** FLT3-ITD mutant AML is associated with poor prognosis. Our group identified sorafenib (S) as potent inhibitor of FLT3-ITD AML. We demonstrated increased preclinical activity of S when combined with the CXCR4 inhibitor plerixafor (P) and G-CSF (G). Here, we report clinical and translational data testing this concept in patients with R/R FLT3-ITD AML, including patients refractory to FLT3-ITD inhibitors. **Methods:** G (10 mg/kg) and P (240 mg/kg) were given s.c. QOD on days 1 through 13, and S (400 to 800 mg) was given on days 1 through 28 (one cycle). Stem cell, adhesion markers, and phospho-proteins were serially assessed by FACS and CyTOF mass cytometry. **Results:** Of 33 patients enrolled, 28 received treatment and 21 were evaluable for toxicity and disease response. Two CRp, four CR and eight PR were achieved, resulting in 62% overall response rate, 28% CR/CRp, and 33% PR. Responses included 3 patients refractory to FLT3inhibitors.Two patients achieved long-lasting molecular remissions. There was no treatment-related mortality. Side effects included hyperleukocytosis, hand foot syndrome, hypertension, diarrhea. Striking mobilization was observed : 30-fold increase in WBC, 40-fold in absolute blasts and increases in circulating LSC : > 100-fold CD34$^+$, CD34$^+$/38$^-$, CD34$^{+/}$38$^-$/123$^+$ (LSC), CXCR4$^+$, VLA-4$^+$, and CD44. Serial FISH analyses demonstrated preferential mobilization of leukemic versus non-leukemic cells and FACS/CyTOF mobilization of primitive LSC, positive for pAKT, pmTOR, pSYK, p4EP1, ERK, and pSTAT5. **Conclusions:** Combination of G-CSF and plerixafor is safe and superior to plerixafor in mobilizing leukemic blasts and LSC in heavily pretreated FLT3-ITD AML patients. Overall response rate was 62%, including 28% CR/CRp. Mobilized LSC displayed increased MAPK/AKT/STAT signaling. This is the first clinical study of G-CSF and plerixafor for the mobilization of leukemic cells, which was aimed at removing these cells from their protective bone marrow microenvironment. The encouraging clinical responses provide proof-of-concept, and can be further improved by more potent FLT3 and CXCR inhibitors.

**7034 General Poster Session (Board #319), Mon, 1:15 PM-5:00 PM**

**The effect of anti-thymocyte globulin on outcomes of reduced intensity conditioning for acute myelogenous leukemia.** *Presenting Author: Patrick Alan Hagen, University of Minnesota, St. Paul, MN*

**Background**: Antithymocyte globulin (ATG) has been administered to patients considered high risk for graft rejection and graft-versus-host disease (GVHD), such as those receiving HLA-mismatched allografts. If the benefits on engraftment and GVHD are offset by increased risk of relapse, delayed T-cell recovery, and increased infections remains controversial. **Methods**: We retrospectively studied the effect of ATG in 144 acute myelogenous leukemia (AML) patients undergoing nonmyeloablative umbilical cord blood transplantation (UCB) or HLA-matched sibling peripheral stem cell transplantation (PBSC). GVHD prophylaxis consisted almost universally of Cyclosporine and Mycophenolate mofetil. ATG was administered to a subgroup of patients who had not received immunosuppressive chemotherapy in the months (UCB = 3 months; PBSC = 6 months) prior to transplantation and considered high risk for graft rejection. **Results**: There were no significant differences between study groups in regards to disease status at treatment, disease risk, cytomegalovirus serostatus, and cytogenetic risk. ATG treated patients had significantly more infections between 46-180 days post-transplantation. The risk of treatment related mortality was 30 vs 20% (p=.45), in particular infection related death at 1 year was 21 vs. 10% (p=.12) for ATG and non-ATG recipients respectively. The cumulative incidences of acute and chronic GVHD were lower, but not statistically significant, in ATG treated patients. The cumulative incidence of relapse at 2 years was also lower (p=.09) in ATG treated patients. Outcomes were not influenced by donor type. **Conclusions**: The lower risk of relapse with ATG likely reflects our indication for ATG, possibly selecting patients with a less aggressive phenotype and longer pre-transplant remission. Regardless, ATG did not adversely influence risk of relapse. The lower, but not statistically significant reduction in the risk of GVHD in the ATG treated patients may reflect the limited number of events in our patients. In summary, we showed that when administering ATG in the non-myeloablative setting according to our institutional criteria in AML patients there was no adverse effect on outcomes.

**7035 General Poster Session (Board #320), Mon, 1:15 PM-5:00 PM**

**Allogeneic stem cell transplantation (SCT) using a CAT-bu conditioning regimen in patients with advanced myelodysplastic/myeloproliferative disorders (MDS-MPDs).** *Presenting Author: Julie Cote, Hôpital Enfant-Jésus, Quebec City, QC, Canada*

**Background:** Many patients with MDS-MPDs are ineligible to allogeneic SCT using a standard myeloablative approach. In this population, we evaluated the efficacy and safety of a novel conditioning regimen called CAT-Bu. **Methods:** The conditioning regimen consisted of CAT (cyclophosphamide IV 300 mg/m2 every 12 hours from day 1 to 3, Cytarabine IV 2000 mg/m2 from day 2 to 6, topotecan 1.25 mg/m2/day by continuous IV perfusion from day 2 to 6) and oral Busulfan adjusted dose from day 14 to 18. Peripheral blood stem cells were infused on day 20. Tacrolimus and mycophenolate were used as graft vs. host disease (GVHD) prophylaxis. All patients received prophylactic trimethoprim/sulfamethoxazole, valacyclovir and posaconazole. Charts from patients who received this regimen between July 2009 and September 2012 were reviewed. **Results:** Sixteen patients received the CAT-Bu regimen. The median age was 60.5 years old. The Hematopoietic Cell Transplant Comorbidity Index was low in 63%. The disorder at diagnosis was MDS in 56% and MPD in 44%. At SCT, active disease was noted in 75% of the population. Nearly half of the patients had transformation to AML (44%). No patient was in complete remission (CR). The majority of donors were fully matched siblings (81%). Median follow up was 729 days for alive patients and 159 days for dead patients. CR was the best response obtained after SCT in 63%. The OS and PFS at 6 months, 1 year and 2 years were respectively: 75%, 56%, 48% and 50%, 44%, 35%. All deaths were related to the hematological neoplasia. Common adverse events were febrile neutropenia (81%), oral mucositis (56%), diarrhea (38%) and hepatic cytolysis (38%). Two grade 4 respiratory distresses were noted. One was probably related to Busulfan's pulmonary toxicity. **Conclusions:** This new sequential approach offers satisfactory efficacy with acceptable toxicity for the studied population, which, for the majority, presented active disease at time of SCT.

**7036 General Poster Session (Board #321), Mon, 1:15 PM-5:00 PM**

**Reduced-intensity cord blood transplantation following a regimen using fludarabine and busulfan in adult patients with advanced hematologic malignancies.** *Presenting Author: Naoko Takei, Department of Hematology, Teikyo University Chiba Medical Center, Chiba, Japan*

**Background:** Cord blood transplantation has grown as an effective alternative therapy for treating patients with advanced or high-risk hematologic malignancies who have no suitable related or unrelated donor. We report the results of reduced-intensity cord blood transplantation (RI-CBT) following a regimen using fludarabine and busulfan in adult patients with advanced hematologic malignancies. **Methods:** 45 patients (median age, 62 years; range, 26-74 years) underwent RI-CBT at Teikyo University Chiba Medical Center and Tsukuba Memorial Hospital between April 2004 and November 2013. Preparative regimens consisted of fludarabine 30 mg/m2 for 6 days and busulfan 0.8 mg/kg x 4 for 2 or 4days. Tacrolimus was used for prophylaxis of graft-vs-host disease (GVHD). The median infused total cell dose was 2.78 x $10^7$/kg (range, 1.94-5.53 x $10^7$/kg). **Results:** 24 patients achieved primary neutrophil engraftment after a median of 22 days(range, 14-47). 12 of 24 patients with engraftment achieved complete donor-type chimerism by day 100. 11 patients developed grade II to IV acute GVHD, and 9 developed chronic GVHD. Transplant-related mortality within 100 days occurred in 11 of 45 patients. 9 patients were alive in remission at median follow up of 27 months (range, 2-117). The estimated 1-year probability of overall survival was 27.2% (95% CI 15.0-41.0). 6 of 45 patients were $\geq$ 70 years old, and all of them died within 100 days. The overall survival probabilities of patients aged 65-69 were found to be similar to younger patients. **Conclusions:** These data suggest that RI-CBT is a feasible option for patients under 70 years of age with advanced hematologic malignancies who lack an HLA-matched donor.

**7037 General Poster Session (Board #322), Mon, 1:15 PM-5:00 PM**

**Inflammation and depression in allogeneic stem cell transplant recipients.** *Presenting Author: Alexandra A. Erdmann, University of Wisconsin, School of Medicine and Public Health, Madison, WI*

**Background:** Depressed mood is a prevalent concern for individuals undergoing allogeneic stem cell transplantation (allo-SCT). Recent research suggests that proinflammatory cytokines can activate central nervous system pathways, eliciting adverse behavioral responses such as depressed mood. We hypothesized that inflammation may contribute to depression in allo-SCT patients. We also examined the extent to which cytokines were associated with neurovegetative (NV) versus cognitive/affective (CA) depression symptoms. **Methods:** Adults with hematologic malignancies undergoing allo-SCT (N = 66) participated in this longitudinal observational study. Participants completed the Inventory of Depression and Anxiety Symptoms pre-transplant and at 1, 3, and 6 months post-transplant. Proinflammatory (IL-6, TNF$\alpha$) and regulatory (IL-10) cytokines were assessed by ELISA in peripheral blood at the same time points. Mixed-effects and subject-level fixed effects regression models were employed to examine relationships between plasma cytokine levels and depression symptoms. **Results:** Participants with elevated IL-6 (z = 3.16, p = .002) and TNF$\alpha$ (z = 2.23, p = .026) reported more severe depressive symptoms compared to those with low/normal levels. Follow-up analyses clarified that these relationships were seen for NV (z = 2.14-3.26, all p values $<$.05) but not for CA symptoms (p values $>$.05). All models adjusted for time since transplant, conditioning regimen, graft-versus-host-disease, and recipient's age. Similarly, within-subjects analyses revealed that among individuals, changes in cytokine levels across the assessments were associated with corresponding changes in depressed mood, with patients reporting greater overall and NV depression symptoms when IL-6 (z = 3.05, p = .003; z = 3.34, p = .001) and TNF$\alpha$ levels were elevated (z = 2.11, p = .037; z = 2.73; p = .007). **Conclusions:** Results provide evidence for a novel biobehavioral pathway by which inflammation from conditioning therapy or transplant-related complications can evoke depressive symptoms among allo-SCT patients, specifically NV symptoms. This potential treatment-related cause of depression could be targeted to improve the quality of life for allo-SCT recipients.

**7038 General Poster Session (Board #323), Mon, 1:15 PM-5:00 PM**

**Effects of acute graft-versus-host-disease on physical and psychological functioning following hematopoietic stem cell transplantation.** *Presenting Author: Mackenzie L Erdmann, University of Wisconsin, School of Medicine and Public Health, Madison, WI*

**Background:** Acute graft-versus-host-disease (aGVHD) is a significant early complication of allogeneic hematopoietic stem cell transplantation (HSCT). Little is known about the effects of aGVHD on quality of life, and no prior studies have examined psychological effects. We compared physical and psychological functioning of HSCT survivors who developed aGVHD to those who did not. **Methods:** Adults with hematologic malignancies were enrolled in this prospective, longitudinal study prior to allogeneic HSCT. Those alive without recurrence at 6 months post-HSCT (N=108) were included in the analyses. Participants completed well-validated self-report measures of physical functioning (fatigue, pain, sleep, physical and functional well-being) and psychological functioning (depression, anxiety, psychological well-being) pre-HSCT and 3 and 6 months post-HSCT. Those diagnosed with mild (grade 1-2) and severe (grade 3-4) aGVHD were compared to those with no aGVHD on all measures after controlling for pre-HSCT measures, age, HSCT regimen, and chronic GVHD. **Results:** 52 participants were diagnosed with mild (n=39) or severe (n=13) aGVHD. By 3 and 6 months post-HSCT, there were no significant differences between those with and without a history of aGVHD on physical functioning measures. There were significant differences in anxiety at 3 and 6 months post-HSCT (F(2, 103)=3.19; p=.049; F(2, 98)=4.99; p=.011). There was also a trend toward a difference in the psychological well-being measure of personal strength at 6 months (F(2, 97)=2.86; p=.070). Follow-up comparisons showed that those with a history of severe aGVHD reported significantly greater anxiety but also a greater sense of personal strength as compared to those with mild or no aGVHD (pvalues$<$.05). **Conclusions:** Findings indicate that HSCT survivors who developed aGVHD, even severe cases, were doing as well as those without aGVHD on all indices of physical functioning and most indices of psychological functioning by 3 and 6 months post-HSCT. However, the experience of severe aGVHD appeared to affect select aspects of psychological functioning, conferring greater anxiety but also an enhanced sense of personal strength.

**7039 General Poster Session (Board #324), Mon, 1:15 PM-5:00 PM**

**Haploidentical stem cell transplantation (Haplo-HSCT) with nonmyeloablative conditioning regimen (NMAC) and postinfusion cyclophosphamide in advanced non-Hodgkin lymphoma (NHL) patients.** *Presenting Author: Sylvain Garciaz, Institut Paoli Calmettes, Marseille, France*

**Background:** In patients lacking HLA identical (HLA-id) donors, haploidentical (Haplo) donors is increasingly considered as a valid alternative stem cell source.The introduction of post-infusion Cyclophosphamide (Cy) as prophylaxis for immunological complications using T-cell replete graft is one of the most usual strategy. However, efficacy is still a matter of debate. Here we reviewed the outcome of 28 consecutives Haplo-HSCT patients with advanced NHL that we compared to an historical control cohort of patients transplanted from HLA-id donors. **Methods:** 28 Haplo-HSCT were performed between 04/06/2010 and 27/09/2013. Diagnoses were aggressive NHL in 22 patients and low-grade NHL in 6. Median age was 48 years (19-67). At transplant, 64% were in complete remission, 29% in partial remission and 7% in stable disease. These 28 patients were fully matched to 61 HLA-id patients. Conditioning regimen varied according to donor source. Haplo-HSCT patients received a NMAC associating of Fludarabine (150mg/m$^2$ total dose over 5 days), pre-infusion Cy (29 mg/kg total dose over two days), Low dose TBI 2 gray and post infusion Cy (100mg/kg total dose over 2 days). The HLA-id cohort reduced intensity conditionning consisted in Fludarabine (150mg/m$^2$ total dose over 5 days), intravenous Busulfan (6.4 mg/kg total dose over 2 days) and antithymocyte globulin (Thymoglobulin; 5 mg/kg total dose over 2 days). **Results:** With a median follow up of 15 months (2-70), the 2-year PFS and OS were 67% and 62% respectively in the Haplo-HSCT group. Incidence of day-100 acute grade 3-4 GVHD was 7%. The 24-months estimated incidence of chronic GVHD (cGVHD) and extensive cGVHD, was 7% and 4%. The 2-year NRM was 18%. The 2-year cumulative incidence of relapse was 20%. There was no statistical difference found when compared to the HLA-id group of patients for all outcomes. **Conclusions:** These results suggest that NMAC HSCT from Haploidentical donors achieves promising anti-tumor effect with an acceptable NRM and a low incidence of GVHD. Haplo-HSCT should represent a valuable alternative for patients with advanced NHL without available HLA-id donors.

**7040 General Poster Session (Board #325), Mon, 1:15 PM-5:00 PM**

**Optimizing donor selection for public cord blood banking in Korea.** *Presenting Author: Junglim Lee, Department of Hematology, Daegu Fatima Hospital, Daegu Fatima Public Cord Blood Bank, Daegu, South Korea*

**Background:** It is well recognized that TNC and CD34 define a superior Cord blood unit (CBU). According to "the Law of Korean CB Banking and Research", only 40% of collected CBUs meet the criteria. To improve a rate of banking, we analyzed the characteristics of CBUs and assessed predictive factors for numbers of TNC and CD34+ in collected CBUs. **Methods:** This study examined 5,065 UCB (2,943 at the Catholic Hematopoietic Stem Cell Bank and 2,122 at the Daegu Fatima Hospital Public Umbilical Cord Bank) collected at two hospitals from Oct 2003 to Jan 2014. The variables were collected from retrospective records at the time of donation. The associations between TNC, CD34+ and variables including maternal age (MA), gestational age (GA), fetal body weight (FBW), time from collection to processing (T) and collecting volume (CV) were analyzed by logistic regression. **Results:** In our study cohort (n=5,064), the median values of TNC, numbers of CD34, MA, GA, FBW, T and CV were $9.02\times10^8$/unit, $2.0\times10^6$/unit, 32.0 years, 277 days, 3,320g, 18 hours and 80.0ml respectively. In univariate analysis, variables that were associated with high TNC (TNC>$9.02\times10^8$/unit) included MA (MA≤32years) [OR 1.32 (95% CI 1.17-1.48 p<0.001)], normal delivery [OR 2.30 (95% CI 1.97-2.66 p<0.001)], GA (GA>277 days) [OR 1.20 (95% CI 1.07-1.34 p=0.002)], female gender [OR 1.27 (95% CI 1.13-1.43 p<0.001)], FBW (FBW>3320) [OR 1.37 (95% CI 1.23-1.53 p<0.001)] and CV (CV>80ml) [OR 2.40 (95% CI 2.15-2.69 p<0.001)]. Variables that were associated with high CD34 (CD34>$2.0\times10^6$/unit) included MA [OR 0.85 (95% CI 0.76-0.95 P=0.005)], normal delivery [OR 1.33 (95% CI 1.15-1.53 p<0.001), GA [OR 1.20 (95% CI 1.07-1.34 P=0.002)], FBW [OR 1.41 (95% CI 1.27-1.58 p<0.001)] and CV [OR 1.42 (95% CI 1.28-1.60 p<0.001)] In multivariate analysis of TNC, CV>80ml [OR 2.84] was the best predictor of followed by normal delivery [OR 2.33], FBW [OR 1.52], female gender [OR 1.36], MA [OR 1.25] and T [OR 1.25]. **Conclusions:** M/D characteristics were associated with normal delivery which is the best predictor for TNC and CD34+ followed by CV for TNC and BW for CD34+ in collected Korean CBUs. These associations could be used to prioritize donations, collections, optimizing and financial modeling in Korean CB banks.

**7041 General Poster Session (Board #326), Mon, 1:15 PM-5:00 PM**

**Myeloablative busulfan with cyclophosphamide (BuCy) versus busulfan with fludarabine (BuFlu) in myeloid neoplasms.** *Presenting Author: Renju V. Raj, University of Iowa, Iowa City, IA*

**Background:** BuCy is considered a standard myeloablative conditioning regimen for allogeneic hematopoietic stem cell transplantation (HSCT). However its use is limited by significant regimen related toxicity. Several reports suggest that the combination of busulfan and fludarabine(BuFlu) in ablative doses may provide effective control of myeloid neoplasms with less toxicity. This study evaluated the effect of replacing BuCy with BuFlu for myeloablative conditioning in myeloid neoplasms. **Methods:** Retrospective analysis of patients (pts) with myeloid neoplasms who underwent allogeneic HSCT after myeloablative conditioning regimen with BuFlu or BuCy between 2006 and 2012 was done. Forty five pts received BuFlu and 38 BuCy. Ten (22.2%) pts in BuFlu and 3 (8%) pts with BuCy had an HLA mismatched transplant. Median age was 58 (range 22-68) in BuFlu group and 53 (range 19-68) in BuCy. Disease risk by CIBMTR classification was advanced in 27 (60%) pts in BuFlu group and 10 (26.3%) in the BuCy. HSCT Comorbidity Index score was high in 24 (53.3%) pts in BuFlu and 17(44.7%) in BuCy. GVHD prophylaxis consisted of tacrolimus and methotrexate in all pts in BuFlu and in 81.6 % pts in BuCy with 7 pts receiving cyclosporine and mycophenolate. Thymoglobulin was administered in unrelated and mismatched donor grafts. Cox proportional hazard models were used to obtain the hazard ratios and 95% confidence intervals. **Results:** All pts engrafted except 1 in the BuCy group. Mortality at day 100 post-transplant was 4.4% in BuFlu and 21% in BuCy (p=0.038). Grade 3 and 4 GVHD was diagnosed in 6.6% in BuFlu and 21% in BuCy group. Risk of relapse or death for pts in the BuCy group was 2.17 times (95% CI 1.08-4.355, p=0.028) higher than for pts in the BuFlu group with a median follow up of 554 days. The trend for overall survival(OS) was better in BuFlu group compared to BuCy (HR 1.97, 95% CI 0.97-3.97, p=0.059). Relapse free survival was also favored in BuFlu pts compared to BuCy (HR 1.550, 95% CI 0.607-3.960, p=0.359) **Conclusions:** In our experience we found that conditioning with BuFlu is better tolerated, has better 100 day mortality, improved time to progression and OS, in spite of the fact that the pts in BuCy group had a higher CIBMTR disease risk score.

**7042 General Poster Session (Board #327), Mon, 1:15 PM-5:00 PM**

**Cyclophosphamide/fludarabine-based nonmyeloablative matched related/unrelated allotransplant for myelodysplasia.** *Presenting Author: Muhammad Rizwan-ul-Haq Khawaja, Indiana University School of Medicine and the IU/Melvin and Bren Simon Cancer Center, Indianapolis, IN*

**Background:** Hematopoietic cell allotransplant (HCT) with reduced intensity conditioning (RIC) offers curative treatment for myelodysplasia (MDS) in patients that are traditionally excluded from myeloablative (MAT) HCT due to age or comorbidities. Concerns regarding disease control with this approach are based on retrospective data pooled from multiple institutions using different RIC regimens. Cyclophosphamide/fludaraine (Cy/Flu) is a minimal intensity RIC regimen which has not been independently compared to MAT. **Methods:** This retrospective study was conducted to compare disease control and survival outcomes of MAT versus Cy/Flu-based nonmyeloablative allotransplant (NMAT), performed at a single institution during 2000-2013. **Results:** Seventy-four patients underwent MAT (n=27) or NMAT (n=47) from a related (n=36) or unrelated (n=38) donor. Patients who received NMAT were older (mean, 57 vs. 44 years; p<0.001), were more likely to have ECOG performance status (PS) greater than zero (17% vs. 0%; p=0.024), to receive mobilized peripheral blood grafts (100% vs. 81%; p=0.005) and cyclosporine-based GVHD prophylaxis (68% vs. 31%; p=0.002) rather than tacrolimus/sirolimus-based prophylaxis. Distribution of related or unrelated donors and IPSS categories were similar in NMAT and MAT groups. Median follow-up was approximately 49 months. Median progression free survival (PFS) was 429 days after NMAT compared to 349 days after MAT (p=0.585); median overall survival (OS) was 488 days and 608 days (p=0.517), respectively. Eighty percent of patients achieved remission following NMAT compared to 71% following MAT (p=0.416). Twenty percent of patients after NMAT experienced progression versus 33% after MAT (p=0.248). After adjusting for age, IPSS categories, PS, donor source, graft source and GVHD prophylaxis, no statistically significant difference in PFS [HR 0.74 (95% CI 0.25-2.17)] or OS [HR 0.73 (95% CI 0.25-2.17)] was found between NMAT and MAT. **Conclusions:** Cy/Flu based NMAT may provide similar disease control and survival in MDS compared to MAT.

**7043 General Poster Session (Board #328), Mon, 1:15 PM-5:00 PM**

**Next-generation sequencing to identify mutations that may predict outcome after allogeneic stem cell transplantation for AML.** *Presenting Author: Marlise Rachael Luskin, Division of Hematology/Oncology, Department of Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

**Background:** Relapse is the most common reason for failure of allogeneic stem cell transplant (SCT). Identifying patients at increased relapse risk is crucial for improving outcomes. Prognostic somatic mutations have been identified in AML but their prognostic value after SCT is unknown. We hypothesize that next generation sequencing (NGS) can predict SCT outcome in AML. **Methods:** We performed NGS for 33 hematologic malignancy associated genes in 62 adult patients treated with SCT for de novo AML (2003-2013). Relapse free survival (RFS) was compared by Cox regression with adjustment for cytogenetic risk, conditioning intensity, donor type and graft source. **Results:** At least 1 mutation was identified in 56 (90%) patients (median 2, range 0-6) including 35 of 36 (97%) patients with intermediate cytogenetics (median 3, range 0-6). Among patients with intermediate cytogenetics transplanted in CR, poor prognostic mutations were found in 9 of 15 FLT3ITD negative patients (2 DNMT3A; 3 DNMT3A + IDH; 1 DNMT3A + TET2 + IDH2; 1 TET2; 1 TET2 + PHF6; 1 ASXL1); among FLT3ITD positive patients, 4 of 9 were additionally DNMT3A mutant which may confer added risk. Among patients with favorable cytogenetics transplanted in CR2, 2 of 8 patients had kit mutations; there were no mutations in DNMT3A, IDH, ASXL1, TET2, or PHF6. Among patients with unfavorable cytogenetics, 4 of 13 had additional poor prognostic mutations (1 FLT3ITD +TET2, 1 TET2, 2 TP53). In FLT3ITD negative patients with any cytogenetic risk, DNMT3A mutant status significantly worsened RFS (adjusted HR=4.76 [95% CI 1.34-16.9]; p=0.016). **Conclusions:** NGS identifies a high frequency of potentially prognostic mutations in SCT patients. Mutant DNMT3A may negatively impact prognosis in FLT3ITD negative AML post SCT. NGS testing of a larger cohort is warranted and underway. Identifying patients at high risk for relapse by molecular profiling may allow early intervention.

**7044 General Poster Session (Board #329), Mon, 1:15 PM-5:00 PM**

**Trends in hospitalization outcomes of elderly patients undergoing allogeneic stem cell transplantation for acute myeloid leukemia/myelodysplastic syndrome (AML/MDS).** *Presenting Author: Guru Subramanian Guru Murthy, University of Arkansas for Medical Sciences, Little Rock, AR*

**Background:** Allogeneic stem cell transplant (AlloSCT) is increasingly used for treatment of elderly patients with AML/MDS. This study aims to explore the US national trends in hospital stay, inpatient cost, and outcomes associated with AlloSCT in elderly patients with AML/MDS. **Methods:** Using Nationwide Inpatient Sample database, we identified all hospitalizations for AlloSCT in patients age ≥ 60 years with AML/MDS from 2007 through 2011. ICD 9 codes were used to identify diagnoses and procedure related information. Data on patient demographics, source of stem cell, length of stay (LOS), complications and deaths were obtained. Outcomes were analyzed using Kruskal Wallis test for comparing means and Chi -square test for categorical variables. Multivariate logistic regression method was used to determine factors associated with prolonged hospital stay and death. **Results:** Based on sample weights, an estimated 4242 AlloSCT procedures for AML/MDS in elderly patients were identified nationwide between 2007-2011. Patients had a median age of 64 years (range – 60-78). Inpatient AlloSCT was more common in males (60.1%) and whites (76.7%). There was a significant reduction in the LOS for AlloSCT from 2007 to 2011. Mean LOS in 2007 was 28.70± 0.69 days, and mean LOS in 2011 was 23.69 ± 0.46 days ($p<0.01$). Inpatient cost showed an increase till 2009 followed by a decline (mean cost - USD 257,291 in 2007, USD 344,454 in 2009 and USD 259301 in 2011, $p<0.01$). In-hospital mortality has decreased from 9.4% in 2007 to 5% in 2011 ($p=0.02$). Complications causing prolonged LOS included acute GVHD (4.2%), septicemia (20.0%), acute renal failure (12.9%), parenteral nutrition (12.8%). On multivariate analysis, stem cell source from bone marrow compared to peripheral blood was associated with higher complications, prolonged LOS (OR 1.88, CI 1.55-2.28, $p<0.01$) and higher mortality (OR 2.45, CI 1.87-3.220, $p<0.01$). **Conclusions:** Our study demonstrates an improvement in the hospitalization outcome of elderly AML/MDS patients undergoing AlloSCT in US. Further focus of research in this risk group to reduce complications would improve mortality and cost benefits.

**7045 General Poster Session (Board #330), Mon, 1:15 PM-5:00 PM**

**LINAC-based intensity modulated total marrow irradiation (TMI) in addition to myeloablative fludarabine/IV busulfan conditioning prior to allogeneic stem cell transplant for high-risk hematologic malignancies: A phase I study.** *Presenting Author: Pritesh Rajni Patel, Division of Hematology/Oncology, University of Illinois at Chicago, Chicago, IL*

**Background:** Total body irradiation (TBI) currently has limited use in stem cell transplant due to significant extra-hematologic toxicity. Intensity modulated total marrow irradiation (TMI) represents an innovative technique to selectively irradiate the bone marrow. We combined a fully myeloablative chemotherapy regimen with escalating doses of TMI in a Phase I trial in allogeneic stem cell transplant. (Id: Clinicaltrials.gov NCT00988013). **Methods:** A Phase 1 trial (3+3 design) for adult patients with high risk (HR) hematologic malignancies enrolled 14 patients who were transplanted from related (n=9) or unrelated (n=5) donors and included: HR acute lymphoblastic (ALL) (n=2) or myeloid (AML) (n=9) leukemia, HR multiple myeloma (n=2) and chronic myeloid leukemia (CML) (n=1) resistant to TKI. Median age was 52 years (range 20-65). Patients received fludarabine 160mg/m$^2$, targeted i.v. busulfan (AUC 4800 $\mu$M/min) and IM-TMI (from 3 to 12 Gy). Dose Limiting Toxicity was defined as any grade 3 or 4 toxicity up to day +30 on the Bearman scale. **Results:** Of 14 patients, 3 were enrolled in cohorts 1 (3Gy) and 2 (6Gy), 6 in cohort 3 (9Gy) and 2 in cohort 4 (12Gy). All patients engrafted. Median time for ANC >0.5 and platelets > 20 x 10$^9$/L were 15 and 15.5 days, respectively. No patient experienced grade 3 or 4 toxicity before day +30. Grade 1-2 mucositis was observed in all patients. After a median follow up of 598 days (range 68-1319 days), 7 patients are alive and 6 remain in remission. Cause of death was TRM (after D30) (n=4: pneumonia, liver failure, GVHD and sepsis), all in cohorts 3 and 4 and relapse (n=3). Cohort 4 was terminated after 2 patients experienced significant toxicity and prolonged hospitalization. Lymphocyte reconstitution at 1, 3 and 6 mo was comparable among the groups. **Conclusions:** This is the first study showing that TMI can be safely combined with fully myeloablative chemotherapy. A dose of 9 Gy TMI will be utilized in a Phase II study. Linac based TMI can potentially be replicated in every transplant center and exploited in new autologous or allogeneic stem cell transplantation studies. Clinical trial information: NCT00988013.

**7046 General Poster Session (Board #331), Mon, 1:15 PM-5:00 PM**

**The impact of CD34$^+$ cell dose and comorbidities on engraftment following autologous hematopoietic stem cell transplantation (ASCT).** *Presenting Author: Mark A Fiala, Washington University School of Medicine in St. Louis, St. Louis, MO*

**Background:** The minimum CD34$^+$ cell dose needed to ensure hematopoietic recovery following ASCT is 2x10$^6$cells/kg. Recent studies suggest that 5x10$^6$cells/kg or 8x10$^6$cells/kg is the optimal dose as it results in more rapid and sustained engraftment. To date, little is known about the impact of comorbidities on engraftment. **Methods:** We performed retrospective chart review of 639 consecutive patients with a diagnosis of multiple myeloma (MM), non-Hodgkin's lymphoma (NHL) or Hodgkin's lymphoma (HL) who underwent mobilization and ASCT at the Siteman Cancer Center/Washington University School of Medicine from 2008 to 2011. Independent variables analyzed were: CD34$^+$cell dose, age, gender, diagnosis, coronary artery disease, diabetes mellitus (DM), hyperlipidemia, and hypertension. Kaplan-Meier curves were performed to compare the median time to neutrophil engraftment (TTNE) and the median time to platelet engraftment (TTPE). **Results:** The median age was 58 years (range 18-74); 58% were male; 52% had MM, 39% had NHL, and 9% had HL. The median CD34+ cell dose administered was 4.1x10$^6$cells/kg (range 1.9-42.5). 8 patients received stem cell doses < 2x10$^6$cells/kg and, therefore, were excluded from analysis. Administration of ≥ 5x10$^6$cells/kg was associated with improved TTNE and TTPE (10 and 16 days, respectively, compared to 11 and 18 days; $p< 0.001$) but had no effect on the rates of platelet engraftment failure or 100 day mortality. Cell doses ≥ 8.0 x10$^6$cells/kg had no additional impact on engraftment kinetics or 100 day mortality. TTNE for patients with DM (n=84) was 11 days compared 10 days for patients without ($p = 0.01$). **Conclusions:** Administration of ≥ 5x10$^6$ CD34$^+$cells/kg resulted in only marginal improvement in TTNE and TTPE, and did not improve the platelet engraftment failure or 100 day mortality rates. Therefore, CD34$^+$ cell doses of ≥ 2x10$^6$cells/kg should be considered effective, and additional days of cell collection to achieve a cell dose of ≥ 5x10$^6$cells/kg may not be warranted. DM has been previously reported to increase the length of hospital stay post-ASCT, but its effect on TTNE observed in our cohort is a novel finding.

**7047 General Poster Session (Board #332), Mon, 1:15 PM-5:00 PM**

**Impact of body mass index (BMI) on plerixafor efficacy during hematopoietic progenitor cell (HPC) mobilization.** *Presenting Author: Rebecca M. Gonzalez, WVU Healthcare, Morgantown, WV*

**Background:** Plerixafor in combination with G-CSF is commonly used to mobilize HPC for autologous transplantation. The effect of BMI on plerixafor mobilization efficacy is controversial, with conflicting results from previous studies. **Methods:** One hundred and fourteen patients received G-CSF (10mcg/kg TBW) daily, with plerixafor (0.24mg/kg TBW) added on the evening of day 4 of G-CSF, to mobilize and collect HPCs from 12/2009-12/2013. The first 83 patients before 11/2012 received upfront plerixafor/GCSF mobilization, and the remaining patients received a "just in time" approach, with plerixafor added if peripheral CD34 count was $<10/\mu$L by day 4 of G-CSF. Patients receiving plerixafor were divided into obese (BMI $\geq$30) and non-obese (BMI $<$30) groups, and were compared to evaluate the effect of BMI on plerixafor HPC mobilization outcomes. **Results:** Patient demographics are listed in Table 1. A median of 2 plerixafor doses were given in both the obese (range 1-4) and non-obese (range 1-5) patients. The median peak peripheral CD34+ count was 38/$\mu$L (range 2-389.2) in obese versus 39.5/$\mu$L (range 3-350) in non-obese patients (*P=0.25*). Median CD34+ collection Day 1 was 2.2 (obese) versus 2.3 x $10^6$ cells/kg TBW (non-obese). Total CD34+ cell yield after a median of 2 apheresis sessions was 4.3 x $10^6$ cells/kg TBW in each group (*P=0.51*). Successful collection of $\geq$ 2 and 5 x $10^6$ CD34+ cells/kg TBW occurred in 90% and 40% of obese compared to 87% and 43% of non-obese patients, respectively (*P = 0.77, 0.71*). **Conclusions:** Obesity is not a negative predictive factor for plerixafor HPC mobilization. All collection parameters were similar between both groups.

**Early rituximab failure (ERF) in relapsed diffuse large b-cell lymphoma (DLBCL) and prediction of futility of autologous hematopoietic cell transplantation (AHCT).** *Presenting Author: Mehdi Hamadani, Medical College of Wisconsin, Milwaukee, WI*

**Background:** The poor prognosis of DLBCL pts relapsing within 1-yr of initial diagnosis after 1$^{st}$line rituximab-based chemotherapies (Gisselbrecht. JCO 2010) has created controversy about the role of AHCT in this setting. **Methods:** Using the CIBMTR database, we compared AHCT outcomes of chemosensitive DLBCL pts who experienced early failure after rituximab-containing 1st line chemotherapies (i.e pts with primary refractory disease or 1$^{st}$ relapse within 1yr of diagnosis; **ERF group**) *against* those who relapsed more than 1yr after diagnosis (Late Rituximab Failure [**LRF**] **cohort**), between 2000-2011.Chemorefractory pts and transformed lymphomas were excluded. Primary outcomes were non relapse mortality (NRM), progression/relapse (P/R), progression-free survival (PFS) and overall survival (OS). **Results:** ERF and LRF cohorts included 201 and 315 pts respectively (Table). On univariate analysis the 3yr NRM, P/R, PFS and OS of ERF vs. LRF cohorts was 12% vs. 7% (p=0.08), 49% vs. 40% (p=0.07), 39% vs. 52% (p=0.005) and 44% vs. 66% (p<0.001), respectively. On multivariate analysis (MVA) ERF was associated with higher NRM (relative risk (RR) 1.73, p=0.04). Within first 9 months post AHCT, ERF had worse R/P (RR 1.85, p<0.001), PFS (RR 2.02, p<0.001) and OS (RR 2.94, p<0.001), but no significant difference for R/P, PFS and OS existed between the two groups, beyond 9 months post AHCT in the MVA. Age $\geq$60yrs was associated with worse NRM (p=0.03), PFS (0.01) and OS (p=0.02) and KPS $<$90 with inferior NRM and OS. **Conclusions:** ERF does not predict futility of AHCT in DLBCL (with 3yr PFS 39% & OS 44%). AHCT remains standard-of-care in chemosensitive DLBCL regardless of the timing of disease relapse.

**7049 General Poster Session (Board #334), Mon, 1:15 PM-5:00 PM**

**Social connectivity and outcomes for adolescents and young adults (AYAs) with acute lymphoblastic leukemia (ALL).** *Presenting Author: Andrew Fintel, The University of Tennessee/The West Clinic, Memphis, TN*

**Background:** While the outcomes for AYAs with ALL are worse when treated on adult rather than pediatric protocols, one criticism is that this may be due to "emancipation" of young adults. **Methods:** Using case listing session of SEER 18 (1973-2010) we examined outcomes for AYAs with ALL defined similar to CALGB 10403 (age 18-30) predicated on marital and insurance status as surrogates of emancipation (limiting analysis to 2007-2010). Analyses were conducted with SEER*Stat 8.1.2, Microsoft Excel 2007 and GraphPad Prism 6. Comparisons were made using the chi-squared test and log rank test (Mantel-Cox); all p-values were 2-sided. **Results:** While age (24 and younger versus 25 and older) was predictive of median OS (NR v 33; p=0.0029) (3-yr OS 66% v 49%); social factors were not as detailed in the Table; NR = not reached. **Conclusions:** Social connectivity, as defined by insurance status and marriage, did not influence outcomes for AYAs with ALL, arguing that intrinsic differences in disease and disease-specific therapies are more important than social issues.

**7050 General Poster Session (Board #335), Mon, 1:15 PM-5:00 PM**

**Cytogenetic and molecular testing in patients with chronic myeloid leukemia (CML) in a prospective observational study (SIMPLICITY).** *Presenting Author: Stuart L. Goldberg, John Theurer Cancer Center, Hackensack, NJ*

**Background:** Few clinical practice data describe response monitoring in patients (pts) with chronic-phase CML (CP-CML) treated with tyrosine kinase inhibitors (TKIs). **Methods:** SIMPLICITY is an ongoing observational study of CP-CML patients receiving first-line imatinib (IM), dasatinib (DAS) or nilotinib (NIL) in the United States (US) and Europe (EU); its primary objective is to understand TKI use and management patterns in clinical practice (NCT01244750). The study includes 3 'prospective' newly-diagnosed cohorts treated with IM, DAS or NIL since 2010 and a 'historical' cohort treated with IM since 2008. Frequency of testing for cytogenetic response (CyR), by FISH or karyotype, and molecular response (MR), by PCR, were analyzed in 6 and 12 month increments from TKI start. **Results:** 949 pts (EU: 34%, US: 66%) were enrolled through 10/03/2013, receiving IM (n=415), DAS (n=275) or NIL (n=259). Mean ($\pm$ SD) follow-up was 19 ($\pm$ 9) months. Demographics were consistent across cohorts (median age: 56 years; 56% male). Of 713 pts with $\geq$12 months' follow-up, 48% were tested for CyR between 0–12 months (excluding diagnostic tests); of these, 40%, 33% and 28% had 1, 2 and $\geq$3 tests, respectively. The proportion of pts tested for CyR in the first 12 months varied by region (EU: 62%; US: 42%). The proportion of pts with $\geq$12 months follow-up that were tested for MR between 0–12 months was 80% across regions (EU: 85%; US: 78%); of these, 28%, 31%, and 41% had 1, 2 and $\geq$3 tests, respectively. Of 1,399 reported MR tests, 72% used the International Scale (IS), 6% did not use the IS and 22% were listed as 'unknown'. The proportion of MR tests that used the IS in EU and US was 86% and 65%, respectively. Of 713 pts, 113 (16%) had neither CyR nor MR testing and 600 (84%) had either a CyR or a MR test in the first 12 months. Comparison of these data with a follow-up independent survey of SIMPLICITY investigators, and monitoring patterns by practice type, will be presented. **Conclusions:** Response monitoring in clinical practice differs from ELN and NCCN recommendations and shows regional variation. More pts are monitored for MR than CyR, with a more pronounced difference between the US and EU in frequency of CyR testing than in MR testing.

**7051 General Poster Session (Board #336), Mon, 1:15 PM-5:00 PM**

**Chronic myelomonocytic leukemia: Next-generation sequencing in 30 treatment-naive cases.** *Presenting Author: Priyanka Priyanka, The University of Texas, School of Public Health, Houston, TX*

**Background:** Chronic myelomonocytic leukemia (CMML) belongs to a subtype of myeloid neoplasms called myelodysplastic / myelproliferative neoplasms. While clonal cytogenetic abnormalities have been identified in CMML, these lack specificity. Recently, next generation sequencing (NGS) data has identified a number of mutations in CMML; however, their significance in pathogenesis and prognosis is not well characterized. **Methods:** We performed NGS in a set of 30 treatment naïve CMML cases presenting at a single institution from 09/2012 to 09/2013 as part of routine clinical work up. Genes analyzed included *CEBPA, DNMT3A, EZH2, FLT3, IDH1, IDH2, JAK2, JAK3, KIT, KRAS, MPL, NPM1, NRAS, PDGFRA, PTPN11, TP53*. Detection of frequently reported (hotspot) mutations in a total of 53 genes was performed on the DNA extracted from bone marrow aspirate specimens. PCR-based DNA analysis was performed for detection of *FLT3* internal tandem duplications (ITD) and codon 835/836 point mutation; and *CEBPA*. **Results:** Of the 30 cases, median age at diagnosis was 71 years (range 42 - 81); male: female ratio was 1:2. Mean hematologic parameters are as follows: hemoglobin: 10.79 ± 2.4 g/dL, WBC: 21.87 ± 27.3 K/UL; absolute monocyte count 3.70 ± 4.4 K/UL; platelets 134.9 ± 86.05 K/UL. Median LDH (n=23 patients) was 667 IU/L (range 323 - 6075). Eleven (36.67%) patients had one, none (0%) had two, 1 (3.3%) had three, 2 (6.6%) had four mutations detected. No mutation was detected in 16 (53.33%) patients. The most frequently identified mutation was in *NRAS* (n=4; 11.4%) followed by *JAK2* V617F (n=3; 10%). Other mutations observed were in *PTPN11* and *TP53 (n*= 2 each; 6.6%) and *NPM1* and *KRAS (n*=1 case each; 3.3%). With univariate analysis, LDH levels were significantly associated with *JAK2*V617F mutation ($p<0.001$) and deletions involving chromosome 13. **Conclusions:** CMML is a heterogeneous disease entity at a genetic level. The presence of multiple genetic mutations in a subset of cases may indicate evolution of the neoplastic clone. Longitudinal analysis to study progressive additional mutations in cases would help to delineate a model for molecular pathogenesis and could lead to developing improved tools for prognosis and treatment of CMML.

**7052 General Poster Session (Board #337), Mon, 1:15 PM-5:00 PM**

**Is obinutuzumab cost-effective in the first-line treatment of CLL?** *Presenting Author: David Leroy Veenstra, University of Washington, Seattle, WA*

**Background:** Obinutuzumab, also known as GA101 (G), is a novel therapy shown to have improved PFS in combination with chlorambucil (GClb) compared to rituximab + chlorambucil (RClb) in the recent CLL-11 trial for previously untreated CLL. The incremental value of G vs. rituximab (R) has not been studied. **Methods:** Patient outcomes were simulated using a 3-state Markov model that included PFS, progression, and death. The patient population was assumed to be analogous to that studied in the CLL-11 trial. Efficacy parameters were 1) probability of progression, and 2) probability of dying after disease progression. The model parameters were fitted to the observed trial data. Drug utilization and adverse events were incorporated based on trial data, and costs were based on Medicare reimbursements and drug wholesale acquisition costs. Sensitivity analyses were conducted to assess uncertainty in the results. **Results:** Treatment with GClb led to an increase in average life years (+0.61 y) and quality-adjusted life years (QALYs)(+0.56 y) relative to RClb, respectively. The average total costs were similar, with higher drug and adverse event costs for GClb being offset by higher cost of disease progression with RClb. In probabilistic sensitivity analyses, the difference in QALYs ranged from 0.03 to 1.02, and the difference in total cost ranged from approximately -$53,000 to $56,0000. There was an 89% probability that G+Clb was cost-effective at the $100,000 per QALY threshold. **Conclusions:** Based on the results of the CLL-11 trial, our analysis suggests treatment with GClb compared to RClb is likely cost-effective. Further analyses based on indirect comparisons with other treatment options, as well as updated follow-up data, will help inform coverage and reimbursement policy decisions.

| Outcome | GClb | RClb | Difference |
|---|---|---|---|
| **Average life years** | 5.05 | 4.44 | 0.61 |
| **Average QALYs** | 3.36 | 2.80 | 0.56 |
| **Total drug cost** | $37,460 | $34,875 | $2,585 |
| **Drug administration** | $1,134 | $803 | $330 |
| **Supportive care** | $128 | $75 | $52 |
| **Adverse events** | $9,851 | $6,766 | $3,085 |
| **Cost of progression** | $40,004 | $46,075 | -$6,070 |
| **Average total cost** | $88,577 | $88,595 | -$18 |

**7053 General Poster Session (Board #338), Mon, 1:15 PM-5:00 PM**

**Feasibility of BIBF1120 (nintedanib) combined with low-dose cytarabine in elderly patients with AML ineligible for intensive treatment.** *Presenting Author: Utz Krug, University Hospital of Muenster, Muenster, Germany*

**Background:** Elderly unfit patients with AML have a dismal prognosis. The oral multikinase inhibitor BIBF1120 (nintedanib) was reported to exert growth inhibitory and proapoptotic effects in myeloid cells, especially when used in combination with cytarabine (AraC). **Methods:** This phase I study evaluated the combination of AraC (20mg subcutaneously twice daily on days 1-10 every 28 days) with BIBF1120 in 3 predefined dose levels (DL: 100, 150, and 200mg orally twice daily) in elderly patients with AML ineligible for intensive treatment or treatment with 5-Aza in a 3+3 design. Protocol-specific definitions: Therapy-related cytopenias constituted no adverse events (AE). AEs of special interest (AESI) were elevation of AST and/or ALT >3x upper level of normal (ULN) combined with an elevation of bilirubin >2x ULN, and any hollow organ perforation occurring after the first intake of study medication. DLT was defined as non-hematological SAR CTC grade ≥IV with possible or definite relationship to BIBF1120 occurring during or up to 28 days after the first cycle. **Results:** Between April 2012 and October 2013, 13 patients were enrolled into the phase I part of this trial (DL1: 3 patients, DL2: 4 patients, DL3: 6 patients). 1 patient in DL2 did not receive study medication and was replaced. Median age was 73 (range: 62 – 86) years. Disease status was untreated (4 patients), relapsed (5) and refractory (4) AML. Cytogenetic risk was favorable (1 patient), intermediate (5), unfavorable (6) or missing (1). 8 SAEs occurred (DL1: 1, DL2: 3, DL3: 5). All of the 3 SARs were neutropenic fever grade 3 (DL2: 1, DL3: 2). 2 SUSARs were observed, 1 fatal hypercalcemia (DL2) and 1 fatal GI tract infection (DL3). No AESI were observed. The phase II recommended dose (P2RD) was set as DL3 by the DMC. 2 patients with relapsed AML responded (1 CR, 1 CRi). Bone marrow blast reductions without fulfilling the PR criteria were observed in 3 patients. One-year survival from start of therapy was 46% after a median follow-up of 308 days. **Conclusions:** BIBF1120 combined with LD-AraC shows a favorable safety profile. Preliminary survival data are promising. Continuation of this trial with a P2RD of 2 x 200mg in a randomised phase II is planned. Clinical trial information: NCT01488344.

**7054 General Poster Session (Board #339), Mon, 1:15 PM-5:00 PM**

**Tyrosine kinase inhibitors as a first-line treatment in patients with newly diagnosed chronic myeloid leukemia in chronic phase: A mixed-treatment comparison.** *Presenting Author: Belal Firwana, University of Missouri, Columbia, MO*

**Background:** Chronic myeloid leukemia (CML) is a myeloproliferative disorder of blood stem cells. After the introduction of tyrosine kinase inhibitors (TKi), patients with CML have had substantially improved responses compared with previous therapies. We sought to summarize the evidence of TKi efficacy and safety in patients with newly diagnosed CML in chronic phase (CML-CP). **Methods:** We included all randomized clinical trials evaluating first-line treatment with a TKi (imatinib, dasatinib, bosutinib or nilotinib) in adults with CML-CP. Staudies of patients with accelerated- or blast-phase CML as well as those on IFN-$\alpha$ or stem cell transplantation were excluded. Main outcomes are complete cytogenetic response (CCyR) and major molecular response (MMR) at 12-month follow-up period. Safety and tolerability outcomes were pooled. A comprehensive literature search was conducted. Bayesian mixed-treatment method was used to rank TKi in terms of effectiveness. **Results:** Eighteen peer reviewed papers and conference abstracts reporting on seven studies were identified involving 2842 patients with CML-CP who were enrolled for initial treatment. At 12-month follow-up, mixed treatment comparison analysis demonstrated superiority of each TKi treatment family over imatinib, except bosutinib and nilotinib, which were not statistically different for CCyR and MMR respectively. Nilotinib ranked first among other TKi in terms of efficacy for CCyR; dasatinib ranked first in terms of MMR. Among second generation TKi, nilotinib had the superior tolerance and the least discontinuation rate from drug-related toxicity, followed by dasatinib then bosutinib. Hematological adverse events were highest for high dose imatinib followed by dasatinib. **Conclusions:** Second generation TKi are associated with a deeper and faster CCyR and MMR compared to imatinib. At 12-month follow-up period, nilotinib ranked first to achieve CCyR and had the lowest treatment discontinuation rate, while dasatinib ranked first to achieve MMR. Long term follow up is required to determine the impact of difference in the response patterns to the overall survival.

**7055 General Poster Session (Board #340), Mon, 1:15 PM-5:00 PM**

**Association of obesity with cytogenetic risk in adult acute myeloid leukemia (AML).** *Presenting Author: Laura Elizabeth Finn, Mayo Clinic, Jacksonville, FL*

**Background:** Obesity, body mass index (BMI) ≥30 kg/m2, is a risk factor for several malignancies. Prospective studies have reported a positive association between obesity and adult leukemia. The association between obesity and AML cytogenetic risk groups is unknown. We therefore evaluated a cohort of 295 AML patients with confirmed cytogenetics analysis diagnosed and treated at Mayo Clinic Florida and Arizona since 1995. **Methods:** Documented patient characteristics including height and weight, past medical history, medications, cytogenetics, treatments, and outcomes regarding their diagnosis of AML were extracted from a central electronic medical record. Standard cytogenetic risk categories (including intermediate abnormal) were applied. The association of obesity with cytogenetic risk was evaluated on multivariable analysis using logistic regression models. **Results:** The median BMI was 26.9 kg/m2 (range 16.9-59.9). 82 patients (28%) in the evaluated cohort were obese. On multivariable analysis obesity had the most significant association with intermediate-abnormal cytogenetics in comparison to additional patient factors evaluated including patient age, secondary AML (sAML), and therapy related AML (tAML). Obesity did not significantly impact remission after induction chemotherapy or survival after AML diagnosis. **Conclusions:** Obesity is significantly associated with intermediate abnormal risk cytogenetics in AML. This supports a link to leukemogenesis and requires validation in a larger controlled prospective therapeutic study.

**Prospective assessment of chemotherapy-induced peripheral neuropathy (CIPN) in children with standard-risk acute lymphoblastic leukemia (SR ALL): Results of Children's Oncology Group (COG) AALL0932.** *Presenting Author: Nina S. Kadan-Lottick, Yale School of Medicine, Smilow Cancer Center, New Haven, CT*

**Background:** Vincristine is associated with CIPN that can impair daily function. **Methods:** Patients 3.0-9.9 years without neurological disorders, enrolled on ALL0932 at 26 sites, were evaluated ~2 weeks post-induction (vincristine x 4 doses, dexamethasone x 28 days, and pegaspargase) by a physical/occupational therapist for peripheral neuropathy, proximal strength and fitness. Parents reported daily physical function with The Pediatric Outcomes Data Collection Instrument (PODCI). Percentages of measured impairments and limited daily function were calculated and analyzed by multivariable logistic regression. **Results:** The 149 (80% of eligible) subjects were 48% female, 56% white non-Hispanic (26% Hispanic, 18% other) and a mean of 5.1± 1.7 years. The table summarizes the substantial frequency of measured and reported impairments. Impaired peripheral motor function in the upper (OR=4.6; p=0.01) and lower extremities (OR=3.4; p=0.06) and younger age (OR=1.7; p=0.02) were associated with report of limited physical function. **Conclusions:** Our data suggest that induction therapy causes significant motor neuropathy predictive of daily physical function in young children with SR ALL. AALL0932 will assess how this neuropathy evolves throughout ALL therapy. Clinical trial information: NCT01190930.

**Covariation of psychological and inflammatory variables in patients with chronic lymphocytic leukemia receiving ibrutinib.** *Presenting Author: Neha Godiwala, The Ohio State University, Columbus, OH*

**Background:** Ibrutinib has been shown to induce durable responses in patients with high risk relapsed/refractory (r/r) chronic lymphocytic leukemia (CLL) (Byrd et al., 2013). Psychological factors, particularly stress, have been shown to covary with immunity and cytokines in solid tumor cancers. This pilot study examines temporal changes and covariation in inflammatory/angiogenic markers and psychological variables among r/r CLL patients receiving Ibrutinib. We hypothesized that these variables would improve during treatment and would covary over time. **Methods:** Patients enrolled in our single-institution phase II trial of Ibrutinib with r/r CLL (N=148) provided blood and psychological data on day 1 (of 28) of cycles 1-3. For this pilot, ELISA assays were performed on a subset (N=24; mean age=65; 50% female) of patients representing a distribution of scores (0-33) on a cancer-specific stress measure. Depressive symptoms, mood disturbance, fatigue, and quality of life (QOL) were also assessed. Assays measured IL-6, TNF-alpha, VEGF, CRP, BAFF, CCL3, and IL-16 levels in the patients' plasma. Hierarchical linear modeling examined change over time for all variables and covariation between psychological and inflammatory/angiogenic markers. **Results:** Improvements were observed in stress, depressive symptoms, fatigue, and QOL (p-values < 0.05). Decreases were observed in IL-16, TNF-alpha, and CCL3 (p-values < 0.05). Controlling for age, chromosome 17p deletion, and gender, covariation between the following variables was found: TNF-alpha with stress, depressive symptoms, mood disturbance, and QOL; IL-6 with mood disturbance, fatigue, and QOL; and VEGF with depressive symptoms (all p-values <0.05). That is, changes in inflammatory/angiogenic markers were correlated with changes in psychological variables. **Conclusions:** These pilot data suggest that in addition to providing clinical benefit, Ibrutinib treatment contributes to improvements in psychological functioning and decreases in inflammation. Clinical trial information: NCT01589302.

**7058 General Poster Session (Board #343), Mon, 1:15 PM-5:00 PM**

**Effect of syk inhibition by TAK659 on proliferative, survival, and migratory signals from the microenvironment in chronic lymphocytic leukemia.** *Presenting Author: Noelia Purroy, Laboratory of Experimental Hematology. University Hospital Vall d'Hebron, Barcelona, Spain*

**Background:** Chronic lymphocytic leukemia (CLL) is characterized by the accumulation and proliferation of monoclonal CD5+ mature B-cells in peripheral blood, lymph nodes (LN), and bone marrow (BM). The microenvironment in BM and LN induces proliferation of CLL cells and protects them from spontaneous and chemotherapy-induced apoptosis. Syk is a tyrosine kinase essential for the BCR signaling pathway that also participates in signaling from chemokine receptors and has been shown to be deregulated in CLL. Therefore Syk has been hypothesized to be a rational candidate for targeted therapy in CLL and its inhibition has been tested with the non-specific Syk inhibitor fostamatinib (R406). Against this background we tested the effectiveness of the highly specific Syk inhibitor TAK-659 in suppressing the induction of survival, proliferation and migration of CLL cells by the microenvironment. **Methods:** To mimic the microenvironment of the proliferative centers ex vivo, we co-cultured primary CLL cells with BM stromal cells (BMSC), CD40L, and CpG ODN along with anti-IgM (BCR stimulation). We evaluated the effects of TAK-659 on BCR signaling, proliferation, apoptosis and chemotaxis. **Results:** The co-culture system with BMSC and different stimuli induced survival and proliferation of primary CLL cells. Moreover, in this system CLL cells became chemoresistant to fludarabine and bendamustine. TAK-659 inhibited the phosphorylation of Syk, Akt, and ERK1/2 after BCR stimulation. TAK-659 induced apoptosis of co-cultured CLL cells at lower doses than R406. In addition, combination of TAK659 and fludarabine showed a synergistic effect in inducing apoptosis. TAK-659 also inhibited co-culture-induced proliferation, as assessed by Ki-67 expression, and significantly decreased chemotaxis of CLL cells toward CXCL12, CXCL13 and BMSCs. **Conclusions:** These findings demonstrate that, in this ex-vivo system, the specific inhibition of Syk by TAK-659 effectively overcomes the microenvironment signals that promote proliferation, survival and chemoresistance of primary CLL cells. Altogether, this study provides a rationale for the clinical development of TAK-659 in CLL.

**7059 General Poster Session (Board #344), Mon, 1:15 PM-5:00 PM**

**Phase 2 trial of GS-9973, a selective syk inhibitor, and idelalisib (idela) in chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphoma (NHL).** *Presenting Author: Paul M. Barr, James P. Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY*

**Background:** GS-9973 is an orally bioavailable, small-molecule, selective inhibitor of Spleen Tyrosine Kinase (Syk). The Kd of GS-9973 for Syk was 7.6 nM with no other kinase < 100 nM. **Methods:** This Phase 2 trial enrolled subjects (subj) with relapsed/refractory CLL (1 cohort) or NHL (4 cohorts). Subj underwent intra-subj dose escalation from GS-9973 400 mg and Idela 100 mg (400/100) BID up to a maximum of 800/150 BID. Plasma drug levels were obtained concurrently with plasma chemo/cytokine levels and phospho flow analysis of circulating leukemic cells. **Results:** This study initiated in July 2013. When enrollment was suspended, 66 subj with CLL (36) or NHL (30) had been enrolled. Median age was 68 (range 28 - 92), 53% were male. The median number of prior treatment regimens was 3 (range 1-9). Of the subj with investigator response assessments, 14 (70%) and 10 (50%) of 20 CLL subj had a decrease of > 50% and > 75% respectively in their measurable lymph node disease; 7 (35%) of 20 NHL subj achieved a decrease of > 50%. (iNHL 6/14; DLBCL 1/4; MCL 0/2). The study was terminated early due to the development of severe, steroid responsive, pneumonitis in 9 subj that occurred despite dose reduction in 4 after a median of 83 (raange 50-105) days on study. Reversible Grade 3 or 4 ALT elevations occurred in 10 (15%) subj. Treatment emergent adverse events occurring in ≥ 15% of subj were fatigue, nausea, pyrexia, rash, diarreha, headache, constipation and cough and were typically low grade. 5 subj died while on study: 2 from disease progression, 1 from pneumonitis, 1 from pneumonia, 1 from sepsis. **Conclusions:** Despite promising activity in CLL, the combination of GS-9973 and Idela resulted in an unexpectedly high rate of pneumonitis and resulted in stopping dosing of the combination These data need to be considered when designing future investigations combining inhibitors of B cell receptor signaling. Additional studies are needed to understand the underlying mechanism of pneumonitis seen with dual Syk and PI3k inhibition Clinical trial information: NCT01796470.

**7060 General Poster Session (Board #345), Mon, 1:15 PM-5:00 PM**

**Long-term evaluation of vascular toxicity in patients with Ph+ leukemias treated with bosutinib.** *Presenting Author: Jorge E. Cortes, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Vascular toxicities (eg, peripheral arterial occlusive disease [PAOD]) have been associated with BCR-ABL tyrosine kinase inhibitor (TKI) treatment (tx). **Methods:** We evaluated vascular (peripheral, cardiovascular, and cerebrovascular) toxicities based on tx-emergent adverse events (TEAEs) with bosutinib (BOS) in 2 ongoing studies: phase 1/2 study of BOS second/third/fourth-line tx (2L/3L/4L, up to 3 y) in Ph+ leukemia patients (pts) resistant/intolerant to prior TKIs; phase 3 study in chronic phase CML pts of BOS vs imatinib (IM) first-line tx (1L; up to 2 y). **Results:** 12.7% of BOS pts had vascular TEAEs (Table) with no significant differences for BOS vs IM (1L: $P \geq 0.122$). Individual cardiovascular TEAE incidences were low; only angina pectoris (1.2%) and coronary artery disease (CAD 1.2%) occurred in >1% of BOS pts. No individual cerebrovascular TEAE occurred in >3 BOS pts. Individual peripheral vascular TEAEs were rare; only hypertension (6.4%) occurred in >2 BOS pts (1L: 6.0% [BOS] vs 4.4% [IM], $P=0.427$). Only 1 pt had PAOD (BOS 3L; y 1). Newly occurring vascular TEAE rates decreased with longer BOS tx (2L/3L/4L: y1, 40/570 [7.0%]; y 2, 21/273 [7.7%]; y 3, 8/208 [3.8%]; 1L [BOS vs IM]: y 1, 16/248 [6.5%] vs 9/251 [3.6%]; y 2, 5/183 [2.7%] vs 5/209 [2.4%]). Risk factors for vascular TEAEs ($P \leq 0.036$) were age ≥65 y (both studies) and history of vascular disorders (2L/3L/4L). Vascular TEAEs were managed mostly by concomitant medication (61.5% of affected pts); few pts required dose delays (n=15) or reductions (n=1). Discontinuation due to vascular TEAEs occurred in 6 (0.7%) BOS pts (2L/3L/4L: CAD n=2, myocardial infarction n=2, cerebrovascular accident n=1; 1L: cerebral haemorrhage n=1 [vs 0 IM, $P=0.497$]). **Conclusions:** Vascular TEAE incidences with BOS in Ph+ leukemia pts were low individually and overall and not significantly different vs IM (1L). Peripheral vascular TEAEs, except hypertension, are rare with BOS. Clinical trial information: NCT00574873; NCT00261846.

**Lipid cell membrane composition: A novel therapeutic target in cancer.** *Presenting Author: Ravi Kiran Bobba, Ellis Fischel Cancer Center, University of Missouri-Columbia, Columbia, MO*

**Background:** Cell membrane cholesterol, more specifically, the lipid composition of lipid rafts is associated with regulation of trans-membrane receptors. **Methods:** We tested the hypothesis that altering membrane cholesterols, via mevalonate pathway inhibitors, Ro 48-8071, TAK-475, BIBB-515 and YM-53601, may have differential effects on cancer cells in in-vitro models of Small Lymphocytic Lymphoma/ Chronic Lymphocytic Leukemia (CLL) cell lines and Peripheral blood lymphocytes of CLL patients. **Results:** In addition to chemo-sensitization of the cells, in-vitro results showed a statistically significant upregulation of cell surface proteins, CD20 and CD52. Treatment with cholesterol inhibitors resulted in significant upregulation of CD20 protein and glycosphingolipid-GM1 both by confocal microscopy and flow cytometry. Flow cytometry of MEC-2 and WAC-3 showed an upregulation of CD20 and CD52. Quantification of membrane lipids showed upregulation of glycosphingolipid-GM1. LysoPC (lysophosphatidylcholine) was an average of 0.0405 ± .0016 in controls was reduced to 0.0278 ± 0.0021 with BIBB-515 treatment and 0.0247 ± 0.0022 with YM-53601 treatment. PC (phosphatidylcholine) was upregulated from 1.0029 ± 0.02378 in controls to 1.0904 ± 0.04489 with BIBB-515 treatment and 1.1088 ± 0.02269 with YM-53601 treatment ($P<0.05$). Spingomyelin/Dihydrosphingomyelin (SM/DSM) was an average of 0.5863 ± 0.0113 in controls and was upregulated to 0.5997 ± 0.0294 with BIBB-515 treatment ($P<.05$) and 0.6735 ± 0.0159 in YM-53601 treatment ($P<.001$). Ether-linked Phosphatidylcholine (ePC) was upregulated from 0.2938 ± 0.0044 in controls to 0.3328 ± 0.0152 with BIBB-515 treatment and 0.3370 ± 0.0061 with YM-53601 treatment ($P<.001$). Treatment with BIBB-515 and YM-53601 did not affect membrane cholesterol levels significantly. Lovastatin significantly reduced membrane cholesterol from controls ($P<0.05$). **Conclusions:** Mevalonate pathway inhibitors lead to alterations in drug-resistant cancer cell membrane lipids by altering the cell surface receptor proteins CD 20 and upregulation of glycosphingolipid-GM1. A specific biochemical alteration in cancer cell membrane lipids represents a potential novel therapeutic approach to cancer.

**7063 General Poster Session (Board #348), Mon, 1:15 PM-5:00 PM**

**Preliminary safety and efficacy of the Bruton's tyrosine kinase (BTK) inhibitor ibrutinib (IBR) in patients (pts) with hairy cell leukemia (HCL).** *Presenting Author: Jeffrey Alan Jones, The Ohio State University, Columbus, OH*

**Background**: Effective treatments (tx) for classical (c) HCL pts refractory to or ineligible for nucleoside analogs (NA) are limited, and there is no accepted standard for either tx-naïve or relapsed variant (v) HCL. IBR, an oral small molecule inhibitor of BTK, is active in several indolent B-cell malignancies, but its activity in HCL has not been previously assessed. We report preliminary safety and efficacy data from a CTEP-supported phase 2, multicenter study. **Methods**: Pts with cHCL (relapsed after ≥1 NA or unfit for NA) and vHCL who require tx are eligible if ECOG ≤2, free of infection and end-organ function preserved. Pts receive continuous IBR 420 mg daily in 28-day cycles. Response, including bone marrow biopsy with immunohistochemistry for MRD, is assessed after 8 and 12 cycles. Pts may continue IBR indefinitely absent unacceptable toxicity or progressive disease. **Results:** 8 pts (1 tx-naïve and 1 relapsed vHCL, 6 relapsed cHCL) have been dosed (range 1-8 cycles) and all remain on tx. Common treatment-related adverse events were grade (Gr) 1/2 diarrhea, rash, arthralgia/myalgia, and transient Gr 1-3 elevation of hepatic transaminases. 3 cases of Gr 3 neutropenia and 2 cases of febrile neutropenia have been observed during cycle 1, all responding to tx interruption and/or brief course GCSF. Redistribution lymphocytosis (peaking at day 8) occurred in both vHCL pts and 1 V34.4 subtype cHCL pt with circulating disease at baseline. Soluble IL2 receptor (sIL2R) levels decreased after tx in all pts and correlated with improvements in symptoms and peripheral blood counts. Marrow clearance (>90% pre-, <2% post-tx) was observed in the first pt undergoing response assessment after 8 cycles. Pretreatment imunoblots demonstrated the presence of pBTK in several pts that was substantially reduced after IRB. This did not correlate with loss of pERK, suggesting that ERK phosphorylation ex vivo may not be a reliable indicator of IBR activity. **Conclusions:** IBR appears well tolerated and demonstrates early evidence of activity in both cHCL and vHCL. sIL2R levels may correlate with response. Accrual continues at 5 US sites. Updated safety and efficacy data will be presented. Clinical trial information: NCT01841723.

**7064 General Poster Session (Board #349), Mon, 1:15 PM-5:00 PM**

**Phase II study of combination of hyperCVAD with ponatinib in frontline therapy of patients (pts) with Philadelphia chromosome (Ph) positive acute lymphoblastic leukemia (ALL).** *Presenting Author: Susan Mary O'Brien, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Combination of chemotherapy (CTX) with TKI is effective in the treatment of Ph+ ALL. Ponatinib is a more potent BCR-ABL inhibitor. The combination of CTX + ponatinib may be associated with better outcome. **Methods:** Pts with newly diagnosed Ph+ ALL received 8 cycles of hyperCVAD every 21 days. Ponatinib was given at 45 mg po daily for the first 14 days of cycle 1 then continuously for the subsequent cycles. Pts in CR received maintenance with ponatinib 45 mg po daily with vincristine/prednisone monthly for 2 yrs followed by ponatinib indefinitely. **Results:** 34 pts with untreated Ph+ ALL and 3 previously treated (1 course) have received a median of 6 cycles; 12 pts are receiving maintenance in CR. Median age was 51 yrs. All pts were in CR after cycle 1. CCyR rates were 94% and 100% after 1 and 2 cycles, respectively. To date, 35 pts (95%) achieved MMR and 26 (70%) CMR. MRD is negative in 35/36 (97%) pts, in whom a sample was sent for assessment. 8 pts received ASCT after a median of 4 courses. Grade ≥ 3 toxicity included infections during induction in 18 pts (49%), increased LFT's in 13 (35%), thrombotic events in 3 (8%), myocardial infarction (MI) in 3 (8%, 2 unexplained, 1 in the context of sepsis ), skin rash in 4 (11%), and pancreatitis in 6 (16%). With a median follow up of 13 months, 31 pts are alive and in CR; 1 pt died in CR from an unrelated cardiac event after being taken off therapy and placed on imatinib, 1 from MOF (C2D13), 1 from NSTEMI (C2D41), 1 from potential MI (C4D42), 1 from head injury sustained after a fall (C4D13), and 1 from sepsis post ASCT. At the last follow-up, 7 pts (19%) are alive post ASCT; 15 pts (41%) on ponatinib at 15 mg daily in 14, and 30 mg daily in 1; Of the other 9 alive pts, 7 were switched to dasatinib, 1 was switched to imatinib, and 1 is no longer receiving treatment. The 1-year PFS and OS rates were 100% and 86%, respectively. **Conclusions:** Combination of hyperCVAD + ponatinib is highly effective in pts with Ph+ ALL. Due to the vascular events observed, some pts switched to alternative TKI; in the remaining, ponatinib dose was modified to 30 mg daily during consolidation with subsequent reduction to 15 mg in pts in CMR. Clinical trial information: NCT01424982.

**7065 General Poster Session (Board #350), Mon, 1:15 PM-5:00 PM**

**Phase II study of the hyper-CVAD regimen in combination with ofatumumab as frontline therapy for adults with CD-20 positive ALL.** *Presenting Author: Elias Jabbour, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The hyperCVAD regimen is an effective frontline program for de novo adult ALL. CD20 expression was identified as an adverse prognostic factor, associated with a higher incidence of relapse and lower 3-year OS rates. Addition of rituximab to the hyperCVAD program in patients with CD20+ ALL improved outcome with 3-year CRD and OS rates by 68% and 65%, respectively. Ofatumumab targets a membrane proximal small-loop epitope on the CD20 molecule and was found to be more potent than rituximab. Combination of the hyperCVAD regimen and ofatumumab may be associated with better responses and higher 3-year PFS and OS rates. **Methods:** Pts with newly diagnosed ALL and pts who received 1 prior course of chemotherapy received 8 courses of hyperCVAD alternating MTX-Ara-C; ofatumumab was given on courses 1 through 4. This treatment is to be followed by POMP maintenance therapy for approximately 30 months, interrupted by intensifications months 6, 7 and 18, 19 with MTX/Pegylated asparaginase and hyperCVAD-ofatumumab. CNS prophylaxis was administered. **Results:** 21 pts with de novo ALL and 2 pts in CR previously treated have received a median of 7 cycles; 7 pts did not receive the full 8 planned courses. 15 pts are receiving maintenance in CR. Median age is 50 years. All but 1 pt (95%) achieved CR after cycle 1; 1 pt died of septic shock at C1D21. 22/23 pts (95%) achieved MRD negativity as assessed by FCI; of whom 14 (64%) after induction. Grade ≥ 3 toxicity included increased LFT's in 7 pts (30%), increased bilirubin in 6 (26%), thrombotic events in 1 (4%) and neuropathy in 1 (4%). Febrile neutropenia episodes during induction and consolidation cycles were reported at rates of 71% and 77%, respectively. With a median follow-up of 12 months, 21 pts are alive; two patients developed sepsis and died at C1D21 and C3D17, respectively. 2 pts have undergone ASCT: due to the lack of MRD negativity achievement in one and a highly complex karyotype at diagnosis in the second; the first relapsed 7 months post ASCT. The 1-year PFS and OS rates were 91% and 91% respectively. **Conclusions**: The combination of hyperCVAD/ofatumumab is safe and highly effective in pts with CD20 + ALL. Clinical trial information: NCT01363128.

**7066 General Poster Session (Board #351), Mon, 1:15 PM-5:00 PM**

**Landmark analysis of overall survival (OS) in patients with chronic (CP) or accelerated (AP) phase chronic myeloid leukemia (CML) treated with omacetaxine mepesuccinate.** *Presenting Author: Meir Wetzler, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** Response milestones are used as prognostic indicators in CML. This analysis compared OS in patients with/without response to omacetaxine. **Methods:** This was a post hoc landmark analysis in a subset of CP and AP patients in 2 phase II trials of single-agent omacetaxine; all had received ≥2 tyrosine kinase inhibitors. Kaplan-Meier analysis was used to estimate OS from time of omacetaxine initiation in patients with/without hematologic response (HR; complete [CHR] in CP and major [MHR] in AP) or cytogenetic response (CyR) at 3, 6, and 12 months (mo); patients unevaluable for response at a timepoint were excluded. **Results:** At 3 months, 53 (70%) CP and 15 (43%) AP patients continued treatment; median OS in these patients was 49.3 mo (95% CI, 27.8-NR) and 21.7 mo (6.8-37.2), respectively (vs 27.2 mo [6.8-37.2] and 8.2 mo [1.9-16.0] in those who discontinued prior to 3 mo). In CP and AP patients evaluable for response at 3 mo, median OS was longer in those with HR vs those without (Table). Median OS was similar in CP patients with/without CyR at 3 and 6 mo. Median OS was not reached in CP patients with CyR at 12 mo (n=12; 11 patients were alive with a median follow-up of 48.7 mo [range, 29.5-57.2]), compared with a median OS of 49.5 mo in those without CyR (n=13). **Conclusions:** HR by 3 mo may be a positive predictor of OS in CML patients treated with omacetaxine. In this heavily pretreated population, presence/absence of CyR by 6 months may not be predictive of OS. These findings are limited by the relatively small number of patients and the noncomparative study design. Clinical trial information: NCT00375219 and NCT00462943.

**Correlation of KIT expression with higher FLT3 mutations and impact on clinical outcome in patients newly diagnosed with acute myeloid leukemia (AML).** *Presenting Author: Hassan Alkhateeb, Mayo Clinic, Rochester, MN*

**Background:** KIT (CD 117) is a transmembrane tyrosine kinase protein receptor encoded by the c-kit protooncogene. KIT mutations were described in AML and impart a prognostic impact on patients (pt) with core binding factor. However, its expression effect on clinical phenotype and outcome is unknown. **Methods:** A retrospective, single institution study of cases with AML at Mayo Clinic between 2003 - 2011 was performed. Pts with blasts KIT expression studied by flow cytometry at diagnosis were included. Appropriate IRB approval was obtained in accordance with the Helsinki declaration. Comparison between groups' medians was done using Wilcoxon test, while survival estimates were calculated using Kaplan-Meier curves. **Results:** Out of 154 pts who had KIT analysis, KIT+ (>20% of blasts) was in 134 (87%). Median age is 62 year, with median white blood cell (WBC) 9 $x10^9$, Hemoglobin (Hgb) 9.3 g/dl, platelet (PLT) 56 $x10^9$, peripheral blood (PB) blast 10%, bone marrow (BM) blasts 56%. Cytogenetics (CG) was diploid in 55% pt. NCCN grouping for CG was favorable, intermediate and poor in 8%, 71%, 21%. FLT3 was mutated in 25%, NPM1 in 38% pts. CR was found in 105 (68%) pts; 77 relapsed. Median OS is 577 days. Group 1 (KIT-) had median age 62 year, Hgb 9.3 g/dl, PLT 82 $x10^9$, WBC 18 $x10^9$, PB blasts 34%, BM blasts 71%. CG was favorable, intermediate and poor in 8%, 58%, 33%. NPM1 and FLT3 were mutated in 50%, 0, respectively. CR was obtained in 75% with 55% suffering a relapse. Group 2 (KIT+) had median age 62 year, Hgb 9.4 g/dl, PLT 56 $x10^9$, WBC 9 $x10^9$, PB blasts 19%, BM blasts 55%. CG was favorable, intermediate and poor in 8%, 74%, 18%. NPM1 and FLT3 were mutated in 37% and 29%. CR was found in 67% with 51% relapsing. Upon comparison, mutated FLT3 was more frequent in group 2 vs 1 (p=0.002). Median OS was not statistically different between group 1 vs 2 (447 vs 592 days, p= 0.25). On multivariate analysis, only NCCN grouping (p=0.006) affected mOS but not age, WBC, PB/BM blasts, or KIT. **Conclusions:** KIT expression was prevalent in AML pts. We found for the first time that KIT-AML pts did not have mutated FLT3 (0%) but KIT expression did not impact clinical outcome. Additional prospective studies are needed to confirm our results.

**7068 General Poster Session (Board #353), Mon, 1:15 PM-5:00 PM**

**Predicting prognosis in patients with acute myeloid leukemia: The role of next-generation sequencing and mutational profiling.** *Presenting Author: Caroline E Sloan, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

**Background**: Although cytogenetics-based prognostication systems are well described in acute myeloid leukemia (AML), Patel *et al.* (NEJM 2012) recently used data from patients <60 years enrolled in a randomized controlled trial to create a new integrated prognostic (IP) schema using mutations in 9 genes. Our objective was to assess whether the IP schema was relevant in clinical practice. **Methods**: Our study consisted of 2 cohorts of patients with de novo AML, each from single large academic institutions. We included 181 patients from the Hospital of the University of Pennsylvania and 188 patients from Washington University (The Cancer Genome Atlas) for whom clinical, cytogenetic and genetic data were available. We evaluated survival outcomes among 4 mutational profiles defined by Patel *et al.* in the IP schema. **Results**: Clinical characteristics and outcomes were similar in both cohorts (n=369 overall, n=217 age <60), so they were combined for further analysis. Median age was 57 years with 59% <60 years. Patients <60 years with intermediate-risk cytogenetics (n=137) were classified as having favorable, intermediate or unfavorable mutational profiles (see table). In patients >60 years, long-term survival was poor for patients with all 4 mutational profiles and was not further evaluated for this study. **Conclusions**: The IP schema identifies mutational profiles that have differential survival in younger patients with intermediate-risk cytogenetics. Our findings validate Patel *et al.*'s IP schema in patients <60 years for some but not all mutational profiles. Performing next-generation sequencing at diagnosis may inform patient management and be cost-effective if gene panels include validated mutations and their use is tailored to patient age.

**Integrated prognostic (IP) assessment of patients <60 years with intermediate-risk cytogenetics.**

| Mutational profile | Prognosis | n | 3-year overall survival | p-value |
|---|---|---|---|---|
| FLT3-ITD negative with mutant NPM1 and IDH1/2 | Favorable | 13 | 55% | 0.004 |
| FLT3-ITD negative with mutant TET2, MLL-PTD, ASXL1 or PHF6 | Unfavorable | 32 | 45% | 0.994 |
| FLT3-ITD positive with trisomy 8 or mutant TET2, MLL-PTD or DNMT3A | Unfavorable | 30 | 17% | 0.039 |
| All others | Intermediate | 62 | 35% | Reference |

**Impact of circulating members of the insulin-like growth factor receptor (IGF-1R) axis on outcomes in acute myeloid leukemia.** *Presenting Author: Reem Karmali, Rush University Medical Center, Chicago, IL*

**Background:** AML is a disease with conservative response rates to standard therapy in the adult population. Dysregulations in insulin-like growth factor receptor-1 (IGF-1R) signaling is implicated in leukemogenesis and chemoresistant disease, but remains poorly elucidated. We explore associations of circulating levels of the IGF-1R axis, consisting of IGF binding proteins 1-7, IGF-1, and c-peptide as a control, with clinical outcomes of patients with aggressive AML. **Methods:** Peripheral blood samples in newly diagnosed non-M3 AML patients (n=30) were collected prospectively under IRB consent. Relevant clinical parameters (cytogenetics, molecular data, treatment response) were annotated for each patient. Circulating levels of the IGF-1R axis were established using Luminex-based assays and analyzed using independent t-tests, ANOVA, and log-rank in SPSS v15.0 and R statistical software. **Results:** The median age was 56. Using the ELN cytogenetic/molecular risk model, patients were stratified as either adverse risk (47% of patients; FLT-3 positive/NMP negative CN AML, c-kit positive CBF AML, MLL gene rearrangement (11q23), chromosome 5 and/or 7 abnormalities, or complex karyotype), good risk (13% of patients; CBF AML without c-kit positivity and FLT-3 negative/NPM mutated CN AML), or intermediate risk (40%; all others). Increased IGFBP-4 correlated with therapy response ($p < 0.05$) using independent t-tests. Median overall survival (OS) in the cohort was 5.2 months. Differences in progression-free survival (PFS) and OS between groups with "low" and "high" protein expression were determined using optimal discovery threshold with log-rank. Increased expression of IGFBP-1 and -6 correlated with improved PFS ($p < 0.03$ and 0.01, respectively) while increased IGFBP-1, -2, -6 and -7 were associated with improved OS ($p < 0.001$, 0.009, 0.003 and 0.001, respectively). A trend for decreased IGFBP-3 in adverse risk patients was noted. **Conclusions:** The IGF-1R axis appears to be relevant in disease refractory AML. IGFBP signatures are predictive tools in AML with applications in remission surveillance, early detection of relapse and the development of IGFBP-directed biologic therapy.

**7070 General Poster Session (Board #355), Mon, 1:15 PM-5:00 PM**

**ASP2215, a novel FLT3/AXL inhibitor: Preclinical evaluation in acute myeloid leukemia (AML).** *Presenting Author: Masamichi Mori, Astellas Pharma Inc., Ibaraki, Japan*

**Background:** Activating mutations in FLT3 receptor tyrosine kinase, characterized by internal tandem duplication (ITD) and tyrosine kinase domain point mutations near position D835, have been identified in up to 30% of AML patients. These mutations are associated with poor prognosis. ASP2215 is a novel small molecule tyrosine kinase inhibitor, currently under clinical trial evaluation. **Methods:** The kinase inhibition profile was investigated using enzyme assays. Antiproliferative activity was evaluated against several AML cell lines with assessment of the inhibition of pFLT3 and downstream molecules using Western blot and flow cytometry. Antitumor activity was evaluated in nude mice transplanted with MV4-11 AML cells. The pharmacokinetics in xenografted mice was also investigated. **Results:** Of the 78 tyrosine kinases tested, ASP2215 inhibited FLT3, LTK, ALK, and AXL kinases by over 50% at 1 nM with an $IC_{50}$ value of 0.29 nM for FLT3, approximately 800-fold more potent than for c-KIT, the inhibition of which is linked to a potential risk of myelosuppression. ASP2215 inhibited the growth of MV4-11 cells, which harbor FLT3-ITD, with an $IC_{50}$ value of 0.92 nM, accompanied with inhibition of pFLT3, pAKT, pSTAT5, pERK, and pS6. ASP2215 also inhibited the growth of Ba/F3 cells expressing FLT3-ITD and/or FLT3-D835 mutation with similar activity. Colony formation of human granulocyte-macrophage decreased to 58% in response to ASP2215 at 100 nM, more than 100-fold higher than required for MV4-11. In MV4-11 xenografted-mice, the concentration of ASP2215 in tumors was more than 20-fold higher than that in plasma with oral administration of ASP2215 at 10 mg/kg for 4 days. Treatment of ASP2215 for 28 days resulted in dose-dependent inhibition of MV4-11 tumor growth and induced complete tumor regression at more than 6 mg/kg. Further, ASP2215 decreased tumor burden in bone marrow and prolonged the survival of mice intravenously transplanted with MV4-11 cells. **Conclusions:** ASP2215, a FLT3/AXL inhibitor, showed potent antileukemic activity against AML with either or both FLT3-ITD and FLT3-D835 mutations. These findings support the development of ASP2215 for the potential use in treating AML.

**7071 General Poster Session (Board #356), Mon, 1:15 PM-5:00 PM**

**ASP2215, a novel FLT3/AXL inhibitor: Preclinical evaluation in combination with cytarabine and anthracycline in acute myeloid leukemia (AML).** *Presenting Author: Yoko Ueno, Astellas Pharma Inc., Ibaraki, Japan*

**Background:** Patients with AML harboring internal tandem duplication (ITD) of FLT3 have a poor prognosis following the current chemotherapeutic treatment of cytarabine (AraC) and anthracycline (daunorubicin, DNR or idarubicin, IDR). ASP2215 is a novel small molecule FLT3/AXL inhibitor in a clinical trial. **Methods:** Cell cycle distribution and apoptosis induction in MV4-11 AML cells, which harbor FLT3-ITD, treated with ASP2215, AraC, and DNR were evaluated via flow cytometry and Western blot. Antitumor efficacy was evaluated in MV4-11 xenografted mice administered with oral daily ASP2215 starting either a week prior to or concomitantly with, intraperitoneal AraC for 5 days, and intravenous DNR or IDR for 3 days. The pharmacokinetics in xenografted mice were also investigated. **Results:** ASP2215 treatment resulted in an increase in the proportion of MV4-11 cells in the G1 phase of the cell cycle at 24 h, and then the concentration-dependent induction of apoptosis, as determined by the increase in annexin V-positive cells and intracellular PARP cleavage. ASP2215 enhanced AraC- or DNR-induced apoptosis regardless of the treatment schedule. In mice xenografted with MV4-11 cells, the simultaneous administration of ASP2215, AraC, and DNR induced tumor regression, including complete remission. In contrast, combination chemotherapy (AraC and DNR) only induced tumor growth inhibition. Further, treatment of ASP2215 for a week followed by combination with DNR and AraC also induced tumor regression with a final tumor volume similar to that of simultaneous combination therapy. No obvious influence of toxicities on body weight, behavior, or diarrhea was noted for treatment of ASP2215. Concentrations of ASP2215, AraC, and DNR in plasma and tumor were not influenced by their use in combination therapy. ASP2215 also enhanced the antitumor efficacy of AraC plus IDR in the same model. **Conclusions:** ASP2215 in combination with AraC and either DNR or IDR induced superior antitumor efficacy compared to combination chemotherapy, regardless of dosing schedule. These findings support the development of ASP2215 in combination with chemotherapy for the potential treatment of AML.

**7072 General Poster Session (Board #357), Mon, 1:15 PM-5:00 PM**

**One-year and longer-term molecular responses to nilotinib and dasatinib for newly diagnosed chronic myeloid leukemia: A matching-adjusted indirect comparison.** *Presenting Author: James E. Signorovitch, Analysis Group, Inc., Boston, MA*

**Background:** Nilotinib and dasatinib are BCR-ABL inhibitors that markedly differ in selectivity. In separate randomized trials, nilotinib and dasatinib have shown superior achievement of molecular response (MR) compared to imatinib for the treatment of newly diagnosed chronic myeloid leukemia (CML) in the chronic phase (CP). In the absence of head-to-head trials, health technology assessment authorities rely on indirect comparisons to inform drug policies. This study compares MR between nilotinib 300mg twice daily and dasatinib 100mg once daily by 12 months and through 48 months via indirect comparison. **Methods:** Data were drawn from individual patients in the ENESTnd trial (nilotinib vs. imatinib) and published results from the DASISION trial (dasatinib vs. imatinib). Patients in ENESTnd were re-weighted to match baseline characteristics reported for DASISION (age, sex, ECOG performance status, white cell count, and platelet count) using a propensity score model. After matching, differences in major MR (MMR measured as a 3-log reduction on the International Scale [IS]), $MR^{4.0}$ (4-log reduction on IS) and $MR^{4.5}$(4.5-log reduction on IS) rates between nilotinib and imatinib were compared with those between dasatinib and imatinib. Cumulative MR rates through 48 months were also compared using adjusted hazard ratios (HRs) relative to imatinib. **Results:** After matching, rates of MR by 12 months were higher with nilotinib vs. dasatinib by 11.7% for MMR ($p = 0.045$), 8.2% for $MR^{4.0}$ ($p = 0.029$), and 8.5% for $MR^{4.5}$ ($p < 0.001$). Through 48 months of follow-up, the adjusted HR comparing MMR achievement with nilotinib vs. dasatinib was 1.44 (95% CI: 1.06, 1.94; p=0.018); the corresponding HRs for $MR^{4.0}$ and $MR^{4.5}$were 1.58 (95% CI: 1.10, 2.26; p=0.013) and 1.30 (95% CI: 0.86, 1.99; p=0.218), respectively. **Conclusions:** This indirect comparison suggested that nilotinib 300mg twice daily was associated with higher rates of achieving MMR, $MR^{4.0}$, and $MR^{4.5}$ by 12 months compared to dasatinib 100mg once daily for the treatment of newly diagnosed CML-CP. Higher rates of MR achievement with nilotinib were also maintained through 48 months of follow-up.

**7073 General Poster Session (Board #358), Mon, 1:15 PM-5:00 PM**

**ENESTnd 5-year (y) update: Long-term outcomes of patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP) treated with frontline nilotinib (NIL) versus imatinib (IM).** *Presenting Author: Richard A. Larson, University of Chicago, Chicago, IL*

**Background:** In ENESTnd, NIL has shown superior efficacy vs IM. Here, we report data based on a minimum follow-up of 5 calendar y. **Methods:** Pts with newly diagnosed CML-CP were randomized to NIL 300 mg twice-daily (BID; n = 282), NIL 400 mg BID (n = 281), or IM 400 mg once-daily (QD; n = 283). *P* values for secondary efficacy endpoints were not adjusted for multiple comparisons and are provided for descriptive purposes only. **Results:** At the data cutoff, 60%, 62%, and 50% of pts in the NIL 300 mg BID, NIL 400 mg BID, and IM arms, respectively, remained on core treatment. Over half of pts in the NIL arms achieved $MR^{4.5}$ ($BCR\text{-}ABL^{IS} \leq 0.0032\%$) by 5 y, and $MR^{4.5}$ rates were significantly higher on NIL vs IM overall and within each Sokal risk group (Table). Rates of major molecular response (MMR; $BCR\text{-}ABL^{IS} \leq 0.1\%$), freedom from progression to accelerated phase/blast crisis (AP/BC), and overall survival (OS) were higher on NIL vs IM. Fewer pts treated with NIL vs IM died from advanced CML. The safety profiles of NIL and IM were as expected. The rates of cardiovascular events (CVEs) of interest remained highest on NIL 400 mg BID and lowest on IM. **Conclusions:** NIL continues to result in superior efficacy vs IM in pts with CML-CP. NIL was generally well tolerated; however, CVEs of interest were more common on NIL vs IM. Clinical trial information: CAMN107A2303.

| | NIL 300 mg BID n = 282 | NIL 400 mg BID n = 281 | IM 400 mg QD n = 283 |

**7074 General Poster Session (Board #359), Mon, 1:15 PM-5:00 PM**

**ASCO 2014: High prevalence of FLT-3 ITD mutations in patients (pts) with AML who present with CNS relapse.** *Presenting Author: Simon Abi Aad, MD Anderson Cancer Center, Houston, TX*

**Background:** Despite CR rates of 70% with modern chemotherapeutic regimens, most pts with AML relapse. CNS relapses have become uncommon with the use of high-dose cytarabine based regimens. The features associated with a higher risk of CNS relapse are not defined. **Methods:** We analyzed adults who presented with AML and CNS relapses from 2000 until 2014. CNS leukemia was diagnosed by the presence of blasts in a cytocentrifuge preparation of CSF. Pts with blasts in the CSF together with high numbers of red blood cells (> 5) were not considered to have CNS disease if the blasts were high in the PB. **Results:** Of the 1312 pts with AML treated at our institution, 71 (5%) had CNS disease. Median age was 57 years. CNS involvement was detected after a median of 8 months from the initial diagnosis. 4 pts (6%) had isolated CNS relapse that was followed by systemic relapse after a median of 2 weeks. CNS involvement was detected in the setting of refractory AML in 31 pts (44%). 64 pts (90%) received previous high-dose cytarabine. 54 pts (76%) had neurologic symptoms at time of CNS relapse. CNS imaging was performed in 67 pts (94%): 41 (61%) had abnormal findings by MRI suggestive of CNS disease. 4 pts had zero cells with blasts detected on cytocentrifuge preparation only. None of the 4 pts had circulating blasts and all had abnormal findings on brain MRI suggestive of CNS relapse. 18 pts (25%) were FLT3-ITD mutated. CNS involvement was more commonly observed in young pts with increased WBC, BM blasts, and LDH, with M4/M5 phenotype, and FLT3/ITD mutated (12% versus 5%, p=0.003). Treatment for CNS disease consisted of IT chemotherapy in all pts, whole brain radiation therapy in 14, and spinal radiation in 8. Therapy was successful in clearing all signs of CNS disease in 29 (41%). 19 of the 29 pts (65%) subsequently had additional CNS relapses after a median of 3 months. The 2-year survival rate after CNS relapse was 13%. There was no difference in overall survival among patients with or without CNS disease. **Conclusions:** CNS relapse is a rare occurrence in AML (5%) and is associated with a poor prognosis. A high prevalence of FLT3-ITD mutations was observed in these pts. FLT3 mutational status and LDH level may identify patients with AML who may benefit from CNS prophylaxis.

**7075 General Poster Session (Board #360), Mon, 1:15 PM-5:00 PM**

**Outcomes among patients with isolated myeloid sarcoma: A SEER database analysis.** *Presenting Author: Maryam Movassaghian, Massachusetts General Hospital/Harvard Medical School, Boston, MA*

**Background:** Myeloid sarcoma (MS) is a rare extramedullary presentation of acute myeloid leukemia (AML), which can involve a number of primary locations. MS can exist concurrently with marrow involvement or as an isolated phenomenon. Little is known about outcomes in isolated MS due to its rarity. We performed an analysis of isolated MS using the Survival, Epidemiology, and End Results (SEER) database. **Methods:** Using the SEER database, we identified 339 patients, aged ≥ 15 diagnosed with isolated MS between 1973-2010. Overall survival (OS) was calculated as the time from diagnosis to death or censored at last visit or study cutoff (12/31/2010). OS was compared between non-MS-AML and MS using the log-rank test, and estimated by site of presentation using the Kaplan and Meier method. Involved sites were categorized as: head/neck, gastrointestinal (GI) mucosa, chest/abdomen, pelvis/genitourinary (GU), lymphatics/spleen, soft tissue, skin, bones, nervous system, eyes/gonads. **Results:** Median age at diagnosis was 64 for patients with MS and 67 for patients with AML. The 30-day mortality rate was lower for patients with MS compared to AML (0.11 vs. 0.23, p<0.0001). OS was significantly higher for MS than for AML (3-year: 0.319 vs. 0.172, p<0.0001). OS varied by the site of involvement. Data for primary sites of disease in the Pelvis/GU, GI mucosa, and eyes/gonads suggest better survival at 6 months compared to involvement of the nervous system, lymphatics/spleen, or soft tissue (Table). **Conclusions:** Population-based survival for patients with isolated MS appears to be superior to AML. MS outcomes vary depending on site of involvement; patients with disease in the pelvis/GU, GI mucosa, and in the eyes/gonads, may have relatively better survival.

| | Number | Median Age | Male (%) | OS at 6 Months |
|---|---|---|---|---|
| Overall | | | | |
| Non MS AML | 49,039 | 67 | 54 | 0.441 [0.437-0.446] |
| MS | 339 | 64 | 55 | 0.57 [0.51-0.62] |
| Disease Site | | | | |
| Head/Neck | 40 | 64 | 53 | 0.64 [0.47-0.77] |
| GI Mucosa | 31 | 50 | 65 | 0.74 [0.55-0.86] |
| Chest/Abdomen | 29 | 58 | 52 | 0.62 [0.42-0.77] |
| Pelvis/GU | 21 | 55 | 24 | 0.95 [0.71-0.99] |
| Lymphatics/Spleen | 45 | 65 | 56 | 0.40 [0.26-0.54] |
| Soft Tissue | 93 | 66 | 53 | 0.45 [0.34-0.55] |
| Skin | 32 | 74 | 66 | 0.61 [0.41-0.76] |
| Bone | 17 | 56 | 47 | 0.53 [0.28-0.73] |
| Nervous System | 11 | 69 | 45 | 0.24 [0.04-0.53] |
| Eyes/Gonads | 20 | 56 | 85 | 0.80 [0.56-0.92] |

**7076 General Poster Session (Board #361), Mon, 1:15 PM-5:00 PM**

**Role of wnt/ß-catenin pathway in myeloid neoplasms with 5q deletion: A new therapeutic target.** *Presenting Author: Nupur Mittal, University of Illinois at Chicago, Chicago, IL*

**Background:** 5q deletion (del 5q) is a recurring cytogenetic abnormality present in around 10% of de-novo and 40% of therapy related myelodysplastic syndrome (MDS)/ Acute myeloid leukemia( AML). These patients often are relatively resistant to conventional therapies and have unfavourable outcome. Del 5q is associated with haplo-insufficiency of APC gene in hematopoietic stem cells (HSCs) which leads to MDS like disease in mice (Blood 2010). APC regulates the function of HSCs largely through $\beta$-catenin dependent mechanisms ( Blood 2013). We have shown previously that Indomethacin induced $\beta$-catenin inhibition leads to growth suppression in human myeloid leukemia cells with del 5q (UoCM1) but has non-specific targets in addition to $\beta$-catenin. **Methods:** Our objective is to show effects of blocking Wnt/$\beta$-catenin pathway by specific $\beta$-catenin inhibition in del 5q myeloid leukemia. Lentiviral particles expressing a control empty backbone or $\beta$-catenin targeting inhibitory shRNA were transduced into UoCM1 and REH (Leukemia cell line with no del 5q) achieving specific $\beta$-catenin knockdown. Growth , proliferation and apoptosis of the transduced cells was assessed by flow cytometry and In vitro colony forming assay. **Results:** Western Blot confirms higher $\beta$-catenin expression in UoCM1 vs REH line. UoCM1 cells transduced with $\beta$-catenin shRNA showed 60% growth inhibition compared to control vector. In contrast, REH demonstrated comparable growth in control and $\beta$-catenin shRNA transduced cells. There was significant decrease in the fractions of cells in S and G2/M phase and increase in apoptosis ($p < 0.05$) in UoCM1 cells with $\beta$-catenin inhibition compared to control. REH showed no difference in distribution in cell cycle and similar frequency of apoptosis in $\beta$-catenin inhibited and control cells. Decrease in colony formation was observed in UoCM1 cells with $\beta$-catenin inhibition. **Conclusions:** 5q del in myeloid leukemia cell line leads to up-regulation of $\beta$-catenin. Blockade of Wnt pathway by specific $\beta$-catenin inhibition suppresses cell growth and induces apoptosis in a human myeloid leukemia cell line with 5q del. This discovery paves the way for new therapeutic strategies targeting $\beta$-catenin and improving survival in 5q del AML/MDS.

**7077 General Poster Session (Board #362), Mon, 1:15 PM-5:00 PM**

**Correlation between peripheral blood and bone marrow regarding FLT3 ITD and NPM1 mutational status in patients with AML.** *Presenting Author: Weigang Tong, Department of Medicine/Division of Hematology, University of Washington, Seattle, WA*

**Background:** Internal tandem duplications (ITD) of the FLT3 gene and mutations in the NPM1 gene are among the most common genetic aberrations in AML. Patients with these abnormalities frequently present with high circulating blast counts. Hence we hypothesized that the diagnosis of FLT3 ITD, or NPM1, positive AML can be made using peripheral blood (PB) without need for a bone marrow (BM), as has been shown to generally be the case with routine cytogenetic studies (Weinkauff et al Am J Clin Pathol 1999;111:733-740). Here we examined whether the same is true for NPM and FLT3. **Methods:** We reviewed 1016 AML ($\geq$ 20% blasts) patients that were treated at SCCA/FHCRC from January 2008 to December 2013. We identified 30 patients in whom FLT3 ITD and 18 patients in whom NPM1 mutation status was performed in both PB and BM within 3 days of each other. We compared the clinical characteristics of these patients, as well as the correlation for FLT3 ITD allelic ratio in both PB and BM using Spearman correlation analysis. **Results:** For the patients with FLT3 ITD data, the median WBC count was 13,090 (range 170-117,470) and median absolute blood blasts were 1,535 (range 0-113,060) while these values were 21,000 (range 1,190-97,000) and 5,200 (range 230-62,000) respectively for the patients with NPM data. Eight of the 30 FLT 3 patients were positive in both PB and BM, 21 were negative in both, only one patient (WBC 19,800) was negative in PB and positive in marrow (low level, $< 0.01$). There were two patients with very low WBC counts (0.4 and 0.17) and no circulating blasts, but FLT3 ITD was detected in both PB and BM. Allelic ratios were highly correlated in PB and BM correlation coefficient 0.92 (95% CI 0.82 to 0.96; $p < 0.0001$). While there was complete concordance between PB and BM with respect to NPM1 mutational status, only 4 of 18 patients were positive for NPM1 mutation as detected in both PB and BM. **Conclusions:** Within the limits of our patient numbers, these data suggest that in patients with AML, peripheral blood can often serve as a substitute for bone marrow in evaluating FLT3 ITD and NPM1 mutational status, perhaps even in patients with lower white cell counts and blast percentage.

**7078 General Poster Session (Board #363), Mon, 1:15 PM-5:00 PM**

**Longer-term follow up of a phase 1 study of ponatinib in patients (pts) with Philadelphia chromosome-positive (Ph+) leukemias.** *Presenting Author: Moshe Talpaz, Comprehensive Cancer Center, University of Michigan, Ann Arbor, MI*

**Background:** Ponatinib is a potent oral pan–BCR-ABL TKI that is active against native and mutated forms of BCR-ABL. The safety and anti-leukemic activity of ponatinib in pts with chronic myeloid leukemia (CML) or Ph+ acute lymphoblastic leukemia were evaluated in a phase I clinical trial. **Methods:** Pts (N=81) with resistant/refractory hematologic malignancies were enrolled in this ongoing, open-label, dose escalation, phase I study. Ponatinib was dosed once daily (2–60 mg). 65 pts had Ph+ leukemia and are included in this analysis (data as of 15 Oct 2013). Median follow-up was 33 (0.5–57) mos. NCT00660920. **Results:** The median age of pts was 55 yrs; median time since diagnosis was 6.5 yrs. Pts were heavily pretreated (94% had received $\geq$2 prior TKIs, 62% $\geq$3). 65% had baseline BCR-ABL mutations (29% with T315I). 38% (58% chronic phase [CP] CML) of pts remained on study. Adverse events (AEs) and progression were the most common reasons for discontinuation in Ph+ pts (20% and 17%, respectively. The most common treatment-emergent AEs were rash (52%), fatigue (52%), abdominal pain (51%), headache (48%), arthralgia (46%). Treatment-emergent vascular occlusive events were observed in 23% (serious events) and 37% (all events) of pts, including cardiovascular, peripheral vascular, cerebrovascular, and venous thrombotic events [serious (all)] in 15% (23%), 5% (9%), 5% (8%), and 0% (5%). Significant anti-leukemic activity was observed; among CP-CML pts, major cytogenetic response (MCyR), complete cytogenetic response (CCyR), and major molecular response (MMR) rates were 72%, 65%, and 51%, respectively; 75% of pts with MCyR, 69% with CCyR, and 53% with MMR are estimated (Kaplan-Meier [KM]) to maintain response for at least 3 yrs (4 yr KM estimates: 75% MCyR, 53% MMR). Of 28 CP-CML pts with CCyR, 23 remained on study (17 with continuous CCyR); of 22 pts with MMR, 20 remained on study (12 with continuous MMR). **Conclusions:** Substantial and durable responses were observed with ponatinib in heavily pretreated CP-CML pts. Vascular occlusive events were observed. Risk and benefit considerations should be evaluated when utilizing ponatinib in this pt population. Clinical trial information: NCT00660920.

**7079 General Poster Session (Board #364), Mon, 1:15 PM-5:00 PM**

**Comparison of angiopoietin-1 and -2 and VEGF expression in bone marrow and peripheral blood leukemic cells of patients with acute promyelocytic leukemia.** *Presenting Author: Mariana Scaranti, Instituto do Câncer do Estado de São Paulo, Universidade de São Paulo, São Paulo, Brazil*

**Background:** Angiogenesis is a well-known hallmark of solid cancer, but its relevance in acute leukemia genesis is controversial. Kini et al. (2001) reported that VEGF is secreted by acute promyelocytic leukemia (APL) cells, which also express VEGF receptor 2 (VEGFR2, or KDR). Moreover, arsenic trioxide, which is the most effective agent in the treatment of refractory APL, was shown to have anti-angiogenesis effect in vitro and to reduce microvascular density in bone marrow cells of APL-treated patients (Alimoghaddam et al., 2006). Considering that VEGF has paracrine and autocrine effects and the microenvironment has an important role in VEGF signaling, we decided to determine whether circulating and bone marrow APL cells differ regarding pro-angiogenic factors expression. **Methods:** We assessed VEGF, angiopoietin-1 (ANG1) and angiopoietin-2 (ANG2) gene expression through quantitative PCR (RT-qPCR) in peripheral blood (PB; n=14) and bone marrow (BM; n=24) cells of PML-RAR$\alpha$ positive APL patients. BM (n=7) and PB (n=3) samples from healthy donors were used as controls. Statistical analysis was performed using STATA 12. The Student t-test was used to compare means between two groups and the Kruskal-Wallis test followed by Dunn's post-test to compare three or more groups. **Results:** ANG1 presented lower expression in BM when compared to PB samples of APL patients (BM = 10.6 $\pm$ 0.97, PB = 7.3 $\pm$ 1.06, p=0.03). ANG2 expression was not detected in all samples. VEGF expression was not differentially expressed between PB and BM of control and APL samples. VEGF and ANG1 gene expression did not show any differences when we compared PB and BM of APL patients and healthy donors. **Conclusions:** ANG1 has a lower expression in BM of APL patients when compared to PB.This could be of importance for leukemia spread from BM to PB, since ANG1 is described as a regulator of endothelial monolayer integrity.

**7080 General Poster Session (Board #365), Mon, 1:15 PM-5:00 PM**

**Central nervous system relapse in adults with acute lymphoblastic leukemia.** *Presenting Author: Muhamed Baljevic, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Recurrence of acute lymphoblastic leukemia (ALL) in the central nervous system (CNS) in adults is associated with poor outcome. Few reports have analyzed the impact of contemporary ALL regimens on outcome of patients (pts) with CNS recurrence. This report provides single institution experience in adults with ALL and CNS relapse. **Methods:** The records of 555 (89%) consecutive pts with newly diagnosed ALL with no CNS disease treated at MDACC between 2001 and 2013 were reviewed. Pts were treated with HCVAD ± tyrosine kinase inhibitors (TKIs) and/or Rituximab (R) or with augmented BFM (AUG-BFM). Among 519 (94%) pts who achieved complete remission (CR), 33 (22%) had a CNS relapse: 8 were treated with HCVAD+R, 11 with HCVAD+TKI, 2 with HCVAD+R+TKI, 1 with HCVAD+Nelarabine, 2 with HCVAD and 9 with AUG-BFM. **Results:** Three groups of pts were identified: (A) with isolated CNS relapse (n=17), (B) with CNS relapse after bone marrow (BM) relapse (n=7), and (C) with simultaneous CNS and BM relapse (n=9). The median age (range) at diagnosis was 39 (15-75) yrs. Only LDH 1463 (335-33811) was significantly different compared to pts without CNS recurrence (p=0.05). The median CR duration prior to CNS recurrence was 15.8 months (mo) (2.5–92.6). Intrathecal chemotherapy was effective in achieving CNS CR in 26 (79%) pts. The median overall survival (OS) was statistically different among the 3 groups: median for group A 55.9 mo, 100% alive at 1-year and 30% at 4-years; group B median 25.6 mo, 78% alive at 1-year and 28% at 4-years; and group C median 16.6 mo, 86% alive at 1-year and 0% at 4-years (p=0.01). Entire cohort OS was 41.3 mo; 91% alive at 1-year and 38% at 4-years. Outcome has improved substantially compared to period before yr 2000, when median OS was 6 mo, with 38% alive at 1-year and 6% at 4-years (Surapaneni et al. Cancer 2002). **Conclusions:** Adults with CNS ALL recurrence have a poor prognosis despite effective treatment, particularly those with combined systemic and CNS relapses. However, outcome of these pts has improved significantly in the last decade. Still, effective CNS prophylaxis remains the single best approach for treating patients with CNS leukemia.

**7081 General Poster Session (Board #366), Mon, 1:15 PM-5:00 PM**

**Ponatinib (PON) in patients (pts) with Philadelphia chromosome-positive (Ph+) leukemias resistant or intolerant to dasatinib or nilotinib, or with the T315I mutation: Longer-term follow up of the PACE trial.** *Presenting Author: Hagop M. Kantarjian, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** PON is a potent, oral, pan-BCR-ABL inhibitor with activity against native and mutant forms of BCR-ABL, including the resistant T315I mutant. The efficacy and safety of PON (45 mg QD) were evaluated in the phase 2 PACE trial. **Methods:** 449 pts resistant or intolerant (R/I) to dasatinib or nilotinib or with the T315I mutation were enrolled. Data are as of 3 Sept 2013; median follow-up 24 (0.1-35) mo. NCT01207440. **Results:** Pts were heavily pretreated: 58% received ≥3 TKIs. 42% remained on study (55% CP-CML). The most common reasons for discontinuation: PD (21%) and AEs (14%, most common was thrombocytopenia, 4%). Table shows response rates at any time. In CP-CML, 89% pts maintained MCyR for at least 2 yr; progression-free survival (PFS) and overall survival (OS) at 2 yr were 67% and 86%. For AP-CML, BP-CML, and Ph+ ALL, OS at 2 yr was 72%, 18%, and 21%, respectively. Most common treatment-emergent AEs (≥30%) were thrombocytopenia (43%), rash (40%), abdominal pain (40%), headache (36%), constipation (36%), dry skin (36%). Pancreatitis and pneumonia were the most common serious AEs (SAEs; both 6%). Vascular occlusive AEs [SAEs] were reported as follows: overall 20% [14%], including cardiovascular 9% [6%], cerebrovascular 6% [4%], peripheral vascular 6% [4%] (collectively arterial thrombotic events, ATEs), venous thromboembolic 5% [3%]. Higher dose intensity, older age, and CV risk factors were associated with a higher likelihood of an ATE; pts with and without CV risk factors experienced these events. OS at 2 years was not reduced in pts with an ATE (73%) vs those without (69%); MCyR in CP-CML pts with vs without ATE was 70% vs 51%. **Conclusions:** PON has substantial clinical activity in heavily pretreated pts with Ph+ leukemias. PON is an important treatment option for pts in whom the need and benefit outweigh the risk. Clinical trial information: NCT01207440.

**Phase 1 study of the angiopoietin 1/2 neutralizing peptibody, trebananib, in acute myeloid leukemia.** *Presenting Author: Eunice S. Wang, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** Angiopoietins (Ang-1/2), pro-angiogenic factors binding to the Tie2 receptor on endothelial cells, have been implicated in the pathogenesis of acute myeloid leukemia (AML). Trebananib is a first-in-class neutralizing peptibody that potently inhibits Ang-1/2 by sequestering these factors and preventing their interaction with Tie2. **Methods:** We performed a phase 1b trial evaluating the safety, tolerability, pharmacokinetics (PK) and biologic effects of trebananib in AML patients (pts). Drug was administered at 2 doses (15 and 30 mg/kg) via weekly IV infusion over 1 hour alone (arm A) or in combination with low dose cytarabine (arm B). PK samples were collected at end of infusion (EOI), and 1-3, 4-6, 72, and 168 hrs after EOI on days 1 and 22. Plasma angiogenic factors were assessed by multiplex flow cytometry prior to first dose, on cycle 1 day 29, and at the end of study. **Results:** Twenty-four pts were enrolled. Median age was 74 years (range 29-84). Sixteen (67%) were male. Six had de novo, 13 had refractory, and 5 had relapsed AML. Three pts had undergone prior transplantation. Drug was generally well tolerated. Dose-limiting toxicities included mucositis (1, arm A, 15 mg/kg) and ataxia (1, arm B, 30 mg/kg). The most common AEs were fatigue, dyspnea, nausea, asthenia, anorexia, and edema. Serious AEs included thrombocytopenia (2), nephrolithiasis (1), and ataxia (1). Using a population PK approach, a 3-compartment model adequately characterized trebananib PK, with a mean clearance (CL) and plasma volume (V) estimated to be 0.09 L/hr and 2.74 L/kg, respectively. A trend existed between body surface area (BSA) and CL and V, suggesting that BSA in part explains the inter-patient variability in pts. No neutralizing antibodies were found. Seven pts had elevated plasma Ang-2 levels of unknown significance. Other factors (VEGF-A/C/D, IL-8, G-CSF, HGF, FGF-1/2, PlGF) were not altered. One pt (15 mg/kg) had a partial response, and 4 pts had stable disease over >1 cycle (2 on each arm, 3 receiving 30 mg/kg). **Conclusions:** Trebananib was well tolerated in AML pts alone and in combination with low dose cytarabine. Drug PK was similar to solid tumor pts. Limited clinical efficacy was seen, supporting novel combination strategies. Clinical trial information: NCT01555268, NCI-2011-02979.

**7083 General Poster Session (Board #368), Mon, 1:15 PM-5:00 PM**

**Obinutuzumab (GA101) 1,000 mg versus 2,000 mg in patients with chronic lymphocytic leukemia (CLL): Results of the phase II GAGE (GAO4768g) trial.** *Presenting Author: Joseph M. Flynn, The Ohio State University, Columbus, OH*

**Background:** Early phase 1/2 trials with GA101 in CLL demonstrated single-agent activity with suggestion of a dose response. GAGE (NCT01414205) is a multicenter, randomized study that evaluated GA101 at 2 doses in patients (pts) with symptomatic, untreated CLL. **Methods:** Randomization of 80 pts with intact organ function and ECOG PS <3 were stratified based on Rai stage (1–2 vs 3–4) and tumor mass (single lesion by CT scan, <5 cm vs ≥5 cm): GA101 1,000 mg (100 mg IV d1, 900 mg d2, 1000 mg d8, d15 of cycle 1; 1000 mg d1 of cycles 2–8) or 2000 mg (100 mg IV d1, 900 mg d2, 1,000 mg d3, 2,000 mg d8, d15 of cycle 1; 2,000 mg d1 of cycles 2–8). Each cycle was 21 days. ORR was assessed at 2 months post-therapy according to the International Workshop on CLL (iwCLL) criteria. Pts had similar pre-treatment demographics in the 2 arms. Median age was 67 (34–91) years, 36% women, 41% Rai stage 3-4, 29% with tumor masses ≥5 cm, 54% unmutated IGHV, and 10% del(17p13). Median follow-up was 11 months. **Results:** Key efficacy and safety results are shown in table below. Most frequent adverse event (AE) was infusion-related reactions (IRRs). No Grade (Gr) 3/4 IRRs occurred after cycle 1. A death (myocardial infarction) occurred after cycle 5, judged by site investigator as unrelated to GA101. **Conclusions:** These results demonstrated single-agent efficacy of GA101 at 1,000- and 2,000-mg doses, with a difference in ORR between the 2 arms (*P* = .08). No new safety signals were observed. Incidences of Gr 3/4 AEs were similar in each arm, except for IRRs. Further study is warranted to determine durability of response and long-term side effects of GA101. Clinical trial information: NCT01414205.

**7084 General Poster Session (Board #369), Mon, 1:15 PM-5:00 PM**

**Clinical impact of dose modification and dose intensity on response to ponatinib (PON) in patients (pts) with Philadelphia chromosome-positive (Ph+) leukemias.** *Presenting Author: Andreas Hochhaus, Universitätsklinikum Jena, Jena, Germany*

**Background:** PON is a potent oral pan–BCR-ABL tyrosine kinase inhibitor with clinical activity in pretreated pts with Ph+ leukemias. Dose modification of PON may be used to avoid or manage adverse events (AEs). This post hoc analysis assessed the clinical impact of dose modification and dose intensity on outcomes of pts in the phase 2 PACE trial. **Methods:** PON starting dose was 45 mg QD. Dose reduction: any reduction below 45 mg/d; dose interruption: treatment held for ≥3 consecutive days. Efficacy analyses were performed on CP-CML pts (N=267). Analysis of arterial thrombotic events (ATEs) included all pts (CP/BP/AP-CML, Ph+ ALL; N=449). Data are as of 3 Sept 2013; median follow-up was 24 (0.1-35) mo for all pts. **Results:** 78% of CP-CML pts had dose modification within the first 12 mo (82% at any time). Responses in pts with/without modification were comparable (Table). Of 149 responders, 87 (58%) achieved MCyR at 45 mg/d, 46 (31%) at 30 mg/d, 16 (11%) at 15 mg/d. Most pts who had a dose reduction after achieving a response maintained that response: MCyR (97%), complete cytogenetic response (CCyR; 96%), major molecular response (MMR; 92%). Among pts with a dose reduction lasting ≥6 mo after achieving response at a higher dose, 100% maintained MCyR (96%, CCyR; 93%, MMR). While dose intensity was the most significant predictor of MCyR by 12 mo (multivariate analysis [MVA]), substantial responses occurred at lower doses; estimated response rates were ~75% at 45 mg, ~60% at 30 mg, and ~30% at 15 mg. ATEs occurred in 17% of pts; each 15 mg/d reduction in avg daily dose is predicted to lead to ~40% reduction in risk of ATE (MVA). 2 yr overall survival was similar for CP-CML pts who had dose modifications (86%) v those who did not (86%) and for pts who had ATE (85%) v those who did not (87%). Of pts with ATEs, 46% had dose modifications. **Conclusions:** Pts on PON who undergo dose modification may still respond to treatment and dose modification may be an effective management tool. Careful consideration of the potential benefits and risks of PON should guide treatment decisions. Clinical trial information: NCT01207440.

**7085 General Poster Session (Board #370), Mon, 1:15 PM-5:00 PM**

**Trends in first-line TKI prescribing preferences (PPrefs) among U.S.-based hematology-oncology physicians (HOPs) for patients with chronic phase chronic myelogenous leukemia (CP-CML).** *Presenting Author: Neil P. Shah, University of California, San Francisco, San Francisco, CA*

**Background:** Imatinib (12/2002), nilotinib (6/2010) and dasatinib (10/2010) are all indicated for first-line treatment of patients (pts) with CP-CML. PPrefs may be influenced by multiple considerations such as assessment of the risk profile of an individual patient's disease, randomized efficacy data, cross trial comparisons of efficacy and toxicity, associated co-morbid conditions, ease of access to and administration/management of specific agents, cumulative pt out of pocket costs, and physician familiarity with available agents. **Methods:** Since 2011 we have used a live, extensively validated research tool to assess PPrefs of U.S.-based HOPs related to first-line TKI selection across several risk-based scenarios in pts with a new diagnosis of CP-CML. Lower risk scenario: 2011/2012 - 59 year old male, spleen palpable 7 cm below the left costal margin (LCM); white blood cell count (WBC) 75,000 with 82% mature polys; 3% basophils, no blasts; Hemoglobin (Hgb) 12.0 gms; Platelets (Plts) 430K. 2013: Identical scenario and labs except age of 63 and spleen palpable 5 cm below LCM. Higher-risk scenarios: 2012: Male, age 59, spleen 11 cm below LCM; WBC 96,000 with 3% blasts, 5% basophils; Hgb 11.1 gms; Plts 935K. 2013: Identical scenario except age of 63, basophils 9% and platelets 965K. **Results:** TKI PPrefs by year and scenario shown in Table. **Conclusions:** PPrefs among US-based HOPs for pts presenting with a new diagnosis of CP-CML appear to be progressively shifting toward use of FDA indicated second generation TKIs as initial therapy. Blood counts and spleen size at presentation appear to impact HOP PPrefs. In 2013, the majority of PPrefs for the higher risk scenario are for second generation agents and there is an equal split in the lower risk population. Among respondents indicating a PPref for a second generation agent as initial therapy, a trend over several years toward increasing PPref for dasatinib is evident.

**7086 General Poster Session (Board #371), Mon, 1:15 PM-5:00 PM**

**Standardized costs and outcome in children treated with gemtuzumab on the AAML0531 trial: A report from the Children's Oncology Group.** *Presenting Author: Richard Aplenc, The Children's Hospital of Philadelphia, Philadelphia, PA*

**Background:** NCI-funded cooperative group oncology group trials report clinical outcomes but do not report cost estimates. The Children's Oncology Group trial AAML0531 randomized 1,022 de novo AML patients to standard chemotherapy ± gemtuzumab (GMTZ). As previously reported, GMTZ improved event-free survival but did not improve overall survival. The Pediatric Health Information Systems (PHIS) database contains standardized inpatient cost data (SC) on children treated at 43 freestanding pediatric hospitals in the United States. We hypothesized that SC would be similar for both treatment arms during on-protocol therapy but lower in the GMTZ arm during all follow up time (defined as time from on-protocol to last COG follow-up). **Methods:** Data from AAML0531 and PHIS were probabilistically merged. PHIS SC were defined by hospital costs multiplied by the ratio of cost to charges and adjusted by consumer price index and geographical region. All available SC were extracted for all merged patients and compared with bivariate statistics. **Results:** Merged patients (n = 373) were representative of the overall trial population. Follow-up time was marginally longer in the GMTZ arm, 223 days vs 238 days, p = 0.1. The overall median SC was $309,785 ($1,943/day) on-protocol and $467,767 ($1,707/day) for all follow-up time. The per day SC did not differ by study arm on-protocol but per day SC were significantly higher in the non-GTMZ arm, $1,877/day vs $1,648/day over all follow-up time, p = 0.03. Table 1 summarizes departmental SC; Room and Board (RB) comprises approximately 50-60% of all SC. **Conclusions:** Merging of PHIS data with COG data enables estimation of regimen specific SC. GMTZ does not increase SC during protocol therapy but is associated with lower per day SC over all follow-up time. Further work is needed to increase the number of patients with SC data, to examine SC variability, and define drivers of SC. Clinical trial information: NCT00372593.

**7087 General Poster Session (Board #372), Mon, 1:15 PM-5:00 PM**

**Distinct biomarkers as prognostic in chronic lymphocytic leukemia patients treated with alvocidib and lenalidomide as single agents or combination regimens thereof.** *Presenting Author: William E. Pierceall, Eutropics Pharmaceuticals, Cambridge, MA*

**Background:** Chronic lymphocytic leukemia (CLL) patient outcomes may benefit from targeting therapies alone or in combination to individuals with favorable molecular profiles. Whether such personalized medicine approaches are best tailored to patients treated with single agent therapies or regimens using those agents in combination is an underexplored question. Here, we assessed mitochondrial apoptosis signaling in CLL patients treated with lenalidomide, alvocidib, or lenalidomide + alvocidib. **Methods:** Pretreatment blood mononuclear cell (PBMC) specimens were assessed measuring mitochondrial outer membrane permeabilization following incubation with BH3 peptides as a surrogate for Bcl-2 family proteins function. The study comprised 106 patients: 62 alvocidib-treated patients, 20 lenalidomide-treated patients, and 24 patients treated with combinational lenalidomide + alvocidib. **Results:** In alvocidib-treated patients assessment of biomarker and clinical response association, Bim AUC=.73 (p=.0004) and Hrk (indicating Bcl-xL-dependence) AUC=.73 (p=.0002). Hrk benefitted from trisomy12 inclusion (AUC=.83; p<.0001). In single agent lenalidomide-treated patients, no biomarkers were associated with response, however, priming of Mcl-1, determined by response to the Noxa peptide, was associated with progression-free survival (p=.032). In lenalidomide + alvocidib-treated patients, the prognostic significance was different from either of the two agents independently as Puma (pan-antiapoptoic modulator of Mcl-1, Bcl-xL, and Bcl-2) was associated with clinical response (AUC=.73; P=.027) that improved with addition of bulky adenopathy (AUC=0.84 p=.0063). **Conclusions:** Alvocidib (cyclin-dependent kinase inhibition) and lenalidomide (immunomodulation) have distinct mechanisms of action and offer separate molecular profiles associated with clinical outcomes. Although the importance of Bcl-2 family regulated apoptosis is consistent, biomarker associated outcomes in combination regimen patients differ from those associated with single agent therapies.

**7088 General Poster Session (Board #373), Mon, 1:15 PM-5:00 PM**

**Hyperdiploidy in AML: Outcomes of acute myelogenous leukemia (AML) patients (pts) with a hyperdiploid karyotype.** *Presenting Author: Aditya Shetty, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Hyperdiploidy with greater than 49 chromosomes is an infrequent phenomenon in AML, with a reported incidence of less than 2%. While autosomal loss is known to have poor prognosis, the outcome of patients with hyperdiploid karyotype (HK) is unclear. **Methods:** We reviewed data of 1313 pts with AML treated at our institution between 2003 and 2013. **Results:** Hyperdiploidy was identified in 41 pts (3%). Baseline characteristics in pts with HK at initial diagnosis included: a median age of 68 years (range, 18-81) and a median white blood cell count of 2.1 (range, 0.4-22.4). Median chromosome number in the HK group was 55 (range, 49-104). The most common chromosomes gained included trisomy 8 in 22 pts (54%), trisomy 22 in 16 pts (40%) and trisomy 21 in 13 pts (33%). A monosomal karyotype (MK) was noted in 23 pts (56%) in the HK group. Structural abnormalities defined as intermediate risk by European LeukemiaNet classification were noted in 11 pts (27%). Hyperdiploidy as the only chromosomal aberrations was noted in 6 pts (15%). Thirteen pts (32%) received high-dose ara-C-based induction and 9 pts (22%) received a clofarabine- based induction. 20 pts (49%) achieved a complete remission. The median CR duration was 5 months (range, 0-81 months). 35 pts (85%) had died, with a median overall survival of 7 months (range, 1-84 months) compared with 10 months (range, 0-120 months) for a control group of all AML pts (non-M3, non-cbf) (p=0.16), 6 months (range, 0-115 months) for AML pts with complex, non-hyperdiploid cytogenetics (p=.100) and 15 months (range, 0-120 months) for AML pts with diploid cytogenetics (p=.001). In subgroup analysis limited by small pt numbers, pts with hyperdiploidy alone had median overall survival of 12 months (range, 1-43 months), compared with 6 months (range, 1-51 months) and 9 months (range, 1-84 months) in the structural abnormalities subgroup and the monosomal subgroup, respectively (p=.237). **Conclusions:** Hyperdiploidy is a rare abnormality in AML with trisomy 8, 22 and 21 being the most commonly gained chromosomes. HK pts had a significantly worse outcome compared to a diploid cohort and a minor trend towards better outcomes compared to AML pts with complex cytogenetics.

**7089 General Poster Session (Board #374), Mon, 1:15 PM-5:00 PM**

**European leukemia net (ELN) 2013 response categories: Impact on clinical outcomes across four frontline tyrosine kinase inhibitor (TKI) modalities in chronic phase CML.** *Presenting Author: Preetesh Jain, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** In 2013 ELN proposed new response categories applicable to TKI frontline therapy for CML. We analyzed the outcome by ELN category of patients (pts) on different TKI as frontline therapy for CML-CP. **Methods:** 487 pts treated by TKI from 2000-2013 were analyzed. Pts received imatinib 400 mg/d (IM400; n=70), imatinib 800 mg/d (IM800; n=201), dasatinib (n=107) or nilotinib (n=109) in consecutive or parallel trials. Median follow-up was 99 months (mo). Pts were followed uniformly with cytogenetics and PCR every 3 mo for the first 12 mo, then every 6 mo. **Results:** Median follow-up was 144 mo for IM400, 119 mo for IM800, 54 mo for dasatinib and 49 mo for nilotinib. Cumulative CCyR rates were 85%, 90%, 98% and 93%, and MMR rates were 84%, 88%, 91%, and 94%, respectively. ITT analysis indicated the proportion of pts falling into optimal, warning and failure categories were 89%, 6%, 6% at 3 mo, 78%, 17% and 6% at 6 mo, and at 12 mo 75%, 13% and 13%, respectively. Rates of optimal response at 3 mo were 75% for IM400, 90% for IM800, 89% for dasatinib and 97% for nilotinib; 41%, 80%, 86% and 89% at 6 mo; and 47%, 77%, 76% and 87% at 12 mo, respectively. Pts with optimal response had longer EFS, FFS, TFS and OS compared to those with warning and failure at all-time points. Within each response category, type of TKI did not affect long-term outcome. (Table) **Conclusions:** Imatinib 400 induces optimal response in fewer pts at all times. Optimal responses predict for better outcomes irrespective of the TKI modality.

**Event-free and overall survival probabilities with different TKI modalities stratified by ELN response.**

| % 5-year EFS | | IM400 | IM800 | Dasatinib | Nilotinib | Overall |
|---|---|---|---|---|---|---|

**CD96 antibody TH-111 for detection of AML leukemic stem cells, and purging of autografts for stem cell transplantation.** *Presenting Author: Matthias Staudinger, Division of Stem Cell Transplantation and Immunotherapy, 2nd Department of Medicine, University Hospital Schleswig-Holstein and University of Kiel, Kiel, Germany*

**Background:** High relapse rates observed in AML patients after autologous stem cell transplantation may be due to residual leukemic stem cells (LSC) in the graft. Therefore, elimination of LSC by targeted therapy represents a promising therapeutic option. Here, strategies are described addressing CD96 - a marker antigen recently identified on AML LSC - for engineering autologous stem cell grafts by magnetic cell sorting (MACS). Moreover, attempts to improve antibody-dependent killing (ADCC) of LSC may allow therapeutic use in other situations. **Methods:** Biotinylated CD96 antibody TH111 raised in our laboratory was used for MACS separation of AML-LSC. Healthy hematopoietic progenitor cells (HPC) viability, their differentiation properties and the efficiency of depletion were analyzed by colony forming assays and flow cytometry. Chimeric ADCC-optimized CD96 antibodies were analyzed for purity by SDS page and specific binding by flow cytometry. Antibody-mediated effector functions were measured in $^{51}$Cr-release assays. **Results:** To determine the efficiency of antibody mediated LSC purging, stem cell containing grafts were spiked with AML cells. Using biotinylated CD96 antibody up to a 1000-fold depletion of targeted cells was achieved. Viability of healthy HPC as well as their potential to proliferate and differentiate were not affected. To recruit NK cells for lysis of CD96$^+$ AML-LSC by ADCC, chimeric antibodies containing wild type or affinity maturated variable regions in combination with an ADCC optimized human $IgG_1Fc$ were generated. Due to a higher antigen binding affinity of the maturated antibody (EC50 of 0.6 $\mu$g/ml vs. 2 $\mu$g/ml), the NK cell mediated lytic properties against CD96-positive target cells were elevated (EC50: 0.02 $\mu$g/ml vs. 0.15 $\mu$g/ml; E:T ratio 2.5:1). **Conclusions:** The efficient elimination of AML-LSC by MACS may be beneficial for the development of graft-engineering strategies to avoid transplantation of AML-LSC and revitalize autologous stem cell transplantation in this indication. The in vivo application may possibly open additional therapeutic avenues in eliminating residual disease in autologous as well as allogeneic situations.

**7091 General Poster Session (Board #376), Mon, 1:15 PM-5:00 PM**

**Economic burden of tyrosine kinase inhibitor (TKI) treatment failure in patients with chronic myeloid leukemia (CML).** *Presenting Author: Yaozhu J Chen, IMS Health, Alexandria, VA*

**Background:** Treatment failure due to TKI resistance or intolerance is a significant challenge in managing CML; however, there are limited data quantifying the associated real-world health care utilization and cost burden. **Methods:** Treatment episodes for adult patients with a CML diagnosis (ICD-9-CM 205.1x) initiating a TKI of interest (index TKI) during 6/2008-12/2011 were identified from the IMS PharMetrics Plus Health Plan Claims Database. Inclusion required 120-days pre- and 360-days post-index continuous enrollment and no clinical trial participation. A patient could contribute ≥1 episode. Treatment failure was defined as switch to a non-index TKI or discontinuation of index TKI (gap of ≥60 days) observed over 1 year post index. Episodes with failure were matched to those without, based on propensity scores generated by logistic regression including baseline demographic and clinical characteristics, index TKI, and therapy line. Mean all-cause 1-year post-index health care utilization and costs (in 2012 USD) per episode were compared between matched episodes. **Results:** Of 1,774 eligible episodes from 1,624 CML patients (mean age=52.9, 47.8% female), 547 Failure episodes (Fs) were matched to 547 Non-Failure episodes (NFs). As expected, compared to Fs, NFs had more TKI fills (F: 7.1; NF: 11.2; p<.05) over the 1 year post index. However, Fs had significantly higher % hospitalized (28.9% v 13.9%), more inpatient days (22.2 v. 8.5), more outpatient visits (24.1 v. 17.8) and more non-TKI prescription fills (34.0 v. 28.7) (all p<.05). Overall, Fs incurred lower pharmacy costs ($51,238 v. $72,450), but higher medical costs ($52,618 v. $18,180, including $31,305 v. $5,287 for hospitalization), and higher total costs ($103,857 v. $90,630) than NFs (all p<.05). A sensitivity analysis excluding 18 episodes (17 Fs, 1NF) with bone marrow or stem cell transplant yielded qualitatively similar results. **Conclusions:** Although TKI failures have lower pharmacy burden, their overall economic burden is higher, primarily due to increased inpatient days. These findings suggest that minimizing TKI failure through more efficacious treatment may decrease the overall health care burden and costs of managing CML.

**7092 General Poster Session (Board #377), Mon, 1:15 PM-5:00 PM**

**Association of epidemiologic exposures with complete remission after therapy in acute myeloid leukemia (AML).** *Presenting Author: Laura Elizabeth Finn, Mayo Clinic, Jacksonville, FL*

**Background:** Complete remission (CR) after induction chemotherapy is a vital prognosticator in AML. Age and comorbidities impact response and tolerance to AML induction chemotherapy however the influence of epidemiologic exposures is unknown. We therefore evaluated relevant exposures in a cohort of 295 consecutive AML patients with confirmed central cytogenetics analysis diagnosed and treated at Mayo Clinic Florida and Arizona since 1995. **Methods:** Documented patient exposures extracted systematically from a centralized EMR included prior chemotherapy/radiation (therapy AML, tAML) or hematologic malignancy (secondary AML), medications, and prior solid organ transplantation. Patients receiving induction chemotherapy and responses to therapy were identified. The association of epidemiologic exposures with CR after induction chemotherapy was evaluated by multivariable analysis using logistic regression models. **Results:** 188 patients received induction chemotherapy. Age was not an independent predictor of CR. tAML after breast cancer was independently and significantly associated with achieving CR after therapy, as was statin use. In contrast prior solid organ transplant, farm habitat, tobacco use, and poor risk cytogenetics were associated with decreased CR. **Conclusions:** Some epidemiologic exposures impact CR after AML induction chemotherapy in AML. This supports a link between exposures and outcome after therapy with curative intent. This requires validation in a prospective therapeutic clinical trial.

**CR after induction chemotherapy (OR, CI 95%).**

**7093^ General Poster Session (Board #378), Mon, 1:15 PM-5:00 PM**

**The benefit of treatment with quizartinib and subsequent bridging to HSCT for FLT3-ITD(+) patients with AML.** *Presenting Author: Mark J. Levis, Department of Oncology, Division of Hematologic Malignancies, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** For FLT3-ITD(+) AML patients (pts) who are relapsed or refractory to chemotherapy, allogeneic HSCT offers the best prospect for long-term survival. Pts are unlikely to undergo HSCT unless their blast count can be reduced to an acceptable minimum, ideally below 5% blasts, which defines composite complete response (CRc: CR + CRp + CRi). Quizartinib is an orally active inhibitor of the FLT3 receptor tyrosine kinase being developed for the treatment of AML pts. We present a new analysis from FLT3-ITD(+) pts who were relapsed or refractory to salvage therapy or HSCT treated with quizartinib across two Phase 2 studies in a total of 212 subjects. **Methods:** In Study A, pts received 90-200 mg/day quizartinib; in Study B, pts were randomized to either 30 mg/day or 60 mg/day quizartinib given orally during continuous 28 day cycles. **Results:** Median baseline blast count in Study A was 81% and 67% in Study B. Median age in Study A was 50yrs and 55yrs in Study B. In Study A, 47 of 136 (35%) proceeded to HSCT; of these 26/47 (55%) had achieved a CRc and 18/47 (38%) a PR prior to HSCT. In Study B 28/76 (37%) pts proceeded to HSCT and of these 23/28 (82%) had achieved a CRc and 4/28 (14%) achieved a PR prior to HSCT. In Study A, pts proceeding to HSCT had a median overall survival (OS) of 34.1 weeks and a 1 yr survival rate of 36% compared to an OS of 18.4 weeks and 1 yr survival of 12% for pts not undergoing HSCT. In Study B, pts randomized to 30 mg/day quizartinib and who underwent HSCT had an OS of 31 weeks compared to 19 weeks for pts without HSCT; pts treated with 60 mg/day and who underwent HSCT had an OS of 28.1 weeks compared to 16.3 weeks for pts without HSCT. **Conclusions:** Pts able to receive a HSCT after response to quizartinib have an improved outcome compared to those who did not have a HSCT. The ability of quizartinib to lower the blast count in a high percentage of pts (46% achieved a CRc) and bridge these pts to a potentially curative HSCT, with an acceptable safety profile, represents an important clinical benefit from quizartinib. Clinical trial information: NCT00989261 and NCT01565668.

**7094 General Poster Session (Board #379), Mon, 1:15 PM-5:00 PM**

**Clinical significance of MYC expression in acute myeloid leukemia.** *Presenting Author: Maro Ohanian, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** MYC, a transcription factor controlling DNA replication, is overexpressed in many cancers, yet rarely investigated in myeloid neoplasms, where its clinical significance is unknown. Objectives:Assess MYC expression by immunohistochemistry (IHC) in bone marrow (BM) of patients (pts) with acute myeloid leukemia (AML), myelodysplastic syndrome (MDS), and acute promyelocytic leukemia (APL). **Methods**: MYC expression by IHC was assessed in BM of pts with AML, MDS, APL, and normal BM. MYC expression showed a distinct nuclear pattern. Cases were considered positive if > 5% blasts were stained. **Results:** We evaluated BM MYC expression in 220 pts during 2006-2013 (97 mo) with newly diagnosed AML (n=162), previously treated AML (induction failure or relapse) (n=30), MDS (n=19), and newly diagnosed APL (n=11). Median age was 60 yrs (13-88); 56% male. Normal BM (negative controls) showed negligible MYC expression (<5%, n=11). Varying degrees of MYC expression were observed in AML pts with median MYC expression of 20% (range 2-90%) and 50% (range 19-75%) in APL. Median MYC expression across diseases was 20%. MYC expression of >5% was observed in 134 (84%) newly diagnosed AML pts, 22 (73%) previously treated AML, all (n=11) APL, but in only 7 (40%) MDS (p= 0.0001 for difference across groups). High MYC expression correlated with high LDH (rs = 0.390, p<0.0001), WBC (rs = 0.205, p=0.006) and BM blasts (rs 0.341, p=0.0001). MYC levels were similar across karyotypes: trisomy 8 (where *MYC* resides), complex, and core binding factor. In newly diagnosed AML pts, 105 were screened for *NPM1* and 81 for *FLT-3 ITD* mutations. MYC expression was higher in 21 *NPM1* mutated pts (P = 0.04) and in 22 *FLT3-ITD* mutated pts (P = 0.01). MYC expression strongly predicted survival in newly diagnosed AML. Normal MYC expression (n=26) had a median OS of 28 mo (CI 19-37); those with increased MYC expression had a median OS of 14 mo (CI 10-18) (Log-rank p=0.023). Among normal karyotype (NK) pts median OS was 40 mo (CI 16-63) if MYC <5% vs. 16 mo (CI 9-23) if MYC >5%. The OS advantage was similar with or without mutated FLT3-ITD. Among NK cases of varying MYC levels, MYC rearrangement was not detected by FISH. **Conclusions:** MYC expression is a strong predictor of survival, particularly in newly diagnosed NK AML.

**7095 General Poster Session (Board #380), Mon, 1:15 PM-5:00 PM**

**Expression and function of TIM-3, a potential therapeutic target in acute myeloid leukemia.** *Presenting Author: Catherine Joy Lee, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** Transmembrane immunoglobulin mucin-3 (TIM-3) is a cell-surface protein that has been identified as a novel acute myeloid leukemia stem cell (AML-LSC) surface marker and a potential candidate for targeted therapy with monoclonal antibodies. However, the function of TIM-3 on LSCs and blasts, and in the pathogenesis of AML, is currently unclear. We have shown in T cells that TIM-3 regulates the growth and survival of normal and transformed cells by activation of kinase Akt (pAkt) and phosphorylation of ribosomal S6 protein (pS6). We hypothesize that TIM-3 may similarly contribute to the survival of AML through activation of pAkt and pS6 in LSCs and leukemic blasts. **Methods:** Established human AML cell lines NB4, U-937, and HL-60 were assessed for surface TIM-3 expression by flow cytometry and western blot when at rest and when stimulated with phorbol 12-myristate 13- acetate (PMA; 5 ng/ml, 10 ng/ml, 50 ng/ml) for 24-72 hrs. Cell surface CD11b was used as a marker for PMA-induced monocytic differentiation. Primary human AML peripheral blood samples were analyzed for TIM-3 and intracellular pS6 expression in the $CD34^+$population by flow cytometry. **Results:** 1) Basal levels of TIM-3 expression were minimal in NB4, U-937, and HL-60 cells; however, TIM-3 expression was up-regulated at least two-fold in all cell lines during PMA-induced differentiation along the monocytic/macrophage lineage by 24 hrs. 2) In a 24-hour kinetics assay, TIM-3 up-regulation occurred at 6 hrs versus 10 hrs for CD11b in NB4 cells. 3) Four primary human AML samples were obtained thus far. We identified a $TIM\text{-}3^+CD34^+pS6^+$population from at least two of these patients. **Conclusions:** We have evaluated the expression and possible function of TIM-3 in AML cell lines and primary human AML samples. In NB4 cells, TIM-3 may be involved in the differentiation pathway of AML cells by PMA as up-regulation of TIM-3 preceded that of CD11b. We have also identified human AML samples that express TIM-3 and pS6 in the $CD34^+$ population. Ongoing studies include the use of TIM-3 modulating antibodies on AML cell lines and on $CD34^+CD38^-TIM3^+$ primary AML samples to determine the role of TIM-3 on downstream signaling activation, and on viability, proliferation, and differentiation.

**7096 General Poster Session (Board #381), Mon, 1:15 PM-5:00 PM**

**A next-generation sequencing approach to capturing CEBPA: A hematologic malignancy sequencing panel capturing clinically useful targets.** *Presenting Author: Jennifer J. Morrissette, Department of Pathology and Laboratory Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

**Background:** The use of next generation sequencing (NGS) for clinical diagnosis of cancer promises to improve diagnosis and lead to more precise cancer care. However, this methodology does not cover all regions of the genome uniformly, with some regions not sequenced with sufficient depth for accurate mutation detection. Here we describe the validation of a 34 gene hematological NGS panel, including one gene, CEBPA, which performed poorly and required an alternative NGS method due to GC–rich regions. **Methods:** Fifty five AML patient samples were obtained from the Stem Cell and Xenograft Core at the University of Pennsylvania and analyzed using an Illumina TrueSeq Custom Amplicon panel with subsequent sequencing on the Miseq. To capture CEBPA we developed a separate method using target amplification by a long range PCR followed by library preparation using the Nextera XT kit (Illumina Inc). **Results:** We found NGS of commonly mutated genes in hematologic malignancies is technically feasible and reliable in a clinical diagnostic laboratory, with >99% sensitivity and specificity on variant detection achieved when allele frequency of a given variant was 5% or higher over regions that met our sequencing QC threshold of 250x. The middle of the coding region for CEBPA demonstrated inefficient capture using amplicon or bead based approaches. Using a long range PCR approach followed by Nextera library preparation, 100% coverage of CEBPA was achieved. Given the high GC content a lower limit of detection for CEBPA, at a 10% allele frequency, allowed for 100% sensitivity and specificity in the samples analyzed. **Conclusions:** We have developed a clinical grade multi-gene test for hematologic malignancies using next generation sequencing technology that can reliably detect somatic mutations including single nucleotide variants, insertions and deletions. For most genes on the panel, a minimal allele frequency of 5% was detectable for indels and SNVs. With CEBPA, there was robust mutation detection at an allele frequency of 10% or greater. This combined approach allows for comprehensive mutation screening of the genes relevant to the prognosis of AML, including CEBPA, with a single approach, NGS.

**7097 General Poster Session (Board #382), Mon, 1:15 PM-5:00 PM**

**Propensity score matched comparison of intermediate-intensity chemotherapy induction versus intensive chemotherapy induction in elderly patients (age ≥ 60) with acute myeloid leukemia (AML).** *Presenting Author: Koichi Takahashi, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** A majority of patients (pts) with AML age ≥ 60 are unable to tolerate intensive chemotherapy (IC) induction. Front-line therapy with clofarabine plus low dose cytarabine (CLDA) has been used for this subset of pts. We hypothesized that CLDA provides equivalent outcome on elderly pts with AML compared to conventional IC induction with less toxicity. **Methods:** Previously untreated pts with AML, age ≥ 60, who received front-line therapy between 2002 and 2012 by one of the following regimens were matched by the propensity score to adjust confounding factors: 1) clofarabine plus low-dose cytarabine (CLDA group: N = 142) or 2) idarubicin plus high-dose cytarabine (IA group: N = 104). **Results:** Propensity matching resulted in 66 pts from each group to be matched for their pre-treatment characteristics including age, performance status (PS), organ function and cytogenetics. Response rate (achieving complete remission [CR] within 2 courses of induction) was similar between 2 groups (CLDA vs. IA, 59% vs. 53%, P = 0.48). Mortality at 4 and 8 weeks were similar between 2 groups (CLDA vs. IA, 5% vs. 11% at 4 weeks and 14% vs. 15% at 8 weeks, P = 0.32 and 0.80, respectively). The median hospital stay during induction was similar between 2 groups (CLDA vs. IA, 27 vs. 26 days, P = 0.15). Comparable proportion of pts were bridged to stem cell transplant during 1st CR (CLDA vs. IA, 6% vs. 5%, P = 1.00). The median overall survival (OS) was similar between 2 groups (CLDA vs. IA, 11.4 months [95% CI: 7.0-15.8] vs. 10.4 months [95% CI: 4.9-15.9], P = 0.60). In an analysis sub-grouped by clinical characteristics, no difference in OS was observed between 2 groups in any of the subgroups. Multivariate analysis for OS showed that adverse risk cytogenetics, age ≥ 70, bone marrow blast > 30%, and PS > 2 adversely affected OS but induction regimen did not affect OS. **Conclusions:** Induction therapy with CLDA showed equivalent response rate and OS in pts with AML age ≥ 60 compared to conventional IC induction. Intensity of induction in elderly AML pts may be attenuated without compromising outcome. Prospective randomized trial to confirm these findings is warranted.

**7098 General Poster Session (Board #383), Mon, 1:15 PM-5:00 PM**

**Phase I/II study of vosaroxin and decitabine in older patients (pts) with acute myeloid leukemia (AML) and high-risk myelodysplastic syndrome (MDS).** *Presenting Author: Naval Guastad Daver, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Vosaroxin is a first-in-class anticancer quinolone derivative (AQD) that intercalates DNA and inhibits topoisomerase II and has previously demonstrated activity in AML. We conducted this study to examine the efficacy and toxicity of the combination of vosaroxin and decitabine. **Methods:** Pts were eligible if they had AML or high-risk MDS (≥ 10% blasts in the bone marrow), were ≥ 60 years, had ECOG PS ≤ 2 and adequate organ function. Pts < 60 years who were unsuitable for standard chemotherapy were also eligible. The treatment regimen included vosaroxin 90 mg/m$^2$ daily on days 1 and 4 with decitabine 20 mg/m$^2$ daily for 5 days. Vosaroxin was reduced to 70 mg/m$^2$ in consolidation cycles, for a total of up to 7 cycles. The primary endpoint is overall response rate (ORR) rate [ORR=CR + CRp + CRi]. **Results:** To date, 23 pts (21 AML, 2 high-risk MDS) with a median (med) age of 71 years (range, 41-78) have been enrolled. They included 11 (48%) with diploid cytogenetics, 7 (30%) with complex cytogenetics including chromosome 5 and/or 7 abnormalities, and 5 (22%) with other. 9 (39%) had antecedent hematological disorders (AHD). 5 pts with AHD had received prior therapy including azacitidine (n=1), ruxolitinib + azacitidine (n=1), lenalidomide (n=1) and hydroxyuea (n=2). Frequently identified mutations included: *IDH1/2* in 8 (35%), *RAS* mutations in 6 (26%), *TP53* in 6 (26%), and *NPM1* in 4 (17%). Med bone marrow blast %, white blood cell, hemoglobin, & platelet counts were 36% (11-97), 4.6 x 10$^9$/L (1.0-25.1), 9.5 g/dL (6.8-11.5), and 42 x 10$^9$/L (7-333), respectively. 16 pts were evaluable for response; 9 (56%) achieved CR, 2 (13%) CRp, and 2 (13%) CRi, for an ORR of 81% with no evidence of minimal-residual disease in 11 of 13 responders (85%). 7 are too early for response assessment. Pts have received a med of 2 cycles (range, 1-5) with med number of cycles to response being 1 (range, 1-4). No pts have relapsed. 1 pt has proceeded to HSCT. Two pts died during induction. Additionally, 1 pt died on day 47 from sepsis and acute myocardial infarction. The main grade ≥ 3 toxicity was mucositis in 2 pts. **Conclusions:** Combination of vosaroxin and decitabine is effective and well tolerated. Enrollment is ongoing. Clinical trial information: NCT01893320.

**7099 General Poster Session (Board #384), Mon, 1:15 PM-5:00 PM**

**Health-related quality of life (HRQL) impact of idelalisib (IDELA) in patients (pts) with relapsed chronic lymphocytic leukemia (CLL): Phase 3 results.** *Presenting Author: Paolo Ghia, Università Vita e Salute; San Raffaele Scientific Institute, Milano, Italy*

**Background:** Pt-reported outcomes (PROs) evaluated HRQL among CLL pts randomized to IDELA + rituximab (R) (n=110) vs double-blind placebo + R (n=110). **Methods:** The 44-item Functional Assessment of Cancer Therapy–Leukemia (FACT-Leu) scale measured Physical (PWB), Functional (FWB), Social (SWB) and Emotional (EWB) Well-being and leukemia-specific concerns (LeuS). The FACT-Leu Total score is the sum of subscales; Trial Outcome Index (TOI) is the sum of PWB, FWB and LeuS. Higher scores reflect better HRQL. Repeated measures mixed-effects models assessed change from baseline within and between-arms. **Results:** IDELA + R was superior for OS: HR=0.28 (0.09, 0.86), p=0.018. In the mixed-effects model analysis, PWB (p=0.015), FWB (p= 0.014), LeuS (p=0.001), TOI (p=0.002), and FACT-Leu Total (p=0.006) scores were significantly higher for IDELA + R. EWB/SWB scores did not change significantly over time. Repeated measure mixed-effects model results are shown in the table. **Conclusions:** In this frail CLL population, IDELA + R had superior efficacy, clinically significant improvements in HRQL, and superior symptom control occurring by 8 weeks compared to R + placebo. Clinical trial information: NCT01539512.

**7100 General Poster Session (Board #385), Mon, 1:15 PM-5:00 PM**

**Final results of a randomized phase 2 study showing the clinical benefit of quizartinib (AC220) in patients with FLT3-ITD positive relapsed or refractory acute myeloid leukemia.** *Presenting Author: Gary J. Schiller, University of California, Los Angeles School of Medicine, Los Angeles, CA*

**Background:** The presence of FLT3-internal tandem duplication (ITD) in patients (pts) with acute myeloid leukemia (AML) is associated with early relapse and poor survival. Quizartinib (AC220) is an orally active inhibitor of the FLT3 receptor tyrosine kinase being developed for the treatment of pts with FLT3-ITD(+) AML. This randomized, open-label, study was conducted to assess the effect of two different dosages of quizartinib in FLT3-ITD+ pts, aged 18 years or older, with relapsed or refractory AML after either one-second line therapy or HSCT. **Methods:** Pts were randomized to quizartinib 30 mg/day (Group A) or 60 mg/day (Group B) given orally during 28-day continuous treatment cycles, until relapse, intolerance or proceeding to HSCT. Primary endpoint was the rate of CRc (CR+CRp+CRi). **Results:** Seventy six pts were randomized equally to the two arms. Demographics and baseline characteristics were balanced between the two arms except for age over 60 years (42% Group A, 26% Group B) and the percentage with secondary AML (8% Group A, 18% Group B). The analysis included a minimum of 8 weeks of follow-up. The median duration of treatment in Group A was 10.9 weeks (range 2.1 to 24.9+ weeks) and 11.0 weeks (range 2.6 to 26 weeks) in Group B. The CRc rate in both groups was 47% and the overall response rate (CRc + partial response (PR)) was 61% in Group A and 71% in Group B. 32% of pts in Group A and 42% in Group B were able to receive a HSCT, mostly after achieving CRc or PR. The median overall survival was 20.7 weeks in Group A; and 25.4 weeks in Group B with 35 of the 76 patients alive at last follow-up (range: 7.4 – 40.4+ weeks). Grade 2 or greater QTcF prolongation occurred in 11% Group A pts and in 17% Group B pts. The most common treatment related adverse events occurring in 15% or more pts were diarrhea (18%), febrile neutropenia (16%), and QT prolongation (15%). **Conclusions:** Quizartinib in second salvage or post HSCT FLT3-ITD+ AML demonstrated a high degree of efficacy (CRc 47%) with an acceptable safety profile, specifically decreased QTcF prolongation rates compared to higher doses used previously. Further analysis with additional follow-up will be available for presentation. Clinical trial information: NCT01565668.

**7101 General Poster Session (Board #386), Mon, 1:15 PM-5:00 PM**

**A decision-analytic model of idelalisib and rituximab combination therapy versus rituximab monotherapy in relapsed, unfit chronic lymphocytic leukemia.** *Presenting Author: Alexander Xenakis, CBPartners, New York, NY*

**Background:** There are few treatment options for relapsed, unfit CLL patients. Idelalisib (IDELA) is a first-in-class inhibitor of PI3Kδ with significant clinical efficacy in relapsed, unfit CLL patients. A recent phase III clinical trial (Study 116) reported that in comparison with rituximab monotherapy (R-MONO), IDELA plus rituximab therapy (IDELA+R) resulted in improved progression-free survival (PFS, HR=0.15) and overall survival (OS, HR=0.28) in relapsed, unfit CLL patients. **Methods:** A decision-analytic model simulated a cohort of relapsed, unfit CLL patients receiving treatment over a 1 to 5 year horizon. Patients received IDELA+R or R-MONO either until death or until transitioning to a progressive-disease (PD) state where they received salvage therapy until death. Survival data for IDELA+R and R-MONO was fit and extrapolated from Study 116. A claims analysis of a large dataset provided disease- and treatment-related adverse events (AEs) and medical resource utilization rates for the PD state. Utility was based on literature review. All outcomes were discounted at 3% per year. **Results:** Treatment with IDELA+R over R-MONO resulted in better health outcomes, increasing life-years (LYs) by 1.0 to 9.7 mos, increasing progression-free life-years (PFLYs) by 4.6 to 11.6 mos, and improving quality-adjusted life-years (QALYs) by 0.1 to 0.7, while decreasing AEs by 46% to 2% and reducing hospitalizations by 48% to 5% over a 1 to 5 year time horizon. **Conclusions:** IDELA+R was projected to yield better health outcomes in relapsed, unfit CLL patients compared to R-MONO, largely driven by and improved PFS and OS; reductions in AEs were specifically related to a delayed progression to the PD state.

| Health outcomes (per patient) | Time horizon (years) | IDELA+R | R-MONO | Δ(IDELA+R-R-MONO) |
|---|---|---|---|---|
| LYs (months) | 1 | 11.2 | 10.2 | +1.0 |
| | 3 | 29.9 | 24.2 | +5.7 |
| | 5 | 40.4 | 30.6 | +9.7 |
| PFLYs (months) | 1 | 10.3 | 5.7 | +4.6 |
| | 3 | 17.4 | 6.0 | +11.4 |
| | 5 | 17.5 | 6.0 | +11.6 |
| QALYs | 1 | 0.7 | 0.6 | +0.1 |
| | 3 | 1.8 | 1.3 | +0.5 |
| | 5 | 2.3 | 1.7 | +0.7 |

| Health outcomes (1,000 patient cohort) | Time horizon (years) | IDELA+R | R-MONO | Δ(IDELA+R-R-MONO) |
|---|---|---|---|---|
| No. AEs incurred | 1 | 99 | 182 | -83 |
| | 3 | 378 | 470 | -92 |

**Feasibility of geriatric assessment for older adults with acute myeloid leukemia (AML) receiving intensive chemotherapy on a cooperative group trial: CALGB 361006 (Alliance).** *Presenting Author: Heidi D. Klepin, Wake Forest University, School of Medicine, Winston-Salem, NC*

**Background:** Geriatric assessment (GA) may improve characterization of fitness for intensive AML therapy and identify vulnerabilities to target for improved treatment tolerance. Feasibility of performing GA prior to intensive induction has not been demonstrated in a multi-site cooperative group trial. **Methods:** CALGB 361006 was a companion study offered to patients (pts) enrolled on CALGB 11001, a phase 2 trial of adults ≥60 years of age with newly diagnosed FLT3 mutated AML testing the efficacy of adding sorafenib to intensive therapy. On CALGB 361006, a GA was administered prior to induction therapy and prior to post-remission therapy. The GA is divided into items completed by a health care professional (HCP) (comorbidity index, performance status, Timed up and go test, cognition screen, nutrition screen) and a self-administered pt questionnaire (physical function, health, falls, comorbidity, medications, mood, social activities/support). Prior to enrollment, phone training on GA procedures was conducted with site research teams. Feasibility outcomes include recruitment, implementation (time to completion, difficulty with administration, percent of pts requiring assistance) and satisfaction with the assessment. **Results:** Among 54 eligible pts, 43 (80%) enrolled on the GA companion (median age 67.6 years, 44% female). Of these, the HCP assessment and pt questionnaire were completed and available for 86% and 88% at baseline respectively. Median time to complete the entire GA was 30 minutes (range 5-65); median time for each component was 10 and 21 minutes for HCPs and pts respectively. Among HCPs, 100% reported no difficulty completing the baseline assessment. Among pts, 84% reported no difficulty understanding any question; 78% required no assistance with completion; 95% reported no upsetting questions. The majority of pts (82%) were satisfied with assessment length. **Conclusions:** Recruitment to and implementation of a primarily self-administered GA is feasible prior to intensive induction for older adults with AML in the multi-site cooperative group setting. Next steps will explore the predictive utility of GA on toxicity.

**7103 General Poster Session (Board #388), Mon, 1:15 PM-5:00 PM**

**Comprehensive genetic characterization of 12 AML cell lines using a novel AML targeted sequencing strategy.** *Presenting Author: Andrew R. Carson, Genection, Inc, San Diego, CA*

**Background:** Next generation sequencing (NGS) has revealed much of the common genomic architecture of Acute Myeloid Leukemia (AML). However, the high cost of NGS and its interpretation limits specificity and coverage in most sequencing strategies. This prevents broad clinical adoption of NGS for characterizing AML samples and cell lines. Instead, investigators use limited diagnostic assays that fail to fully characterize complex variants such as internal tandem duplications in *FLT3*. Full characterization of variants in AML cell lines is essential, as these cells may be used to model cancer pathogenesis, develop therapeutics, and standardize diagnostic performance. Furthermore, discerning clonal architecture may prove crucial for personalized therapies. To illustrate the increased capacity and resolution of NGS for the comprehensive characterization of AML samples, we sequenced the "AMLome" (the complement of genes known or predicted to be involved in AML pathogenesis) of 12 AML cell lines using a novel AML specific targeted strategy. **Methods:** To examine the AMLome, we targeted coding regions of 171 genes and potential genomic breakpoints in 34 genes within known somatic gene fusions using the MyAML gene panel. We sequenced target loci to an average depth of coverage >350x on the Illumina MiSeq platform. Using a custom bioinformatics pipeline, we performed mutation detection analyses to identify single nucleotide variants (SNVs), indels, inversions and translocations. In addition, we calculated allelic frequencies to investigate potential aneuploidy and clonality. **Results:** Targeted sequencing of 12 AML cell lines identified previously unreported genomic variants with the potential to significantly impact experiments using these cell lines. These mutations include potential activating missense SNVs in oncogenes, damaging missense SNVs and frameshift indels in tumor suppressors, and translocations creating possible fusion genes. **Conclusions:** We demonstrate that by targeting the AMLome using the MyAML gene panel, we comprehensively characterize mutations within AML cell lines. Our results also suggest that this strategy can be extended to the characterization of AML patient samples.

**7104 General Poster Session (Board #389), Mon, 1:15 PM-5:00 PM**

**A DNA methylation signature for stemness in acute myeloid leukemia.** *Presenting Author: Timothy J Triche, University of Southern California, Los Angeles, CA*

**Background:** In an effort to assign immunophenotypes to AML samples where no immunohistochemistry had been recorded, we trained a DNA methylation classifier using Illumina HumanMethylation450 beadarray data from normal and malignant cells with known immunophenotype. Remarks from clinical malignant hematologists led us to investigate whether a resulting CD34-associated signature was also prognostic. **Methods:** Data from flow-sorted cells and from blasts with immunohistochemistry results were used to identify differentially methylated regions, which we then ranked and fit via logistic regression as predictors of CD34, CD33, CD14, and myeloperoxidase status. A strong DNA methylation signature was associated with CD34 immunophenotype in normal hematopoeitic stem/progenitor cells (HSPCs), cultured peripheral blood HSPCs from other groups, and CD34-positive TCGA AML samples. In cross-validation, a panel of 20 differentially methylated regions correctly predicted immunophenotype for 96% of AML, normal CD34+ cells, normal CD14+ cells, and normal neutrophil granulocytes when true labels were masked. When we plotted percent methylation across each region in unsorted TCGA AML blast samples and our own, a gradient appeared, with normal CD34+ cells at one extreme, normal CD14+ cells near the other, and AML blasts in between. We thus fit reduced signatures, as well as the normalized rank for each AML, as predictors of overall and relapse-free survival in the TCGA AML cohort (N=191 samples with usable data) using the 'glmnet' package in R. **Results:** The DNA methylation "stemness" score was a significant ($p < 0.02$) predictor of poorer overall and event-free survival in TCGA AML cases. The individual differentially methylated regions comprising the signature overlapped numerous intronic and intergenic enhancer elements, microRNAs, Piwi RNAs, and noncoding transcripts known to play roles in specification of hematopoeitic cell fates. Many of the associated transcripts are expressed at low but detectable levels in normal CD34+ HSPCs but not in progeny, or vice versa. **Conclusions:** Epigenetic plasticity, as reflected by HSPC-like DNA methylation, is a negative prognostic factor for overall and event-free survival in AML.

**7105 General Poster Session (Board #390), Mon, 1:15 PM-5:00 PM**

**Treatment patterns, mortality, and costs of care in unfit patients (pts) with relapsed chronic lymphocytic leukemia (CLL).** *Presenting Author: Helen Varker, Truven Health Analytics, Inc., Cambridge, MA*

**Background:** CLL pts who are ineligible for treatment due to age or with major comorbidities and pts who relapse after initial therapy represent significant unmet needs for this disease. To better understand these populations, we examined the prevalence, treatments, outcomes, and costs for pts who might be considered unfit for chemotherapy and, among unfit treated pts, those who showed evidence of relapse after initial therapy. **Methods:** The Truven Health MarketScan Database was used to identify pts with newly diagnosed CLL in 2004-2013 using ICD-9-CM diagnosis codes. Pts were defined as unfit for chemotherapy if their age was $\geq 80$ or had evidence of major comorbidity. Unfit and relapsed (U/R) pts were defined as having $\geq 2$ lines of antineoplastic therapy where the 2$^{nd}$line represented a change in therapy. Pts were followed from the index date until end of enrollment or death. Reimbursements were adjusted to 2013 dollars. **Results:** Of a total of 80,096 pts with CLL, 18,776 met the unfit criteria; and 1,109 pts met the U/R criteria. Unfit pts were 57% male, mean age of 69 (SD 18), and had a Charlson comorbidity score (CCI) of 2.4 (SD 2.0). Comorbidities at diagnosis: lipometabolic disorders (37%), hypertension (37%), diabetes mellitus (20%), chronic pulmonary disease (17%), congestive heart failure (7%), renal disease (7%). U/R pts were 63% male, mean age of 63 (SD 20), and had a CCI score of 3.4 (SD 2.2). Mean survival times for unfit and U/R pts were 26.7 (SD 23.8) months and 21.8 (SD 20.2) months, respectively. Among U/R pts, the most common 1st-line regimens were rituximab (R) ± prednisone(P)/ dexamethasone (D) (24.0%), R + bendamustine ± P/D (9.6%), and R + cyclophosphamide + fludarabine ± P/D (7.2%). Among U/R pts, per patient per month total costs by 1st and 2nd lines of therapies were $15,907 (SD $19,893) and $18,506 (SD $36,977) respectively. **Conclusions:** The most commonly used regimens for U/R CLL pts included rituximab. Survival for U/R after therapy is modestly lower than for those who might be considered unfit at diagnosis, suggesting that some who might otherwise be considered unfit can benefit from therapy. Medical costs were substantial for this cohort of pts.

**7106 General Poster Session (Board #391), Mon, 1:15 PM-5:00 PM**

**Activity of the Wee1 inhibitor MK1775 plus cytarabine in AML through interference with DNA repair capacity at the DNA level.** *Presenting Author: Raoul Tibes, Mayo Clinic, Scottsdale, Scottsdale, AZ*

**Background:** Cytarabine (AraC) resistance is a fundamental characteristic of refractory/relapsed AML. In previous RNAi screens we identified WEE1 kinase as top candidate target whose inhibition sensitized to AraC in AML. The WEE1 inhibitor MK1775 potently synergized with AraC ex vivo and in vitro and clinical trials are in preparation. However, a mechanistic understanding has remained elusive. **Methods:** In siRNA rescue screens of 44 genes involved in WEE1 and DNA damage repair (DDR) pathway regulation were conducted and below described experiments conducted. **Results:** Several RNAi hits converged on DDR repair genes with a focus on the MRN (MRE11, Rad51, NBS1) complex. Interfering with MRN complex members significantly altered the response of AML cells to combined AraC+MK1775 vs. single agent MK1775 or AraC. Unexpectedly the ATM-CHEK1 pathway was not activated, and Homologous recombination (HR)-mediated repair was compromised as shown by a DR-GFP expression vector. Consistently other HR markers decreased as well. The cell cycle was globally dysregulated by slower S-phase kinetics (progression), an expected abrogated G2/M checkpoint as well as de-regulated DNA replication origin formation and firing as evidenced by Cdt1 and Mus81. As a consequence high-single and double strand breaks (H2AX) occurred with early mitotic entry (increased phospho-histone H3) induced by AraC + MK1775 vs. single agents. Changes were followed by massive induction of apoptosis, with specific anti-apoptotic members decreasing and pro-apoptotic BH3 members increasing. Finally, AraC+MK1775 dramatically reduced colony formation vs. single agent MK1775 or even high-dose AraC incubations indicating a stem cell targeting combination, which was p53 independent. **Conclusions:** Herein we propose combined AraC+MK1775 as a potent AML regimens by directly interfering with DDR via compromising the MRN complex with subsequent reduced HR, early abortive mitotic entry subsequent massive ÒdefaultÓ apoptosis, in a p53 independent manner. These data provides a rationale to clinically evaluate AraC+MK1775 in patients with AML, points towards a mechanistic understanding as well as offers suggestions for biomarkers.

**7107 General Poster Session (Board #392), Mon, 1:15 PM-5:00 PM**

**Cellular level of Abelson interactor-1 as a marker predicting chemoresistance.** *Presenting Author: Anna Chorzalska, Brown University, Providence, RI*

**Background:** In hematological malignancies, quiescent leukemic stem cells are responsible for persistence of minimal residual disease and relapse. Emerging evidence points to the involvement of the bone marrow microenvironment in survival and systemic retention of leukemic stem cells. Integrins, particularly $\alpha4\beta1$, which controls hematopoietic stem cell trafficking, were shown to be required for leukemic stem cells lodging in the bone marrow niche, and were shown to be crucial for the persistence of minimal residual disease. We have just recently obtained evidence that $\alpha4$ integrin interacts directly with Abelson interactor-1 (Abi-1) and this signaling cross-talk is involved in acquired drug resistance in Bcr-Abl positive leukemic cells. **Methods:** Gene expression analyses were performed on human Bcr-Abl positive CD34+ leukemic progenitor cells isolated at first diagnosis or at relapse. Imatinib mesylate resistant cell lines were used to confirm gene profiling data and determine the effect of deregulated $\alpha4$-Abi-1 cross-talk on adhesion and cell cycle. Immunodeficient NOD.Cg-Prkdc$^{scid}$ Il2rg$^{tm1Wjl}$/SzJ (NSG) mice were used in xenotransplant experiments to confirm critical role of Abi-1 in lodging of Bcr-Abl positive cells to the bone marrow. **Results:** We present evidence that signaling crosstalk between $\alpha4$ integrin and Abi-1 is involved in acquisition of an anchorage-dependent phenotype and drug resistance in Bcr-Abl positive leukemia cells. Comparison of Abi-1 (ABI-1) and $\alpha4$ integrin (ITGA4) gene expression in relapsing Bcr-Abl positive CD34+ progenitor cells demonstrated a reduction in Abi-1 and an increase in $\alpha4$ integrin mRNA in the absence of Bcr-Abl mutations. This inverse correlation between Abi-1 and $\alpha4$ integrin expression, as well as linkage to elevated phospho-Akt and phospho-Erk signaling, was confirmed in imatinib mesylate (IM) resistant leukemic cells. **Conclusions:** Obtained results indicate that the $\alpha4$-Abi-1 signaling pathway may mediate acquisition of the drug resistant phenotype of leukemic cells and ABI-1/ITGA4 gene levels may be used as a markers predicting chemoresistance.

**7108 General Poster Session (Board #393), Mon, 1:15 PM-5:00 PM**

**The clinical characteristics and therapeutic outcomes of elderly patients with chronic myeloid leukemia: A retrospective multicenter study.** *Presenting Author: Serdal Korkmaz, Cumhuriyet University, Department of Hematology, Sivas, Turkey*

**Background:** We aimed to investigate if older age leads to limitations in starting dose of imatinib in daily practice of chronic myeloid leukemia (CML) and the compliance with tyrosine kinase inhibitors (TKIs) therapy in elderly patients. **Methods:** To analyze the clinical characteristics and therapeutic outcomes of elderly patients with CML aged >65 years, data were collected from 13 institutions in Turkey, retrospectively. **Results:** A total of 69 cases were evaluated retrospectively. Of the patients, 42 (60.9%) were females. The median age was 71 years (range; 66-85). Ninety-six percent (66/69) of the patients were in chronic phase when diagnosed. Of the patients, 3 (4.3%) were in accelerated phase. The sokal risk at diagnosis was low in 3 patients, intermediate in 29 patients, and high in 37 patients. RT-PCR was the most used method to diagnose patients. Sixty-three (91.3%) patients were under imatinib tharapy as first line. The initial dose of imatinib was 400 mg/day in 59 (93.6%) patients, 100 mg/day in 2 (3.2%) patients, 300 mg/day in one (1.6%) patient, and 600 mg/day in one (1.6%) patient. Imatinib treatment induced 57 (90.5%) complete hematologic responses (CHR) at 3 months and 29 (46%) complete cytogenetic responses (CCyR) at 6 months, and 49 (77.7%) major molecular responses (MMR) at 12 months. Of the patients, 2 have discontinued imatinib for hematologic and/or non-hematologic toxicities; as a result of resistance in 7 patients, and loss of MMR in 5 patients, nilotinib and dasatinib were used in 14 patients as second-line therapy. Second-line TKIs induced 9 (64.3%) CHR at 3 months and 4 (28.6%) CCyR at 12 months, and 7 (50%) MMR at 18 months. Fifty-six (81.2%) of the patients are still alive and being followed up regularly. The median overall survival and progression free survival rates were 35 months (range; 1-95) and 17 months (range; 0.8-95), respectively. **Conclusions:** No need to reduce starting dose of imatinib and no upper age limit should be applied for the administration of TKIs to elderly patients with CML. Elderly patients should receive TKIs according to the same guidelines that apply to younger patients.

**7109 General Poster Session (Board #394), Mon, 1:15 PM-5:00 PM**

**GATA1 in patients with essential thrombocythemia and anagrelide treatment.** *Presenting Author: Ciro Roberto Rinaldi, University of Lincoln, Lincoln, United Kingdom*

**Background:** GATA1 is the founding member of the GATA transcription factor family and is essential for cell maturation and differentiation within the erythroid and megakaryocytic lineages. Disturbance of its functions causes severe hematopoietic dysfunction and can result in blood disorders, such as thrombocytopenia, anaemia and even leukaemia. Several studies, have suggested a connection between GATA1 and myeloproliferative neoplasia (MPN). We previously reported, high GATA1 transcript levels are found in the bone marrow of patients with ET and PV, independent of the JAK2 V617F mutation, but not in other MPN. Anagrelide (ANA) has been proven to be an effective drug in reducing platelet count in ET. However, the mechanisms by which this drug induces this effect is still unclear. Recently Erusalimsky has reported that ANA results in down-modulation of GATA1 and its co-factor FOG1 in MK during in vitro differentiation. **Methods:** In this study, we analysed by Real Time PCR the expression of GATA1 in peripheral blood (PB) samples from 30 patients with ET and compared the levels of expression before and after treatment with common cytoreductive agents such as hydroxyurea (HU) and ANA. **Results:** We confirmed the data obtained in BM, with a significant up-regulation of GATA1 in ET compared to controls. When we measured the expression of GATA1 before and during treatment with ANA, there was a significant reduction of the GATA1 expression at 3 and 6 months of therapy, concomitantly with a reduction in platelets (PLT) counts. Interestingly, this was not equally observed in patients treated with HU, where despite reduction in PLT counts, the GATA1 levels rose. Furthermore, when we analysed patients on combination treatment ANA + HU, GATA1 expression reduced only when patients were taking ANA. When ANA treatment was stopped and the patient continued only on HU, GATA1 levels rose again. This data suggests a direct effect of ANA on GATA1 expression. **Conclusions:** GATA1 may represent a generic molecular marker in ET and a possible additional diagnostic criteria in thrombocytosis. GATA1 overexpression is independent from JAK2 mutations, and responds specifically to ANA therapy suggesting a role in monitoring therapy response.

**7110 General Poster Session (Board #395), Mon, 1:15 PM-5:00 PM**

**Predictive analysis of microenvironment impact on clinical outcomes to drug agents using simulation of myeloproliferative neoplasms.** *Presenting Author: Peter P. Sayeski, University of Florida, Gainesville, FL*

**Background:** The Jak2-V617F mutation is frequently found in MPN. The bone marrow micro-environment of MPN patients constitutes high levels of TNF$\alpha$, IFN$\gamma$ and IL-6. Since resistance to drug agents is of great clinical relevance, we teased the impact of the individual cytokines on drug efficacy. **Methods:** To predict the response to the JAK2 inhibitor class of agents, we (1) employed predictive simulation to model JAK2 bearing cell lines (2) identified novel synergistic combinations of Bcl-2 and JAK2 inhibitors against this JAK2 driven pathogenesis, (3) simulated the impact of TNF$\alpha$ and IFN$\gamma$ on growth and proliferation and (4) validated the outcomes on Jak2 mutant cells. We used a previously characterized JAK2 small molecule inhibitor, G6, which exhibits significant efficacy in Jak2-V617F-mediated MPN and ABT737 was the selected Bcl-2 agent. The predictive simulation approach from Cellworks provides a representation of disease physiology incorporating signaling and metabolic networks with an integrated phenotype view. We modeled the JAK2-V617F expressing HEL and SET-2 cell lines along with G6 and ABT737. We then screened prospectively these agents, both individually and in combination, and with and without the microenvironment inflammatory cytokines. **Results:** The simulation identified a dose response based synergistic impact of the combination of G6 and ABT737 on cell proliferation and viability.TNF$\alpha$ increased the sensitivity of the single drug agents and their combinations. IFN$\gamma$ sensitized the drug action further beyond a certain dose threshold. IL-6 did not show any impact on the cells due to lack of IL-6 signaling within these cells. Simulation studies though have predicted IL-6 induced resistance to these drug agents and possibly cancelling out the positive impact of TNF$\alpha$ and IFN$\gamma$ clinically. **Conclusions:** Thus, this study validates the impact of the micro-environment on drug response and the use of simulation based technology to predict patient responses to drug agents. By accurately predicting responses of a patient's cells to targeted agents *a priori*, the *in silico* simulation model provides an innovative approach to precision medicine for Jak2-mediated MPN.

**7111 General Poster Session (Board #396), Mon, 1:15 PM-5:00 PM**

**A phase 2 study of IPI-926, an oral hedgehog inhibitor, in patients with myelofibrosis.** *Presenting Author: Koji Sasaki, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Aberrant expression of the Hedgehog (Hh) signaling pathway initiates cancer, promotes tumor survival, and is related to the development of desmoplastic tumor stroma. We conducted a phase 2 study of IPI-926, an oral Hh inhibitor, in patients (pts) with myelofibrosis (MF); NCT01371617. **Methods:** Pts with performance status ≤2, adequate organ function, no active infection, and a life expectancy of at least 3 months, received 160 mg IPI-926 orally daily in continuous 28-day cycles. Response was defined by IWG consensus criteria. Using a Simon 2-Stage method to differentiate a response rate of ≤10% and >30%: ≈12 evaluable pts with MF were to be enrolled; if at least 2 responses occurred, up to 35 pts were to be enrolled. **Results:** 14 pts were treated for a median of 5.1 months (range, 0.7-7.3). Their age was 71 years (range 55-82), with a median of 5.8 years since diagnosis; 4 had palpable spleen of median 10.5 cm (range 6-23), 6 (43%) were transfusion dependent, 8 (57%) had primary MF, and all had ≥ intermediate-2 MF. While several pts had reduction in spleen size by palpation (<50%), no pt had significant improvement in symptoms. One pt had clinical improvement with transfusion independence for 6 months. Two patients progressed to acute leukemia, and 11 were taken off therapy due to no response and/or side effects. Adverse events of any grade (in >30% of patients) included elevated AST or ALT in 11 pts, nausea in 8, increased conjugated bilirubin in 7 (3 with gr 3 toxicity), decreased appetite in 6 (1 with gr 3 toxicity), and constipation or vomiting in 5 pts each. Correlative studies on samples after >3 months on therapy were analyzed: 2/8 pts had reduction in GLI1 mRNA in bone marrow (BM) aspirate cells; 3/10 pts had reductions in GLI1 protein by immunohistochemistry in BM biopsies by 3 months; 4/10 pts had minimal to modest decreases in fiber-length density in BM biopsies at 3 months. Serum cytokine levels measured at baseline and after 4 weeks of treatment were not qualitatively different. **Conclusions:** The safety and clinical activity (ORR ≤ 10%) of IPI-926 did not support continued evaluation as a monotherapy in MF. The preliminary biologic activity suggests Hh pathway inhibitors in combination with other novel agents in MF should be considered. Clinical trial information: NCT01371617.

**7112 General Poster Session (Board #397), Mon, 1:15 PM-5:00 PM**

**Survival outcomes of primary myelodysplastic syndrome in United States.** *Presenting Author: Guru Subramanian Guru Murthy, University of Arkansas for Medical Sciences, Little Rock, AR*

**Background:** Hypomethylating agents were approved for use in treatment of MDS after 2004. This study aims to delineate the discrepancies in survival of MDS at population level before and after approval of these agents. **Methods:** Using Surveillance, Epidemiology and End Results (SEER-17) database, adult patients with primary MDS, diagnosed between 2001 to 2010 were identified. Overall survival analysis was performed using Kaplan-Meier method and compared by log rank. Period of diagnosis for survival was analyzed between 2001-2005 and 2006-2010. Multivariate analysis was performed using Cox Proportional Hazards regression method. **Results:** 22,051 patients with MDS with a median age of 76 years were included. Median overall survival (OS) for different age groups was as follows: age $<$ 60 – 59 months, age 60 to70 – 36 months, age $>$ 70 – 23 months, $p < 0.001$). We found that 5 year OS has improved across all age groups diagnosed from 2006-2010 compared to 2001-2005 (age $<$ 60 – 50.3% vs. 16%, age 60-70 – 37.8% vs. 14 %, age $>$ 70 – 23% vs. 3% $p<0.01$). Females had a better overall survival than males (32 month vs 24 months respectively, $p < 0.001$). Blacks had a higher overall survival than whites or other races (34 months vs 27 months) (p-not significant). On multivariate analysis age $>$ 60 years ( HR-1.38 95% CI 1.30-1.46, $p<0.01$) and male sex ( HR-1.17, 95% CI 1.13-1.21, $p<0.01$) were significantly associated with higher mortality. Diagnosis after the year 2005 was associated with decreased mortality (HR 0.78, 95% CI 0.74-0.82, $P<0.001$). **Conclusions:** Overall survival has continued to improve across all age groups with introduction of hypomethylating agents and better supportive care.

**7113 General Poster Session (Board #398), Mon, 1:15 PM-5:00 PM**

**PKC412 (midostaurin) is safe and highly effective in systemic mastocytosis: Follow up of a single-center Italian compassionate use.** *Presenting Author: Cristina Papayannidis, DIMES, Institute of Hematology, Bologna, Italy*

**Background:** Treatment of SM usually focuses on symptom relief by histamine receptor antagonists and other supportive therapy. However, in aggressive and leukemic variants, cytoreductive and targeted drugs must be applied. **Methods:** From 2008, 22 patients (male/female=11/11) affected by SM have been referred to our Institution. Twelve (55%) was diagnosed with ASM, presenting with systemic symptoms associated with signs of organ involvement (skeletal lesions, ascites, liver function impairment or bon marrow disfunction). Therefore, due to the failure of a first line therapy (IFNalfa, Imatinib and 2CdA in 56%, 11% and 33% of the patients, respectively), a personalized use of PKC412 was asked and obtained for 9 out of 12 ASM patients. Thus, from March 2011, 9 (M/F =3/9) patients with ASM have been treated with PKC412, administered orally, at the dosage of 100 mg twice daily, continuously. The median age was 60 years (range 39-75); the median time from diagnosis was 6 months (range 2-53). Median serum tryptase level was 100 mcg/L(range 19.3-1160). *C-kit* mutation D816V was present in 8 out of 9 patients. Cytogenetic analysis was normal in all the patients. **Results:** Seven out of nine patients were evaluable for response. The median duration of therapy was 517 days (range 327-970+). According to European Criteria, a Major response was observed in one patient, and a partial response in 6 patients. Overall, the drug was well tolerated, and no serious adverse events were observed. All the patients obtained a quick improvement of clinical symptoms, in terms of weight gain, bowel function and skeletal pain. At the bone marrow evaluation, the persistence of the D816V c-kit mutation was observed, despite a significant decrease of mast cell marrow involvement. **Conclusions:** In a small cohort of ASM patients, the prolonged therapy with PKC412 is safe and effective, mainly on symptoms improvement and haematological profile. Nevertheless, the persistence of the D816V c-kit mutation suggests that many other oncogenic factors may be responsible for the pathogenesis of the disease.

**7114 General Poster Session (Board #399), Mon, 1:15 PM-5:00 PM**

**Phase 2 trial of PRM-151, an antifibrotic agent, in patients with myelofibrosis: Stage 1 results.** *Presenting Author: Srdan Verstovsek, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** PRM-151 (PRM) is a recombinant form of Pentraxin-2, an endogenous human protein that acts at sites of tissue damage, inducing macrophage differentiation to prevent and reverse fibrosis. PRM has broad anti-fibrotic activity in multiple preclinical models of established fibrotic disease and no dose limiting toxicities in Phase 1 trials. This study investigates the potential of PRM in myelofibrosis (MF) to reduce bone marrow (BM) fibrosis and to improve key MF-related disease features including abnormal blood counts, splenomegaly, and symptoms. **Methods:** Patients with Intermediate-1, intermediate-2, or high risk MF with grade $>$2 BM fibrosis, either on no current therapy or on a stable dose of ruxolitinib (RUX) for at least 12 weeks were eligible for stage 1 of this open label adaptive trial. Assignment to one of the 4 treatment arms was per investigator and patient choice: PRM IV 1-hour infusion on days 1, 3 and 5, then weekly (QW) or every 4 weeks (Q4W), alone or with continuous oral rux. Primary endpoint is overall response rate by IWG-MRT criteria (spleen by palpation). A decrease in BM fibrosis by $\geq$ 1 grade with otherwise stable disease is also considered a response. BM biopsies are obtained at baseline, 3 and 6 months, read by local pathologists and a blinded central reviewer. **Results:** 27 subjects were enrolled in Stage 1: 7 PRM QW, 7 PRM Q4W, 7 PRM QW + RUX, 6 PRM Q4W + RUX. As of January 13, 2014, 15 and 6 subjects have completed 8 and 12 wks of treatment, respectively (none have yet completed 24 wks). There was no apparent treatment-related myelosuppression, and among all AEs, only herpes labialis and anemia occurred in $>$1 subject. There have been 4 serious adverse events in 3 subjects: 1 with abdominal pain, 1 with hypoxia, and an 85 year old subject who died from gastroenteritis and pneumonia. Improvement in bone marrow fibrosis (Grade 3 to 1; Grade 2 to 0; read by a local pathologist) was observed in 2 of 6 subjects at the 3-month BM mark (1 on PRM Q4W, 1 on PRM Q4W + RUX). **Conclusions:** In stage 1 of this phase 2 trial of MF patients, PRM has shown good tolerability both alone and in combination with RUX. Updated safety and efficacy data on all 27 subjects will be presented at the meeting, including central BM (3 and 6 month) reviews. Clinical trial information: NCT01981850.

**7115 General Poster Session (Board #400), Mon, 1:15 PM-5:00 PM**

**Clinical relevance of genetic mutations on treatment response to the demethylating agents in myelodysplastic syndromes.** *Presenting Author: Hyun Ae Jung, Department of Medicine, Division of Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** In the post-epigenetic therapy era, treatment approaches for patients with MDS have improved significantly over the last decade, especifically, in terms of quality of life and leukemic transformation and survival. Unlike, conventional chemotherapy, it often takes several cycles of hypomethylating agent to visualize the effect of the therapy. However, previous study had heterogenous study populations and had low response rate to hypomethylating agent. We investigate the prevalence of recurrent genetic mutations in de novo MDS patients and elucidate the prognostic and predictive role of mutations on the 1st line decitabine treatment in MDS. **Methods:** We investigated genes including spliceosomal machinery genes (SRSF2, USAF1, ZRSR2) and methylating machinery genes (TET3 and DNMT2) and NRAS by Sanger sequencing in patients who were diagnosed with de novo MDS at Samsung medical Center between June 2008 and December 2011 and who were treated with 1$^{st}$line 5-day regimen of decitabine treatment. **Results:** We analyzed clinical data including treatment outcomes in 70 patients (total 290 cycles). The overall response (complete remission, partial remission, marrow complete remission and hematologic improvement) rate was 52.5%. The median time to any response was two (range 1-6). Patients who showed hematologic improvements had significantly longer survival than those who did not (9.8 vs 22.9 months, P-value=0.004). The prevalence of mutations in the methylating machinery genes were 17.1% (N=12). In the baseline characteristic between wild type and mutated genes, there was no significant difference. The overall response rate was significantly higher in the patient who had the mutations in methylating machinery genes (46.6% vs 82.3%, P-value=0.027). **Conclusions:** The current results showed that methylating machinery gene TET2$^{MUT}$, DNMT3A$^{MUT}$ had clinical relevance as preditive biomarker for hypomethylating agents.

**7116 General Poster Session (Board #401), Mon, 1:15 PM-5:00 PM**

**Impact of high-dose radiation exposure on myelodysplastic syndrome patients treated with azacitidine in Nagasaki atomic bomb survivors.** *Presenting Author: Tatsuro Jo, Department of Hematology, Japanese Red Cross Society Nagasaki Genbaku Hospital, Nagasaki, Japan*

**Background:** Myelodysplastic syndromes (MDS) may arise de novo or secondarily after treatment with chemotherapy and/or radiation therapy for other cancers or, rarely, after environmental exposures. High-dose radiation exposure (such as an atomic bomb) increases the risk of developing MDS. Azacitidine (AZA), a hypomethylating agent, is the mainstay of therapy in MDS in Japan. But there have no reports investigating the efficacy of AZA in atomic bomb survivors suffering from MDS. **Methods:** We retrospectively evaluated 33 pts diagnosed MDS between April 2011 and April 2013 at Nagasaki Genbaku Hospital. All patients, included 13 atomic bomb survivors, received AZA. The primary objective was to estimate overall survival rates (OS). **Results:** The Table summarizes baseline characteristics and response rates. There was no clear difference in the background excluding age ($P$=0.0258) between atomic bomb survivors (A) and non-atomic bombed (non-A) pts. ORR (CR/mCR/PR) was no difference ($P$=0.2635), but the median OS at November 2013 was significantly different between two groups (13 months for A vs undefined for non-A, $P$=0.0429). **Conclusions:** These data demonstrated that despite the same ORR, OS of MDS pts in Nagasaki atomic bomb survivors was significantly short compared to non-atomic bombed pts. A certain influence by exposure of the atomic bomb can be considered. Further studies to clarify the cause are warranted.

**Impact of palifermin use on pediatric patient (PedPts) hematopoietic cell transplant (HCT) outcomes.** *Presenting Author: Wael Saber, Medical College of Wisconsin, Milwaukee, WI*

**Background:** Palifermin (KGF) is an FDA approved prophylactic human keratinocyte growth factor for prevention of severe chemoradiotherapy-related mucositis. Clinical trials that evaluated KGF enrolled few PedPts. Using CIBMTR data, this study evaluates effects of KGF use in a pediatric population. **Methods:** We performed a 1:3 (KGF vs. no KGF) matched cohort analysis (matched on HCT, donor type, disease, disease status and age). Stratified Cox models were built and propensity scores were used to adjust for potential confounders. **Results:** From 2005-2012 816 patients were selected; 60% underwent Allogeneic HCT (AlloHCT), mostly for acute lymphoblastic leukemia (ALL). 40% underwent Autologous HCT (AutoHCT), mostly for solid tumors (Table 1). Two-year survival (OS) and disease-free survival (DFS) in AlloHCT group (58 vs. 66%, p=0.10; 49% vs. 60%, p=0.06) and AutoHCT group (73% vs. 77%, p=0.47; 60% vs. 64%, p=0.63) were not different between KGF and no KGF, respectively. Similarly, in multivariate analysis, there were no differences in outcomes between the two groups. **Conclusions:** Among PedPts undergoing HCT, KGF use is not associated with OS, DFS, neutrophil recovery or graft vs host disease (GVHD) rates. Due to data limitations, rate of mucositis was not assessed in this study.

**Characteristics of patients with blastic plasmacytoid dendritic cell neoplasm (BPDCN): Male predominance, propensity for extramedullary involvement, and poor outcomes.** *Presenting Author: Naveen Pemmaraju, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare and aggressive hematologic malignancy. Little is known about characteristics and outcomes of patients (pts) with BPDCN. **Methods:** We performed an updated retrospective review of pts age ≥ 18 years with a pathological diagnosis of BPDCN. **Results:** 26 pts were evaluated at our institution (Oct 1998-Dec 2013). Median age was 58 years (range 20-86). 23 (88%) were male. Bone marrow (BM) was involved in 17 (65%), skin in 13 (50%), lymph nodes in 7 (27%), CSF in 3 (12%) and 1 (4%) pt each had disease involving the brain, uterus/ovary, elbow/soft tissue, and pleural fluid. Tumor immunophenotype: CD4+ (23/23), CD56+ (21/23), TCL-1+ (14/15), CD 123+ (13/14). CD22 was expressed in 2/5 pts. Cytogenetics in 14 pts showed: diploid (8), complex karyotype (5), and del (12p13) (1pt). Median CBC was: WBC 5.6 x $10^9$/L (1.7-76.5), Hb 12.3 g/dL (8.3-14.6), and platelet count 160 x $10^9$/L (44-294). Median BM blasts: 19% (0-94). Therapies given: 16 (62%) first-line therapy with Hyper-CVAD, 4 (15%) CHOP, 2 (8%) bortezomib-based, 1 clinical trial (DT-IL3), 1 daunorubicin+ARAC, 1 oral MTX, 1 interferon-based therapy. Five (19%) pts received radiation (XRT) as part of their therapy. Median follow-up time: 24 months (5-59 mo). Median number of chemotherapy regimens: 2 (1-6). CR was achieved in 14 pts. The median CR1: 18 mo (4-39 mo). Median overall survival (OS) was 29 mo (1-59 mo). 8 pts (31%) received stem cell transplant (SCT) (3 autologous, 3 allogeneic, 2 cord). Median OS for pts receiving SCT was 31 mo (13-40 mo) versus a median OS for non-SCT group (n=18) of 29 mo (1-59), p= 0.98. **Conclusions:** We observed a large male predominance, propensity for extra-medullary disease involvement, and overall poor outcomes despite intensive multi-agent chemotherapy and SCT for pts with BPDCN. A better understanding of the biologic basis of this disease and novel, targeted treatment approaches are urgently needed. Among novel therapies available, targeting cell surface CD123 appears to be most promising (DT-IL3) and investigation is ongoing (5/5 (100%) evaluable patients with major responses; Frankel,AE et al. ASH 2013).

**TPS7119 General Poster Session (Board #404A), Mon, 1:15 PM-5:00 PM**

**An open-label, phase 1b, dose-escalation study (CA180-373) of dasatinib plus nivolumab, an investigational anti-programmed cell death 1 (PD-1) antibody, in patients (pts) with previously treated chronic myeloid leukemia (CML).** *Presenting Author: Kimmo Porkka, University of Helsinki and Helsinki University Central Hospital Cancer Center, Helsinki, Finland*

**Background:** CML has become a chronic disease for many pts treated with BCR-ABL1 tyrosine kinase inhibitors (TKIs). However, new approaches are needed to increase the prevalence of deep responses suitable for treatment discontinuation and to treat resistant/recurrent CML. Immune cell–mediated approaches (eg, stem cell transplantation, interferon-$\alpha$) can be effective. PD-1 ligation provides a negative costimulatory signal governing the balance between T-cell activation and tolerance. The potent second-generation TKI dasatinib may have synergy with nivolumab, a fully human IgG4 PD-1 immune checkpoint inhibitor antibody. Nivolumab has shown encouraging clinical activity against several solid tumors. PD-1 is upregulated on CD8+ T cells in CML pts (Christiansson *PLoS ONE* 2013;8: e55818) and blocking the PD-1/ligand interaction prolonged survival in a murine model (Mumprecht *Blood* 2009;114:1528-36). The study will assess safety, tolerability, and preliminary efficacy of dasatinib + nivolumab in previously treated CML in chronic or accelerated phase (CP/AP). **Methods:** In this open-label, phase 1b dose-escalation study, pts must be aged ≥18 years (y) and have Philadelphia chromosome–positive CML-CP/AP, ECOG performance status ≤1, and no known dasatinib-resistant BCR-ABL1 mutations. Pts must have received ≥2 prior TKIs, be progressing, or have had resistance, intolerance, or suboptimal response to the most recent therapy. Treatment in the dose-escalation phase is dasatinib 100 mg (CP) or 140 mg (AP) once daily with nivolumab 0.3 mg/kg (dose level [DL] –1), 1 mg/kg (DL 1), or 3 mg/kg (DL 2) by intravenous injection every 2 weeks for ≤2 y, followed by ≤1 y of dasatinib only. Treatment in the expansion phase will be dasatinib (same doses) + nivolumab (dose based on safety). The primary objective is to determine safety and tolerability. Secondary endpoints are major molecular response (MMR) and molecular response ($MR^{4.5}$ rates at 6, 12, 24, and 36 months and time to and duration of MMR and $MR^{4.5}$ up to 36 months. Estimated completion: August 2018. Clinical trial information: NCT02011945.

**TPS7120^ General Poster Session (Board #404B), Mon, 1:15 PM-5:00 PM**

**Multicenter, phase III, open-label, randomized study in relapsed/refractory CLL to evaluate the benefit of GDC-0199 (ABT-199) plus rituximab compared with bendamustine plus rituximab.** *Presenting Author: Mehrdad Mobasher, Genentech, Inc., South San Francisco, CA*

**Background:** Response rate to initial treatment of CLL is high, but relapsed/refractory (R/R) CLL may be characterized by resistance to chemotherapy. Bendamustine and rituximab (B+R), commonly used to treat patients with relapsed CLL, has shown an overall response rate (ORR) of 59% and median progression-free survival (PFS) of 15.2 mo. Despite progress, CLL remains incurable, and new treatments are needed to improve outcomes. Universal overexpression of Bcl-2, an anti-apoptotic protein, and dysregulation of the intrinsic apoptotic pathway in CLL likely contributes to chemotherapy resistance. GDC-0199/ABT-199 (199), a selective, potent, orally bioavailable Bcl-2 inhibitor, has shown preliminary anti-tumor activity, including complete remissions, in R/R CLL. This study will compare 199+R vs B+R to determine if 199+R provides a more effective and tolerable treatment strategy for R/R CLL, providing a chemotherapy-free regimen. **Methods:** Approximately 370 patients will be enrolled at approximately 150 sites in North America, Europe and Asia Pacific, and randomized 1:1 to receive 199+R (Arm A) or B+R (Arm B). In both arms, R treatment will consist of infusions on Day 1 of each 28-day cycle for 6 cycles (Cycle 1: 375mg/m$^2$; Cycles 2-6: 500mg/m$^2$). In Arm A, after an initial ramp-up period, patients will receive 400mg of 199 daily. After completion of 199+R, 199 will be continued until disease progression or for a maximum of 2 years. In Arm B, bendamustine will be infused (70mg/m$^2$) on Days 1 and 2 of each 28-day cycle for 6 cycles. Patients in both arms will be followed until disease progression. Key eligibility criteria include a diagnosis of R/R CLL; previously treatment with 1-3 lines of therapy; ECOG PS $\leq$1; and adequate marrow function. The primary outcome is investigator-assessed PFS (time from randomization until disease progression or death from any cause). Secondary outcomes include ORR, adverse events, and patient-reported outcomes. The study opened in Dec 2013; primary estimated completion is Aug 2020. Clinical trial information: NCT02005471.

**TPS7121 General Poster Session (Board #405A), Mon, 1:15 PM-5:00 PM**

**A phase 2 open-label study of the efficacy of ABT-199 (GDC-0199) in patients with relapsed or refractory (R/R) chronic lymphocytic leukemia (CLL) harboring 17p deletion.** *Presenting Author: William G. Wierda, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Evasion of apoptosis is a hallmark of cancer. Overexpression of the anti-apoptotic Bcl-2 protein is associated with tumorigenesis and resistance to chemotherapy. ABT-199 is a selective, potent, orally bioavailable small molecule Bcl-2 antagonist that works by directly relieving the inhibition of apoptosis, downstream of p53. Preliminary phase 1 data with ABT-199 indicate promising therapeutic activity, with a greater than 80% overall response rate in patients (pts) with heavily pretreated CLL, independent of poor prognostic indicators including 17p deletion [del(17p)]. This Phase 2 multinational study is designed to evaluate ABT-199 monotherapy in patients with R/R CLL harboring del(17p). **Methods:** ABT-199 treatment starts with a lead-in 20mg daily dosing period with weekly dose increases up to 400 mg daily as the study final dose. Treatment continues once daily until progression or discontinuation for toxicity. Study visits are weekly through week 4 or 5, every 4 weeks until week 36, and every 12 weeks thereafter. Key eligibility criteria include relapsed or refractory CLL harboring del(17p) in $\geq$7% of cells, as determined by central diagnostics; clinically measurable disease; and no previous allogeneic hematopoietic cell transplant (alloHCT), evidence of Richter's transformation, or uncontrolled autoimmune cytopenias. The primary objective of this study is to evaluate overall response rate (ORR), using IWCLL 2008 criteria. Secondary objectives are to evaluate the complete remission rate, partial remission rate, duration of response, progression-free survival, time to progression, overall survival, and the percentage of pts who are able to proceed to alloHCT. Minimal residual disease status in the peripheral blood and bone marrow will be assessed as an exploratory objective. Pharmacokinetic data will be evaluated using a population approach. The ORR for ABT-199 will be tested to reject the null hypothesis of a 40% ORR once 70 pts have completed 6 months of treatment or after all enrolled pts have discontinued ABT-199, whichever is earlier. The study began in June, 2013 and is currently enrolling patients. (NCT01889186) Clinical trial information: NCT01889186.

**TPS7122 General Poster Session (Board #405B), Mon, 1:15 PM-5:00 PM**

**DUO: A phase 3 trial of the PI3K-$\delta,\gamma$ inhibitor IPI-145 versus ofatumumab in patients with relapsed or refractory chronic lymphocytic leukemia or small lymphocytic lymphoma.** *Presenting Author: Ian Flinn, Sarah Cannon Research Institute, Nashville, TN*

**Background:** Phosphoinositide 3-kinase (PI3K)-$\delta,\gamma$ isoforms are preferentially expressed in leukocytes and are central to the growth and survival of certain B and T cell malignancies. Inhibition of these isoforms by IPI-145, an oral PI3K-$\delta,\gamma$ inhibitor, has unique therapeutic potential in hematologic malignancies. IPI-145 has shown clinical activity and a favorable safety profile in a broad range of hematologic malignancies in an ongoing phase 1 trial (IPI-145-02). Based on these data, the DUO phase 3 trial (IPI-145-07; ClinicalTrials.gov number: NCT02004522) has been initiated to evaluate the efficacy and safety of IPI-145 compared to ofatumumab in patients with relapsed or refractory chronic lymphocytic leukemia (CLL) or small lymphocytic lymphoma (SLL). **Methods:** This open-label, two-arm trial includes adult patients with active CLL/SLL who meet at least one of the International Workshop on CLL (IWCLL) 2008 treatment criteria; have disease progression during or after previous CLL therapy; are not appropriate for purine analog-based therapy; and not refractory to ofatumumab. The trial will enroll approximately 300 patients, randomized 1:1 to IPI-145 or ofatumumab at sites in and outside the US. Patients randomized to IPI-145 will receive 25 mg IPI-145 orally, twice daily in 28-day treatment cycles for up to 18 cycles or until disease progression or unacceptable toxicity. After 18 cycles, patients may receive additional cycles of IPI-145 for up to 3 years, if they have documented evidence of response and disease requiring continued treatment. Patients randomized to ofatumumab will receive treatment consistent with the approved product label. Patients on both arms will be followed for up to 3 years from the first dose of study drug. The primary efficacy endpoint is progression-free survival. Key secondary endpoints include safety, overall survival and pharmacokinetic parameters. Patients with progressive disease during the trial may be eligible to receive the opposite study medication in a separate Infinity-sponsored extension protocol (IPI-145-12). This trial is currently enrolling patients. Clinical trial information: NCT02004522.

**TPS7123 General Poster Session (Board #406A), Mon, 1:15 PM-5:00 PM**

**A phase 3, randomized, double-blind, placebo-controlled study evaluating the efficacy and safety of idelalisib in combination with bendamustine and rituximab for previously untreated chronic lymphocytic leukemia.** *Presenting Author: Gilles A. Salles, Lyon Sud University Hospital, Pierre-Bénite, France*

**Background:** PI3K$\delta$ is critical for activation, proliferation and survival of B cells and plays a role in homing and retention in lymphoid tissues. PI3K$\delta$ signaling is hyperactive in many B-cell malignancies. Idelalisib (GS-1101) is a first-in-class, targeted, highly selective, oral inhibitor of PI3K$\delta$ that reduces proliferation, enhances apoptosis, and inhibits homing and retention of malignant B cells in lymphoid tissues (Lannutti et al, 2011). A recent phase 3 trial demonstrated that idelalisib plus rituximab is highly active in pts with relapsed CLL compared to placebo plus rituximab: patients receiving idelalisib had improved rates of overall response (81% vs. 13%) and overall survival at 12 months (92% vs. 80%), with an acceptable safety profile (Furman et al, 2014). The regimen of bendamustine + rituximab has demonstrated efficacy in the treatment of patients with previously untreated CLL. **Methods:** 280 patients with previously untreated CLL and measurable lymphadenopathy will be enrolled in this global phase 3, multicenter, randomized, double-blind, placebo-controlled trial. Pts will be randomized in a 1:1 ratio to Arm A or B of the study. On Arm A, subjects will receive idelalisib (150 mg BID continuously for 96 weeks) plus rituximab (6 infusions of 375 – 500 mg/m$^2$ over 6 months) and bendamustine (12 infusions of 90 mg/m$^2$ over 6 months). In Arm B, subjects will receive placebo instead of idelalisib. Stratification factors include *IGHV* mutational status, del(17p) status, and Rai stage. The primary endpoints of the study are minimal residual disease and PFS. The secondary endpoints are ORR, nodal response rate, CR, and OS. The difference in PFS will be compared between Arm A and Arm B in the ITT analysis set using Kaplan-Meier methods and the stratified log-rank test. The study opened for enrollment in Jan 2014. Clinical trial information: NCT01980888.

**TPS7124 General Poster Session (Board #406B), Mon, 1:15 PM-5:00 PM**

**Treatment-free remission (TFR) following nilotinib (NIL) in patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP): ENESTfreedom, ENESTop, ENESTgoal, and ENESTpath.** *Presenting Author: Francois-Xaxier Mahon, Université Victor Ségalen, Bordeaux, France*

**Background:** Approximately 40% of pts who achieve deep, sustained molecular response (MR) on imatinib (IM) are able to successfully maintain TFR (Mahon FX, et al. *Lancet Oncol.* 2010;11:1029-1035). NIL results in higher rates of deep, sustained MR vs IM and may enable more pts to achieve successful TFR. Four ongoing studies will evaluate the key factors for achieving and sustaining TFR following NIL in pts with CML-CP (Table). **Methods:** Each study includes a NIL consolidation phase, during which pts undergo frequent molecular monitoring, followed by a TFR phase. In ENESTfreedom and ENESTop, pts with $MR^{4.5}$ (BCR-ABL $\leq$ 0.0032% on the international scale [$BCR\text{-}ABL^{IS}$]) on NIL directly enter the 1-y consolidation phase upon enrollment. In ENESTgoal and ENESTpath, pts without deep MR on IM are switched to NIL upon enrollment; after switching to NIL, pts in ENESTgoal who achieve $MR^{4.5}$ and pts in ENESTpath who complete 2 y of NIL therapy and achieve $MR^4$ ($BCR\text{-}ABL^{IS} \leq 0.01\%$) will be randomized to a 1- or 2-y consolidation phase. Each study protocol defines a required MR level that pts must maintain during the consolidation phase to be eligible for the TFR phase. During the TFR phase of each study, pts must re-initiate therapy if their MR rises above a defined threshold (ie, molecular relapse). The rate and duration of successful TFR on NIL will be evaluated in each study. Clinical trial information: NCT01784068.

**TPS7125 General Poster Session (Board #407A), Mon, 1:15 PM-5:00 PM**

**Phase 3 study of oral lenalidomide as maintenance therapy for patients with B-cell chronic lymphocytic leukemia (CLL).** *Presenting Author: Asher Alban Akmal Chanan-Khan, Mayo Clinic, Jacksonville, FL*

**Background:** Despite recent advances in chemo-immunotherapy combinations for the treatment (Tx) of CLL, most patients (pts) relapse and eventually die from the disease. Maintenance therapy has made impact in other B-cell cancers, such as myeloma; its role and the optimal agent in CLL is unknown. Recent trials of rituximab have shown promise as maintenance therapy; however, the clinical use may be limited due to the intravenous formulation. Lenalidomide (LEN) shows encouraging efficacy in CLL pts; this and its positive impact on survival outcome as maintenance Tx in myeloma pts rationalizes its investigation in CLL. Additionally, the oral formulation makes it better suited as a long-term, single-agent Tx regimen. **Methods:** This phase 3, multicenter, randomized, double-blind, placebo controlled, parallel-group study investigates the efficacy and safety of oral LEN as maintenance therapy for CLL pts who showed a partial response (PR) to second-line therapy. Primary objectives are PFS and OS. Secondary objectives include safety, tumor response, response duration and health-related quality of Life. Additionally, the occurrence of secondary primary malignancy is monitored. Eligible pts ($\geq$18 years) have previously received a chlorambucil-, a purine analog-, an anti-CD20-antibody-, or a bendamustine-based regimen in first- and/or second-line therapy, and must have achieved $\geq$PR to second-line therapy. Pts with del(17p) may have previously received an alemtuzumab-containing regimen. 400 pts (260 pts currently enrolled) with $\geq$PR following second-line therapy will be enrolled and randomized (1:1) to either the placebo or the LEN arm. Pts will receive placebo or 2.5 mg LEN per day (QD) on days 1-28 of each 28-day cycle. Subsequent LEN dose escalation to 5 mg QD at cycle 2 and to 10 mg at cycle 6 may occur, if tolerated in the previous cycle. Prior to study commencement, pts are tested for poor prognostic indicators (del(17p), del(11q), unmutated IGVH and high B2M). Exploratory biomarkers include (ZAP-70, immune cell analysis and CD80). This study is conducted in accordance with good clinical practice and all applicable regulatory requirements. Clinical trial information: NCT00774345.

**TPS7126 General Poster Session (Board #407B), Mon, 1:15 PM-5:00 PM**

**Connect MDS and AML: The myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) disease registry.** *Presenting Author: David P. Steensma, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Diagnostic approaches, treatment (tx) patterns, and clinical outcomes for patients (pts) with MDS or AML outside of clinical trials are poorly characterized. The Connect MDS and AML Registry (Clinicaltrials-.gov Identifier NCT01688011) is a prospective, longitudinal, multicenter observational registry for pts newly diagnosed with MDS or AML. It is designed to capture diagnostic evaluation, risk assessment, and tx patterns; objective clinical and pt-reported outcomes (PROs); and biospecimens from pts cared for in community or academic centers. **Methods:** Approximately 1,500 pts from $\approx$ 150 clinical sites across the United States will be enrolled into 4 cohorts: IPSS low/Int-1–risk MDS (n = 700, including $\approx$ 250 del(5q) MDS), Int-2/high-risk MDS (n = 200), unknown-risk MDS due to unsuccessful bone marrow cytogenetics (n = 100), and AML (n = 500). Pts must have confirmed newly diagnosed ($\leq$ 60 days prior to enrollment) MDS or primary or secondary AML, excluding acute promyelocytic leukemia, based on WHO 2008 diagnostic criteria. AML pts must be $\geq$ 55 years of age. First pt was enrolled in December 2013. Pts will be followed for up to 8 years, until withdrawal from the study, death, or study end. There will be 1 initial remote monitoring visit. Appropriate methods for observational data will be utilized. Primary objectives are to describe current and evolving patterns of diagnosis/prognosis, evaluation, tx, clinical monitoring, and outcomes; compare actual clinical practice with existing management guidelines; describe tx sequencing and associated short- and long-term outcomes, including response, safety, disease progression, and survival; and summarize PROs and health economic outcomes and their association with pt characteristics, tx, and clinical outcomes. Additionally, biospecimens will be collected for correlative studies, including assessment of somatic mutations. Registry results may provide new insights into how tx regimens and tx sequencing data combined with baseline prognostic factors relate to clinical outcomes of pts with MDS or AML. Furthermore, PROs and correlative molecular data will help elucidate the association of tx patterns with relevant effectiveness outcomes.

**TPS7127 General Poster Session (Board #408A), Mon, 1:15 PM-5:00 PM**

**A phase 3, randomized, double-blind, placebo-controlled study evaluating the efficacy and safety of idelalisib (GS-1101) in combination with bendamustine and rituximab for previously treated chronic lymphocytic leukemia (CLL).** *Presenting Author: Herbert Aaron Eradat, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA*

**Background:** PI3K$\delta$ is critical for the activation, proliferation and survival of B cells and plays a role in homing and retention of B cells in lymphoid tissues. PI3K signaling is hyperactive in many B-cell malignancies. Idelalisib is a first-in-class, selective, oral inhibitor of PI3K$\delta$ that reduces proliferation, enhances apoptosis, and alters trafficking of malignant B cells in lymphoid tissues (Lannutti, 2011). Phase 1 trials demonstrated that idelalisib is highly active in heavily pretreated pts with CLL as a single agent or in combination with rituximab (R), bendamustine (B), or BR: pts experienced reductions in disease-associated chemokines, profound and rapid reductions in lymphadenopathy, and durable clinical benefit with an acceptable safety profile (Sharman et al, 2011; Coutre et al, 2012; Furman et al, 2014). **Methods:** Study will enroll 390 pts with previously treated CLL who have measurable lymphadenopathy, have received prior therapy containing a purine analog or B and an anti-CD20 monoclonal antibody, are not refractory to B, have experienced CLL progression within 36 months from the completion of the last prior therapy, and are currently sufficiently fit to receive cytotoxic therapy. Pts will be randomized in a 1:1 ratio to Arm A or B of the study. On Arm A, subjects will receive idelalisib continuously at 150 mg BID + R at 375 mg/m$^2$ (1$^{st}$ dose) and then 500 mg/m$^2$ every 4 weeks for 6 cycles + B at 70 mg/m$^2$ on Days 1 & 2 of each 4-week cycle for 6 cycles. On Arm B, subjects will receive placebo instead of idelalisib. Stratification factors include IGHV mutational status, del17p/p53 mutation status, and refractory/relapsed status. The primary endpoint is PFS and key secondary endpoints include ORR, lymph node response rate, CR rate, and OS. This is an event-driven trial and primary endpoint evaluation will be based on independent central review. For the primary efficacy analysis, the difference in PFS between the treatment arms will be assessed in the ITT analysis set. The study was initiated in June 2012. Clinical trial information: NCT01569295.

**TPS7128^ General Poster Session (Board #408B), Mon, 1:15 PM-5:00 PM**

**RESPONSE 2: A phase 3b study evaluating the efficacy and safety of ruxolitinib in patients with hydroxyurea (HU)-resistant/intolerant polycythemia vera (PV) versus best available therapy (BAT).** *Presenting Author: Francesco Passamonti, Ospedale di Circolo e Fondazione Macchi, Varese, Italy*

**Background:** PV is a myeloproliferative neoplasm characterized by clonal stem cell proliferation, hyperviscous blood, significant morbidity, and reduced life span. Advanced PV results in splenomegaly, severe constitutional symptoms, and possible evolution to myelofibrosis and acute myeloid leukemia (AML). Nearly all patients (pts) have a mutation in *JAK2*, and > 95% have the *JAK2* V617F allele. HU is the myelosuppressive agent of choice in high-risk pts, but it often loses efficacy over time and may cause unacceptable skin toxicities. Therapeutic options in the case of HU resistance are limited, and survival is significantly reduced. A phase 2 study in HU-resistant/-intolerant PV pts showed that ruxolitinib, a potent and selective JAK1/JAK2 inhibitor, was well tolerated and achieved rapid and durable clinical responses, including hematocrit (Hct) normalization, phlebotomy independence, resolution of splenomegaly, and improvements in symptoms (Verstovsek et al, *Cancer,* 2013). RESPONSE, a phase 3 trial, was designed to compare the efficacy and safety of ruxolitinib with best available therapy (BAT) in HU-resistant/-intolerant PV pts with splenomegaly. **Methods:** RESPONSE 2 is an open-label, randomized (1:1), phase 3b study (NCT02038036) designed to compare the efficacy and safety of ruxolitinib with BAT in PV pts (per revised WHO criteria) who require phlebotomy and are HU-resistant/-intolerant. Target enrollment is 104 pts and includes pts without splenomegaly, expanding the RESPONSE patient population. The primary endpoint is the achievement of Hct control, defined as Hct < 45% at week 16 and maintained until week 28, and no phlebotomy from week 4 to week 28, with ≤ 1 phlebotomy postrandomization and prior to week 4. Secondary endpoints include peripheral blood count remission, partial remission (ELN and IWG-MRT criteria), and resolution of symptoms in MPN-SAF TSS at week 28. The BAT group may cross over to ruxolitinib on or after week 28 if they have Hct > 45%, receive phlebotomy, or need to discontinue BAT. Pts will be treated for 52 weeks to assess safety and durability of response. Clinical trial information: NCT02038036.

**7500 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**A multinational phase III randomized trial with or without consolidation chemotherapy using docetaxel and cisplatin after concurrent chemoradiation in inoperable stage III non-small cell lung cancer (CCheIN).** *Presenting Author: Keunchil Park, Department of Medicine, Division of Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** Currently, the recommended treatment for inoperable stage III non-small cell lung cancer (NSCLC) is concurrent chemoradiotherapy (CCRT). The efficacy of consolidation chemotherapy after CCRT needs to be confirmed. The aim of this phase III randomized trial is to determine the efficacy of consolidation chemotherapy with docetaxel (D) and cisplatin (P) following definitive CCRT with the same agents in stage III inoperable NSCLC. **Methods:** Patients with inoperable stage III NSCLC were randomized to either CCRT alone (observation arm) or CCRT followed by consolidation chemotherapy (consolidation arm). N2 or N3 disease was confirmed by PET and/or pathology. CCRT with D (20 mg/m$^2$) and P (20 mg/m$^2$) was administered every week for 6 weeks with a total dose of 66 Gy of thoracic RT as 33 fractions. In the consolidation arm, patients were further treated with 3 cycles of D and P (35 mg/m$^2$each on day 1 and 8, every 3 weeks). The primary endpoint is progression-free survival (PFS). The secondary endpoints are overall survival, response rate, pattern of failure, and safety. Total target number of patients is 434. **Results:** From Oct 2005 to Apr 2011, 437 patients were enrolled and randomized. 419 patients completed CCRT phase (intent-to-treat population; observation 208, consolidation 211). Patients' characteristics were well-balanced in both arms. In the consolidation arm, 142 patients (67%) received consolidation chemotherapy, of whom 95 (67%) completed 3 planned cycles. The median PFS was 8.0 months (95% CI, 7.5 ~ 8.8) in the observation arm and 9.1 months (95% CI, 7.9 ~ 10.9) in the consolidation arm (P=0.38). Median overall survival was 20.6 (95% CI, 17.5 ~ 26.3) and 21.2 months (95% CI, 17.7 ~ 24.7), respectively (P=0.48). Exploratory biomarker study using tissue and blood is under way. **Conclusions:** This study suggests that consolidation chemotherapy with DP after CCRT with weekly DP in stage III NSCLC does not prolong PFS. Clinical trial information: NCT00326378.

**7501 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**A randomized, double-blind phase 3 trial of adjuvant erlotinib (E) versus placebo (P) following complete tumor resection with or without adjuvant chemotherapy in patients (pts) with stage IB-IIIA EGFR positive (IHC/FISH) non-small cell lung cancer (NSCLC): RADIANT results.** *Presenting Author: Karen Kelly, UC Davis Comprehensive Cancer Center, Sacramento, CA*

**Background:** The proven efficacy of E in advanced NSCLC warranted its evaluation in the adjuvant setting. BR.21 data suggested pts with EGFR positive tumors (IHC/FISH) were more likely to benefit from E. **Methods:** Completely resected IB-IIIA NSCLC pts were randomized 2:1 to receive E 150 mg qd or P for 2 years. Pts were stratified according to stage, histology, prior adjuvant chemotherapy, smoking status, *EGFR* FISH status, and country. The primary endpoint was disease free survival (DFS) in the full analysis set (FAS). Secondary endpoints included overall survival (OS) in the FAS and DFS and OS in the *EGFR* mutation (*EGFR* M+) subset (del19/L858R). Hierarchical testing procedure was used. **Results:** Between NOV 2007 and JUL 2010, 973 pts were randomized. Baseline characteristics were balanced between arms (age > 65 41%; female 41%; stage IB 51%, II 33%, IIIA 16% [AJCC 6$^{th}$ ed]; adenocarcinoma 59%; prior adjuvant chemotherapy 53%; never smoker 20%; Asian 17%; *EGFR* FISH+ 72% and *EGFR* M+ 16.5%). The planned number of events (410) for the final DFS analysis was reached in APR 2013; 277 (28%) pts had died. Median follow-up was 47 months (m). No statistically significant difference in DFS was observed in FAS; hierarchical testing rendered all secondary endpoints non-significant. The median treatment duration was 12 m for E and 22 m for P in FAS. Rash and diarrhea occurred in 58% and 52% pts for E vs 17% and 16% for P. Grade ≥3 rash and diarrhea occurred in 12.6% and 6.2% pts for E vs 0.3% and 0.3% for P. No drug-related adverse events led to death. **Conclusions:** Adjuvant E did not prolong DFS in the overall population. Further investigation in *EGFR* M+ pts is warranted. The safety profile of E was consistent with that in advanced disease. Clinical trial information: NCT00373425.

**Full analysis set.**

**7502 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Randomized trial on thoracic radiotherapy (TRT) in extensive-stage small cell lung cancer.** *Presenting Author: Ben J. Slotman, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Prophylactic cranial irradiation (PCI) reduces the risk of brain metastases and improves survival in ES-SCLC after response to chemotherapy. As a majority of patients have intrathoracic disease after chemotherapy, this randomized study assesses the role of TRT in ES-SCLC. **Methods:** Patients (WHO 0-2) with confirmed ES-SCLC with a response after 4-6 cycles of standard chemotherapy were randomized to receive TRT (30 Gy/10fx) or no TRT. All received PCI. Primary study endpoint was overall survival. Acute toxicity was graded using CTCAE v3.0. The study had 80% power to detect a hazard ratio of 0.76 at 1 year (2-sided 5% signif.). Accounting for 5% dropout before treatment, 483 patients had to be randomized. Analysis was based on intent to treat. **Results:** Between Feb'09 and Dec'12, 498 patients were enrolled (249 per arm); Median follow-up was 24 months. 88% had residual intrathoracic disease. Baseline characteristics were well balanced. Mean age was 63 year (range 36-85), 89% had WHO 0-1; 11% WHO2. Mean interval between start of chemotherapy and randomization was 16 weeks. Three patients subsequently withdrew informed consent leaving 247 (TRT) versus 248 patients (control arm). In the TRT arm, 5 patients did not receive TRT due to progression or refusal. No severe toxicities were observed. At the time of analysis (Dec'13), 76 patients were still alive. Progression-free survival was longer in the TRT-arm (HR=0.73, CI 0.61-0.87; p=0.001). Curves for overall survival overlapped during the first 9 months and then diverged in favour of the TRT-arm. The survival difference at 1 year was not statistically significant (33% vs 28%; HR=0.84, CI 0.69-1.01; p=0.066). Survival at 2 years was 13% (CI 9-19) for the TRT and 3% (CI 2-8%) for the control arm (P=0.004). **Conclusions:** TRT improves progression-free survival. Although TRT did not influence the risk of death in the first year, it led to a significant increase in 2-year survival. TRT should therefore be offered to all ES-SCLC patients with a response to initial chemotherapy. This study was supported by grants from the Dutch Cancer Society (CKTO) and Cancer Research UK and supported by the Dutch Lung Cancer Research Group and The Christie NHS Foundation Trust Clinical Trials Unit. Clinical trial information: NTR1527.

**7503 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Prophylactic cranial irradiation (PCI) has a detrimental effect on the overall survival (OS) of patients (pts) with extensive disease small cell lung cancer (ED-SCLC): Results of a Japanese randomized phase III trial.** *Presenting Author: Takashi Seto, Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan*

**Background:** A previous study has shown that PCI reduced the risk of brain metastases (BM) and prolonged the OS of patients with ED-SCLC (Slotman B et al, NEJM 2007). There were, however, several concerns that arose in association with that study, including the lack of magnetic resonance imaging (MRI) assessment to confirm the absence of BM before enrollment, the use of induction chemotherapy other than platinum, and variations in the radiation doses. **Methods:** From March 2009, pts with ED-SCLC who had any response to first-line platinum doublet chemotherapy were randomized to either PCI (25Gy/10 fractions) or observation (Obs) alone. The patients were required to prove the absence of BM by MRI prior to enrollment. The primary endpoint was OS and a planned sample size of 330 was determined to detect the hazard ratio (HR) of 0.75 at a significance level of 0.05 and a power of 80%. Secondary endpoints included time to BM (evaluated every 3 months by imaging), progression-free survival (PFS), and adverse effects (AEs). **Results:** In July 2013, a preplanned interim analysis was conducted for the survival data of 163 pts from 41 centers. The study was terminated because of futility; with a median follow-up of 9.4 months and 111 observed deaths, the median OS was 10.1 and 15.1 months for PCI ($n$=84) and Obs ($n$=79), respectively (HR=1.38, 95%CI= 0.95-2.01; stratified log-rank test, $P$=0.091). Bayesian predictive probability of showing superiority of PCI over Obs was 0.01%. PCI significantly reduced the risk of BM as compared to Obs (32.4% vs 58.0% at 12 months; Gray's test, $P$<0.001), whereas PFS was comparable between the two arms (median, 2.2 vs. 2.4 months; HR=1.12, 95%CI=0.82-1.54). No significant difference in AEs greater than Grade 2 was observed between the two arms. **Conclusions:** PCI after response to chemotherapy had a negative impact on OS in pts with ED-SCLC. Clinical trial information: 000001755.

**7504** **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**A randomized phase III study of cisplatin (CDDP), etoposide (ETOP) and irinotecan versus topotecan as second-line chemotherapy in patients with sensitive relapsed small-cell lung cancer (SCLC): Japan Clinical Oncology Group study JCOG0605** *Presenting Author: Koichi Goto, Division of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** ETOP and irinotecan are drugs known to exert promising activity in SCLC. A phase II study of weekly chemotherapy using a combination of CDDP, ETOP and irinotecan (PEI), which are known to inhibit both topoisomerase I and II, showed quite favorable outcome in patients with sensitive relapsed SCLC. A phase III study confirming the superiority of PEI over topotecan as second-line chemotherapy in patients with sensitive relapsed SCLC was conducted. **Methods:** SCLC patients who responded to first-line treatment and relapsed/progressed more than 90 days after the completion of first-line treatment were eligible for this study. Additional eligibility criteria included age 20-75 years, PS of 0-2, and adequate organ functions. Patients were randomized 1:1 to PEI, which consisted of CDDP (25 mg/m$^2$) weekly for 10 weeks, ETOP (60 mg/m$^2$) for 3 days on weeks 1, 3, 5, 7, and 9, and irinotecan (90 mg/m$^2$) on weeks 2, 4, 6, 8 and 10 with granulocyte colony-stimulating factor support, or to topotecan (1.0 mg/m$^2$) on days 1-5, every 3 weeks for 4 courses. The primary endpoint was overall survival. The planned sample size was 180 patients, to attain 80% power with a one-sided alpha of 5%. **Results:** From Sep. 2007 to Nov. 2012, 180 patients were randomized to topotecan (n=90) and PEI (n=90): median age 64 (44-75) years; M/F 155/25; LD/ED 45/135; PS 0-1/2 175/5. The overall survival was significantly longer in the PEI arm than in the topotecan arm (HR 0.67; 90% CI 0.51-0.88; p=0.0079) with MST 18.2 months vs. 12.5 months. PFS was also significantly longer in the PEI arm (HR 0.50; 95% CI 0.37-0.68; p<0.0001) with the median PFS 5.7 months vs. 3.6 months. Grade 3/4 adverse events in PEI and topotecan arms, respectively, were: neutropenia 83.3% vs. 85.6%; anemia 84.4% vs. 27.8%; thrombocytopenia 41.1% vs. 27.8%; diarrhea 7.8% vs. 0%; febrile neutropenia 31.1% vs. 6.7%. There was 1 treatment-related death in the PEI arm, and 2 in the topotecan arm. **Conclusions:** The combination chemotherapy with CDDP, ETOP and irinotecan should be considered as the standard second-line chemotherapy for sensitive relapsed SCLC. Clinical trial information: 000000828.

**7505** **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Randomized phase II-III study of bevacizumab in combination with chemotherapy in previously untreated extensive small-cell lung cancer: Results from the IFCT-0802 trial.** *Presenting Author: Jean-Louis Pujol, Centre Hospitalier Universitaire, Maladies Respiratoires, Montpellier, France*

**Background:** A randomized phase II-III trial was designed to assess efficacy and safety of adding bevacizumab (Bev) to first-line standard chemotherapy (CT) in extensive small-cell lung cancer (SCLC). **Methods:** Patients with SCLC were enrolled and then received two induction cycles of CT, three weeks apart (cisplatin - etoposide, or cisplatin - cyclophosphamide - epidoxorubicin - etoposide [PCDE]). Responders were randomly assigned 1:1 to receive 4 additional cycles of CT alone or CT plus Bev (7.5 mg/kg) followed by single-agent Bev until progression or unacceptable toxicity. The primary endpoint was response rate (RR) after 4 cycles (i.e. two cycles after randomization). **Results:** 147 patients were enrolled. After the 2 first CT cycles, RR was observed in 99 patients (67.3%) and among them, 74 patients were eligible for Bev and randomly assigned to CT only (n = 37) or CT plus Bev (n = 37). Median number of CT was 6 in CT alone group and 6 in CT plus Bev group. The median number of additional Bev administrations in the latter group was 4. The percentage of still-responder patients after 4 cycles, including 2 with bevacizumab in the experimental arm, did not differ between the CT arm (89.2%) and the CT+bevacizumab arm (91.9%). Neither progression-free survival (PFS) nor overall survival (OS) significantly differed (median PFS : 5.5 and 5.3 months; median OS: 13.0 and 11.1 months, in CT alone and CT plus Bev groups respectively). In the CT alone group and the CT plus Bev group, 22 (59.5%) versus 23 (62.2%) of patients respectively, experienced one or more grade 3-4 adverse events. Specific Bev-induced toxicity was observed in 15 (40.5%) patients; one unexpected toxicity (fatal subdural hematoma) was reported in the combination group. Evaluation of serum biomarkers will be presented. **Conclusions:** Bev did not increase the proportion of responder patients at cycle 4. This phase II study failed to demonstrate any signal suggesting an outcome improvement in extensive-SCLC. Consequently this trial will not go further the phase 3 part of the program. Clinical trial information: NCT00930891.

**7506** **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**A randomized double-blind phase II trial of platinum (P) plus etoposide (E) with or without concurrent ZD6474 (Z) in patients (pts) with previously untreated extensive-stage (ES) small cell lung cancer (SCLC): Hoosier Oncology Group LUN06-113.** *Presenting Author: Rachel E. Sanborn, Earle A. Chiles Research Institute and Providence Cancer Center, Portland, OR*

**Background:** Standard treatment with P + E results in median survival for ES SCLC 10 months. Dose escalation, addition of third cytotoxic agents, and maintenance therapy have failed to improve outcomes. Overexpression of VEGF is associated with poor prognosis in SCLC. This trial evaluated the efficacy and tolerability with the addition of Z (dual VEGF and EGFR inhibitor) to PE. **Methods:** Randomized, double blind, placebo controlled study of P (cisplatin 60 mg/m$^2$ or carboplatin AUC 5) day 1, E (120 mg/m$^2$ with cis or 100 mg/m$^2$with carbo) IV days 1-3, with Z (100 mg) or placebo po daily, q3 wks for 4 cycles. 6 pts were initially enrolled on P+E+Z for safety assessment. Pts with untreated ES SCLC or high grade poorly differentiated neuroendocrine tumors and ECOG 0-1 were eligible. Pts with symptomatic brain metastases (mets) or prolonged QTc were ineligible. 1°endpoint was time to disease progression (TTP). Secondary endpoints were safety, response rate (RR), disease control rate (DCR), and overall survival (OS). VEGF polymorphisms were also evaluated. **Results:** 74 pts enrolled (33 placebo, arm A; 41 Z, arm B) Median age 63/64 A/B; female/male 48.5%/51.5% A, 41.5%/58.5% B; ECOG 0/1 36%/64% A, 34%/66% B. Brain mets at diagnosis, 30% A, 39% B. Median number of cycles received was 4 (both arms). Cisplatin/carboplatin 51.5%/48.5% A, 61%/39% B. All Grade (Gr) 3-4 toxicity: 37% A, 69% B (heme, 20% A; 30% B, mainly neutropenia both arms; non-heme, 17% A; 33% B). Gr 5 toxicity, 1 each: A, 3 (cardiac infarct, pulmonary hemorrhage, pneumonitis); B, 2 (infection, respiratory failure). No differences were seen in bleeding/hemorrhage (1 gr 3/4 each, 1 gr 5 A). 3 pts had Gr 3/4 hypertension in B (0 in A). RR 65.4% A, 51.4% B; P=0.31. DCR 73% A, 74% B; P=1.0. Median OS 10.2 months (mo) A, 10.7 mo B; P=0.90; HR 0.78 (B v A). Median TTP 5.6 mo A, 5.5 mo B; P=0.66; HR 1.13 (B v A). **Conclusions:** The addition of Z to PE did not improve TTP, RR, DCR, or OS for patients with extensive SCLC. An increase in toxicity was seen with Z compared with placebo. Z in combination with PE cannot be recommended for further study in unselected pts with ES SCLC. Clinical trial information: NCT00613626.

**7507** **Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Randomized trial of arginine deprivation with pegylated arginine deiminase in patients with malignant pleural mesothelioma.** *Presenting Author: Peter Wojciech Szlosarek, St. Bartholomew's Hospital, London, United Kingdom*

**Background:** Argininosuccinate synthetase 1 (ASS1)-deficient malignant pleural mesothelioma (MPM) cells are sensitive to arginine deprivation. We examined the efficacy and safety of the arginine-lowering agent pegylated arginine deiminase (ADI-PEG20, Polaris Group, US) among patients with MPM. **Methods:** Patients with good performance status (0-1), non-resectable disease, ASS1-deficient MPM, and measurable disease by modified RECIST were randomized (2:1) in a multicenter phase II trial. They received best supportive care (BSC) or BSC plus ADI-PEG20 (i.m. injection 36.8mg/m2, weekly). Primary endpoint was progression-free survival (PFS); target hazard ratio (HR) 0.60. Other endpoints: overall survival (OS), tumor response rate (modified RECIST), and toxicity. We measured plasma [arginine], [citrulline] and [ADI-PEG20 antibody], ASS1 methylation status, and metabolic response by [18F]Fluorodeoxyglucose Positron Emission Tomography (FDG-PET). [ClinicalTrials.gov NCT01279967, funding Cancer Research UK]. **Results:** We screened 214 patients (March 2011-May 2013), and randomized 68 with ASS1-deficient MPM: 44 ADI-PEG20+BSC and 24 BSC alone. PFS HR was 0.53 (95% CI 0.31 to 0.90, p=0.02), median 98 vs. 59 days favouring ADI-PEG20+BSC. The OS HR was 0.81 but the curves crossed, so we used the restricted mean survival times: 390 vs. 317 days (difference +73 days favoring ADI-PEG20+BSC,p=0.20). The best response was stable disease: at 4 months 67% ADI-PEG20+BSC vs. 50% BSC alone. The main grade 3/4 toxicities associated with ADI-PEG20+BSC were: neutropenia (11%), thromobocytopenia (5%), fatigue (7%), anaphylactoid reactions (7%), skin rash (2%), and serum sickness (2%). Plasma arginine levels declined with ADI-PEG20+BSC only, and correlated with the following FDG-PET changes in 39 evaluable ADI-treated patients with aberrant MPM ASS1 methylation: 46% partial response, 31% stable disease, 15% progressive metabolic disease, and 8% mixed metabolic response. **Conclusions:** Arginine deprivation using ADI-PEG20 in patients with ASS1-deficient MPM almost doubled PFS and was generally safe. It should be examined further either alone or in combination with selected therapies. Clinical trial information: NCT01279967.

**7508 Poster Highlights Session (Board #1), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A randomized trial of prophylactic cranial irradiation versus observation in patients with fully resected stage IIIA N2 non-small cell lung cancer and high risk of cerebral metastases after adjuvant chemotherapy.** *Presenting Author: Si-Yu Wang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

**Background:** Prophylactic cranial irradiation (PCI) significantly decreases the incidence of brain metastases in patients with non-small cell lung cancer (NSCLC), but its impact on survival is uncertain. Previously, we built a mathematical model to predict the risk of developing cerebral metastases in patients with locally advanced NSCLC. The purpose of this study is to evaluate if PCI improves survival in patients with resected stage IIIA N2 NSCLC and high risk of cerebral metastases after adjuvant chemotherapy. **Methods:** In this open-label, randomized trial, patients with fully resected stage IIIA N2 NSCLC and high cerebral metastases risk without recurrence after postoperative adjuvant chemotherapy were randomly assigned to receive PCI (30 Gy in 10 fractions) or observation. The primary end point was disease-free survival (DFS). The secondary end points included the incidence of brain metastases, overall survival (OS) and toxicity. **Results:** From January 2005 to January 2009, 156 eligible patients were randomized (81 in PCI group and 75 in control group). This study was terminated early as a result of slow accrual. The PCI group had significantly lengthened DFS compared with the control group, with a median DFS of 28.5 months versus 21.2 months (hazard ratio [HR], 0.67; 95% confidence interval [CI], 0.46-0.98; P=0.037). The 3-year and 5-year DFS were respectively 42.0% and 26.1% with PCI, and 29.8% and 18.5% with observation. PCI was associated with a decrease in risk of brain metastases (5-year brain relapse rate, 13.6% vs 41.3%; odds ratio, 0.223; 95% CI, 0.102-0.489; P<0.001). The median OS was 31.2 months in the PCI group and 27.4 months in the control group (HR, 0.81; 95% CI, 0.56-1.16; P=0.310). The 3-year and 5-year OS were respectively 44.5% and 27.4% with PCI, and 38.7% and 22.8% with observation. While main toxicities were headache, nausea/vomiting and fatigue in the PCI group, they were generally mild. **Conclusions:** In patients with fully resected stage IIIA N2 NSCLC and high risk of cerebral metastases after adjuvant chemotherapy, PCI prolongs DFS and decreases the incidence of brain metastases.

**7509 Poster Highlights Session (Board #2), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Postoperative radiotherapy (PORT) for pathologic N2 non-small cell lung cancer (NSCLC) treated with adjuvant chemotherapy: A review of the National Cancer Database.** *Presenting Author: Cliff Grant Robinson, Washington University School of Medicine in St. Louis, St. Louis, MO*

**Background:** Adjuvant chemotherapy confers a 5% overall survival (OS) benefit for NSCLC patients following resection. Historic trials predating widespread use of chemotherapy suggested no OS benefit to PORT for N2 disease, felt to be from competing risks of older RT techniques and subsequent toxicity. We investigated the impact of modern PORT on OS for N2 NSCLC patients treated nationally with surgery and adjuvant chemotherapy. **Methods:** Patients with pathologic N2 NSCLC who underwent complete (R0) resection and adjuvant chemotherapy from 1998 to 2010 were identified from the National Cancer Database. Only patients for whom complete radiation and chemotherapy details were available were included. Patients were stratified by the use of PORT (≥45 Gy) as coded in the database. A total of 4,585 patients were identified (1,909 PORT, 2,676 no PORT) with a median follow-up of 22 months. The impact of PORT on OS was explored using Cox regression. **Results:** Patients treated with PORT were slightly younger (median 63.5 vs. 65 years, p<0.001) and healthier (Charlson 0 in 60.8% vs. 55.2%, p<0.001), though less likely to be treated at an academic facility (31.6% vs. 40.9%, p<0.001). Patients treated with PORT had fewer pneumonectomies (5.9% vs. 9.9%, p<0.001) and more sublobar resections (16.3% vs. 9.8%, p<0.001), and slightly smaller tumors (34.6 vs. 36.7 mm, p<0.015). On multivariate analysis, factors independently predictive of improved OS for the entire group were younger age, treatment at an academic facility, higher income, lower Charlson score, smaller tumor, ≥ lobectomy, and use of PORT (HR 0.873, 95% C.I. 0.789-0.965). Use of PORT was associated with a significant increase in median and 5-year overall survival compared to no PORT, 45.9 vs. 40.7 months and 39.1% vs. 34.7% (p=0.005), respectively. **Conclusions:** For NSCLC patients with N2 disease following complete resection and adjuvant chemotherapy, modern PORT appears to confer an additional 5% survival advantage beyond that achieved with adjuvant chemotherapy alone. Investigators are encouraged to enroll on prospective trials such as LungART, a randomized trial of modern PORT vs no PORT in resected NSCLC.

**7510 Poster Highlights Session (Board #3), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase III study of surgery (S) versus definitive concurrent chemoradiotherapy boost (def ccCRTx-BOx) in patients (pts) with operable (OP+) stage IIIA(N2)/selected IIIb (sel IIIB) non-small cell lung cancer (NSCLC) following induction (IND) chemotherapy (CTx) and concurrent CRTx (ESPATUE).** *Presenting Author: Wilfried Ernst Erich Eberhardt, Department of Medical Oncology, Ruhrlandklinik, West German Cancer Center, University Hospital Essen. University Duisburg-Essen, Essen, Germany*

**Background:** Def ccCRTx or ccCRTx + S are accepted therapies (Tx) for OP+ stage IIIA(N2) NSCLC (Albain 2009). Our multicenter phase-II showed efficacy of CTx + ccCRTx + S in IIIA(N2) / sel IIIB (CISTAXOL: Eberhardt 2013). Here we compared S with ccCRTx-BOx in OP+ stage III NSCLC following IND. With 246/500 planned pts (1/04-8/12) trial closed for slow accrual + futility. Here we report final analysis (29-Jan-2014). **Methods:** Pathologically proven OP+ IIIA(N2) / sel IIIB NSCLC pts, adequate organ function / functional OP+, received IND CTx (3 cycles CDDP/taxol) and ccCRTx to 45 Gy (1.5Gy bid/cc CDDP/vinorelbine). Pts were reevaluated in last week ccCRTx (PET-CT) and discussed by multidisciplinary board. OP+ pts were randomized (rand) to def ccCRTx-BOx risk adapted to 65/71 Gy (arm A) or S (arm B). Primary endpoint: overall survival (OS). **Results:** 246 pts (70 F 176 M; T1-3N2 75 T4N0-1 80 T4N2/anyT N3 91; age 59 (33-74); SQC 95 ADC 107, other 44) enrolled at 5 centers. 245 started IND, 161/246 OP+ pts (65.4%) were rand to arm A or B (strata: TN-group, PCI-policy, region) - post rand crossover due pts preference: 6.8%. 46 non-rand pts received def ccCRTx-BOx. Pts characteristics were well balanced. Pneumonectomy in 26%, R0-Res in 81% of arm B. Med F-UP post rand 78.2 mo. 36 are actually long-term surv with F-UP > 5 y. OS did not differ between arms ( logrank p = 0.31 ). OS at 5 y 34.1% (27.6-40.8) in 246 initially recruited (IR) and 216 (87.8%) received def local Tx. **Conclusions:** Long-term OS at 5 y in rand OP+ pts was excellent with both Tx. These high-volume center data confirm earlier trials: Both options are acceptable and should be discussed with individual pts. Clinical trial information: 70-3070-Eb.

**7511^ Poster Highlights Session (Board #4), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II study of cetuximab, pemetrexed, cisplatin and concurrent radiotherapy in patients with locally advanced, unresectable, stage III, non-squamous, non-small cell lung cancer (NSCLC): Results of the IFCT-0803 trial.** *Presenting Author: Jean Tredaniel, Groupe Hospitalier Paris Saint-Joseph, Paris, France*

**Background:** Cisplatin-based chemotherapy and concurrent radiotherapy, the standard treatments for locally advanced unresectable NSCLC have reach a plateau. New therapeutic combinations of molecular targeted drugs are needed. IFCT-0803 phase II trial aimed to evaluate the benefit of adding cetuximab to a combination of radio and concomitant chemotherapy with cisplatin and pemetrexed in patients with stage III, non-squamous NSCLC. **Methods:** Based on a 2-stage Simon approach, a total of 106 patients were to accrue. An interim analysis of the first 34 patients authorized the continuation of the study. Eligible patients receive thoracic radiation (66 Gy) along with cisplatin (75 mg/m$^2$) and pemetrexed (500 mg/m$^2$) on D1 administered every 21 days for four cycles; weekly cetuximab (400 mg/m$^2$) for the first week, then 250 mg/m$^2$) is added from the first week of therapy for a total of 12 doses. The primary objective is to assess the disease control rate at the 16th week (16W-DCR), one month after the treatment completion. **Results:** 99 patients at inclusion were: 60 male, 57 years (median age), PS 0 = 60, ever smoker = 7, stage IIIA = 48 and IIIB = 49, adenocarcinoma = 77. Compliance was good for the first 92 eligible patients : Day 1 chemotherapy was administered to 100% of patients on cycle 1, 98.9% on cycle 2, 93.4% on cycle 3 and 84.8% on cycle 4. Radiotherapy protocol was respected: median was 33 for number of fractions, 66 Gy for total dose, 48 days for treatment duration. The endpoint 16W-DCR was 93.3 % (IC95% : 88.1 - 98.5). 30 patients had a maximal toxicity of grade 3 and 10 of grade 4. Two toxic deaths were observed, one by a traumatic subdural hematoma, as the patient experienced a grade 4 thrombocytemia, another occuring two months post-treatment completion, caused by a grade 4 radiation pneumonia, whereas concurrent cancer progression was documented. **Conclusions:** IFCT-0803 trial showed both the feasability and high DCR for radiation, cisplatin, pemetrexed and cetuximab combination, with a tolerable toxicity profile. Our data will be updated at the ASCO meeting, the accrual goal (106 pts) being reached on Jan. 2014. Clinical trial information: NCT01102231.

**7512 Poster Highlights Session (Board #5), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Multidisciplinary treatment for stage IIIA non-small cell lung cancer (NSCLC): Does institution matter?** *Presenting Author: Pamela Samson, Washington University in St. Louis, St. Louis, MO*

**Background:** It has been reported that survival is improved for early stage NSCLC when surgery is performed at high volume academic centers. However, the impact of institution has not been well described in the setting of surgery for stage IIIA NSCLC, in which a wide variety of neo-/adjuvant therapies are often employed. **Methods:** Treatment data of clinical stage IIIA NSCLC patients undergoing resection was obtained from the National Cancer Database (NCDB). Information on patient and tumor-related variables, therapy modalities, 30-day mortality, and survival was abstracted. Multivariable regression models were fitted to evaluate variables influencing 30-day mortality and overall survival (OS). **Results:** From 1998-2010, 11,492 clinical stage IIIA NSCLC patients were treated at community centers, while 7,743 patients were treated at academic centers. Academic center patients were more likely to be younger, female, non-Caucasian, live in an urban area, have a lower Charlson Comorbidity Index (CCI), and have a higher income and travel distance (all $p < 0.001$). Academic center patients were more likely to receive neoadjuvant chemotherapy (49.6% vs. 40.6%, $p < 0.001$). Increased 30-day mortality was associated with increasing age, male gender, pre-operative radiation therapy, increased CCI, and pneumonectomy. Patients undergoing surgery at academic centers experienced decreased 30-day mortality (OR 0.75, 95% CI 0.60 – 0.93, 3.3% vs. 4.5%, $p < 0.001$). Decreased long term survival was associated with increasing age, male gender, increased CCI, larger tumors, and pre-operative radiation therapy. Neoadjuvant chemotherapy (HR 0.66, 95% CI 0.62-0.70), surgery at an academic center (HR 0.92, 95% CI 0.88 – 0.97), and surgical treatment with lobectomy (HR 0.72, 95% CI 0.67 – 0.77) were associated with improved OS. Median OS for academic center patients was longer (33.8 vs. 28.9 months, $p < 0.001$). **Conclusions:** Stage IIIA NSCLC patients treated with pulmonary resection at academic centers had a lower 30-day mortality rate and increased OS compared to patients treated at community centers. Possible contributing factors include high-volume surgical centers and an increased rate of neoadjuvant chemotherapy.

**7513 Poster Highlights Session (Board #6), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Adjuvant erlotinib (E) versus placebo (P) in non-small cell lung cancer (NSCLC) patients (pts) with tumors carrying *EGFR*-sensitizing mutations from the RADIANT trial.** *Presenting Author: Frances A. Shepherd, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** E, anEGFR TKI, prolongs survival in pts with advanced NSCLC. Pts with tumors carrying *EGFR* exon 19 del or 21 L858R mutations are particularly sensitive to EGFR TKIs. **Methods:** RADIANT was a randomized trial of postoperative E *v* P in pts with completely resected stage IB-IIIA NSCLC. Pts were stratified by histology (adenocarcinoma, other), stage (IB, II, IIIA), adjuvant chemotherapy (yes, no), smoking history (never, current/former), *EGFR* FISH (positive, negative/undetermined) and country. Pts were randomized 2:1 to receive E 150mg/day or P for up to 2 yr. Among 973 randomized pts, *EGFR* mutation status was determined for 921 (95%); 161 (17%) had mutations (55% exon 19 del, 45% exon 21 L858R). These pts form the basis of this report. **Results:** Pts with mutations were more frequently female (65%) and non-smokers (63%); 47% had stage IB, 29% stage II, 22% stage IIIA; 49% received adjuvant chemotherapy; 47% were Asian. Some imbalances were observed (E: less chemo and lower stage; P: smaller tumor size). There were 102 pts randomized to E and 59 to P. Median duration (range) of treatment was 21.2 (0.16-22.93) m for E and 21.9 (2.43-22.93) m for P; 34 (34%) and 24 (41%) pts completed >22 m of E and P, respectively. DFS events occurred in 71 (44%) pts. Pts on E had longer disease-free survival (DFS) *v* P (median 46.4 *v* 28.5 m; HR 0.61, 95% CI 0.38-0.98, p=0.039); however, this result is not statistically significant due to the hierarchical testing procedure. The effect on DFS remained consistent after adjusting for other prognostic variables via an exploratory multivariate Cox model (HR 0.60, 95% CI 0.36-0.98, p=0.046). There were more brain relapses on E (40%) *v* P (13%), and fewer bone relapses 14% *v* 29%. Deaths occurred in 35 (21.7%) pts. There was no significant difference in overall survival (OS median not reached in either arm; HR 1.09, 95% CI 0.56-2.16, p=0.815). For drug-related events, AE, serious AE and discontinuations for AE were higher with E compared to P (98% *v* 61%; 4% *v* 0%; 25% *v* 0%, respectively). **Conclusions:** Although not statistically significant, these data suggest adjuvant E prolongs DFS in pts with completely resected *EGFR* mutated NSCLC. OS interpretation is limited. Clinical trial information: NCT00373425.

**7514 Poster Highlights Session (Board #7), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**SELECT: A multicenter phase II trial of adjuvant erlotinib in resected early-stage EGFR mutation-positive NSCLC.** *Presenting Author: Nathan A. Pennell, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

**Background:** EGFR mutant NSCLC is exquisitely sensitive to EGFR tyrosine kinase inhibitors (TKIs). Retrospective data suggests adjuvant TKIs may improve outcomes. This trial is the first to prospectively test the efficacy of adjuvant erlotinib in EGFR-mutant NSCLC. **Methods:** Eligible pts had resected stage IA-IIIA NSCLC harboring a TKI-sensitizing EGFR mutation. Pts were treated with erlotinib 150 mg/day for 2 years after completion of standard adjuvant chemotherapy and/or radiotherapy. With a sample size of 100 pts the study was powered to demonstrate a primary endpoint of 2-year disease free survival (DFS) >85%, compared to a historical control of 76% in resected early-stage EGFR-mutant NSCLC. **Results:** 100 pts were enrolled at 7 sites between 1/08 and 5/12; 45% stage I; 27% stage II; 28% stage IIIA. 89 pts have reached 2 year follow-up (2 year follow-up on the entire cohort will be presented at the annual meeting). Toxicities were typical of erlotinib with no G4/5 events and 1 G2 pulmonary fibrosis. 40% of pts required dose reduction to 100 mg/day and 16% two dose reductions to 50 mg/day. 69% of pts completed at least 22 months of erlotinib. With median follow-up of 3 years, the 2-year DFS is 90% (97% stage 1, 73% stage 2, 92% stage 3). Median DFS and OS have not been reached. 24 pts have recurred, only 2 during erlotinib treatment and 22 after stopping erlotinib with a median time to recurrence of 12 months after stopping erlotinib. 63% (n=15) of pts with recurrence underwent repeat biopsy, and only 1 T790M was detected. 71% (n=17) of recurrent pts were re-treated with erlotinib with 10 pts remaining on erlotinib, treatment range 2-42 months. 8 pts have died. **Conclusions:** Pts with EGFR mutation-positive NSCLC treated with adjuvant erlotinib have an improved 2-year DFS compared to historical genotype-matched controls. Recurrences are rare on erlotinib and most occur in the 12m after discontinuation, suggesting longer duration of adjuvant treatment may be beneficial. Recurrent cases after adjuvant erlotinib remain generally sensitive to EGFR TKIs. Clinical trial information: NCT00567359.

**7515 Poster Highlights Session (Board #8), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**NEOSCAN: Phase II trial of neoadjuvant chemotherapy for resectable lung cancers with switch to chemo alternative in $^{18}$F-FDG PET nonresponders.** *Presenting Author: Mark G. Kris, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Perioperative chemotherapy improves survival in pts with resectable lung cancers. Administering chemotherapy prior to surgery enables assessment of response and opportunity to switch non-responding pts to potentially more effective regimens. Response measured by PET correlates better than CT with clinical outcomes. This trial assessed PET-guided neoadjuvant chemotherapy, assigning pts with suboptimal PET response after 2 cycles of platinum-based therapy to alternative "switch" chemotherapy. **Methods:** We enrolled pts with clinical stage IB-IIIA NSCLCs (primary tumor >2 cm and SUVmax≥4.5) deemed to be resectable by a thoracic surgeon. All pts had a pretreatment PET. Pts received 2 cycles of cisplatin (or carboplatin) + gemcitabine (squamous) or pemetrexed (adenocarcinoma/other), followed by repeat PET. If PET showed ≥35% decrease in SUVmax, pts continued on platinum-based therapy. Pts with suboptimal response (<35% decrease) were switched to vinorelbine + docetaxel q2 weeks (2 doses = 1 cycle). The primary endpoint was partial metabolic response after 2 cycles of "switch" therapy as assessed by PERCIST (SUVmax decrease ≥30% using the pre-switch scan as new baseline). We powered the study to detect a 30% response rate to "switch" chemotherapy (≥6 responses in ≤25 pts who received vinorelbine + docetaxel). **Results:** 32 pts were enrolled (7 gemcitabine, 25 pemetrexed). 21 (66%) had >35% decrease in SUVmax and continued platinum-based therapy. 11 (34%) had <35% decrease and switched therapy. The study met its primary endpoint when 6 of 9 pts (66%, 95% CI 35-88%) who received vinorelbine + docetaxel had a PERCIST partial metabolic response. 27 pts have been surgically explored with 23 (85%) $R_0$ resections, including 7 of 7 who switched chemotherapy and were explored. There were no on-study deaths. **Conclusions:** Pts with resectable lung cancers who have a suboptimal PET response to histology-selected, platinum-doublet neoadjuvant chemotherapy can be effectively treated with vinorelbine and docetaxel followed by surgery. We now plan to correlate pathologic response in resected tumors with SUV change. Clinical trial information: NCT01443078.

**Driver mutations associated with smoking and other environmental factors: Prospective and integrative genomic analysis from the Japan Molecularepidemiology for Lung Cancer Study (JME).** *Presenting Author: Norimasa Ito, National Hospital Organization Kinki-Chuo Chest Medical Center, Osaka, Japan*

**Background:** Driver mutations are critical for lung cancer development as well as therapeutic targets. Its associations with environmental factors, sex hormones and virus remain elusive. **Methods:** This is a prospective, multicenter study on molecular epidemiology sponsored by the Japanese National Hospital Organization. Eligible are newly diagnosed patients with stage I to IIIB non-small cell lung cancer (NSCLC) who underwent surgery. Somatic mutations were examined by multiplex targeted deep sequencing (Illumina), validated by sensitive PCR methods, in surgical specimens, and human papilloma virus (HPV) using a PCR-based microarray system. The SWOG 0424 questionnaire was used to obtain information on patient demographics and detailed environmental factors. The sample size was 900 cases consisting of 450 ever-smokers and 450 never-smokers. **Results:** From July 2012 to December 2013, 958 patients were accrued from 43 institutions, and 901 samples were successfully tested for molecular analyses. Histology was adenocarcinoma (77 %), squamous cell carcinoma (16 %) and others (7 %). At least one somatic mutation was identified in 67 % of ever-smokers and 69 % of never-smokers. Common mutations were shown in the Table. 899 cases were also examined by Scorpion-ARMS method for KRAS and 864 cases by Cycleave method for EGFR, and the concordance rate between the deep sequencing and the PCR methods was 79.0 % in KRAS and 93.4 % in EGFR. Only 2 cases (0.3 %) were HPV-positive. **Conclusions:** The mutational spectrum showed a unique signature of exposure to smoking and other environmental factors. Little evidence was observed for an association between HPV and NSCLC. International collaboration with SWOG 0424 is planned to clarify the mechanisms of lung cancer development. Clinical trial information: UMIN000008177.

**PD-L1 expression and genotype in non-small cell lung cancer (NSCLC).** *Presenting Author: Sascha Ansen, Department I of Internal Medicine, Center for Integrated Oncology, University Hospital of Cologne, Cologne, Germany*

**Background:** Tumor cells expressing programmed cell death 1 ligand (PD-L1) are believed to suppress immune responses through activation of the PD-1/PD-L1 pathway. Recent data indicate that PD-L1 tumor status might be predictive for responses to PD-1- and PD-L1- directed therapies. **Methods:** PD-L1 expression was evaluated in genomically annotated 259 adenocarcinomas (AD) and 180 squamous cell carcinomas of the lung (SQ) using immunohistochemistry (IHC). Moreover, PD-L1 expression and its correlation with clinical data, histology and genotype were analyzed. **Results:** Tumors were considered PD-L1 positive if tumor cells showed at least weak membranous staining by IHC. 83 of 259 patients (pts.) with AD were positive for PD-L1 surface expression (=32,0%). The observed staining intensity was weak, intermediate and strong in 38, 33 and 12 cases respectively. 55 of 180 pts. with SQ were PD-L1$^{+}$(=30,6%). The observed staining intensity was weak, intermediate and strong in 27, 21 and 7 cases respectively. For AD and SQ no significant association between PD-L1 expression and clinical characteristics (gender, smoking history, stage) could be found. PD-L1 expression in AD or SQ was not significantly associated with ALK translocation (n=178; n=138), BRAF mutation (mut.) (n=113; n=98), DDR2 mut. (n=59; n=64), EGFR mut. (n=124; n=101), FGFR2 mut. (n= 117; n=91), HRAS mut. (n=94; n=73), KRAS mut. (SQ, n=101), NFE2L2_exon2 mut. (AD, n=97), NRAS mut. (n=109; n=81), PIK3CA mut. (n=121; n=99), STK11 mut. (SQ, n=101), TP53 mut. (n=124; n=101) or RB1 deletion (SQ, n=109). However, PD-L1 expression in AD is significantly more frequent in KRAS mutated than in KRAS wild-type samples (n=126; p=0,002) and significantly more frequent in samples with deletion of RB1 (n=143; p=0,024). On the contrary, PD-L1 expression in AD is significantly less frequent in samples with STK11 mutations (n=122; p=0,022). Finally, PD-L1 expression in SQ is significantly more frequent in samples with a mutation in exon 2 of NFE2L2 (n=88; p=0,025). **Conclusions:** PD-L1 expression in the two most common histological NSCLC subtypes is associated with distinct genotypes that might further facilitate identification of pts. most suitable for therapeutic anti PD-1 and anti PD-L1 intervention.

**7518 Poster Highlights Session (Board #11), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Second primary lung cancers: Analysis of E5597 selenium chemoprevention study.** *Presenting Author: Rathi Narayana Pillai, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Non-small cell lung cancer (NSCLC) patients that undergo curative resection are at risk for development of second primary lung cancer (SPLC). The E5597 trial is the largest placebo-controlled lung cancer chemoprevention study conducted in the US. We report on the SPLC diagnosed in this cohort. **Methods:** E5597 randomized 1,561 (2:1) patients with resected stage I NSCLC to selenium or placebo for a total of four years with the primary objective of decreasing the incidence of SPLC. The study was stopped at first interim analysis for futility in October 2009. The participants were followed for incidence of all second primary tumors (SPT). **Results:** There were 290 (19%) incidences of SPT, of which 113 (7.2%) were SPLC among 112 cases (1 case with 2 incidences) as of January 2014 with median follow-up time of 5.6 years. 82 incidences in 81 cases occurred in the selenium arm (S) and 31 cases in the placebo arm (P). The median age was 67 years, and there were a higher proportion of women (52.7%). Although several patients continued smoking or had only quit within a year of SPLC (40.2%), most patients had quit smoking for at least one year (57.2%). The most common histology was adenocarcinoma (40.7%), followed by other (30.1%), squamous cell (25.6%), and large cell (1.8%). Almost all SPLC cases were detected by imaging (88.5%), but 31.9% were also clinically evident. Nearly two thirds of SPLC were stage I-II (61%). The incidence rates of SPLC were higher in the S arm compared to P arm: 1.42 versus 1.05 per 100 person years, respectively (95% CI 0.77-2.38). The median time to SPLC from randomization was 3.0 years (range 0.9-9.3 years) and from initial diagnosis of lung cancer was 4.2 years (range 0.8-28.5). **Conclusions:** SPLC is the most common second primary cancer in NSCLC patients. Continued surveillance even after tobacco cessation, is warranted for earlier detection of SPLC.

**7519 Poster Highlights Session (Board #12), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized phase III trial in extensive-disease small cell lung cancer comparing first-line etoposide to topotecan in combination with platinum.** *Presenting Author: Morten Mau-Soerensen, Department of Oncology, Rigshospitalet, Copenhagen, Denmark*

**Background:** Randomized trials in extensive disease (ED) small cell lung cancer (SCLC) comparing the camptothecins to standard etoposide based chemotherapy have reached conflicting results. Here we report the results of an interim analysis of a phase III trial randomly allocating patients (pts) with ED SCLC to etoposide or topotecan in combination with platinum. **Methods:** Previously untreated pts with ED SCLC were randomized to six cycles of T (topotecan 2.0 mg/m$^2$ IV, day 1-3; cisplatin 50 mg/m$^2$ IV, day 3) or E (etoposide 120 mg/m$^2$, day 1-3; carboplatin IV AUC = 5, day 1) every 3 weeks. Primary end-point was overall survival (OS) and secondary end-points were response, progression-free survival (PFS), and safety. A sample size of 380 pts was estimated to detect an increase in 2-year survival from 7.5 to 15 % ($\alpha$=0.05, $\beta$=0.20.) ClinicalTrials.gov NCT 00812266. **Results:** The trial was prematurely stopped due to poor accrual according to a pre-planned interim analysis after the accrual of 281 pts reducing power to 0.66. Prognostic factors were equally balanced between arms. WHO performance status > 2 were recorded in 20.0% and 50% were females. Median age was 64 years (40 – 82). Most frequent grade 3/4 non-hematological adverse events (AEs) were infections (E 17.1 vs T 12.1%) and fatigue (E 14.2 vs T 12.7%). Most common grade 1/2 non-hematological AEs were alopecia (E 91.3 vs T 88.0%), nausea (E 55.9 vs T 57.9%) vomiting (E 27.6 vs T 24.1%), auditory toxicity (E 25.2 vs T 33.8%), and neuropathy (E 33.9 vs T 39.8%). Grade 4 leuco- and thrombocytopenia were observed in 21.1 and 12.8% of pts in arm E, respectively, compared to 6.7 and 5.2% in arm T ($p < 0.01$). Overall response rates were 69.1 % in arm E compared to 59.8% in arm T (NS). Median PFS was 6.6 months in E arm and 6.9 month in arm T, HR = 0.93, 95% CI 0.72-1.19, p=0.55. Median OS and 2-yr survival rates were 10.9 months and 9.2% in arm T, compared to 9.8 months and 8.7% in arm E, respectively, HR = 0.87, 95% CI 0.67-1.17, p=0.26. **Conclusions:** No differences in OS or PFS were observed comparing first line E with T in ED SCLC. Significantly more hematological toxicity was noted in the E arm. A biomarker study is planned to identify pts that derive most benefit from either T or E. Clinical trial information: NCT00812266.

**7520 Poster Highlights Session (Board #13), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized phase 2 trial comparing amrubicin (A) with re-challenge of platinum doublet (P) in patients (pts) with sensitive-relapsed small-cell lung cancer (SCLC).** *Presenting Author: Atsushi Nakamura, Sendai Kousei Hospital, Sendai, Japan*

**Background:** When this trial was planned, A was believed to be a promising new anthracycline agent for sensitive-relapsed SCLC. While re-challenge of P that had been used for the first-line treatment was also believed to be effective for sensitive-relapsed SCLC, although prospective evaluation of it had not been reported. Thus this randomized phase 2 study was conducted to select A or P for future phase 3 trial. **Methods:** Sensitive-relapsed SCLC pts were randomized to receive A (40 mg/m2, day1-3, every 3 weeks) or P (every 3-4 weeks). The modification of P such as the 20%-dose reduction of combined third-generation or change of platinum agent from cisplatin to carboplatin according to patients' condition was permitted. The primary endpoint was overall response rate (ORR), and secondary endpoints were progression-free survival (PFS) and toxicity profile. According to the Simon's Two-Stage phase 2 design, 28 pts were required in each arm (p0=0.3, p1=0.5, alpha=0.10, beta=0.20), and the treatment that achieved $>$ 12 out of 28 pts with partial response would be judged as effective. **Results:** From February 2008 to June 2013, 60 pts were enrolled from 14 institutions. Two patients in A arm and one patient in P arm did not receive any protocol treatment due to rapid disease progression. Evaluated patients' characteristics were as follows: Male/Female, 53/4; median age, 66 (range 44-80); Performance status 0/1/2, 32/21/4. The median numbers of treatment cycles were 4 (range 2-8) in A arm and 3 (range 1-7) in P arm. ORRs and disease control rates were 67% (90%CI, 52-82) and 86% for A, and 43% (90%CI, 28-58) and 80% for P, respectively. Median PFS was 5.4 months in A arm and 5.0 months in P arm. Grade 3 toxicity was observed in 33% of patients in A arm including 19% of febrile neutropenia, while 17% in P arm without any febrile neutropenia. There was no grade 4 toxicity or treatment-related death in this trial. **Conclusions:** Both treatments met the primary endpoint. Since A produced higher ORR and median PFS than P with acceptable toxicity, we select A for subsequent phase 3 trial. Clinical trial information: UMIN000002617.

**7521 Poster Highlights Session (Board #14), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized phase 2 study of carboplatin plus irinotecan (CI) versus carboplatin plus amrubicin (CA) for extensive disease small-cell lung cancer (ED-SCLC): NJLCG0901.** *Presenting Author: Yosuke Kawashima, Sendai Kousei Hospital, Sendai, Japan*

**Background:** Cisplatin-based regimens are standard first-line chemotherapy for ED-SCLC. In patients unfit for cisplatin due to advanced age or poor performance status (PS), carboplatin plus etoposide (CE) is as effective as cisplatin plus etoposide (JCOG9702 trial). Carboplatin plus irinotecan (CI) and carboplatin plus amrubicin (CA) are promising new carboplatin-based regimens identified in our previous studies (NJLCG0405 and NJCLG0701). Accordingly, we conducted this randomized phase 2 study to identify the appropriate regimen for comparison with CE in future phase 3 trials. **Methods:** Chemotherapy-naïve ED-SCLC patients were randomly assigned to receive 4–6 cycles of carboplatin (area under the curve [AUC] 5.0, day 1) plus irinotecan (70 mg/m$^2$, days 1 and 8) every 3 weeks (CI arm) or carboplatin (AUC 4.0, day 1) plus amrubicin (35 mg/m$^2$, days 1–3) every 3 weeks (CA arm). The primary endpoint was the overall response rate (ORR). Secondary endpoints were progression-free survival (PFS), overall survival(OS), and toxicity. Assuming that an ORR of 80% in eligible patients indicates potential usefulness and an ORR of 60% is the lower limit of interest, the target sample size was 35 patients in each arm (alpha, 0.05; beta, 0.20). **Results:** Between December 2009 and March 2013, 71 patients were enrolled. One patient in each arm did not receive any protocol treatment due to rapid disease progression. Characteristics of treated patients were as follows: median age, 70 years (range 51–84 years); proportion of males, 84%. The ORRs were 79% (95% confidence interval [CI]: 62–91) and 89% (95%CI: 73–97), median PFS were 5.1 and 6.3 months (hazard ratio [HR] = 0.51, 95%CI: 0.30–0.85, p = 0.01), and median OS were 14.9 and 15.9 months in the CI and CA arms, respectively. Toxicities of grade 3 or higher severity were neutropenia (CI, 53% and CA, 89%), anemia (CI, 26% and CA, 20%), thrombocytopenia (CI, 18% and CA, 14%), and febrile neutropenia (CI, 12% and CA, 29%). No treatment-related deaths were observed. **Conclusions:** CA was numerically effective than CI in chemo-naïve ED-SCLC patients, with acceptable toxicity. CA could be selected for future phase 3 trials. Clinical trial information: UMIN000008970.

**7522 Poster Highlights Session (Board #15), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Safety and antitumor activity of the PARP inhibitor BMN673 in a phase 1 trial recruiting metastatic small-cell lung cancer (SCLC) and germline BRCA-mutation carrier cancer patients.** *Presenting Author: Zev A. Wainberg, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA*

**Background:** BMN 673 is the most potent inhibitor of PARP1/2 in clinical development (IC50$<$1nM), inducing synthetic lethality in tumors deficient in homologous recombination. Based on preclinical data showing high PARP expression in SCLC models and significant antitumor activity of BMN 673, an expansion cohort of SCLC patients was also studied. **Methods:** Safety, pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity of BMN 673 were evaluated in a 2-stage study. In dose escalation (Stage 1), cycle 1 was 6 wks, with drug taken on days 1 and 8-35, for PK and PD assays, followed by daily continuous dosing in 4-wk cycles. Stage 2(expansion at MTD) recruited pts with tumors defective in DNA repair: Previously treated extensive stage SCLC (second line), Ewing's sarcoma (ES), or tumors in germline (g) BRCA mutation (mut) carriers. **Results:** Stage 1: The MTD and Recommended Phase 2 Dose (RP2D) was established at 1 mg/d in 39 pts (33F/6M) treated at doses ranging from 25 to 1100 $\mu$g/d. Dose-limiting thrombocytopenia occurred in 1/6 and 2/5 pts at 900 and 1100 $\mu$g/d, respectively. Stage 2: To date, 54 pts [38F/16M, median age 52 (range 18-78)] have been enrolled: 15 SCLC, 12 ES and 27 gBRCA mut. RECIST confirmed responses have been reported in 2/11 (18%) evaluable previously treated SCLC pts [Clinical Benefit Rate (PR+SD $>$ 8 wks): 6/11 pts (55%); median PFS: 7.4 wks, 95% CI 4.3-19.4]; 12/26 (46%) gBRCA mut ovarian cancer pts (median PFS: 32.3 wks, 95%CI 28.2-38.6); and 8/18 (44%) gBRCA mut breast cancer pts (median PFS: 31 wks, 95% CI 13.1-45.4). No responses were seen in ES pts. Overall, the most frequent adverse events were mild to moderate and included fatigue (all grades=30%), nausea (26%), alopecia (25%), anemia (23%), thrombocytopenia (20%) and neutropenia (14%). **Conclusions:** BMN 673 is well tolerated at the RP2D of 1 mg/d. BMN 673 has antitumor activity in pts with advanced previously treated SCLC and significant activity in pts with gBRCA mut ovarian and breast cancer. A phase 3 trial in gBRCA mut breast cancer is ongoing. Clinical trial information: NCT01286987.

**7523 Poster Highlights Session (Board #16), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase 1 study of veliparib, a poly (ADP-ribose) polymerase (PARP) inhibitor, in combination with cisplatin and etoposide in extensive-stage small cell lung cancer (SCLC) patients: An Eastern Cooperative Oncology Group study (E2511).** *Presenting Author: Taofeek Kunle Owonikoko, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Veliparib is a small molecule inhibitor of PARP currently in advanced clinical testing. Based on promising preclinical evidence of therapeutic potentiation when combined with cisplatin and etoposide in SCLC, a phase 1 study was conducted to establish the safety of the 3-drug combination. **Methods:** The study employed the 3+3 dose escalation design to establish the safety and recommended phase 2 dose (RP2D) of veliparib when combined with fixed doses of cisplatin (75mg/m$^2$ on D1) and etoposide (100mg/m$^2$on D1-3) without prophylactic growth factor support in a 21-day cycle. The starting dose of Veliparib was 60mg (bid D1-7) with plan to escalate to 100mg (D1-7) if no dose limiting toxicity (DLT) or de-escalate to 40mg (bid D1-7) if DLT was observed in 2 of 3 or $\geq$2 of 6 treated patients. Patients with treatment-naïve, extensive stage SCLC were included. DLT was assessed during cycle 1. **Results:** The study enrolled 9 patients with extensive stage SCLC; Gender: M/F (4/5); Age: median/range (60, 51-78); Race: White/African American (8/1). Veliparib was well tolerated at the 60mg dose (0 of 3 patients with DLT). DLT was seen in 1 of 6 patients treated at the 100mg dose (grade 5 cardiac failure). We established the maximum tolerated dose of veliparib of 100mg bid on D1-7 in combination with standard doses of cisplatin and etoposide as the RP2D. Grades 3-5 adverse events irrespective of attribution included - G3: dehydration (1), febrile neutropenia (1), hyponatremia (1), diarrhea (1), nausea (3), thrombocytopenia (1), fatigue (2), neutropenia (1), leukopenia (3); G4: hyponatremia (1), respiratory failure (1), thrombocytopenia (1), neutropenia (5), leukopenia (2); G5: heart failure (1). Unconfirmed investigator-assessed efficacy outcome in 7 evaluable patients were stable disease in 2/7 (28.6%), partial response in 4/7 (57.1%) and complete response in 1/7 (14.3%) patients. **Conclusions:** The study demonstrated the safety of combining veliparib with cisplatin and etoposide in previously untreated SCLC patients. A randomized phase II efficacy study of this combination is currently ongoing. Clinical trial information: NCT01642251.

**7524 Poster Highlights Session (Board #17), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Analysis of small cell lung cancer (SCLC) patients (Pts) treated on cancer therapy evaluation program (CTEP)-sponsored phase I trials: 1992-2012.** *Presenting Author: Patrick M. Forde, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Platinum-refractory SCLC has a poor prognosis with a median survival of 2-6 months. Second-line and later treatment options are limited and pretreated patients with preserved ECOG performance status (PS) are often considered for early phase clinical trials in solid tumors. We conducted an analysis of the CTEP database and report the largest cohort to date of SCLC pts treated on phase I studies. **Methods:** Data from all SCLC patients enrolled on CTEP-sponsored phase I trials from 1992-2012 were analyzed. Trials were conducted at the National Institutes of Health and other institutions in the United States under CTEP sponsorship. Trials were categorized as chemotherapy (C), biologic therapy (B), combined biologic-chemotherapy therapy (BC) or immunotherapy (I). Demographics, rates of toxicities, response rate (RR), clinical benefit rate (CBR = RR +stable disease rate) and treatment duration were analyzed using descriptive statistics. **Results:** 84 pts enrolled during the specified time period, (median age 59 (interquartile range, IQR 52 – 63) ECOG PS 0-1 86.9%; 2, 11.9%; 3, 1.2%). The cohort was heavily pretreated (median 4 lines (IQR 2 – 5)). Pts received the following treatment types (no. of pts (%)) - C, 47 (56%); B, 18 (21.4%); BC, 14 (16.7%); I, 5 (6%). Treatment-related toxicities occurred as follows – grade 1/2, 71 (84.5%); grade 3/4, 39 (46.4%); grade 5, 1 (1.9%). RR was 6 (7.1%) and the CBR was 23 (27.1%). Responses only occurred with C (4 pts) and BC (2 pts). Median treatment duration was 42 days (IQR 25 – 63). **Conclusions:** Toxicities in phase I SCLC pts are higher than those previously reported in the general population of phase I solid tumor pts (G3/4 toxicity rate 46.4% vs. 36-38% (CTEP & non-CTEP databases)). This may partly reflect a relatively higher proportion of SCLC pts with ECOG PS >1 (13.1% vs. 6% of unselected solid tumor pts on CTEP phase I studies). CBR and median treatment duration are comparable to SCLC pts who have been treated with single agent chemotherapy in the second or subsequent line setting but lower than those observed in the general phase I pt population. Phase I study enrollment represents a reasonable option for pretreated SCLC pts with good ECOG PS.

**7525 Poster Highlights Session (Board #18), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II trial of sunitinib in patients with thymic epithelial tumors (TET).** *Presenting Author: Anish Thomas, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

**Background:** There are no standard treatments for patients with advanced TETs after failure of platinum-based chemotherapy. In thymic carcinoma, KIT over-expression and mutations are found in about 80% and 8% cases respectively. Expression of angiogenic markers correlates with invasiveness of TETs. This non-randomized, phase II trial evaluated the efficacy of sunitinib, whose targets include KIT and vascular endothelial growth factors (VEGFR), in TETs. **Methods:** Patients with TET who had progressive disease following at least one platinum-based chemotherapy were enrolled. Sunitinib was administered orally at 50 mg once daily in 6 week cycles for 4 weeks followed by 2 weeks off until disease progression. Tumor response was assessed by CT scans every 6 weeks. Correlative studies included exome sequencing of 197 cancer related genes and peripheral blood T cell subset analyses. Primary end point was objective response rate in 2 parallel cohorts [thymoma (T) and thymic carcinoma (TC)]. **Results:** Between May 2012 and October 2013, 24 patients with TC [median age 58 (41-81); males 63%] and 16 with T [median age 54 (31-74); males 44%] enrolled. Median of 4 (range, 1-11) and 5 (range, 1-12) cycles were administered in patients with TC and T respectively. Among 23 evaluable patients with TC, there were 6 (26%) partial responses, 15 (65%) stable disease [including 9 (39%) minor responses: 10-29% reduction] and 2 (9%) progressive disease. After median follow up of 13.9 months, the median progression-free survival (mPFS) for TC was 6.7 months and median overall survival (mOS) 16.3 months. In contrast, only 1 of 16 (6%) patients with T had a partial response, 12 (75%) stable disease [including 3 (19%) minor responses] and 3 (19%) progressive disease. After median follow-up of 12.7 months, the mPFS was 8.5 months for T and mOS not reached. Most common grade 3 or 4 sunitinib-related adverse events were lymphopenia, fatigue, oral pain and thrombocytopenia. KIT mutations were absent in 20 tumors assessed, which included 11 TC and 4 partial responders. **Conclusions:** Sunitinib demonstrated anti-tumor activity unprecedented for a targeted agent in previously treated patients with TC. Activity was modest in T. Tumor sequencing and T cell subset analyses will be presented. Clinical trial information: NCT01621568.

**7526 Poster Highlights Session (Board #19), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase II study of milciclib (PHA-848125AC) in patients (pts) with thymic carcinoma (TC).** *Presenting Author: Benjamin Besse, Gustave Roussy, Villejuif, France*

**Background:** TC and B3 thymoma (B3T) are rare malignant tumors of the thymus. Outcomes of clinical trials focusing on TC and B3T have highlighted the challenging nature of this disease and the need to identify new agents. Milciclib is an inhibitor of cyclic-dependent kinase and Src family members, and a limited number of additional kinases. We have initiated a single-arm Phase II study in advanced TC/B3T based on 2 partial responses (PRs, one pt with thymic carcinoma and one pt with B3 thymoma) observed in a phase I study conducted with Milciclib. **Methods:** Pts with histologically confirmed TC/B3T who received only one prior systemic therapy were enrolled. Pts received Milciclib 150 mg daily 7d on/7d off in 2-week cycles. The primary endpoint was progression free survival rate at 3 months (PFS-3 rate). Based on the Simon's 2-stage design, the sample size of 54 evaluable pts confers 80% power to reject the null hypothesis of a PFS-3 rate lower than 33% . At least 14 successes out of 54 evaluable patients were required for Milciclib to deserve further investigation. **Results:** To date, 43 pts have been treated (male/female 18/25; median age 55, range 21-80, TC/B3T 26/9). The second stage of the trial is ongoing and 599 cycles have been administered with a median number of 7 cycles/pts. Out of 30 pts whose data are available and mature, 14 are successes (PFS-3 rate = 46.7%; 95%CI 28.3-65.7%) including a RECIST 1.1 PR. Toxicity was generally moderate. The most common Grade 3-4 AE are nausea and asthenia (8.3%), vomiting, myasthenic syndrome, dehydration, hypophosphatemia, cytolytic hepatitis, plantar fascitis (4.2%). The most common Grade 3-4 hematological and biochemical toxicities are neutropenia (8.4%), creatinine, amylase and lipase increase (5.6%). **Conclusions:** The study has already met its predefined primary endpoint in treated patients and therefore we thought it was useful to report these data in a rare disease although the per protocol analysis is to be done on evaluable patients. This supports its full investigation as potential new therapeutic agent to treat TC/B3T. Clinical trial information: NCT01011439.

**7527 Poster Highlights Session (Board #20), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II study of everolimus in patients with thymoma and thymic carcinoma previously treated with cisplatin-based chemotherapy.** *Presenting Author: Paolo A. Zucali, Humanitas Cancer Center, Rozzano, Italy*

**Background:** Alterations of the serine-threonine kinase mammalian target of rapamycin (mTOR) signalling pathway are common in cancer, and thus mTOR is being actively pursued as a therapeutic target. In particular, mTOR is emerging as a potential target, following tumor responses observed in phase I trials, with recent data from several groups. The aim of this study is to determine the activity of Everolimus monotherapy in patients (pts) with advanced or recurrent thymoma (T) or thymic carcinoma (TC) previously treated with cisplatin-containing chemotherapy. **Methods:** Pre-treated T and TC pts were prospectively enrolled in single arm, single-stage, open label, multicentre, phase II trial. Pts received continuous treatment with oral everolimus 10 mg once daily until documented disease progression, unacceptable toxicity, or patient refusal. Tumour assessment was done every six weeks, safety was assessed every 21 days. A Fleming phase II trial was designed considering a disease control rate (DCR) of 40% or lower as clinically unworthy, whereas a rate of 60% or higher was considered of potential interest, $\alpha=\beta=0.10$. It was calculated that 21 pts with disease control would be observed in the first 41 evaluable pts. Progression free survival (PFS), overall survival (OS), and safety were also evaluated. **Results:** Results of the first 35 enrolled pts are presented. Patient characteristics are as follow: median age is 51 years (range 37;81), male/female 20/15 (57%/43%), TC/T 12/23 (34%/66%), and locally advanced/metastatic disease 9/26 (26%/74%). We observed complete remission (CR) in 1 patient (TC), partial response (PR) in 3 pts (2TC/1T), and stable disease (SD) in 21 pts (16T/5TC), for a total of 25 pts who reached DC.With a median follow up of 10 months, median PFS was 12.1 months, while median OS was 24.0months. Seven pts (20%) presented a serious adverse event but only 3 of them permanently discontinued treatment. **Conclusions:** The primary end-point of this study was reached. These results suggest that Everolimus is able to achieve a satisfactory number of DC in this setting of pts. The efficacy should be better evaluated in subsequent larger study phases. Clinical trial information: NCT02049047.

**7528 Poster Highlights Session (Board #21), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Capecitabine plus gemcitabine in thymic epithelial tumors: Final analysis of a phase II trial.** *Presenting Author: Carlo Buonerba, Department of Clinical Oncology and Endocrinology and Rare Tumors Reference Center Campania Region, University Federico II, Naples, Italy*

**Background:** Thymic epithelial tumors (TETs) are rare malignancies, with an estimated incidence of about 3 cases per 100,000 inhabitants. No standard treatment is available for recurrent disease. In 2005, a multi-institutional phase II trial was started on the combination of gemcitabine and capecitabine in pretreated patients with TETs. Final results of this phase II study are presented. **Methods:** Eligibility criteria for the study were mainly the following: histologic diagnosis of TET by central review; at least one prior systemic chemotherapy treatment; progressive disease. Treatment consisted of oral capecitabine (650 mg/mq twice daily on days 1–14) and i.v. gemcitabine (1000 mg/mq on days 1 and 8) every 3 weeks. The radiographic response rate was chosen as primary end point and employed to calculate the study sample. Secondary end points were progression-free survival, toxicity, and overall survival. **Results:** Thirty patients (18 men, 12 women; median age 57 years, range 48–61 years)were enrolled in this phase II trial from November, 2005 to June 2013. The majority of patients (73%) had thymoma, while the remaining had thymic carcinoma.Of note, 63% of patients showed disease progression within 2 months from the last dose of the last systemic therapy received. The most important grade 3 toxicity was neutropenia in eight patients. Twelve patients had a response (three complete responses and eight partial responses). Among thymic carcinoma patients, we observed three partial responses. Median PFS was 11 months (95% CI 3–17 months). The PFS for patients with thymoma and thymic carcinoma was 11 months (95% CI 6–17 months) and 6 months (95% CI 3–11 months), respectively. Thirteen patients are dead at the time of the analysis (median OS, 16 months). **Conclusions:** Capecitabine and gemcitabine is a highly active combination therapy in thymic epithelial tumors and should be routinely included in the managment of recurrent/metastatic disease.

**7529 Poster Highlights Session (Board #22), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Recurrence of epigenetic gene mutations in thymic epithelial carcinomas revealed by targeted exome sequencing of cancer-associated genes.** *Presenting Author: Yisong Wang, Georgetown University, Washington, DC*

**Background:** Genetic alterations and etiology of thymic epithelial tumors (TET) are largely unknown, hampering development of effective targeted therapies for TET patients. **Methods:** TET patients enrolled in a clinical trial of molecularly-guided targeted therapies underwent exome capture sequencing of 197 cancer-associated genes. Somatic non-synonymous sequence variations including missense, nonsense, splice site mutations and indels were identified by comparative sequence analyses of tumor/blood paired samples. **Results:** Targeted exome capture sequencing of 78 advanced stage TETs (46 thymic carcinomas and 32 thymomas)/blood pairs revealed a total of 134 somatic non-synonymous sequence variations in 68 genes. Somatic non-synonymous sequence variations were found in 50% (39/78) of the TETs analyzed. Thymic carcinomas (67%; 31/46) showed higher incidence of somatic non-synonymous mutations than thymomas (25%; 8/32)($p=0.0002$). TP53 (n = 13; 17%) was the most frequently mutated gene in TETs, and TP53 mutant patients showed poorer overall survival than TP53 wild-type patients ($p < 0.0001$). In thymic carcinomas, genes in epigenetic modification machinery [BAP1 (n = 6; 13%), SETD2 (n = 4; 9%), DNMT3A (n = 3; 7%), TET2 (n = 3; 7%), WT1 (n = 2; 4%), SMARCA4 (n = 2; 4%), and ASXL1 (n = 2; 4%)] were found recurrently mutated, whereas in thymomas, a preponderance of epigenetic gene mutations was not observed. **Conclusions:** Our results highlight the potential importance of epigenetic machinery in thymic carcinoma and indicate that substantial difference in genetic makeup exists between thymic carcinomas and thymomas. Targeting of epigenetic pathways may be of benefit to patients who carry those mutations.

**7530 Poster Highlights Session (Board #23), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Next-generation sequencing in malignant pleural mesothelioma: A retrospective study.** *Presenting Author: Giorgio V. Scagliotti, Department of Oncology, University of Turin AOU San Luigi Gonzaga, Orbassano, Italy*

**Background:** The understanding of molecular pathogenesis of malignant pleural mesothelioma (MPM) has lagged behind other common malignancies. According to the COSMIC database the most frequently mutated genes in MPM include CDKN2A, NF2 and BAP1, followed by other 12 genes having been found mutated in a fraction of MPM cases (c-MET, VHL, WT1, etc). **Methods:** A consecutive series of 123 MPM tissue samples with clinical annotates, collected at two institutions (Orbassano n=93; Alessandria n=30), were retrospectively analyzed through Next-Generation Sequencing (NGS) to explore genomic profiling.Genomic DNA was extracted by tumour microdissected, formalin-fixed, paraffin embedded (FFPE) samples. Amplicons NGS libraries for 50 oncogenes included in Ion AmpliSeq Cancer Hotspot Panel v.2 were generated as indicated, and sequenced in Personal Genome Machine Ion Torrent. Additional customized genomic analyses included all exons of BAP1 and NF2. Variant Caller included in Torrent Suite Software was utilised to identify mutations in the samples, annotation was performed with Annovar software. **Results:** All patients had advanced stage and were treated with pemetrexed-based chemotherapy, 70% were males, 50% current smokers, median age 66.5 (range 36-82) years and histological subtypes were 96/22/5 epithelioid/biphasic/sarcomatous. Synonymous/intronic variations represented 61.2% of all detected mutations. More frequently altered genes were APC, BAP1, CSF1R, FLT3, NF2, KDR, PIK3CA, TP53. Irrespective of allelic frequency, at least 1 variation in top genes was recorded in all patients, and at least 5 mutated genes were detected in 68 patients. KIT3 and PIK3CA mutations are associated with younger age while VHL1 and BAP1 with epithelioid histology. Moreover, BAP1 mutation is associated with negative nuclear protein expression at immunohistochemistry. **Conclusions:** These preliminary data indicate that NGS technology is feasible in FFPE MPM tissues and some of the detected genetic mutations are novel observations of potential prognostic and therapeutic interest.

**7531 Poster Highlights Session (Board #24), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase 2 single-arm study with tremelimumab at an optimized dosing schedule in second-line mesothelioma patients.** *Presenting Author: Luana Calabrò, Medical Oncology and Immunotherapy, University Hospital of Siena, Siena, Italy*

**Background:** We reported encouraging clinical activity of tremelimumab (treme), a fully human IgG 2 monoclonal antibody specific for cytotoxic T lymphocyte-associated antigen 4, at 15 mg/kg q3 months (mos), in second-line malignant mesothelioma (MM) patients (pts). Durable partial responses in 2 pts, 31% disease control, 10.7 mos median overall survival (OS), and 1- and 2-y survivals of 48% and 37% were observed (*Lancet Oncol*, 2013). These findings and pharmacokinetic studies in melanoma pts, led us exploring the activity and safety of treme at an optimized dosing schedule in MM pts in the MESOT-TREM-2012 study (ClinicalTrials.gov Id NCT01655888). **Methods:** MM pts progressing on a first-line platinum-based regimen received treme at 10 mg/kg i.v. on day 1, q4 weeks (wks) for 6 doses (induction phase), followed by q12-week dosing (maintenance phase), until progressing disease (PD) or severe toxicity. Primary endpoint was objective response (OR) rate; among secondary were DCR, OS, and safety. Tumor assessment *per* immune-related (Ir) RECIST Criteria was done at screening and q12 wks. Adverse events (AEs) were collected according to the CTC v3.0. **Results:** From July 2012 to July 2013, 29 MM pts, 20 males and 9 females, median age 65 (42-78) years, 11 stage III and 18 stage IV, ECOG performance status 0-1 (23 pts) or 2 (6 pts), were treated. Nineteen pts had a good EORTC prognostic score; 21 pts had epithelioid histotype, 6 biphasic, 1 sarcomatoid, and 1 undefined. As of Jan 2014, all pts received at least 1 dose of treme (median 6, range 1-10). The study met its primary endpoint since at a median follow-up of 14.5 mos 4 irPR were observed. Eleven pts had stable disease of median duration 7.7 mos (range 2.6-16.6+), and the irDCR was 51.7%. Median OS was 11.3 mos (95% CI: 5.6-17.0). Grade 1-2 and 3 treatment-related AEs occurred in 89.6% and 3.4% of pts, respectively; no grade 4 AEs occurred. Most common treatment-related AEs were gastrointestinal (65.5%), dermatologic (48.2%), and fever (34.4%). **Conclusions:** At an optimized dosing schedule treme continues to show clinical activity and an acceptable safety profile in MM pts. A phase 2b global trial is ongoing. Clinical trial information: NCT01655888.

**7532 Poster Highlights Session (Board #25), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Antimesothelin vaccine CRS-207 plus chemotherapy as front-line treatment for malignant pleural mesothelioma (MPM).** *Presenting Author: Raffit Hassan, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

**Background:** CRS-207 is live-attenuated *Listeria monocytogenes* engineered to express the tumor-associated antigen mesothelin which is highly expressed in malignant pleural mesothelioma (MPM). CRS-207 stimulates potent innate and adaptive cellular immunity. Chemotherapy may act synergistically in combination with CRS-207 by altering the tumor environment to be more susceptible to immune-mediated killing. **Methods:** Key eligibility criteria included patients who were chemotherapy-naïve, had unresectable MPM, good performance status (ECOG 0 or 1) and adequate organ function. Eligible patients received 2 prime vaccinations with CRS-207 ($1 \times 10^9$ CFU; 250 mL IV over 2 hours) 2 weeks apart, followed by up to 6 cycles of pemetrexed (500 mg/m$^2$) and cisplatin (75 mg/m$^2$) 3 weeks apart and 2 CRS-207 boost vaccinations 3 weeks apart. Subjects were followed every 8 weeks until disease progression. Clinically stable patients could continue CRS-207 maintenance vaccinations every 8 weeks. Objectives of the study were safety, immunogenicity, objective tumor responses and tumor marker kinetics. **Results:** Sixteen subjects (88% male; median age: 69) have been enrolled and as of Feb 1 2014, 13/16 are still on treatment. Median time on treatment was 134 days (range: 0-330 days). No treatment-related serious adverse events or unexpected toxicities have been observed. The most common adverse events related to CRS-207 were Grades 1/2 infusion-related fever, chills/rigors, hypotension and nausea/vomiting. Of 15 subjects evaluable for response, 60% (9/15) had confirmed partial response (PR) post CRS-207 and chemotherapy and 27% (4/15) had stable disease (SD). Treatment, follow-up and immune response evaluations are ongoing. **Conclusions:** CRS-207 can be safely combined with standard of care chemotherapy and showed encouraging anti-tumor activity with 9 out of 15 subjects having confirmed durable PR and 4 SD. These results are considerably better than those expected with chemotherapy alone and warrant further evaluation. Clinical trial information: NCT01675765.

**7533 General Poster Session (Board #141), Sat, 1:15 PM-5:00 PM**

**Postoperative chemotherapy as effective as preoperative for N2-positive stage III non-small cell lung cancer.** *Presenting Author: Daniel J Boffa, Yale School of Medicine, New Haven, CT*

**Background:** Neoadjuvant chemotherapy followed by surgery is superior to surgery alone for stage III non-small cell lung cancer (NSCLC) with mediastinal (N2) lymph node involvement. It is unclear, however, if postoperative (adjuvant) chemotherapy is as effective as preoperative (neoadjuvant) chemotherapy in this setting. The objective of this study was to determine the survival of resected stage III NSCLC according to the timing of chemotherapy. **Methods:** The National Cancer Database (NCDB) was queried for patients with clinical T1-4N2M0 NSCLC (clinical Stage III - N2) undergoing resection via lobectomy or pneumonectomy between 2003 and 2006. **Results:** The efficacy of post-operative (adjuvant) therapy in clinical Stage III - N2 NSCLC was evaluated in two ways. First we examined a cohort of 698 treatment-naïve (no preoperative treatment) clinical N2 patients confirmed to be pathologic N2 by the surgical resection of primary tumor (cN2pN2). We compared surgery "alone" to surgery followed by adjuvant chemotherapy. The 5-year survival of cN2pN2 patients was significantly higher with adjuvant chemotherapy (36%, n= 212) or chemoradiation (33%, n= 230) than surgery alone (21%, n= 256, p<.0001). In a multivariable analysis adjusting for patient demographics, tumor attributes, a modified Charlson comorbidity index and type of resection, the use of postoperative chemotherapy (HR, 0.66 95%CI [0.52-0.84], *p*=.0005) and chemoradiation (HR 0.75, 95%CI [0.59-0.95], *p*=.016) were both superior to surgery alone. There was no significant difference between chemotherapy and chemoradiation. We next directly compared postoperative chemotherapy (adjuvant) to preoperative therapy (neoadjuvant) in clinically staged III – clinical N2 NSCLC. A multivariable Cox model including variables noted above indicated that adjuvant therapy (n = 649) was associated with a similar outcome to neoadjuvant therapy (n = 1,356) HR 1.05, 95% CI [.92 – 1.18], p = .475). **Conclusions:** Chemotherapy appears to be similarly effective in stage III NSCLC patients with N2 disease when given before or after resection in the NCDB. This finding, could impact the role preoperative mediastinal staging in operable stage III lung cancer.

**7534 General Poster Session (Board #142), Sat, 1:15 PM-5:00 PM**

**When is a pathologic diagnosis preferred before stereotactic ablative radiotherapy for stage I lung cancer? A decision analysis.** *Presenting Author: Alexander V. Louie, Department of Radiation Oncology, London Regional Cancer Program, London, ON, Canada*

**Background:** The practice of treating a solitary pulmonary nodule (SPN) suspicious for stage I NSCLC with stereotactic ablative radiotherapy (SABR) in the absence of pathologic confirmation of malignancy is growing. In the absence of randomized evidence, the appropriate lung cancer prevalence threshold of when such a strategy is warranted can be informed using decision analysis. **Methods:** A decision tree and Markov model were constructed to evaluate the relative merits of observation, performing SABR without pathology, or performing a biopsy prior to SABR, when faced with a SPN at different lung cancer prevalences. Diagnostic characteristics, as well as disease, treatment, and toxicity parameters were extracted from the literature. Toxicity, recurrence rates, and health utilities (derived via mapping procedures) were abstracted from a prospectively collected database of 382 patients receiving SABR for confirmed or suspected stage I NSCLC. Deterministic analysis and probabilistic sensitivity analyses on all model inputs were performed to inform the appropriate lung cancer prevalence threshold between treatment strategies. The model was validated internally and externally. A 5-year time horizon using a cycle length of one month was employed and quality adjusted life years (QALYs) were discounted at a rate of 3%. **Results:** At a lung cancer prevalence of 65%, performing a biopsy was the preferred treatment strategy, yielding 2.640 QALYs, compared to 2.563 and 2.086 for the no biopsy and observation strategies, respectively. The prevalence threshold between observation and performing a biopsy was 17.0%; and between performing SABR without pathology and performing a biopsy prior to SABR was 85.0%. The latter finding was confirmed on probabilistic sensitivity analysis (85.2%; 95% CI: 80.0%–87.2%). This predicted lung cancer prevalence threshold was most sensitive to the diagnostic sensitivity of transthoracic biopsy (range: 77.2–94.0%). **Conclusions:** This model suggests that if there are concerns about increased morbidity related to biopsy for a SPN, SABR is warranted as a treatment strategy when the prevalence of lung cancer exceeds a point estimate of 85%.

**7535 General Poster Session (Board #143), Sat, 1:15 PM-5:00 PM**

**Analysis of treatment duration and safety of adjuvant erlotinib (E) versus placebo (P) after surgery in patients (pts) with non-small cell lung cancer (NSCLC): RADIANT trial.** *Presenting Author: Mary E.R. O'Brien, The Royal Marsden Hospital, Sutton, United Kingdom*

**Background:** We describe treatment duration and safety in the safety full analysis set (sFAS) and in the subset of pts with *EGFR* del19 and L858R mutations (*EGFR* M+). **Methods:** RADIANT was a randomized trial of adjuvant E *v* P in pts with stage IB-IIIA NSCLC following complete tumor resection w/ or w/o adjuvant chemotherapy. Pts were randomized (2:1) to receive up to 2 years of E 150mg/day or P. AEs were graded with NCI CTCAE v3.0. Dose reductions to 100mg and then 50mg were allowed; pts not tolerating 50mg/day were discontinued. **Results:** The sFAS included 954 pts, of whom 159 (16.7%) were *EGFR* M+. AEs led to treatment termination in 33.6% of pts on E versus 8.5% on P in sFAS, and 30% versus 5.1% in the *EGFR* M+ subset. In sFAS, 22.6% of E pts had Gr ≥3 skin disorders (rash, dermatitis acneiform, pruritus, etc.) and 6.2% had Gr ≥3 diarrhoea. The figures were similar for *EGFR* M+ pts. In sFAS, pts received 11.9 versus 21.9 m (median) of E versus P, and 27% *v* 46% were treated for >22 m. For *EGFR* M+ pts median treatment duration was 21-22 m in both arms and 34% versus 40.7% (E vs P) received >22 m of therapy. In sFAS, 26.7% versus 10.8% (E vs P) pts in received <3 m of therapy, as did 21% versus 8.5% *EGFR* M+ pts. AEs led to dose interruption, reduction, or both in 18.5, 24.5, 25.5% in sFAS; the figures were generally similar for *EGFR* M+ pts. **Conclusions:** The safety profile of E was consistent with that in advanced disease, although Gr ≥3 skin disorders was more frequent than previously reported in advanced NSCLC (9-14%). For E, AE frequency was similar between sFAS and *EGFR* M+ subset. While treatment duration was longer in the *EGFR* M+ subset than sFAS, frequency of AE leading to treatment termination was similar. Further investigation of E in *EGFR* M+ is warranted. Clinical trial information: NCT00373425.

**Nonadherence of adjuvant radiation in NSCLC patients with N2 disease after lobectomy.** *Presenting Author: Yan Xing, Department of Medicine, Harvard Medical School, Mount Auburn Hospital, Cambridge, MA*

**Background:** National Comprehensive Cancer Network (NCCN) guidelines recommend adjuvant radiotherapy (XRT) for NSCLC patients with N2 disease after lobectomy. The purpose of this study is to identify factors associated with non-adherence if any to NCCN guidelines for the above patients in a large population database. **Methods:** SEER registry was queried for NSCLC patients with N2 disease and lobectomy, diagnosed between 2004-2010. Patients with distant metastases were excluded. The study period was divided in two eras (2004-2006 and 2007-2010) because the landmark publication in this field by Lally et al. was published on Jun 12, 2006. Multivariate logistic regression analyses were performed to identify factors predicting non-adherence. **Results:** A total of 2,112 N2 NSCLC patients who had lobectomy were included in the final cohort, 773 (36.6%) of whom received adjuvant XRT according to NCCN guidelines. There were 34.3% and 38.3% of N2 NSCLC patients who received adjuvant XRT in 2004-2006 and 2007-2010 respectively. 40.3% of patients who had larger lymph nodes (LN) burden (≥ 20% LNs removed were positive) received adjuvant XRT compared to 28.2% in patients with small LN burden. Multivariate analyses revealed that age ≥ 70 years, unmarried, west region, diagnosed in early period (2004-2006), T1 and smaller LN burden were associated with non-adherence with guidelines (Table). **Conclusions:** Although treatment trends are improving since 2007, adjuvant XRT for NSCLC patients with N2 disease continues to be underutilized, particularly in the elderly, unmarried, west regions of the United States, T1 and smaller LN burden.

**Factors associated with no adjuvant XRT in N2 NSCLC patients after lobectomy.**

**KIF5B-RET fusion gene and oncogenic mutations of EGFR or KRAS gene in lung adenocarcinomas.** *Presenting Author: Jin Hyoung Kang, Division of Medical Oncology, Department of Internal Medicine,Seoul St.Mary's Hospital, The Catholic University, Seoul, South Korea*

**Background:** The KIF5B-RET rearrangement is detected with the frequency of 1~2% in 'triple marker'-negative lung adenocarcinomas, i.e., EGFR, KRAS and EML4-ALK wild type. These mutational changes are known to be mutually exclusive, but the co-existence of ALK rearrangement with activating mutations of EGFR is rarely found. **Methods:** We examined the KIF5B-RET fusion gene in frozen tissues from 156 surgically resected lung tumors using RT-PCR with direct sequencing and the mutation status of EGFR and KRAS genes using PNA clamping (PANAGENE, KOREA). We tested KIF5B-RET translocation in FFPE (Formalin Fixed Paraffin Embedded) using fluorescence in situ hybridization (FISH) with Zytolight Spec RET dual color break-apart probe (zytovision) and KIF5B-RET SY translocation FISH probe (abnova). We also measured c-RET mRNA and protein expression by qRT-PCR and immunohistochemistry (IHC), respectively. **Results:** The existence of KIF5B-RET fusion gene was identified in 11 pts (7.1 %). The mean age was 64.8(52~82) and M: F ratio 5:6. Of 11 pts, 3 pts (27.3 %) harbored wild type of EGFR and KRAS gene. However, KIF5B-RET fusion gene coincided with EGFR or KRAS mutation in 8 pts (72.7 %). These eight pts were also positive for both KIF5B-RET fusion (41.9%, 22.2~72.4 %) and RET break-apart probes (23.7%, 14.3~37.8 %). However, there were no correlations between RET mRNA and protein expression in the KIF5B-RET-positive pts. The median DFS and OS were 23.0 months (8.0~111) and 27.8 months (2.6~114.5), respectively. **Conclusions:** Taken together, our data suggest one-step screening platform for KIF5B-RET as well as EGFR, K-RAS, ALK oncogenic mutations be necessary for lung adenocarcinoma pts because EGFR or KRAS mutation are not infrequently found in KIF5B-RET-positive pts. Now, we are undergoing the clinical study for combined treatment of EGFR TKIs with RET inhibitors for lung adenocarcinoma pts harboring both KIF5B-RET rearrangement and EGFR mutation.

**7538 General Poster Session (Board #146), Sat, 1:15 PM-5:00 PM**

**A novel gene signature to predict distant metastasis in stage I lung cancer patient following local therapy with surgery or stereotactic body radiation therapy (SBRT).** *Presenting Author: Sungjune Kim, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** The standard management for stage I non-small cell lung cancer is surgical resection and SBRT. Adjuvant therapy is typically not given in this group of lung cancer patients. Unfortunately, 14% to 23% who undergo surgery for a stage I NSCLC ultimately fail distantly. **Methods:** Moffitt Cancer Center (MCC) has launched a major initiative termed Total Cancer Care (TCC) to innovate personalized compiling 40,000 tumor microarray databank linked to longitudinal clinical data. We conducted a retrospective chart review of pathologic T1-T2N0 NSCLC patients in the TCC database, and classified patients according to their recurrence pattern. CEL files from Affymetrix microarray from pathologic specimens from these patients were obtained from TCC, and gene expression profile was analyzed. **Results:** We identified a cohort of 143 patient treated with surgical resection. 56 patients were without evidence of disease at least 3 years following surgery (Control cohort), 34 patients failed locally and in regional lymph nodes (Loco-regional failure cohort), and 53 patients developed distant metastasis (distant failure cohort). 144 genes were identified that showed significant differences in RNA expression level between control cohort vs. distant failure cohort. However, only 1 gene was associated with loco-regional failure. 144 genes identified were validated against the Director's Challenge database. Over 90% of the genes identified from this study correctly predicted survival outcome from the Director's Challenge database. **Conclusions:** We have identified a group of genes that predict distant metastasis among surgically resected pathologic T1-T2N0 adenocarcinoma of the lung. We are currently developing the scoring system to classify this earliest stage lung adenocarcinoma patients into 3 groups, low risk, intermediate risk, and high risk for distant failure based on our gene signature. The outcome of this study will identify a select group of stage I lung adenocarcinoma patients who will benefit from adjuvant chemotherapy after local therapy with surgery or SBRT. Ultimately, we are planning to translate these findings to a clinical trial.

**7539^ General Poster Session (Board #147), Sat, 1:15 PM-5:00 PM**

**Final overall survival (OS) results from a phase II study of pemetrexed (Pem) and cisplatin (Cis) with concurrent thoracic radiation (RT) after Pem-Cis induction in patients with unresectable locally advanced (LA) nonsquamous non-small cell lung cancer (NS-NSCLC).** *Presenting Author: Silvia Novello, S. Luigi Hospital, University of Turin, Orbassano, Italy*

**Background:** This single arm multicenter phase II study assessed the efficacy and safety of Pem-Cis induction chemotherapy (CT) followed by full-dose Pem-Cis + concurrent RT in patients (pts) with LA NS-NSCLC. The 1yr PFS rate (primary endpoint) was 51.3% (ECCO 2013), incidences of Grade (G)3/4 (esophagitis 12%, neutropenia 11%) and G1/2 toxicities were low during CT and CT+RT (ECCO 2013, WCLC 2013). Here we report the final results after 2yr follow-up. **Methods:** Pts with unresectable Stage IIIA/B NS-NSCLC (AJCC V6) and ECOG-PS 0-1 received 2 cycles of Pem 500/Cis 75mg/m$^2$on Day (d)1, q21d. Pts who did not progress, with no residual neurological toxicity >G2, ECOG-PS 0-1 and lung V20<35% continued with 2 cycles of full dose Pem-Cis + concurrent RT (2Gy/fraction, 66Gy total). All pts received vitamin supplementation/dexamethasone prophylaxis as per Pem label. **Results:** Of 90 pts enrolled (all treated), 75 (83.3%) completed induction CT and started concurrent CT+RT (baseline for 90/75 pts: median age 61/62yrs, male 57%/53%, ECOG-PS 0 66%/65%, mean (SD) FEV 2.3(0.62)/2.3(0.59)L, adeno 90%/92%, Stage IIIA 36%/37%). Post discontinuation, 16.7% of pts had surgery, 26.7% RT, and 36.7% systemic CT. Median OS was 26.2mo (table). Tumor response rate (table) included 9 CRs (10.0%; 6 after surgery, 3 after CT-RT only), all were still progression-free at study end (CR for 3.8-19.6mo). Late toxicities included serious adverse events (SAE) related to study drug (3 pts: G3 leukopenia, G3 hypoacusis, G2 pulmonary embolism) and SAEs of radiation pneumonitis (2 pts: 1 G3, 1 G2). **Conclusions:** Pem-Cis induction CT followed by full-dose Pem-Cis and concurrent RT was effective (median OS 26mo), acute and late toxicity was manageable during both induction CT and concurrent CT+RT. Clinical trial information: NCT01000480.

**Impact of comorbidity and age on survival among older veterans with early stage non-small cell lung cancer (NSCLC).** *Presenting Author: Melisa L. Wong, University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA*

**Background:** Older age has been shown to be a stronger predictor of treatment receipt than comorbidity for NSCLC of all stages. We hypothesized that comorbidity would be a stronger predictor of survival than age among veterans with early stage NSCLC. **Methods:** We obtained first-line treatment and overall survival to 5 years from the Veterans Affairs Central Cancer Registry for 6,361 veterans age ≥ 65 diagnosed with stage I-II NSCLC from 2003-2008. Veterans were grouped by age (65-74, ≥ 75), Charlson comorbidity index (CCI 0, 1-3, ≥ 4), and stratified by first-line treatment. Log-rank tests and Cox proportional hazards models were used to identify differences in 5-year survival according to comorbidity and age. **Results:** Median age at diagnosis was 74 and median CCI was 2 (range 0-13). 2,840 (45%) patients received surgery: 2,219 lobectomies (includes 135 pneumonectomies) and 621 sublobar resections. 1,645 (26%) patients received radiation and 1,876 (29%) received other/no treatment. When stratified by age and comorbidity, veterans with CCI 0 who underwent surgery had similar 5-year survival regardless of age and veterans with CCI ≥ 4 had the worst 5-year survival across all treatment groups. In the lobectomy group, 5-year survival for veterans with CCI 0 was 64% for age 65-74 and 59% for age ≥ 75; for veterans with CCI ≥ 4, 5-year survival was 49% for age 65-74 and 50% for age ≥ 75 (log-rank test, p = .002). In multivariable analysis, severe comorbidity was one of the strongest predictors of 5-year survival for all treatment groups along with stage and geographic region. The hazard ratio for 5-year mortality for CCI ≥ 4 was 1.45 (95% CI 1.16-1.83) in the lobectomy group and 1.75 (95% CI 1.11-2.75) in the sublobar resection group. Age had only a modest effect on mortality in the lobectomy group (HR 1.16; 95% CI 1.01-1.34) and radiation group (HR 1.15; 95% CI 1.01-1.31) but was not prognostic in the other treatment groups. **Conclusions:** Severe comorbidity is a much stronger predictor of overall survival than age in early stage NSCLC. Therefore, elderly patients with minimal comorbidity should be considered for surgical evaluation.

**7541 General Poster Session (Board #149), Sat, 1:15 PM-5:00 PM**

**Patterns of surveillance after curative intent surgery in elderly stage I-IIIA non-small cell lung cancer patients.** *Presenting Author: Christine Agnes Ciunci, Hospital of the University of Pennsylvania, Philadelphia, PA*

**Background:** The optimal strategy for imaging surveillance of stage I-IIIA non-small cell lung cancer (NSCLC) patients (pts) after curative intent surgery is unknown. In general, current guidelines recommend imaging with chest CT every 6-12 months for the first 2 years, then annually. In the absence of strong evidence to implement guidelines, variability in imaging has been noted in limited survey data. There are no population studies identifying how pts are being followed in practice. **Methods:** We performed an observational retrospective cohort study using the Surveillance, Epidemiology and End Results (SEER)-Medicare database to determine the primary surveillance modality, either chest CT or chest x-ray (CXR), in elderly stage I-IIIA NSCLC pts who underwent lobectomy or pneumonectomy. We defined the primary modality as CT for pts undergoing at least 1 CT in both years 1 and 2 of surveillance, and as CXR for pts who did not fit the CT criteria, and who had at least 2 CXR's in both years 1 and 2 of surveillance. **Results:** 10,959pts were identified as undergoing curative intent surgery, of whom 94% had lobectomy and 6% had pneumonectomy. 58% of pts were ages 65-74, and 42% were 75 or older. 50% of pts were female. 70%, 16% and 14% of pts were stage I, II and IIIA respectively. 68% had non-squamous histology and 32% had squamous. 5,714 (52%) pts were followed by CT surveillance, and 2,491 (23%) were followed by CXR. 2,754 (25%) pts did not fit the criteria for either.Despite current guidelines, only 47% of stage I, 63% of stage II, and 66% of stage IIIA pts completed at least 1 CT in both years 1 and 2 after surgery. In this population, as stage and age decreased, surveillance of some sort was used less frequently ($p<0.001$), and CXR over CT surveillance increased ($p<0.001$). Pneumonectomy pts were more likely than lobectomy pts to have surveillance ($p=0.002$). **Conclusions:** This is the first population-based study to characterize the patterns of surveillance after curative intent surgery in elderly NSCLC pts. More evidence is needed to evaluate the effectiveness of different surveillance strategies to better shape guidelines and practice.

**7542 General Poster Session (Board #150), Sat, 1:15 PM-5:00 PM**

**Phase II study of induction chemotherapy with carboplatin, paclitaxel, and bevacizumab followed by surgery in patients with stage III nonsquamous non-small cell lung cancer: The Tokyo Cooperative Oncology Group trial (TCOG1002)** *Presenting Author: Toshihiko Iizasa, Chiba Cancer Center, Chiba, Japan*

**Background:** The clinical staging and treatment of locally advanced non-squamous non-small-cell lung cancer (NSCLC) remains controversial. We performed a phase II trial of induction chemotherapy with carboplatin, paclitaxel, and bevacizumab followed by surgery in patients with stage III non-squamous NSCLC. **Methods:** This study was a multicenter phase II trial (TCOG 1002). After staging N status by endobronchial ultrasonography or positron emission tomography, patients with stage III non-squamous NSCLC received induction chemotherapy with carboplatin (AUC6), paclitaxel (200mg/m$^2$), and bevacizumab (15mg/kg) twice every 3 weeks, followed by carboplatin (AUC6) and paclitaxel (200mg/m$^2$) 3 weeks later. Surgery was then performed. The primary endpoint was overall response rate. **Results:** Among 26 patients enrolled, 24 underwent surgery after induction chemotherapy. Their demographic characteristics were as follows: 12 men and 12 women, 42 to 73 years of age (mean 58.7 ± 8.3 years); 23 adenocarcinomas; stage IIIA, 22 patients and stage IIIB, 2 patients; performance status (PS) 0, 22 patients. Induction chemotherapy was completed according to the protocol in 21 (88%) of the 24 patients. The response rate was 62.5% (partial remission, 15 patients; stable disease, 9 patients). The most frequent grade 3-4 toxicities were neutropenia, 16 cases; leukopenia, 4 cases; liver dysfunction, 2 cases; hypertension 1 case; and febrile neutropenia, 1 case. Complete resection was performed in 20 (83%) of the 24 patients (17 lobectomies and 5 bilobectomies). There were no severe perioperative complications. The pathological response rate was 32% (complete response, 1; major response, 6; minor response, 15). Nodal downstaging was found in 6 patients (N0, 4; N1, 2). **Conclusions:** Induction chemotherapy with carboplatin, paclitaxel, and bevacizumab followed by surgery is safe and feasible in patients with stage III non-squamous NSCLC. Our results indicate that further studies are warranted to confirm the safety and efficacy ofthis treatment regimenin stage III non-squamous NSCLC. Clinical trial information: UMIN000004327.

**7543 General Poster Session (Board #151), Sat, 1:15 PM-5:00 PM**

**Stereotactic body radiotherapy versus lobectomy for operable clinical stage IA pulmonary adenocarcinoma: Comparison of prospective clinical trials with propensity score analysis (JCOG1313-A).** *Presenting Author: Junko Eba, Japan Clinical Oncology Group Operations Office, National Cancer Center, Tokyo, Japan*

**Background:** No randomized controlled trials comparing stereotactic body radiotherapy (SBRT) and lobectomy for operable early-stage non-small cell lung cancer have been successfully conducted. This study compared survival outcomes in two multi-institutional prospective clinical trials for SBRT (Japan Clinical Oncology Group [JCOG] 0403) and lobectomy (JCOG 0201). **Methods:** Inclusion criteria for this combined analysis consisted of: being operable, cT1N0M0, and adenocarcinoma diagnosed prior to treatment. Forty out of 169 patients enrolled in JCOG 0403 between 2004-2007, and 219 out of 811 patients enrolled in JCOG 0201 between 2002-2004 were included. The primary endpoint was overall survival adjusted with propensity score analysis. The patient selection factors included in the logistic model to estimate the propensity score were age, sex, and two findings on CT: tumor diameter and consolidation/tumor ratio (CTR). **Results:** The age distribution was quite different, with little overlap: the median was 79 (interquartile range (IQR): 74.5-83.5) in SBRT and 62 (IQR: 55-68) in lobectomy, although other factors were well balanced: males/females were 20/20 in SBRT and 108/111 in lobectomy; the median tumor diameter was 2.36 (IQR: 1.92-2.55) in SBRT and 2.20 (IQR: 1.90-2.70) cm in lobectomy; and the median CTR was 1.00 (IQR: 0.85-1.00) in SBRT and 1.00 (IQR: 0.68-1.00) in lobectomy. In propensity score matching analysis, 21 patients from each group were matched and the hazard ratio (HR) was 9.00 (95% CI: 1.14-71.04), favoring lobectomy. In the inverse probability of treatment weighting (IPTW) analysis, subjects were limited to those aged 75 or younger because JCOG0201 only included those 75 or younger. Thirteen patients for SBRT and 219 for lobectomy were compared and the HR was 1.19 (95% CI: 0.38-3.73), favoring lobectomy. **Conclusions:** Although all estimates tended to favor lobectomy over SBRT, no confirmatory conclusion was drawn due to the sample size for SBRT being too small. Further investigation with a larger sample size for a younger population with SBRT is needed to facilitate a valid comparison with surgery.

**7544 General Poster Session (Board #152), Sat, 1:15 PM-5:00 PM**

**Candidates for intensive local treatment in cIIIA-N2 NSCLC: Impact of mediastinal nodal extent and appearance.** *Presenting Author: Hidehito Horinouchi, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

**Background:** Clinical stage IIIA non-small cell lung cancer (NSCLC) with N2 nodal involvements (cIIIA-N2) includes a broad spectrum of patients. Phase III trials examining higher radiotherapy dose and surgery after neoadjuvant therapy have failed to yield satisfactory results. **Methods:** Between 1997 and 2010, we analyzed consecutive NSCLC patients diagnosed as having cIIIA-N2 disease and received chemoradiotherapy (CRT). The appearance of the mediastinal lymph nodes (MLNs) was classified into discrete (D) or infiltrative (I) according to the criteria proposed by the ACCP (Silvestri et al., Chest 2013). The extent of MLN involvement (MLNI) was divided into limited (close to the primary tumor) or extended (including upper MLNI in the case of tumors in the lower lobes and vice versa). **Results:** A total of 148 patients with cIIIA-N2 NSCLC received CRT; male/female, 118/30; median age, 62 years. The disease characteristics were as follows; appearance of the involved MLNs (D/I), 83/63; extent of MLNI (limited [L]/extended [E]), 81/64; histology (squamous [sq] /non-squamous [non-sq]), 36/112. The median progression-free survival (PFS) and median overall survival (OS) (95% confidence interval) in the entire subject population were 9.9 (9.0-12.3) months and 34.7 (28.8-41.1) months, respectively. Discrete appearance, limited extent of MLNI and treatment initiation after 2005 contributed to a significantly better PFS and OS. The percentages of cases with local relapses within the irradiated field according to the disease characteristics were as follows; MLN appearance (D/I), 24.6/18.9%; MLNI (L/E), 25.9/17.9%; histology (sq/non-sq), 52.0/12.6%. **Conclusions:** Among patients with cIIIA-N2 NSCLC, those with a discrete appearance of the involved MLNs and a limited extent of MLNI could be a favorable subgroup. With regard to local relapses after CRT, development of a better strategy for local treatment in this population (especially patients with a sq histology) is warranted.

**7545 General Poster Session (Board #153), Sat, 1:15 PM-5:00 PM**

**A randomized phase III trial comparing triple weekly usage with weekly usage of paclitaxel in concurrent chemoradiotherapy for patients with locally advanced non-small cell lung cancer.** *Presenting Author: Guangying Zhu, Department of Radiation Oncology, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China*

**Background:** Optimum management of clinically locally advanced non-small cell lung cancer (LANSCLC) presents challenges because of the high local recurrence rate. NCCN guidelines recommend concurrent chemoradiotherapy (CCRT) as the standard therapy for LANSCLC. A phase III study was performed to compare triple weekly usage (group 1) with weekly usage (group 2) of paclitaxel in concurrent chemoradiotherapy for patients with locally advanced non-small cell lung cancer. **Methods:** It is a multi-center, randomised, controlled, phase III trail. After 2 to 4 cycles of induction chemotherapy, patients with LANSCLC were randomly assigned to two groups. In group 1, chemotherapy consisted of paclitaxel (15 mg/m$^2$, 3times/week, 270 mg/m$^2$ over six weeks). In group 2, chemotherapy consisted of paclitaxel (45 mg/m$^2$, 1 time/week, 270 mg/m$^2$over six weeks). Radiotherapy consisted of 60-70Gy (2Gy per fraction and 5 fractions per week). **Results:** From March 2006 to February 2013, 115 patients were enrolled into the study. Sixty-three patients were enrolled in group 1, among which 3 patient had radiation esophagitis of Grade 3, 3 patients developed leucopenia of Grade 3, 12 patients had radiation pneumonitis of Grade 3, and 1 patient had radiation pneumonitis of Grade 5 and died of respiratory failure. Fifty-two patients were enrolled in group 2, 5 patient had radiation esophagitis of Grade 3, 15 patients developed leucopenia of Grade 3 or 4, 6 patients had radiation pneumonitis of Grade 3, and 2 patients had radiation pneumonitis of Grade 5 and died of respiratory failure. The response rate for the group 1 was significantly higher (87.3%) than that of the group 2 (57.7%) (p value 0.023), and the median PFS in the two groups were 11.0ms and 7.4ms (p value =0.039). **Conclusions:** The study results showed that triple weekly usage is more safe and effective than weekly usage of paclitaxel with CCRT for patients with LANSCLC. Clinical trial information: ChiCTR-TRC-10000786.

**7546 General Poster Session (Board #154), Sat, 1:15 PM-5:00 PM**

**Genetic features of pulmonary adenocarcinoma presenting with ground-glass nodules (GGN): Differences between those with growth potential and those without.** *Presenting Author: Yoshihisa Kobayashi, Department of Thoracic Surgery, Aichi Cancer Center Hospital, Nagoya, Japan*

**Background:** Some pulmonary GGNs become larger or increase solid component, whereas others, mainly pure GGNs, remain unchanged for years. We have previously reported that 3-year follow-up is a reasonable benchmark to distinguish GGNs with growth from those without growth, and that smoking history and larger diameter were associated with growth (Lung Cancer 83:61-66, 2014). However, genetic differences between them remain unclear. This study aimed to evaluate the genetic features of resected GGNs and clarify the differences. **Methods:** We examined 97 pulmonary nodules with ground-glass component ≥50% on CT in 90 patients that had been resected in 2012 and 2013. The tumors were evaluated for clinicopathologic features including lesion diameter, presence of invasion, and presence of EGFR/KRAS/ALK/HER2 mutations. **Results:** There were three atypical adenomatous hyperplasia (AAH), 17 adenocarcinoma in situ (AIS), 25 minimally invasive adenocarcinoma (MIA), and 52 invasive adenocarcinoma (IA). We identified mutations or rearrangements in 75 % (73/97): EGFR in 65% (63/97), KRAS in 4% (4/97), ALK in 5% (3/66), and HER2 in 7% (3/41). Smoking history, lesion diameter, solid component (mixed versus pure), tendency to grow, and pathological diagnoses (MIA/IA versus AAH/AIS) were significantly different (P <0.2) in tumors with any of driver oncogene mutation (mut+) as compared with those with no mutation (mut-), whereas age and gender were not (Table). In multivariate analyses, tendency to grow [Odds ratio (OR) 8.34, P <0.01], MIA/IA [OR 6.74, P = 0.01], and non-smoking history [OR 3.63, P = 0.02] were independent factors for mut+. **Conclusions:** Mut+ GGNs were associated with tendency to grow, MIA/IA, and non-smoking history. These results may suggest that mut- GGNs could remain unchanged and thus could be candidates for observation alone without surgical intervention.

| Variables | Mut+ (N=73) | Mut- (N=24) | p |

**7547 General Poster Session (Board #155), Sat, 1:15 PM-5:00 PM**

**Early detection of lung cancer based on three-dimensional, morphometric analysis of cells from sputum.** *Presenting Author: Alan Nelson, Visiongate, Inc., Phoenix, AZ*

**Background:** Utilizing a new 3D morphometric analytical device called Cell-CT, we analyzed cells from sputum to detect lung cancer in patients with malignant nodules found using low-dose x-ray CT (LDCT). This study assesses the sensitivity and specificity of the Cell-CT analysis for lung cancer in this context. **Methods:** Case sensitivity was assessed by analyzing sputum from patients with biopsy-confirmed non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC). Spontaneously produced sputum was collected over three consecutive days and fixed. Specimens were then enriched for epithelial cells and stained with hematoxylin. These cells were imaged using VisionGate's Cell-CT system that computes 3D cell images with isometric, sub-micron resolution. Cell images were then automatically analyzed by a computer classifier to identify abnormal cells. Of the 800 measured features, the strongest 25 were used in the classifier. The diagnosis for these cells was computer-generated and manually confirmed by a cytotechnologist. Specificity was assessed by analyzing cells in sputum from normal patients who were at high risk for lung cancer. Bronchial epithelial cells were counted to determine specimen adequacy. **Results:** 26 NSCLC and 4 SCLC, or 30 total cases were processed that met the criteria for adequacy. Moderate/severe dysplasia or cancer cells were found in 28 of the 30 cases. In 26 of the 28 cases, cancer cells were present. Cancer and dysplastic cells were detected by the Cell-CT for an overall case sensitivity of 93.3%. 15 of 30 cases were either stage I or stage II lung cancer, and 14 of these 15 cases (or 93.3%) were detected. 5,146 sputum cells from 17 normal patients at high risk for lung cancer were processed with zero false positive indications. The lower 95% confidence bound for specificity is 99.8%. **Conclusions:** With a sensitivity of 93.3% to early stage lung cancers and a lower limit to specificity of 99.8% based on a non-invasive sputum analysis, the Cell-CT platform could be deployed to help eliminate false positives from LDCT. Further studies will establish the Cell-CT performance across a broader range of clinical conditions to evaluate the potential use of the Cell-CT as a primary screener for lung cancer.

**7548 General Poster Session (Board #156), Sat, 1:15 PM-5:00 PM**

**Computed tomography (CT) imaging features in early-stage lung adenocarcinoma differentiating exon 19 and exon 21 epidermal growth factor receptor (EGFR) mutated tumors.** *Presenting Author: Benjamin F. Chu, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

**Background:** Imaging studies provide essential clinical information for lung cancer diagnosis, treatment and management. Features such as ground glass opacity (GGO), while commonly seen in early stage lung cancer, have minimal clinical implication. We previously described a correlation between GGO and exon 21 mutation in a subset of our current cohort. Here, we report our analysis in a single institution confirming GGO component as an imaging characteristic differentiating exon 19 and exon 21 EGFR-mutated (MT) tumors. **Methods:** Since 2009, our institution has prospectively characterized the EGFR status of all non-squamous lung carcinomas. Our inclusion criteria included tumor size $< 3$ cm and positive EGFR mutation. We randomly selected wild type (WT) patients matched by age and tumor size. The CT imaging of these patients was evaluated by a single radiologist (EO). **Results:** Imaging features were extracted from 20 WT and 45 EGFR-MT tumors. Of the EGFR-MT tumors, 21 had the exon 21 point mutation and 24 had in-frame exon 19 deletion. There were 69% (31) solid nodules in EGFR-MT and 90% (18) in WT tumors. While solid nodule was the primary feature seen in both WT and EGFR-MT tumors, exon 21-MT tumors were associated with GGO component ($p = 0.006$). This tendency, however, is not present in the exon 19-MT tumors. Lack of pleural attachment is seen more frequently with exon 19-MT tumor as compared to WT tumors. Other imaging features such as internal air bronchogram, and spiculated/lobulated border did not differentiate between groups. **Conclusions:** Among these treatment-naive lung adenocarcinomas, we discovered a propensity for exon 21-MT tumor to develop GGO on CT imaging. While both exon 21 point mutation and exon 19 deletion are predictive of response to EGFR tyrosine kinase inhibition, they exhibited distinct radiological phenotypes suggesting a different underlying biology.

**7549 General Poster Session (Board #157), Sat, 1:15 PM-5:00 PM**

**When should surgeons begin surveillance with CT scans after lobectomy for stage 1A non-small cell lung cancer?** *Presenting Author: Mohan K. Mallipeddi, Duke University Medical Center, Durham, NC*

**Background:** Guidelines for surveillance after resection of stage 1A non-small cell lung cancer (NSCLC) vary in terms of recommended modality and frequency. The purpose of this study was to assess the optimal time to start surveillance when using CT scans. **Methods:** All patients who underwent lobectomy from 1996 to 2010 for stage 1A NSCLC without induction or adjuvant therapy and who had CT surveillance that started within 15 months of resection were reviewed. Only patients followed for at least two years or until new or recurrent disease was discovered were included. Patients were grouped as "early CT" if their initial surveillance CT scan was $6\pm3$ months after lobectomy and "late CT" if their initial surveillance CT scan was $12\pm3$ months after lobectomy. Between the two groups, the incidence of new or recurrent disease on the initial CT scan was compared using Fisher's exact test and overall survival was compared using the log-rank test. **Results:** During the study period, 198 patients met inclusion criteria. There were 99 cases in both the early and late CT groups. Overall, 11% of patients (21/198; 8 local only, 13 distant) had recurrent disease and 16% of patients (31/198) were found to have new primaries over their follow up period. On average, recurrent disease was found $26\pm19.8$ months and new primaries were found $45.7\pm28.9$ months after resection ($p=0.009$). For the 31 patients with new primaries, 29 (94%) received some form of local therapy; surgery was used in 21 patients (68%). Repeat surgery was used in 3 of the 8 patients with local recurrence (37.5%), though 2 of these 3 developed contralateral lung metastases within 4 years of reoperation. In the early CT group, new or recurrent disease was found on the initial surveillance scan in 2% of patients (2/99) compared to 4% of patients (4/99) in the late CT group ($p=0.7$). The 5-year survival from initial resection of the two groups was not significantly different. **Conclusions:** Both recurrent disease and new primary cancers are relatively common after lobectomy for stage 1A NSCLC, but rarely are evident on CT scan within 15 months of surgery. Waiting to starting CT scan surveillance until 9 to 15 months after surgery is unlikely to miss clinically important findings.

**7550 General Poster Session (Board #158), Sat, 1:15 PM-5:00 PM**

**Serum biomarker analysis of WJOG4107: A randomized phase II trial of adjuvant chemotherapy with S-1 versus CDDP+S-1 for resected stage II-IIIA non-small cell lung cancer (NSCLC).** *Presenting Author: Tetsuya Mitsudomi, Department of Thoracic Surgery, Kinki University Faculty of Medicine, Osaka-Sayama, Japan*

**Background:** We conducted a randomized phase II trial for patients with resected stage II-IIIA NSCLC comparing postoperative long-term oral S-1 (80 mg/m2/day for consecutive 2 weeks q3w for 1 year) (S) ($N=100$) and cisplatin (CDDP) (60 mg/m2 day1) plus oral S-1, (80 mg/m2/day for 2 weeks) q3w for 4 cycles (CS) ($N=100$), and previously reported that the disease-free survival rate at 2 years (DFS@2yr), a primary endpoint, was 66 % (95%CI, 55-74%) for S and 58% (48-67%) for CS (Yoshioka et al., ESMO 2012). Here, we report the results of pre-planned serum biomarker analysis to identify biomarkers that are significantly associated with patient outcome. **Methods:** Serum samples were obtained from the 197/200 patients. Concentrations of 16 growth factors and 27 cytokines were measured by Luminex. Concentration of each protein was dichotomized at its median. **Results:** As is often the case with interaction test, a p-value of less than 0.10 was considered to be statistically significant and was used for this study. HGF, GCSF and leptin showed the moderate association with prognosis by multivariate Cox regression analysis considering treatment arm, age, sex, histology, smoking history, and stage with P for treatment-protein interaction $<0.10$ (HGF, $P=0.0576$; GCSF, $P=0.0579$; leptin, $P=0.0741$). Furthermore, patients with lower serum HGF level showed significantly favorable prognosis than those with higher serum HGF level in postoperative long-term S-1 therapy ($P=0.0072$ by the log-rank test). DFS@2yr for HGF low/S and HGF high/S were significantly different, 77% (95%confidence interval: 66-91%) and 56% (44-72%), respectively, while those of HGF low/CS and HGF high/CS were almost identical, 61% (48-77%) and 61 (48-78%), respectively. **Conclusions:** Low serum HGF level may define patient subset that would benefit from postoperative long-term S-1 therapy. It is possible to hypothesize that low HGF may enhance S-1- induced apoptosis through inhibition of angiogenesis, because HGF is a potent angiogenetic factor and S-1 acts on tumor angiogenesis (Cancer Lett., 2008, 267, 26). Indeed, NK4 (HGF/MET antagonist) reportedly enhances 5FU-induced apoptosis.

**7551 General Poster Session (Board #159), Sat, 1:15 PM-5:00 PM**

**The effect of institutional clinical trial enrollment volume on survival of patients with stage III non-small cell lung cancer treated with chemoradiation: A report of the Radiation Therapy Oncology Group (RTOG) 0617.** *Presenting Author: Bree Ruppert Eaton, Department of Radiation Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** This analysis evaluates the potential association between institutional clinical trial accrual volume and the outcome of patients with locally advanced non-small cell lung cancer (LA-NSCLC) receiving chemoradiation therapy (CRT) on a phase III trial (RTOG 0617). **Methods:** Patients with LA-NSCLC were randomized to 60 Gy vs. 74 Gy with concurrent carboplatin and paclitaxel +/- cetuximab, with initial results reported at ASCO 2013 (abst # 7501) and IASLC 2013. Participating institutions were divided into tertiles based on accrual to RTOG 0617. Those within the two lowest accrual tertiles were categorized as low volume centers (LVC), and those within the highest accrual tertile were categorized as high volume centers (HVC). **Results:** Range of accrual for LVC ($n=195$) vs. HVC ($n=300$) was 1-3 vs. 4-18 patients. Patients treated at HVC were more likely to be treated with intensity modulated RT (54.0% vs. 39.5%, $p=0.002$), to have a lower mean esophageal RT dose (26.1 Gy vs. 28.0 Gy, $p=0.03$), and to have a lower heart RT dose (V5Gy 38.2% vs. 54.1%, $p<0.001$; and V50Gy 3.6% vs. 7.3%, $p<0.001$). All other clinical variables were similar between the two cohorts. Treatment at a HVC was associated with significantly better OS and PFS compared with treatment at a LVC, median OS: 26.2 months vs. 19.8 months (HR 0.7, 95% CI 0.56 – 0.88, $p=0.002$), and median PFS: 11.4 months vs. 9.7 months (HR 0.80, 95% CI 0.65 – 0.99, $p=0.04$). HVC remained favorably associated with both OS ($p=0.013$) and PFS ($p=0.028$) when accounting for other factors. Additional factors associated with better OS were 60 Gy dose level ($p=0.006$), low heart V5Gy ($p=0.003$), and upper lobe tumor location ($p=0.014$); and with better PFS were 60 Gy dose level ($p=0.006$) and low heart V5Gy ($p=0.004$). Patients treated at HVC had a lower incidence of grade 5 adverse events (AEs) (5.3% vs. 9.2%, $p=0.09$) and were less likely to have RT terminated due to AEs (1.3% vs. 4.1%, $p=0.07$) than those treated at LVC. **Conclusions:** Treatment at institutions with higher clinical trial accrual was associated with better OS and PFS among patients with LA-NSCLC participating in a phase III trial. Clinical trial information: NCT00533949.

**7552 General Poster Session (Board #160), Sat, 1:15 PM-5:00 PM**

**Nodal stage of surgically resected non-small cell carcinoma of the lung and its effect on recurrence pattern and survival.** *Presenting Author: Satvik Ramakrishna, Northwestern University, Chicago, IL*

**Background:** Current NCCN guidelines recommend post-operative radiotherapy (PORT) for patients with resected non-small cell lung cancer (NSCLC) with N2-involvement. We investigated the relationship between nodal-stage and local-regional recurrence (LR), distant recurrence (DR) and overall survival (OS) for patients having an R0 resection. **Methods:** A multi-institutional database of consecutive patients undergoing $R_0$resection for Stages I-IIIA NSCLC from 1998-2009 was used. Patients receiving any radiation therapy before relapse were excluded. Variables analyzed were age, sex, surgical procedure, extent of lymph node sampling, histology, LVI, tumor size, tumor grade, chemotherapy, nodal stage, and visceral pleural invasion. Cumulative incidence rates were calculated for LR and DR as first sites of failure and Kaplan-Meier estimates for OS. Competing-risk analysis was used to compare times to recurrence events. Multivariate Cox modeling was used to analyze OS. **Results:** 1,288, 210 and 78 patients were identified with N0, N1, and N2 involvement respectively. 161 patients received chemotherapy. Median follow-up was 28.7 months. Patients with N1 or N2 nodal stage had similar rates of LR as patients with N0 disease, but were both at significantly increased risk for DR (N1, HR = 1.77, p = 0.0012; N2, HR = 2.27, p <0.001) and death (N1, HR = 1.464, p =0.0004; N2, HR = 2.32, p <0.0001). LR was associated with squamous histology, visceral pleural involvement, tumor size and segmentectomy in the Cox model. **Conclusions:** The risk of LR did not vary substantially in relation to N-stage in our population, though DR did. Although the number of patients with N2 disease was small, these findings call into question the NCCN guidelines. Prospective studies of PORT after R0 resection are needed.

| | Cumulative Incidence rates (%) | | | | Kaplan-Meier estimates (%) | |

**7553 General Poster Session (Board #161), Sat, 1:15 PM-5:00 PM**

**Are the criteria indicating patients to be "medically inoperable" that are used in clinical trials on stereotactic body radiotherapy appropriate for patients with early-stage non-small cell lung cancer?** *Presenting Author: Kazuya Takamochi, General Thoracic Surgery, Juntendo University School of Medicine, Tokyo, Japan*

**Background:** The standard treatment for patients with early stage non-small cell lung cancer (NSCLC) is surgical resection. Stereotactic body radiotherapy (SBRT) has recently been investigated as an alternative treatment in place of surgery in clinical trials, especially for medically inoperable (MI) patients. However, no clear rationale for the criteria used to determine whether or not a patient is MI has yet been demonstrated. **Methods:** Between January 2004 and October 2012, 740 patients underwent surgical resection for clinical stage IA NSCLC. In the present study, MI was defined as patients with FEV1.0≤0.8L, %DLCO<40%, PaO2≤70mmHg, PaCO2>50mmHg, or three or more severe comorbidities, based on the criteria of MI that are frequently used in clinical trials in SBRT for NSCLC patients. The clinicopathological characteristics and surgical outcomes were compared between the MI patients (n = 91) and non-MI patients (n = 649). **Results:** The proportion of males ($P = 0.002$), elderly ($P < 0.001$), smokers ($P < 0.001$) and those with a non-adenocarcinoma histology ($P < 0.001$) were higher in MI patients than in non-MI patients. No statistical difference was observed in the proportion of pathological stage IA between the groups (69% in MI vs 77% in non-MI, $P = 0.09$). Limited operation (wedge lung resection or segmentectomy) was performed for 37 (41%) MI and 227 (35%) non-MI patients ($P = 0.3$). Mediastinal lymph node dissection was performed for 48 (53%) MI and 413 (64%) non-MI patients ($P = 0.05$). Although the rates of overall morbidity (39% in MI vs 23% in non-MI, $P = 0.002$) and 90-day mortality (3% in MI vs 0.5% in non-MI, $P = 0.03$) were higher in the MI patients, there were no statistical differences in 30-day mortality (1% in MI vs 0.2% in non-MI, $P = 0.2$), overall survival ($P = 0.2$) or cancer-specific survival ($P = 0.7$) between the groups. **Conclusions:** Surgical resection can be performed in MI patients with an equivalent survival to non-MI patients. The current criteria that are used to determine whether or not a patient is MI for clinical trials in SBRT for NSCLC patients are therefore not considered to be appropriate to evaluate the true operability.

**7554 General Poster Session (Board #162), Sat, 1:15 PM-5:00 PM**

**Clinical characteristics and outcomes of atypical carcinoid (AC) tumor of the lung: A Surveillance, Epidemiology, and End Results database analysis.** *Presenting Author: Conor Ernst Steuer, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** AC is a rare form of thoracic malignancy. The limited knowledge of the presentation and treatment of this tumor comes largely from small, single institution experiences. We analyzed the Surveillance, Epidemiology, and End Results database (SEER) to better understand the clinic characteristics of this disease. **Methods:** Demographic, treatment and outcome data on all patients with pulmonary AC was obtained from the SEER database with 18 reporting sites from 1973-2010 using SEER*Stat 8.1.2. All analyses were performed using SAS 9.3. **Results:** Out of 947,463 patients diagnosed with lung and bronchus tumors from 1985 to 2010, 441 patients with AC were identified. Demographic data and median overall survival (OS) for patient subgroups are presented in the table below. The median OS for all patients is 26 months. The 3-year survival rate (N=254) is 67%. The 3-year survival rate for distant (M1), regional (lymph node involvement), and localized (lung only) disease is 26%(13/50), 69%(50/72), and 85%(99/116) respectively. Older age, black race, and advanced disease are associated with a worse overall prognosis. Univariate analyses showed patients treated with surgery had reduced risk of death OS (HR .19, p <0.001) while radiation treatment was associated with increased risk of death (HR 2.45, p <0.001). **Conclusions:** Atypical carcinoid tumors are more frequent in women and present with early stage disease in nearly 80% of the patients. Patients who were able to undergo surgical resection had superior outcomes.

| Variable | Level | N (%) | Median OS (months) |
|---|---|---|---|
| Age | Median (range) | 65 (21 - 90) | |
| Race | | | |
| White | | 381 (87.19) | 28 |

**7555 General Poster Session (Board #163), Sat, 1:15 PM-5:00 PM**

**Lobectomy, sublobar resection, and stereotactic radiation for early-stage non-small cell lung cancers in the elderly.** *Presenting Author: Shervin Mohajer Shirvani, Banner MD Anderson Cancer Center, Gilbert, AZ*

**Background**: Early-stage non-small cell lung cancers (NSCLC) among the elderly are expected to rise dramatically due to demographic trends and CT screening. However, no modern trials have compared the most commonly delivered treatments. Therefore, we determined clinical characteristics and outcomes associated with three definitive therapies for early-stage NSCLC in the elderly population. **Methods***:* The SEER–Medicare database was used to compare the outcomes of 9,093 patients with early-stage, node-negative NSCLC who underwent treatment with lobectomy, sublobar resection, or stereotactic ablative radiation (SABR) between 2003 and 2009. Overall survival and lung-cancer specific survival were compared using Medicare claims through December 2012. Proportional hazards regression and propensity score matching (PSM) were used to adjust outcomes for key patient, tumor, and practice environment factors. **Results**: Median age was 75 years, and treatment distribution was as follows: Lobectomy (79.4%), sublobar resection (16.5%), and SABR (4.2%). Unadjusted 90-day mortality was highest for lobectomy (4.0%) followed by sublobar resection (3.7%, P=0.79) and SABR (1.3%, P=0.008). At three years, unadjusted mortality was lowest for lobectomy (25.0%), followed by sublobar resection (35.3%, P<0.001) and SABR (45.1%, P<0.001). Proportional hazards regression demonstrated that sublobar resection was associated with worse overall survival (Hazard ratio [HR] 1.32; 95%CI 1.20-1.44) and lung-cancer specific survival (HR 1.50; 95%CI 1.29-1.75) compared to lobectomy. PSM analysis reiterated these findings. In proportional hazards regression, SABR was associated with better overall survival than lobectomy in the first 6 months after diagnosis (HR 0.45; 95%CI 0.27-0.75), but worse survival thereafter (HR 1.66; 95%CI 1.39-1.99). PSM analysis of well-matched SABR and lobectomy cohorts demonstrated similar overall survival (HR 1.01; 95%CI 0.74-1.38). **Conclusions**: Lobectomy was associated with better outcomes than sublobar resection in elderly patients with early-stage NSCLC. PSM analysis suggests that SABR may be a good option for those with very advanced age and multiple comorbidities.

**7556 General Poster Session (Board #164), Sat, 1:15 PM-5:00 PM**

**Computed tomographic window setting for predicting invasive adenocarcinomas in pulmonary nonsolid tumors.** *Presenting Author: Takashi Eguchi, Shinshu University, Matsumoto, Japan*

**Background:** Nonsolid pulmonary tumors are occasionally diagnosed as invasive adenocarcinomas. Preoperatively distinguishing adenocarcinoma in situ (AIS) or minimally invasive adenocarcinoma (MIA) from invasive adenocarcinoma is essential for treatment decision making. However, this distinction is potentially difficult to make using the conventional computed tomographic (CT) settings, that is, the lung and mediastinal windows. This study aimed to evaluate novel CT window settings for preoperative detection of invasive adenocarcinomas. **Methods:** We retrospectively evaluated 101 nonsolid tumors resected between July 2006 and November 2013. In the preoperative CT procedures performed, the predictive invasion diameter was determined as the maximum diameter of the residual tumors under the window level/window width settings as follows: −600/0, −550/0, −500/0, −450/0, −400/0, −350/0, and −300/0. Correlation analyses were used to verify whether each viewing condition could be useful for predicting pathological invasion. Then, a receiver operating characteristic (ROC) curve analysis was performed to evaluate the usefulness of the predictive invasion diameter for predicting pathological invasive adenocarcinomas that have a maximum invasion diameter of more than 5 mm. **Results:** Thepathological classification of the lesions was AIS for 47 lesions, MIA for 30 lesions, and invasive adenocarcinoma for 24 lesions (lepidic, 10 lesions; papillary, 8 lesions; and acinar, 6 lesions). The mean pathological invasion diameter was 2.9 ± 3.7 mm. The correlation coefficients between the pathological and predictive invasion diameters under the −600/0, −550/0, −500/0, −450/0, −400/0, −350/0, and −300/0 settings were 0.60, 0.61, 0.64, 0.66, 0.57, 0.47, and 0.41, respectively. In the ROC analysis, the sensitivity and specificity for predicting invasive adenocarcinomas in the window setting of −450/0 was 91.7% and 81.5%, respectively. For this, the cutoff predictive invasion diameter was set at 5.3 mm, and the area under the curve was 0.91. **Conclusions:** The window level/window width setting of −450/0 might be useful for predicting invasive adenocarcinomas in pulmonary nonsolid tumors.

**7557 General Poster Session (Board #165), Sat, 1:15 PM-5:00 PM**

**A randomized phase II trial of concurrent chemoradiation of oral vinorelbine and two doses of radiotherapy, 60 and 66 Gy, in local-regionally advanced non-small cell lung cancer (LA-NSCLC).** *Presenting Author: Olfred Hansen, Odense University Hospital, Odense, Denmark*

**Background:** A high rate of isolated loco-regional failure is a problem in RT of LA-NSCLC. This study tested two doses of radiotherapy (RT), 60 Gy/ 30 F (A) and 66Gy/ 33 F (B), 5 F W, concurrent with oral Vinorelbine (Nav) 50 mg q 3 wk. **Methods:** The primary endpoint was local progression failure free survival (LPFS) 9 months (m) after start of RT. Secondary endpoints included overall survival (OS) and safety. The results were compared with a historical cohort (CTRL) of pts, stage 2B-3B and PS 0-1 treated with same induction chemotherapy as in the study and 1 cycle of Ca-Nav during RT 66 Gy/33 F. Main inclusion criteria were histological/cytological proven stage 2B-3B NSCLC, PS 0-1. Prior to randomization the pts received induction chemotherapy, and the pts had to be proven able to receive 66 Gy/33F. No elective nodes were treated. Follow up with CT was every 3 m from RT start. At 9 m. a FDG-PET-CT scan was applied. The LPFS was calculated as the time of randomization to the date of the scan demonstrating local or distant failure. From Jul 2009-Aug 2013, 121 pts were randomized from 5 centers. All together, 117 pts were eligible. By Jan 2014, 102 pts had +10 m. follow-up forming the basis of this preliminary analysis. The final analysis is expected in May 2014. **Results:** The LPFS at 9 m. was arm A: 46% (95% CI: 40%; 53%), and in B: 56% (95% CI: 40%; 63%), and 76% (95% CI 67%; 82%) in CTRL. The overall survival in A, B, and CTRL were similar. No hematological G4 side effects were observed. Dysphagia and dyspnoe tended to be higher in B. One G4 pneumonitis was observed in Arm and 1 G5 in Arm B, and 1 G5 in CTRL. **Conclusions:** Both regimens were well tolerated, but neither of the arms met the phase II criteria. OS was comparable to CTRL. This suggests that the inferior local control observed at 9 m was due to the use of FGD-PET-CT, but omission of platin-chemotherapy during RT may have influenced the results. Clinical trial information: NCT 00887783.

**7558 General Poster Session (Board #166), Sat, 1:15 PM-5:00 PM**

**The impact of *EGFR* mutation on definitive concurrent chemoradiation therapy for inoperable stage III lung adenocarcinoma.** *Presenting Author: Kosuke Tanaka, Department of Thoracic Oncology, Aichi Cancer Center Hospital, Nagoya, Japan*

**Background:** Concurrent chemoradiation therapy (CRT) is the current standard of care for patients with locally advanced lung adenocarcinoma, however little has been reported about the impact of *EGFR* mutation to CRT efficacy. **Methods:** From 2005-2012, we retrospectively screened 73 unresectable stage III adenocarcinoma patients who were examined *EGFR* mutation status and received definitive concurrent CRT consisting of platinum doublet in first-line setting, and compared the clinical outcomes and recurrence patterns according to mutation status. **Results:** Among 73 patients, *EGFR* mutation was detected in 21 (28.8%). Overall response rate did not differ between *EGFR*-mutant and wild-type patients (66.7% vs. 74.0%, $p$=0.362). Median recurrence-free survival (RFS) in concurrent CRT was significantly shorter in *EGFR*-mutated patients than wild-type patients (8.7 [95%CI: 6.7-10.8] vs. 13.5 [95%CI: 11.0-18.3] months, $p$=0.022). The 2 year recurrence-free survival rate was 5.6% and 23.8% in *EGFR*-mutant and wild-type patients, respectively ($p$=0.090). Distant metastases were more frequently identified as the first recurrence site in *EGFR* mutant patients than in wild-type patients (81.0% vs. 38.5%, $p$<0.001). The brain was the most affected site in *EGFR*-mutant patients (8/17; 47.1%). None of the *EGFR*-mutant patients relapsed with primary lesions, whereas 11 wild-type patients showed primary lesion recurrence (0% vs. 21.2%, $p$=0.017). Overall survival did not differ according to *EGFR* mutation status (51.1 months vs. not reached, $p$=0.186). **Conclusions:** Concurrent CRT gave shorter RFS in *EGFR*-mutated stage III adenocarcinoma patients compared with wild-type patients, mainly due to distant metastasis relapse, regardless of better local control. Because of these distinct biological features, we will need different strategies against *EGFR*-mutant, locally advanced, adenocarcinoma patients.

**7559 General Poster Session (Board #167), Sat, 1:15 PM-5:00 PM**

**MiRNA profiling by NGS in resectable non-small cell lung cancer: Prognostic implications.** *Presenting Author: Sandra Gallach, Fundación para la Investigación del Hospital General Universitario de Valencia, Valencia, Spain*

**Background:** MicroRNAs (miRNA) regulate gene expression, and are implicated in several processes like tumorogenesis. Here, we applied a multiplexed NGS approach to study differentially expressed miRNAs (tumor/ normal) in a cohort of resectable NSCLC patients and its correlation with clinical outcome. **Methods:** RNA was isolated from frozen lung specimens (tumor/ normal) from 33 patients. High-quality samples were analyzed and enriched in the miRNA fraction. Libraries were prepared according to manufactured instruction (SOLID), and miRNAs were sequenced. Data analysis was carried out using CLCbio software. First, raw data were annotated using miRBase and normalized by total reads followed by differential expression analysis. Results validation were performed by RTqPCR in an independent cohort (n= 195). Functional studies of differentially expressed miRNAS were done using in silico tools. Statistical significance was considered at p<0.05. **Results:** 28 miRNAs were significantly up-regulated and 11 were down-regulated in tumor samples compared with normal lung. Most of them were validated by RTqPCR in an independent cohort of samples obtaining the same results (Wilcoxon test). Survival analysis were done for those validated miRNAs. We found that patients with overexpression (2.0X tumor/ normal) of miR21, miR196b and miR188-5p had worse clinical outcome (Table). In silico functional studies showed several GO terms and KEGG pathways related to cell cycle, apoptosis, angiogenesis, among others, that were significantly overrepresented among the miRNAs differentially expressed in NSCLC. **Conclusions:** 25 miRNAs were found differentially expressed and validated in NSCLC. These miRNAs were found to regulate important KEGG and GO process involved in carcinogenesis. Prognostic analysis showed that higher levels of miR21, miR196b and miR188-5p were related to shorter PFS and OS in our cohort of resectable NSCLC.

| | PFS | | OS | |
|---|---|---|---|---|
| | Median Survival (months) | p | Median Survival (months) | p |
| **miR188-5p (high vs low)** | 22.1 - 81.2 | 0.005 | 42.6 - NR | 0.015 |
| **miR196b (high vs low)** | 25.6 - NR | 0.031 | 42.6 - NR | 0.006 |
| **miR21 (high vs low)** | 37.9 - NR | 0.015 | 81.2 - NR | 0.023 |

**7560 General Poster Session (Board #168), Sat, 1:15 PM-5:00 PM**

**Breath analysis as a noninvasive biomarker for early detection of lung cancer.** *Presenting Author: Nir Peled, Thoracic Cancer Unit, Davidoff Cancer Center, Rabin Medical Center, Petach Tikwa, Israel*

**Background**: The search for non-invasive diagnostic methods of lung cancer (LC) has led to new avenues of research, including the exploration of the exhaled breath. Previous studies have shown that LC can be detected through exhaled-breath analysis. This study evaluated the potential of exhaled-breath analysis for the distinction of early and advanced LC and for control (COPD) and lung cancer patients in an international setting. **Methods**: Breath samples were taken from untreated lung cancer patients and matching COPD controls. Patients were enrolled in Israel, Colorado and Florida. All samples were analyzed in a central lab (Technion Institute; Haifa, Israel). Analysis was performed by both gold nanoparticle-based Artificial Olfactory System (NaNose) and gas-chromatography linked with mass-spectrometry (GC-MS). Pattern recognition methods were used to analyze the results obtained from GC-MS and NaNose to correlate the results with the clinical data. **Results**: A total of 358 subjects were enrolled in this study (Israel: 174; Denver: 111; Florida: 73). 213 patients had lung cancer, among 62 early disease and 143 were at advanced stage. 145 patients did not have cancer. In our preliminary sub-analysis, of 80 cancer patients (64 advanced stage) and 31 COPDs subjects: discriminant function analysis of the signals of the sensor array distinguished significantly between control versus early LC ($p < 0.0001$; accuracy 85.11%), between control and advanced LC ($p < 0.0001$; 82.11%) and between early and advanced LC ($p< 0.0001$; 78.75%). **Conclusions**: In this multi-national pilot study, breath analysis discriminated malignant disease from benign conditions in a high-risk cohort based on LC-related volatile organic compound profiles. Furthermore, it discriminated between early versus advanced disease. These achievements stand in consistency with the requirements of society for rapid and early diagnosis of diseases as a part of therapeutic approach and facilitating rapid treatment. Clinical trial information: NCT01386203.

**7561 General Poster Session (Board #169), Sat, 1:15 PM-5:00 PM**

**Treatment-related deaths after concurrent chemoradiotherapy in locally advanced non-small cell lung cancer: A meta-analysis of randomized studies.** *Presenting Author: Jing Zhao, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, GRU Cancer Center/Medical College of Georgia, Georgia Regents University, Augusta, GA*

**Background:** Treatment related deaths (TRDs), defined as grade 5 events that were not explained by tumor progression, may occur after concurrent chemoradiotherapy (cCRT) in patients with locally advanced non-small cell lung cancer (NSCLC). The purpose of this study is to 1) compare the TRDs rates between patients treated with cCRT and non-cCRT (sequential chemoradiotherapy or radiotherapy alone); 2) determine whether radiation dose and chemotherapy regimens were independent risk factors associated with TRDs after cCRT. **Methods:** Eligible studies include randomized controlled trials for locally advanced NSCLC patients with any treatment arms of cCRT and TRDs data reported between January 1, 1999 and November 30, 2013. The log-rank test was used to calculate pooled hazard ratios (HRs), with a fixed effect model. $X^2$ tests and $I^2$ were used to study heterogeneity between trials. **Results:** Twenty-eight studies (5897 patients) were eligible. The TRD rates were 3.0%, and 3.7% for cCRT and non-cCRT, respectively ($P = 0.313$). In univariate analysis, radiation dose ($> 60$ Gy), number of drugs for cCRT (above one), regimens for cCRT (other than etopside + cisplatin) or consolidation chemotherapy were not significantly correlated with TRDs. In 9 trials available for comparing TRD between cCRT and non-cCRT, the HR of TRD for two groups was 1.22 (95% CI: 0.72-2.06; $P = 0.455$). The test for heterogeneity was not significant ($X^2 = 9.62$, $P = 0.38$, $I^2 = 6\%$). Four of 28 trials were included in the analysis of correlation between TRDs and dose fractionated methods. After pooling the data, no significant difference was found in TRDs treated between standard-fractionated radiation and hyper-fractionated radiation (HR = 0.99, 95% CI: 0.46-2.13, $P= 0.977$). Choice of chemotherapy agent (3rd generation chemotherapy regimens or other regiments) and consolidation versus no-consolidation, each available in 4 trails, did not significantly impact TRD rates. **Conclusions:** Compared to sequential chemoradiotherapy or radiotherapy alone, cCRT did not significantly increase the TRD. Neither radiation dose nor chemotherapy regimens increases the treatment mortality.

**7562 General Poster Session (Board #170), Sat, 1:15 PM-5:00 PM**

**Tumor expression levels of CSC markers in resectable non-small cell lung cancer.** *Presenting Author: Silvia Calabuig, General University Hospital Research Foundation, Valencia, Spain*

**Background:** Cancer stem cells (CSCs) have been proposed as the driving force of tumorigenesis and the seeds of metastases. However, their existence and role remain a topic of intense debate. The purpose of this study is to analyze differentially expressed CSC genes from a large cohort of resectable NSCLC patients and its prognostic implications. **Methods:** mRNA was isolated from 188 frozen samples from resectable NSCLC patients (tumor and normal lung). The mRNA expression of *OCT4, NANOG, SOX2, CD44, CD133,* was analyzed by RTqPCR using hydrolysis probes. Relative expression levels were obtained using *GUSB* as endogenous gene and Pfaffl formulae. Statistical significance was considered at $p<0.05$. **Results:** Patient's median age was 64 years [26-85], 87.8 % were males and 66 % presented PS= 0. Squamous histology represented a 45.9%. There were positive correlations (Spearman test) between the expression levels of the CD44 and OCT4 ($p=0.002$), OCT4 and NANOG ($p<0.001$) whereas no correlation were found between CD133 and the other CSC markers studied. Correlation analysis of gene expression values and clinico-pathologic characteristics of the cohort showed that the higher levels of CD44, OCT4 and NANOG were associated with poor differentiation grade ($p=0.003$, $p=0.05$, $p=0.007$). Clinico-pathological variables such as histology, PS, stage or smoking status show no association with the levels of expression of the analyzed genes. Kaplan-Meier curves show no statistical differences between groups (median as cut-off) for CD133, NANOG and OCT-4. Interestingly, higher levels of CD44 correlates with increased overall survival in our cohort of resected NSCLC patients (median 42.90 months vs NR, $p=0.013$). **Conclusions:** CD44 may play a role as prognostic biomarker in NSCLC. Our results are in concordance with recent findings regarding the relationship between increased levels of expression of CD44 and better overall survival for patients with resectable NSCLC. Therefore, further investigations of the role of CD44 in CSC maintenance and regulation are still needed. Supported in part by ISCIII grants PI12/02838, RD12/0036/0025, SEOM grant 2012.

**7563 General Poster Session (Board #171), Sat, 1:15 PM-5:00 PM**

**A comparative study of blood-based *KRAS* mutation analysis in circulating tumor cells versus circulating plasma DNA to predict primary tumor mutations in lung cancer.** *Presenting Author: Eric Kian Saik Lim, Royal Brompton Hospital, London, United Kingdom*

**Background:** Biopsy of the primary tumour for predictive testing is not always convenient nor possible and may incur both delays and complications. In a move towards blood based predictive testing for personalised medicine, we sought to determine the test performance of circulating tumour cell (CTC) versus circulating tumour DNA (ctDNA) as a surrogate of the underlying tumour mutations using *KRAS* (a common mutation) as a prototype. **Methods:** *KRAS* mutation status in primary tumours were analysed using cobas4800 (Roche) allele-specific PCR. From 9ml of blood, ScreenCell MB devices were used to capture CTCs and the DNA was extracted from CTC and matched plasma using QIAamp DNA kits (QIAGEN). *KRAS* mutation detection was undertaken using custom-designed high-resolution melting assay and confirmed by pyrosequencing using *therascreen* kit (QIAGEN). **Results:** From January 2012 to 2013 the peripheral blood of 92 patients who underwent surgery for lung cancer at The Royal Brompton Hospital were analysed for mutations in codons 12/13 of *KRAS* gene. The total number of patients with *KRAS* mutations in FFPE tumour tissue was 18 (19.6%), the ctDNA was 17 (20%) and CTC DNA was 47 (58.8%). In total 9 primary tumours identified as "wild-type" in FFPE tissue appeared mutant in ctDNA. After 7 FFPE samples were re-tested by pyrosequencing, 6 previously undetected KRAS mutations were revealed. After re-testing FFPE tissue, the final concordance between primary tumours and ctDNA was 92% and concordance between CTC DNA was 52%. The sensitivity and specificity for blood based predictive *KRAS* testing was 81% (95% CI 58%-96%) and 97% (87%-100%) for ctDNA and 86% (61%-98%) and 38% (23%-56%) for CTC DNA. **Conclusions:** Blood based mutation testing is feasible and FFPE tumour biopsies cannot always be considered to be the "reference" as *KRAS* mutations not initially detected in the tumour were detected in the blood. ctDNA may be more reflective of the global tumour burden and is more closely indicative of underlying tumour mutation compared to CTC DNA due to tumour heterogeneity.

**7564 General Poster Session (Board #172), Sat, 1:15 PM-5:00 PM**

**Cisplatin and etoposide versus carboplatin and paclitaxel with concurrent radiation for stage III non-small cell lung cancer: An analysis of Veterans Health Administration data.** *Presenting Author: Rafael Santana-Davila, Medical College of Wisconsin, Milwaukee, WI*

**Background:** For the definitive treatment of stage III NSCLC, the optimal chemotherapy regimen to use with radiation is not clearly defined. Using a large cohort of patients treated across the entire VHA system, we compared the outcome of patents treated with EP vs. those treated with CP. **Methods:** Using the VA Central Cancer Registry, patients with stage III NSCLC diagnosed between 2001 and 2008 were identified. For analysis, patients were included if concurrent chemoradiotherapy was initiated within 4 months of diagnosis and excluded if treated with surgery or sequential chemoradiotherapy (i.e. chemotherapy was not started within 7 days of the start of radiotherapy). **Results:** Out of 13,572 pts identified, 1435 pts were eligible for analysis of which 26% (n=380) received EP. In multivariable analysis, the use of EP was not associated with any survival advantage (HR 0.94, 95% CI 0.81-1.09, p=0.41). In a propensity score analysis that matched 292 pts treated with EP with the same number of patients treated with CP, there was no survival advantage for EP (HR 1.01, 95% CI 0.86-1.2, p=0.87). Subsequently, a multivariate model weighted on the inverse propensity for being treated with EP was fitted and similarly showed no survival advantage for EP (HR 0.93, 95% CI, 0.80-1.07, p=0.32). Finally, an instrumental variable analysis was used to compare matched patients between eight VHAs that were "EP-encouraged" (i.e. >50% received EP, mean 71.1%) with 12 VHAs that were "EP-discouraged" (i.e. <10% received EP, mean 2.8%). This analysis found no survival advantage for EP (HR 1.02, 95% CI, 0.71-1.45, p=0.93). When adverse events were compared to CP, patients treated with EP had increased hospitalization (2.6 vs. 1.7, p<0.01), outpatient visits (16.4 vs. 12.2, p<0.01), infectious complications (48.9% vs. 39.3%, p<0.01), acute renal failure (48.9 vs. 18.6%, p<0.01), and mucositis/esophagitis (20.8 vs. 14.9%, p<0.001). **Conclusions:** After accounting for various prognostic variables, matched cohorts, and regional differences, there was no difference in survival between patients treated with EP and CP, however EP was associated with increased morbidity.

**7565 General Poster Session (Board #173), Sat, 1:15 PM-5:00 PM**

**Significance of the estrogen signaling pathway in *EGFR* wild-type lung adenocarcinoma.** *Presenting Author: Kazumi Tanaka, Division of Thoracic and Visceral Organ Surgery, Gunma University Graduate School of Medicine, Maebashi, Japan*

**Background**: Estrogen and growth factor pathways are potential targets for novel preventative and treatment strategies of lung adenocarcinoma. The purpose of this study is to examine the correlation among estrogen receptor (ER), aromatase expression, and other prognostic factors including epidermal growth factor receptor (*EGFR*) mutation in lung adenocarcinoma. **Methods**: We evaluated 150 resected primary lung adenocarcinoma specimens. Expression of aromatase, ER$\alpha$, ER$\beta$, progesterone receptor (PR), and HER2 was evaluated with immunostaining. Aromatase expression was scored from 0 to 3+ according to immunoreactive intensity. *EGFR* mutation was evaluated with SmartAmp2 method. Overall survival (OS) and recurrence free survival (RFS) was calculated by Kaplan-Meier method, and differences in survival were determined by log-rank test. Cox proportional hazards model was used to evaluate independent prognostic factors. **Results**: Expression of aromatase, ER$\alpha$, ER$\beta$, PR, and HER2 were detected in 79.3%, 1.3%, 88.0%, 2.7%, 39.3% of all patients, respectively. In all patients, high aromatase expression (2+, 3+) was an independent predictor of poor OS (Hazard Ratio [HR]=2.3; 95% confidential interval [CI], 1.2-4.4; *P*= .017), while no prognostic significance was seen in RFS. ER$\beta$ was not an independent predictor of OS and RFS. In patients with wild-type *EGFR*, high aromatase expression was an independent predictor of poor OS (HR=2.6; 95%CI, 1.2-5.9; *P*= .019) and RFS (HR=2.5; 95%CI, 1.2-5.4; *P*= .020). Positive ER$\beta$ was also an independent predictor of poor RFS (HR=4.0; 95%CI, 1.2-13.2; *P*= .022). Furthermore, high aromatase expression was a significant predictor of poor survival only in women (OS, *P*= .010; RFS, *P*= .007), while positive ER$\beta$ was a significant predictor of poor survival only in men (OS, *P*= .073; RFS, *P*= .051). No prognostic significance was seen in patients with *EGFR* mutations. **Conclusions:** Aromatase and ER$\beta$ expression were independent negative prognostic factors in *EGFR* wild-type adenocarcinoma. We further showed that in patients with wild-type *EGFR*, high aromatase expression was a significant predictor of poor survival only in women, while ER$\beta$ expression was a significant predictor of poor survival only in men.

**7566 General Poster Session (Board #174), Sat, 1:15 PM-5:00 PM**

**Evaluation of a lung cancer RNA expression subtyping panel and comparison with histologic diagnosis in lung tumor samples from multiple data sets including The Cancer Genome Atlas (TCGA).** *Presenting Author: Mark Robert Miglarese, GeneCentric Diagnostics, Durham, NC*

**Background:** Lung cancer subtypes are described by morphological and molecular characteristics. Differentiation between various subtypes is important for guiding patient management. Variability in morphology, limited tissue, and the need for performing a growing number of genomic tests pose challenges to the current diagnostic standard. **Methods:** The Lung Subtype Panel (LSP), a previously published 57 gene expression panel for prediction of lung tumor morphologic class (Wilkerson *et al*.JMD 2013), was investigated using 2,168 lung cancer samples from multiple publically available data sets (TCGA, NCI, UNC, Duke, Expo, Seoul, Tokyo, and France). Data sets with both gene expression data and morphologic classification were selected. Three platforms for gene expression were represented: Affymetrix U133+2 (n=883), Agilent 44K (n=334), and Illumina RNA-seq (n=951). A centroid predictor was used to assign an expression-defined histologic class. Predicted results were compared with tumor morphologic classification and percent agreement was calculated. **Results:** Ten lung tumor RNA expression datasets were combined into three platform specific data sets comprised of a diverse patient population, including smokers and nonsmokers with Stage I – Stage IV disease. Using the centroid predictor for two classes only (adenocarcinoma or squamous cell carcinoma), the agreement of the predictor with morphologic classification ranged from 79%-94% across the 3 data sets. Analysis of the 4-class predictor is underway and will be reported. To estimate an error rate in morphologic classification, a subset of tumors were reviewed by multiple pathologists, which showed an agreement rate of 65% (CI 49%-73%). **Conclusions:** In multiple datasets with over two thousand lung cancer samples, molecular profiling using the Lung Subtype Panel compared favorably to light microscopic derived diagnoses, and showed a higher level of agreement than seen by reassessment by multiple pathologists. RNA-based tumor subtyping can provide valuable information, especially when tissue is limiting and the overall morphologic diagnosis remains unclear.

**7567 General Poster Session (Board #175), Sat, 1:15 PM-5:00 PM**

**Clinical characteristics and molecular profile in patients with non-small cell lung cancer harboring *CRKL* amplification.** *Presenting Author: Hirotsugu Kenmotsu, Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

**Background:** It has been reported that *CRKL* amplification, associated with overexpression, has induced cell transformation as well as resistance to EGFR inhibitors. We analyzed *CRKL*amplification in archived genomic DNA samples from the Shizuoka Lung Cancer Mutation Study. **Methods:** To identify *CRKL* amplification, we performed copy number analysis using the real-time PCR system. The standard curve was generated by PCR of serially diluted plasmid clones of *CRKL* and a reference gene. Triplicate reactions were performed using 2 ng of genomic DNA extracted from surgically resected tissues and tumor biopsies from non-small cell lung cancer (NSCLC) patients. Biopsy samples were obtained from NSCLC patients with EGFR mutations. In surgically resected tissues, TruSeq amplicon cancer panel was used for the detection of somatic mutations in 48 cancer related genes followed by ultra-deep sequencing (Illumina) at an average coverage of approximately 3,400x. *ALK*, *ROS1* and *RET* translocations and *EGFR, MET, PIK3CA, FGFR1* and *FGFR2* amplifications were also detected by multiplex RT-PCR and quantitative PCR, respectively. **Results:** Between July 2011 and March 2013, 268 NSCLC patients treated with surgical resection, and 40 NSCLC patients with *EGFR* mutations, were enrolled in this study. Patient characteristics (treated with surgical resection) were as follows: median age (range) 69 (38-92) years; female 35%; never-smoker 27%; histology adenocarcinoma/squamous cell carcinoma/others 74/23/3 %; and differentiation well/moderate/poor 21/53/23 %. We detected *CRKL* amplification in 7.5% of 268 NSCLC patients treated with surgical resection. Frequencies of *CRKL* amplification in patients with gene alterations were as follows: 7.5 % of 93 *EGFR*; none of 38 *KRAS*, 8.7% of 23 *PIK3CA*; 8.8% of 91 *TP53*, none of 4 *EML4-ALK*, and 50% of 4 *KIF5B-RET*. 18% of 40 patients with *EGFR* mutations showed *CRKL* amplification before EGFR-TKI treatment. **Conclusions:** C*RKL* amplification was identified in 7.5% of NSCLC patients. These results suggest that *CRKL* amplification may be mutually exclusive with mutations in *KRAS*, and frequently observed in those with *KIF5B-RET*.

**7568 General Poster Session (Board #176), Sat, 1:15 PM-5:00 PM**

**Association between metformin (M) use and survival among non-small cell lung cancer (NSCLC) patients (pts).** *Presenting Author: Alice K Fortune-Greeley, Center for Health Services Research & Development, Durham VA Medical Center, Durham, NC*

**Background:** The antidiabetic drug M may improve cancer-specific survival; however, little is known about the association between M use and survival among NSCLC pts. **Methods:** We retrospectively identified pts diagnosed with stage I-IV NSCLC from the Veterans Affairs Central Cancer Registry. A diagnosis of type 2 diabetes (DM) within 6 months of diagnosis was obtained from VA administrative data. Anti-DM medication (med) use, including M, was identified using VA pharmacy data. We used Cox proportional hazards regression controlling for age, race, BMI, stage, co-morbidities, HbA1C, and NSCLC treatment to estimate adjusted hazard ratios (AHR) to compare mortality risk among (1) DM pts with M use (2) DM pts with non-M anti-DM med use (3) DM pts with no anti-DM med use and (4) non-DM pts. **Results:** Between 2001-2008, 51,824 pts were diagnosed with NSCLC, 19% (n=9,982) of whom had a diagnosis of DM. Of the DM pts, 33% (n=3,309) were treated with M, 41.2% (n=4,113) were treated with non-M anti-DM meds, and 26% (n=2,560) were not treated with any anti-DM meds. When compared to non-DM pts, DM pts treated with M had similar survival [AHR: 0.99; 95% CI: (0.96, 1.03)] while DM patients treated with non-M anti-DM meds [AHR: 1.14; 95% CI: (1.10, 1.18)] or who received no anti-DM meds [AHR: 1.10; 95% CI: (1.05, 1.15)] were associated with poorer survival. DM pts treated with M were associated with improved survival compared to DM pts treated with non-M anti-DM [AHR: 0.86; 95% CI: (0.82, 0.91)]. DM pts treated with M had a similar improved survival relative to DM pts treated with non-M anti-DM meds across all stage groups [stage I/II: AHR 0.85; 95% CI: (0.77-0.93), stage III: AHR 0.88; 95% CI: (0.81-0.97), stage IV: AHR 0.86; 95% CI: (0.80-0.99)], including stage IA [AHR 0.83; 95% CI: (0.75-0.93)]. **Conclusions:** M use in NSCLC pts with DM is associated with (1) similar survival to non-DM pts, and (2) improved survival among DM NSCLC pts. These associations were observed regardless of stage, suggesting a broad anti-NSCLC effect of M or an unidentified confounding factor.

**7569 General Poster Session (Board #177), Sat, 1:15 PM-5:00 PM**

**Concordance of PD-L1 expression by different immunohistochemistry (IHC) definitions and in situ hybridization (ISH) in squamous cell carcinoma (SCC) of the lung.** *Presenting Author: Alex Martinez Marti, Medical Oncology Department, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Recent clinical trials have shown that immune-checkpoint blockade can result in striking and durable responses in advanced non-small cell lung cancer. Preliminary data suggest a relationship between PD-L1 expression by IHC and objective response. No consensus about PD-L1 positivity expression exists. The aim of this study is to compare different IHC definitions and to explore the value of ISH for PD-L1 expression. **Methods:** Formalin-fixed paraffin-embedded tumor tissue samples from SCC were included. Clinical characteristics were analyzed. PD-L1 protein expression was evaluated by IHC using a mouse monoclonal antibody (clone h5H1). Three definitions for IHC positivity were applied: IHC 1 ≥5% of tumor cells exhibiting cell-surface staining; IHC 2 ≥1% of tumor cells exhibiting cell-surface staining; IHC 3 H-score, cut off: negative (0), positive (1-300). PD-L1 gene expression was evaluated by ISH with RNA Scope probe (Advanced Cell Diagnostics). For ISH, cut off: negative (<1), positive ( ≥1). Comparisons were made using *kappa*(k) correlation index. **Results:** 114 SCC tumors were included, median age 68.5 years, males 90.4%, current/former smokers 99.1%. By stage: IA 9.6%, IB 20.2%, IIA 16.7%, IIB 18.4%, IIIA 28.1%, IIIB 2.6%, and IV 4.3%. IHC and ISH results (see Table). According to IHC 3 20 (20.6%) SCC were positive for PD-L1. No differences by age, sex, smoking or stage were found. Median OS was 67.3 months (m), being of 58.7m for PD-L1 negative patients and of 81.5m for PD-L1 positive patients (p=0.598). A higher percentage of tumors resulted positive by ISH (29.4%), mainly due to a 13% of tumors that persistently remain negative by any IHC. K correlation index between IHC 1 versus (vs) IHC 2, IHC 1 vs IHC 3 and IHC 2 vs IHC 3 were of 0.94, 0.96 and 0.98, respectively. K correlation index for IHC3 vs ISH was 0.44. **Conclusions:** Our data suggests that the accuracy of different IHC definitions for PD-L1 expression have a high concordance. Results of ISH gene expression for PD-L1 warrant further investigation and can detect a subset of patients with PD-L1 pathway activation that remains negative by IHC.

**7570 General Poster Session (Board #178), Sat, 1:15 PM-5:00 PM**

**Clinicopathologic characteristics and prognostic impact of MET receptor overexpression in patients with stage I-IIIA squamous cell lung carcinomas (SQCLCs).** *Presenting Author: Matthew David Hellmann, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** MET is an oncogenic driver involved in cellular proliferation, survival, and invasion (Rong et al, PNAS 1994) and has been identified as a therapeutic target in some patients with lung cancers (Dziadziuszko et al, J Thorac Oncol 2012; Spigel et al, J Clin Oncol 2013). The clinicopathologic features and outcomes of patients with stage I-IIIA SQCLCs with MET receptor overexpression have not previously been described. **Methods:** A cohort of histopathologically-defined completely resected SQCLCs were tested for membranous MET receptor expression using IHC (Ventana, SP44) and assessed by two thoracic pathologists independently (TA, NR). Expression was scored using the METmAb scoring system, in which "MET+" tumors had moderate/strong intensity expression (i.e., ≥2+) in ≥50% of tumor cell membranes. Associations between MET status and clinical features, DFS, and OS were assessed using the Fisher's exact, unpaired T-, log-rank tests and Kaplan-Meier methods. Multivariate DFS and OS analyses were performed using Cox regression. **Results:** 17 of 62 stage I-IIIA SQCLCs were MET+ (27%, 95% CI 18-40%). There were no differences in age (p=0.31), gender (p=1.0), or tobacco exposure (p=0.78) between pts with MET+ and MET- SQCLCs. Median DFS and OS were significantly inferior in pts with MET+ vs MET- SQCLCs (15 vs 37 mo, p=0.01; 32 vs 54 mo, p=0.04, respectively). In this cohort, age or KPS were not associated with OS or DFS. In multivariate analyses including stage, gender, and MET status, outcomes of pts with MET+ SQCLC remained significantly inferior (HR for recurrence=4.1, 95% CI 1.6-10; HR for survival=2.2, 95% CI 1.0-4.7). **Conclusions:** More than a quarter of pts with stage I-IIIA SQCLCs are characterized by MET receptor overexpression. DFS and OS are significantly shorter in pts with MET+ SQCLCs. Pts with MET+ SQCLCs represent an oncogene-defined subgroup and should be considered for enrollment in clinical trials of agents targeting the MET pathway in this illness.

**The impact of a novel lung gross dissection protocol on intrapulmonary lymph node (LN) retrieval from lung cancer (LC) resection specimens.** *Presenting Author: Raymond U. Osarogiagbon, Boston Baskin Cancer Foundation, Baptist Cancer Center, Memphis, TN*

**Background:** Although thorough pathologic LN staging provides the greatest prognostic information in patients with potentially curable non-small cell LC, N1 nodal metastases are frequently missed. We tested the impact of corrective intervention with a novel gross dissection protocol on intrapulmonary LN retrieval. **Methods:** Retrospective review of consecutive lobectomy, or greater, LC specimens over a period of 15 months before and 15 months after training pathology technicians on the novel dissection protocol. **Results:** N= 152 specimens before, and 110 after introduction of the novel dissection protocol. The median number of intrapulmonary LN retrieved increased from 2 to 5 (p<.0001), and the 75th – 100th percentile range of detected intrapulmonary LN metastasis increased from 0 – 5 to 0 – 17 (p=.0003). In multivariate analysis (table), the extent of resection, examination period (pre- / post-intervention), and pathologic N1 (vs. N0) status were most strongly associated with increased intrapulmonary LN retrieval. **Conclusions:** A novel pathology dissection protocol is a feasible and effective means of improving intrapulmonary LN retrieval for examination. Dissemination and implementation studies of this novel pathology dissection protocol are warranted.

**7572 General Poster Session (Board #180), Sat, 1:15 PM-5:00 PM**

**Phase II study of biomarker guided neoadjuvant treatment strategy for IIIA-N2 non-small cell lung cancer based on EGFR-mutation status.** *Presenting Author: Wenzhao Zhong, Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China*

**Background:** Neoadjuvant EGFR-TKI therapy and customized adjuvant therapy are appealing but controversial strategy in patients with IIIA-N2 NSCLC. The purpose of this study was to evaluate the role of biomarker guided neo-adjuvant treatment strategy in patients with IIIA-N2 non-small cell lung cancer (NSCLC) stratified by epidermal growth factor receptor (EGFR) mutation status. **Methods:** Patients with resectable histologically documented stage IIIA-N2 NSCLC were assigned to either a neoadjuvant erlotinib arm or a gemcitabine/carboplatin (GC) arm based on EGFR mutation status (NCT00600587). The primary endpoint of this phase II study was response rate (RR). The secondary endpoints were progression-free survival (PFS) and overall survival (OS). **Results:** Twenty-four patients with IIIA-N2 NSCLC were enrolled in the trial from January 2008 until May 2011. The overall RR was 42%, and 58.3% (7/12) for the erlotinib arm with mutant EGFR, 25.0% (4/12) for the GC arm with wild-type EGFR ($P = 0.18$). Six cases in the erlotinib arm and seven cases in the GC arm received surgical resection. Median PFS was 6.9 months for the erlotinib arm and 9.0 months for the GC arm ($P = 0.071$). Median OS was 14.5 months for the erlotinib arm and 29.3 monthsfor the GC arm ($P = 0.304$). The median OS of the resected patients was 28.9 months for the erlotinib arm and 55.8 months for the GC arm ($P = 0.218$). In the overall population, the PFS and OS were 7.9 and 24.1 months, respectively. In addition, all six cases in the erlotinib arm that underwent resection gained partial response to tyrosine kinase inhibitor (TKI) re-treatment after progression, with a 2nd median PFS of 11 months. **Conclusions:** Biomarker guided neo-adjuvant treatment strategy in patients with IIIA-N2 NSCLC is feasible. Erlotinib had a tendency to improve the response, while the benefit did not transfer to better PFS or OS in this subgroup. Further randomized controlled studies of neoadjuvant combined with adjuvant EGFR-TKI are required to establish the role of perioperative TKI therapy in patients with IIIA-N2 NSCLC. Clinical trial information: NCT00600587.

**7573 General Poster Session (Board #181), Sat, 1:15 PM-5:00 PM**

**Role for surgical resection in the multidisciplinary treatment of stage IIIB non-small cell lung cancer (NSCLC).** *Presenting Author: Matthew Bott, Washington University School of Medicine in St. Louis, St. Louis, MO*

**Background:** The role of multi-modality therapy in stage IIIB NSCLC remains inadequately studied. Although chemoradiation is currently the mainstay of treatment, randomized trials evaluating the efficacy of surgical resection are lacking and surgery is offered selectively. **Methods:** Data of clinical stage IIIB NSCLC patients undergoing multimodality therapy were obtained from the National Cancer Database (NCDB). Information on patient- and tumor-related variables, therapy modalities, and outcomes was abstracted. Multivariable Cox regression models were fitted to evaluate variables influencing overall survival (OS). **Results:** From 1998-2010, 7,662 clinical stage IIIB NSCLC patients were treated with chemoradiation ($\leq$ 60 Gy radiation dose) (CR group), while 1,715 patients were treated with chemotherapy, radiation, and surgery in any order (CRS group). CRS patients were more likely to be younger, Caucasian, receive treatment at academic centers, and have slightly smaller tumors (all $p < 0.01$). There was no difference in Charlson Comorbidity Index (CCI) between the groups ($p = 0.5$). In the CRS group, 55% of patients received preoperative chemoradiation, 5% preoperative chemotherapy, and 3% preoperative radiation. The remaining CRS patients received adjuvant therapy (chemoradiation 30%, radiation 7%). Thirty-day surgical mortality was 3%. Factors associated with improved OS in multivariate analysis included younger age, female gender, decreased CCI, smaller tumor size and surgical resection (HR 0.57, 95% CI 0.52-0.63). Among patients treated with surgery, incomplete resection was associated with decreased OS (HR 1.52, 95% CI 1.20-1.92). Median OS was longer in CRS patients (25.9 months vs. 16.3 months, $p<0.001$). In a subset analysis of patients with N3 disease, median OS was longer in CRS patients (48.2 months vs. 26.5 months $p<0.001$) with 5-year OS of 26.3% after surgery. **Conclusions:** Surgical resection as a part of multimodality therapy is associated with improved overall survival in carefully selected patients with stage IIIB NSCLC. Multidisciplinary evaluation of these patients is critical.

**7574 General Poster Session (Board #182), Sat, 1:15 PM-5:00 PM**

**Role of PET scan in predicting response to neoadjuvant chemotherapy and long-term outcomes for stage II lung cancer.** *Presenting Author: Ankit Bharat, Feinberg School of Medicine, Northwestern University, Chicago, IL*

**Background**: While the role of neo-adjuvant chemotherapy (NAT) in stage IIIA non-small cell lung cancer (NSCLC) is well established, its efficacy in stage II is unclear. We evaluated the role of PET scan in predicting long-term outcomes in patients with stage II NSCLC undergoing surgical resection following NAT. **Methods**: Clinical stage II NSCLC (7th ed. AJCC) patients that underwent NAT between 1995 and 2010 were identified using a prospectively maintained database. All patients underwent clinical staging using CT scan and PET scan, with or without invasive lymph node staging. Chemotherapy regimen was unchanged during the study period. **Results**: Fifty-five patients with clinical stage II were identified who received NAT prior to surgery. The mean age was 63.1±10.2. Patients were predominantly white (69%) and female (53%). Most tumors were adenocarcinomas (70%), and most patients underwent a lobectomy (87%). Seventeen patients (30%) developed temporary interruption due to side effects from NAT. The 30-day perioperative mortality was 0%. Overall five-year and recurrence free survival were 65% and 70%, respectively. Mean preoperative PET SUV was 13.4±8.9 that decreased to 4.7±3.2 after NAT ($p<0.01$). Twenty-six (47%) patients had a greater than 50% reduction (PETc) while 15 (27%) did not (PETu) and 10 (18%) did not have restaging PET. There was no difference in invasive lymph node staging performed between PETu and PETc (30% vs 36%, $p=0.8$). The mean preoperative tumor size was no different (PETu 4.1 vs PETc 5.0). On final path the mean tumor size reduced 24% for PETc in contrast to 2% for PETu although this was not statistically significant. There was a 19% incidence of nodal metastasis in PETc group compared to 13% in PETu ($p=0.07$). PETc demonstrated a significantly improved survival compared to PETu (82.1% vs 40.8%, $p=0.04$). **Conclusions**: In patients with clinical stage II NSCLC, surgery after NAT was associated with low perioperative mortality and good long-term survival. Patients with a >50% reduction of SUV had a significant improvement in long-term survival.

**7575 General Poster Session (Board #183), Sat, 1:15 PM-5:00 PM**

**Diffusion of stereotactic body radiotherapy (SBRT) for early-stage non-small cell lung cancer (NSCLC) in the Medicare population, 2007-2009.** *Presenting Author: James B. Yu, Yale School of Medicine, New Haven, CT*

**Background:** Although the standard of care for early stage NSCLC is surgery, SBRT has emerged as an alternative for elderly patients who refuse surgery or are medically inoperable. As patterns of care may evolved since the introduction of SBRT for NSCLC in 2003, we investigated the adoption of SBRT vs. surgery in the Surveillance, Epidemiology, and End Results (SEER)– Medicare database in the years 2007-2009. **Methods:** We identified patients age > 67 who were diagnosed with stage I NSCLC from 2007 through 2009 and had undergone SBRT or surgery based on Medicare claims. Patient and hospital referral region (HRR) characteristics were recorded. Disability status (DS), a validated claims-based proxy for poor performance status, Elixhauser comorbidity index, and life expectancy (LE) were calculated using Medicare claims 12 months prior to diagnosis. The trend in receipt of SBRT was assessed for different categories of age, DS, and LE for patients whom SBRT was available in their HRR of residence. **Results:** There were 383 SBRT patients and 3,852 surgery patients. The proportion of patients undergoing SBRT rose from 4.4% in 2007 to 12.7% of treated patients in 2009 ($p<.001$). Patients who were older (Age 85-94; Odds Ratio (OR) vs. age 66-69: 5.98 [95% CI 3.34-8.08] , $p<.001$), female (OR 1.49 [95% CI 1.16-1.91], $p=.002$), with higher comorbidity (3+ conditions vs. 1: OR 4.23 [95% CI 2.97-6.02], $p<.001$) or disability status (Highest DS quartile vs. lowest OR 1.96 [95% CI 1.41-2.72],$p<.001$) were significantly more likely to undergo SBRT. The proportion of patients receiving SBRT (vs. surgery) increased in particular for patients with a shorter LE: SBRT use among patients with LE < 5 years from 11.8% in 2007 to 35.0% in 2009. In comparison, SBRT use for LE ≥ 5 years increased from 3.9% to 10.6% in the same period. **Conclusions:** The use of SBRT has disseminated rapidly into the care of older persons with early localized lung cancer, particularly those shorter life expectancies. Prospective studies are needed to identify patient and treatment factors associated with optimal outcomes.

**7576 General Poster Session (Board #184), Sat, 1:15 PM-5:00 PM**

**A phase II study of S-1 and concurrent thoracic radiotherapy (TRT) for elderly pts with locally advanced non-small cell lung cancer (LA-NSCLC): Okayama Lung Cancer Study Group trial 0801.** *Presenting Author: Yoshiro Fujiwara, Department of Respiratory Medicine, Okayama University Hospital, Tsuyama, Japan*

**Background:** Although thoracic irradiation is one of the standard therapies in elderly pts with LA-NSCLC, its treatment outcome is still poor. We previously reported safety profiles of S-1, an oral fluoropyrimidine possessing a radio-sensitizing effect, and concurrent TRT in such population [Lung Cancer 2011]. The objective of this study was to assess the efficacy and safety of S-1 with concurrent TRT for elderly pts with LA-NSCLC. **Methods:** Pts with stage III, aged ≥76 years and PS 0-1, and without any prior chemotherapy were eligible for this study. ps were treated with S-1 (40 mg/m²/dose b.i.d. on days 1-14 and 29-42) and TRT (60 Gy/30 fr over 6 weeks starting on day 1). Primary endpoint was response rate (RR), and required sample size was 30 pts, with a rate of 50% would be the lower limit of interest, with $\alpha = 0.05$ and $\beta = 0.20$. **Results:** Between 2007 and 2012, 30 pts were enrolled (24 men; median age, 79 years; PS 0, 15; IIIA, 20; Sq, 12). Median Charlson score was 1 ranging from 0 to 3. The proportion of actual dose schedule relative to the planned one of S-1 and TRT was 95 and 98%, respectively. Partial response was observed in 19 pts (63%; 95% confidence interval: 45-82%), which did not meet the endpoint. At the time of this analysis, 26 pts recurred at the local and distant sites in 18 and 10 pts, respectively. At a median follow-up of 23.7 months, median progression-free survival and MST were 13.0 months and 65.2 months, respectively. No difference in efficacy (response and survivals) was observed stratified by histology (sq vs. non-sq). Toxicities were generally mild, including G3/4 neutropenia (13%), G3 febrile neutropenia (7%) and G3 pneumonitis (10%). No one developed Gr3/4 esophagitis. No toxic deaths occurred. **Conclusions:** Although this study did not meet the primary endpoint, concurrent S-1 and radiotherapy yielded a favorable survival data. Also, it was well-tolerated in elderly pts with LA-NSCLC. Clinical trial information: UMIN000013077.

**7577 General Poster Session (Board #185), Sat, 1:15 PM-5:00 PM**

**Increasing ER stress response in pemetrexed-resistant mesothelioma cells.** *Presenting Author: Yuying Luo, New York University Langone Medical Center, New York, NY*

**Background:** Clinically silent progression and extraordinary resistance to therapy dictate poor survival for malignant pleural mesothelioma (MPM) patients. Current standard therapies such as antifolate (pemetrexed) treatment only minimally increase patient survival. Induction of ER-stress is a desired response of tumor cells to chemotherapy. We tested the hypothesis that butein (3,4,2',4'-tetrahydroxychalcone), a naturally occurring compound shown to counteract pemetrexed resistance in vitro and in vivo, may function by enhancing the ER-stress response of pemetrexed-treated MPM cells. **Methods:** MPM and benign mesothelial cells were treated with vehicle or butein, alone or in combination with pemetrexed. Levels of known ER-stress markers were evaluated by western blotting. The splicing of XBP-1, a transcription factor activated by ER-stress, was evaluated by PCR. Induction of CHOP, a main effector of ER-stress induced apoptosis was visualized and quantified by a CHOP-mCherry reporter and measured at the endogenous level by RT-qPCR. Established ER-stress inducing agents served as positive controls. Viability (vital cell count) and clonogenicity assays were used to evaluate the in vitroeffect of butein and butein + pemetrexed treatment. **Results:** MPM cells were resistant to pemetrexed treatment. MPM cells treated with butein demonstrated increased levels of ER-stress markers (BiP, CHOP, spliced XBP-1) as well as increased CHOP mRNA levels and promoter activation (fig.1). Moreover, butein was a stronger ER-stress inducer than pemetrexed. In line with this, viability and cytotoxicity assays revealed the potential for butein to strongly enhance the sensitivity of the mesothelioma cells to pemetrexed. Interestingly, butein treatment alone did not affect the viability of pemetrexed-sensitive hTERT transformed normal mesothelial cells (LP9). **Conclusions:** Butein triggers ER stress in MPM cells and may potentiate the ER-stress response of pemetrexed-treated cells. This may be one underlying mechanism for the anticancer effects of butein. Given its lack of effects on untransformed mesothelial cells, we propose that butein may be tested as an addition to the current clinically limited therapies for MPM.

**7578 General Poster Session (Board #186), Sat, 1:15 PM-5:00 PM**

**Malignant pleural mesothelioma: A 21-year single-center experience.** *Presenting Author: Mathieu D. Saint-Pierre, University of Ottawa, Ottawa, ON, Canada*

**Background:** Malignant pleural mesothelioma (MPM) is associated with a poor prognosis as most patients (pts) have advanced disease at diagnosis. Commonly used palliative chemotherapy (CT) is platinum based, and since 2004 the partner drug is usually a folate antimetabolite, either pemetrexed or raltitrexed. Selected pts presenting with early stage disease are considered for extrapleural pneumonectomy (EPP), although this approach remains controversial. We performed a single institution chart review investigating efficacy of EPP, and outcomes from CT pre- and post-2004. **Methods:** With ethics approval, all MPM pts from 1991 to June 2012 were identified. Data collected included age, gender, asbestos exposure, presenting symptoms, performance status (PS), histology, stage, bloodwork, treatment modalities, and date of death or last follow-up. Primary endpoint was overall survival (OS). Cox models were applied to determine variables associated with OS. **Results:** Of 245 identified pts, 87% were male, mean age 68 (range 21 to 88). Histology was epithelioid (63%), sarcomatoid (14%), mixed (11%) or unknown (12%). Common presentations were dyspnea (76%) and effusion (73%). Median OS for all pts was 9.4 months (mo). In univariate analysis, factors associated with shorter survival were: increasing age, poor PS, stage, sarcomatoid histology, weight loss >5%, leucocytosis (≥8.7) and thrombophilia (>400). In multivariate analysis PS, stage, histology, leucocytosis and thrombophilia remained independently associated with shorter OS. Among all pts who received CT (n=139), there was no difference in OS between the periods 1991-2004 (pre-pemetrexed) and 2004-2012 (pemetrexed era); 14.2 vs 13.2 mo (p=0.35). 20 pts underwent EPP, of which 11 had trimodality therapy with induction CT and post-op radiation. Their median OS was 24.7 vs 9.1 mo in non-EPP pts (p=0.0001). However, after multivariate analysis, the benefit of EPP was no longer statistically significant; HR 1.57, 95% CI 0.80-3.08 (p=0.19). **Conclusions:** In this review we did not observe an incremental improvement in survival after pemetrexed became available. Secondly, the longer OS seen in EPP pts is likely secondary to pt selection, rather than the intervention. The role of EPP remains unclear.

**7579 General Poster Session (Board #187), Sat, 1:15 PM-5:00 PM**

**A phase II trial of prolonged, continuous infusion of low-dose gemcitabine plus cisplatin in patients with advanced malignant pleural mesothelioma.** *Presenting Author: Oscar Rodriguez, Instituto Nacional de Cancerología, Mexico City, Mexico*

**Background:** Low-dose, prolonged infusion of gemcitabine has effects similar to standard doses in several cancers. We evaluated the toxicity and efficacy of low-dose gemcitabine in prolonged infusion plus cisplatin in patients with advanced pleural mesothelioma. **Methods:** Patients with mesothelioma received gemcitabine (250 mg/m$^2$) in a 6-h infusion plus cisplatin (35 mg/m$^2$) on days 1 and 8 every three weeks. We used the modified Response Evaluation Criteria In Solid Tumors. This study is registered in Clinical Trials (NCT01869023). **Results:** We included 44 patients; 82.1% were low risk according to the European Organisation for Research and Treatment of Cancer prognostic group. 39 patients had an objective evaluable response; partial response was observed in 53.8% (21/39), stable disease in 33.3% (13/39) and progression in 12.8% (5/39). The median progression free survival was 6.9 months (95% IC 3.2-10.6 months) and the associated factors were the EORTC risk and histology. The median overall survival was 20.7 months (95% IC 10.7-30.8 months). The functional, physical and emotional roles and dyspnoea, insomnia and pain symptom scales improved. The most commonly graded 3/4 side effects were neutropenia (24.4%), lymphopenia (14.6%), thrombocytopenia (14.7%) and anaemia (12.2%). **Conclusions:** Low-dose, prolonged gemcitabine infusion plus cisplatin has acceptable toxicity and high efficacy with improved quality of life, representing an affordable regimen for the low-income population. Clinical trial information: NCT01869023.

**Efficacy data.**

| Best tumor response | n = 39* | % |

**7580 General Poster Session (Board #188), Sat, 1:15 PM-5:00 PM**

**Prognostic significance of circulating secreted protein acidic and rich in cysteine (SPARC) in malignant pleural mesothelioma (MPM).** *Presenting Author: Steven Chuan-Hao Kao, Chris O'Brien Lifehouse, Sydney, Australia*

**Background:** Supervised proteomic analyses (discovery with isobaric tag for relative and absolute quantitation [iTRAQ] and validation with enzyme-linked immunosorbent assay [ELISA]) using 12 MPM patients from two phase II studies identified circulating SPARC as a promising prognostic marker, with high SPARC level associated with poor survival ($p<0.01$). We aimed to determine the independent prognostic significance of circulating SPARC in an independent cohort of MPM patients. **Methods:** Serum samples from MPM patients treated at the Netherlands Cancer Institute between 1995 and 2011 were included in this validation study. The samples were collected at the time of diagnosis and stored at -80°C, with clinical data collected prospectively. SPARC concentration was measured using the SEA791Hu ELISA kit (USCN Life Science Inc) according to the manufacturer's instruction. The primary end point of the study was overall survival (OS) from the date of sample collection, determined by the Kaplan-Meier method. The independent prognostic value of SPARC (categorised into high vs. low according to median concentration) was examined using Cox regression analysis, incorporating known prognostic factors in a multivariate model, including age (<60 vs. ≥60 years), gender (male vs. female), stage (I-II vs. III-IV) and histological subtype (epithelial vs. non-epithelial). **Results:** A total of 97 patients were included: median age 60 years; 85% male; 50% stage I-II; and 75% epithelial subtype. Treatment received included: 67% chemotherapy; 22% radical surgery; and 18% supportive care alone. The median OS was 13.5 months (92 patients deceased). The median SPARC concentration was 1745$\mu$g/ml. In the multivariate analyses, male gender (median OS: 10.8 vs. 22.4 months; $p=0.05$), stage III-IV (median OS: 10.1 vs. 17 months; $p=0.05$) and high SPARC level (median OS: 9.3 vs.19 months; $p=0.05$) were independently associated with poor OS. **Conclusions:** This validation study is the first to demonstrate the prognostic role of circulating SPARC in MPM, with high SPARC level being an independent predictor of poor OS.

**7581 General Poster Session (Board #189), Sat, 1:15 PM-5:00 PM**

**A multicenter phase II toxicity study of lung-sparing intensity modulated radiation therapy (IMRT) for malignant pleural mesothelioma (MPM).** *Presenting Author: Marjorie Glass Zauderer, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Given the trend away from extrapleural pneumonectomy (EPP) towards pleurectomy/decortication (P/D), we are developing a technique to deliver radiation to the pleura in patients with two intact lungs. In our initial experience with 36 patients (20 post P/D), 20% had grade ≥ 3 pneumonitis, most treated effectively with steroids, and survival was promising (Rosenzweig 2012). We now report our prospective, multicenter, phase II study of the safety and efficacy of pleural IMRT as part of a multimodality, lung-sparing, treatment approach. **Methods:** Patients with stage I-IV MPM received <4 cycles of pemetrexed and platinum chemotherapy. If feasible, P/D was performed. IMRT was delivered to the pleura (goal of 50.4 Gy, 28 fractions). The primary endpoint was the incidence of ≥ grade 3 radiation pneumonitis (RP); those who received any IMRT were considered evaluable. A Simon two-stage design was used: among the initial 9 patients, one case of grade 3 reversible RP occurred, so the cohort expanded to 28. **Results:** 39 patients are enrolled: 23 evaluable, 5 to receive IMRT, and 11 off-study before IMRT (7 due to disease progression, 3 were poor IMRT candidates at the time of simulation, and 1 withdrew consent). Demographics are in Table 1. 21 patients completed IMRT: 4 had grade 2 RP and 1 had grade 3 RP and was weaned from oxygen after a course of steroids. No grade 4 or 5 radiation-related toxicities were observed. Follow-up PFTs demonstrated an average decrease in DLCO of 18% (range 6-34%) from baseline. **Conclusions:** Pleural IMRT for MPM is safe with an acceptable rate of RP and feasible in a multicenter setting. The incorporation of IMRT with chemotherapy and P/D could form a new treatment paradigm for locally advanced MPM. In order to increase the number of patients able to complete all therapy and to improve local control in areas of bulkier disease, we plan a follow up study with upfront P/D, followed by chemotherapy and then radiation with dose-painting techniques. Clinical trial information: NCT00715611.

**Blood tests in malignant pleural mesothelioma (MPM).** *Presenting Author: Kazue Yoneda, Second Department of Surgery, University of Occupational and Environmental Health, Kitakyushu, Japan*

**Background:** Serum mesothelin is the best available blood test for diagnosing MPM, but provides a poor sensitivity (J Clin Oncol 2012). We previously showed that two blood tests, a test for circulating tumor cell (CTC) and a test for endothelial cell (CEC), provided significant diagnostic and prognostic performance (ASCO 2011 and 2012), and we compared these blood tests in the present study. **Methods:** A total of 140 patients, who present at Hyogo College of Medicine Hospital with suspicion of MPM, were enrolled; the final pathological diagnosis was MPM in 107 patients and non-malignant diseases in 33 patients. CTC-count in 7.5mL of peripheral blood and CEC-count in 4.0ml of peripheral blood were quantitatively evaluated with the "CellSearch" system. The MESOMARK ELISA kit was sued for measurement of serum soluble mesothelin-related peptides (SMRP). **Results:** A receiver-operating characteristic (ROC) curve analysis showed each test provided a significant diagnostic performance; at the cut-off value of 1/7.5mL (for CTC-test), 70/4.0mL (for CEC-test), and 2nmol/L (for SMRP-test), each test provided a high specificity (over 90%) but a poor sensitivity (28%-44%) (Table). When these tests were combined and a patient with positive result in any test (CTC≥1, or CEC≥70, or SMRP≥2) was judged to have MPM, the diagnostic performance improved with the sensitivity of 79% (specificity, 76%). In addition, patients with positive-CTC (CTC≥1) or higher-CEC (CEC≥70) showed a significantly poor prognosis (median survival time, 11 months vs 23months; $p<0.001$). **Conclusions:** Novel blood tests (CTC-test and CEC-test) improved a diagnostic performance of SMRP-test, and provided a significant prognostic value in MPM.

**7583 General Poster Session (Board #191), Sat, 1:15 PM-5:00 PM**

**Dendritic cell vaccination in malignant pleural mesothelioma: A phase I/II study.** *Presenting Author: Zwi N. Berneman, University of Antwerp, Antwerp, Belgium*

**Background:** The prognosis of malignant pleural mesothelioma (MPM) is dismal, with a median overall survival from diagnosis of 12 months. New therapeutic approaches are needed. We evaluated the feasibility, safety, immunogenicity and clinical efficacy of consolidative treatment with autologous dendritic cells (DC) electroporated with mRNA encoding the MPM-associated Wilms' tumor 1 (WT1) antigen. **Methods:** Ten patients (median age 62 [range: 53-73]) with unresectable MPM and non-progressive disease after platinum/pemetrexed-based chemotherapy underwent leukapheresis. CD14+ monocytes were isolated, cultured into mature DC according to our clinical-grade protocol (Van Tendeloo et al. PNAS 2010) and electroporated with mRNA derived from a codon-optimized *WT1* construct with a sig-LAMP sequence and a deletion of the nuclear localization signal. Biweekly intradermal vaccinations were administered for an intended period of 6 months, followed by monthly or bimonthly injections. Delayed type hypersensitivity (DTH) was tested, in order to assay in vivo T-cell responsiveness to the DC vaccine. Overall survival was measured from entry into trial. **Results:** Leukapheresis was successful in all patients, with a mean number of 19.4 ± 6.9 DC vaccines produced (range: 7-29); 3 patients underwent an additional leukapheresis. A mean number of 18.4 ± 10.7 vaccines were administered (range: 5-44). DC vaccination was well-tolerated; no systemic toxicity was recorded; local reactions at the injections sites occurred in all patients, but were mild and self-limiting. At a median follow-up of 22.7 months, 6 patients are alive, 4 have died and median survival has not yet been reached. The 6-, 12- and 18-month survival rates were 100%, 90% and 75%, respectively. Significant DTH responses (i.e. ≥ 10 mm² induration [Disis et al. Clin Cancer Res 2000]) were elicited in all patients except UPN006, who had the lowest survival (7.3 months). **Conclusions:** WT1-targeted DC vaccination is feasible and well-tolerated in MPM patients. In vivo evidence of vaccine-elicited immunity to the DC vaccine administered was obtained in 9/10 patients. Overall survival data suggest that adjuvant DC-based immunotherapy provides a clinical benefit for patients with MPM. Clinical trial information: NCT01291420.

**7584 General Poster Session (Board #192), Sat, 1:15 PM-5:00 PM**

**Impact of treatment-free interval (TFI) and disease control rate (DCR) on survival outcome in relapsed malignant pleural mesothelioma (MPM).** *Presenting Author: Vanesa Gregorc, Department of Oncology, Istituto Scientifico San Raffaele, Milan, Italy*

**Background:** Both TFI (the time elapsing from end of first line to start of second line therapy) and DCR (the nonprogression rate at first tumor evaluation) have been found to predict overall survival (OS) in some tumor types. **Methods:** The impact of TFI and DCR on the outcome of relapsed MPM patients who had failed a pemetrexed-based regimen was tested in an individual patient data pooled analysis. Second line therapy (n=450) was single agent NGR-hTNF (n=50, ph 2 trial) or chemotherapy (gemcitabine, vinorelbine or doxorubicin) plus NGR-hTNF/placebo (n=400; ph 3 trial). In both trials, tumor evaluation was done every 6 weeks by MPM-modified RECIST. OS was computed from second line therapy and median follow-up time was 19.3 months. TFI data were treated as a continuous or dichotomous variable using the median value as cutpoint (4.6 months; 95% CI 4.0-5.0). In multivariable models, hazard ratios (HR) for OS were derived from Cox models adjusted for baseline factors: age (median, 66 years), sex (men, 75%), PS (1-2, 66%), histology (nonepithelial, 19%), EORTC score ($\geq$ 1.27, 35%), best response to first line therapy (DCR, 74%), neutrophil to lymphocyte ratio (NLR; median, 4). **Results:** TFI data individually predicted for OS when tested as continuous (HR=1.02; p=0.005) or median value (HR=1.35; p=0.005). A TFI shorter than 4.6 months remained independent predictor of poor OS on multivariate analysis (HR=1.38; p=0.01) along with male sex (1.70; 0.001), PS of 1-2 (1.48; 0.004), nonepithelioid histology (1.77; 0.002), EORTC score $\geq$ 1.27 (1.36; 0.05) and NLR $\geq$ 4 (2.1; <0.0001). A short TFI was also related to worse progression free survival (adjusted HR=1.36; p=0.009) and DCR (adjusted odds ratio=0.62; p=0.02). After second line therapy, the 6-week DCR was 54%, while 46% of cases had early progression or were unevaluable. Using DCR at 6 weeks as a time dependent covariate, the nonprogression rate was univariately associated with OS improvement (HR=0.58; p<0.0001), which persisted after adjusting for baseline risk factors (HR=0.61; p<0.0001). **Conclusions:** In relapsed MPM, a prior short TFI is an independent predictor of poor prognosis and the 6-week DCR can be used as early surrogate endpoint for survival. Clinical trial information: NCT00484276-NCT01098266.

**7585 General Poster Session (Board #193), Sat, 1:15 PM-5:00 PM**

**Association of activation of mTOR and MAPK signal pathway with prolonged survival in patients with malignant pleural mesothelioma.** *Presenting Author: Ayumi Kuroda, Hyogo College of Medicine, Department of Thoracic Surgery, Nishinomiya, Japan*

**Background:** Malignant Pleural Mesothelioma (MPM) is a rare disease with poor prognosis. The combination chemotherapy with cisplatin and pemetrexed is the first line of MPM. The AKT/mTOR (Mammalian Target of Rapamycin) pathways and Ras/Raf/MEK/ERK (MAPK) pathway are known to be activated in some kind of cancer. The purpose of this study is to evaluate the correlation between the activation of these pathways and prognosis of MPM patients. **Methods:** 46 patients with MPM underwent a multimodality therapy including extrapleural pneumonectomy (EPP) at Hyogo College of Medicine, Nishinomiya, Japan from April 2004 to October 2012. These 46 cases consisited of 35 males (76.0%) and 11 females (23.9%) with median ages of 59.8 years (ranged from 37 to 71 years). Histologic subtype was 43 epithelial type (93.4%), 2 biphasic type (4.3%), 1 desmoplastic type (2.1%). Paraffin embedded surgical sample was used for immunohistochemistry to evaluate the expression of phospho-AKT, phospho- mTOR (p-mTOR), phospho-S6 Ribosomal Protein (p-S6RP), phospho-4EBP-1, phospho-mitogen-activated protein kinase kinase(p-MEK) and phospho-extracellular signal-regulated kinase(p-ERK) . Overall survival (OS) from the time of surgery was determined by Kaplan-Meier method and results were compared by log-rank test. **Results:** OS was significantly better in phospho-S6RP positive patients (32/46) in comparison with phosphor-S6RP negative patients (14/46) (43.6 months vs. 14.4 months, P=0.03). OS was significantly better in phospho-mTOR positive patients (18/46) in comparative with phosphor-mTOR negative patients (28/46) (37.1 months vs. 14.4 months, P=0.08).OS was significantly better in phospho-MEK negative patients (6/46) in comparative with phosphor-MEK positive patients (40/46) (31.7 months vs. 17.4 months, P=0.08). **Conclusions:** In MPM patients, high phospho-S6RP expression was predictive of improved OS. And this study support that the AKT/mTOR and MAPK pathways is promising candidate of molecular target therapy for MPM.

**7586 General Poster Session (Board #194), Sat, 1:15 PM-5:00 PM**

**Old and new prognostic factors in a series of 910 patients with malignant pleural mesothelioma (MPM).** *Presenting Author: Anthony Linton, Asbestos Diseases Research Institute, Sydney, Australia*

**Background:** Whilst the prognosis of most MPM patients is poor, a small proportion demonstrate long term survival. We investigate patient and treatment factors associated with survival and the impact of chemotherapy (CT) and surgery in a large patient series. **Methods:** Data sets of patients registered with the NSW Dust Diseases Board (2002-2009) were reviewed and prognostic factors such as age, gender, histological subtype and stage evaluated using Kaplan-Meier and Cox regression analysis. The impact of treatment, smoking and asbestos exposure were evaluated and subgroup analyses explored long(er) (>20 months) vs. short(er) (< 20 months) survivors. **Results:** We identified 910 patients: 90% male; median age 72 yrs; histological subtype (epithelioid 60%; biphasic 13%; sarcomatoid 17%; unknown 10%); stage (Tx-I-II 48%; III-IV 52%); calretinin expression (74.8%). Treatment: CT 41%, extrapleural pneumonectomy (EPP) 6%. Median age of first occupational asbestos exposure was 18 yrs; cumulative exposure 24 yrs. Median overall survival (OS) was 10.1 mo. Longer OS (p<0.001) was associated with: age <70yrs (13.5 vs. 8.5 mo.); female gender (12.0 vs. 9.9 mo.); epithelioid subtype (13.4 vs. 6.2 mo.); calretinin expression (11.0 vs. 5.5 mo.); NLR (neutrophil lymphocyte ratio) <5 (12.0 vs. 7.5 mo.); platelets <400 (11.6 vs. 7.1 mo.); and normal hemoglobin (16.6 vs 8.8). Patients undergoing CT (15.6 vs. 6.6 months; p<0.001) and EPP (24.8 vs. 9.5 months; p<0.001) had improved survival. Smoking history and cumulative asbestos exposure did not affect survival. On multivariate analysis, all variables remained significant, including EPP and CT use (time dependent analysis). 24% of patients survived >20 months: 16% underwent EPP, 61% received CT; but 31% received neither. Epithelioid histology, calretinin expression, age, stage and hemoglobin levels were independently associated with survival >20 months. **Conclusions:** In this large, population-based series, we validated calretinin expression, age, gender, histological subtype, stage and NLR as significant prognostic factors. Patients undergoing EPP/CT demonstrated better survival but 84% and 39% of long survivors respectively did not receive EPP or chemotherapy.

**7587 General Poster Session (Board #195), Sat, 1:15 PM-5:00 PM**

**Metabolomic analysis of pegylated arginine deiminase treatment in patients with malignant pleural mesothelioma.** *Presenting Author: Essam Ahmed Ghazaly, Centre for Haemato-Oncology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

**Background:** Arginine is a key amino acid for tumorigenesis modulating a diverse array of metabolic pathways, from synthesis of proteins, NO and polyamines to nucleotide turnover and mTOR signalling. Tumors deficient in the urea cycle enzyme, argininosuccinate synthetase 1 (ASS1), are especially sensitive to deprivation of exogenous arginine using the drug pegylated arginine deiminase (ADI-PEG20, Polaris Group, US). Previously, we have reported the metabolic changes induced by ADI treatment in a panel of ASS1-deficient bladder cancer and malignant pleural mesothelioma (MPM) cell lines. Here, we examined the metabolic effects in plasma of patients with MPM treated with ADI [ClinicalTrials.gov NCT01279967]. **Methods:** MPM plasma samples (29 patients treated with ADI-PEG20 and 6 control patients over a 9 wk period) were analysed by ultra performance liquid chromatography-mass spectrometry (UPLC-MS) for untargeted identification and quantitation of the metabolomic changes. The top metabolic changes were then assessed by targeted UPLC-MS/MS. **Results:** ADI-PEG20 induced marked changes in plasma, which clearly discriminated treated from untreated patients using partial least squares discriminant analysis (PLS-DA), a multivariate statistical approach. As expected, the plasma [arginine] decreased (126$\pm$15$\mu$M wk 0 vs 3.2$\pm$2.5 $\mu$M wk3) with a reciprocal increase in the plasma [citrulline] (56$\pm$6$\mu$M wk 0 vs 879$\pm$113 $\mu$M wk3) in ADI-PEG20 treated patients only. In addition, ADI-PEG20 treatment triggered the following novel plasma metabolite changes: increased [thymine] (3.0$\pm$0.4 $\mu$M week 0 vs 11.5$\pm$1.5 $\mu$M wk 3), [carnitine] (43$\pm$5 $\mu$M week 0 vs 96$\pm$7 $\mu$M wk 3) and [proline] (147$\pm$18 $\mu$M wk 0 vs 246$\pm$37 $\mu$M wk 3), while decreasing [isoleucine] (53$\pm$11 $\mu$M week 0 vs 17$\pm$4 $\mu$M wk 3). A 2-fold increase in plasma [glutamine] and [glutamate] was detected in non-responder patients as assessed by PET-CT, reaching a maximum by wk 5 of ADI-PEG20 treatment. **Conclusions:** This study has identified several metabolic changes in plasma that may be employed as potential biomarkers for optimizing the efficacy of ADI-PEG20 in the treatment of MPM and other arginine-dependent cancers. Clinical trial information: NCT01279967.

**7588 General Poster Session (Board #196), Sat, 1:15 PM-5:00 PM**

**Enhancing accurate prediction of survival outcomes and aiding decision making in malignant pleural mesothelioma (MPM) using a three-item index from the LCSS-meso PRO measure: Results from a randomized 444 patient (pt) prospective trial.** *Presenting Author: James Thomas Symanowski, Levine Cancer Institute, Carolinas Healthcare System, Charlotte, NC*

**Background:** Accurate prediction of survival of patient groups is required for appropriate trial design, while attention to the effect of treatment on PROs can help guide individual patient management. No pt reported factor is routinely used for these purposes, as performance status (PS) is not pt rated; nor is PS change known to guide accurately treatment changes. **Methods:** This study analyzes data from the prospective MPM EMPHACIS study comparing pemetrexed + cisplatin with cisplatin in 444 pts. LCSS-meso was given to all pts. An index of the 3 global LCSS items (symptom distress, activity level, quality of life) was correlated with survival outcomes. **Results:** Baseline and 6 week LCSS results and survival data were available for 83% of pts. Survival results were analyzed for differences for those scoring less than or greater than the median for each LCSS symptom and global factor. Unlike individual symptoms which are found only in subsets of pts, the 3 LCSS pt reported global items each apply to all pts. Median survival differences above (positive factor) or below (negative factor) medians for each global item varied by $< 6$ months. An index was created using the number of negative factors, 0 to 3, based on scoring less than the median for each of these 3 factors; see the Table. A landmark survival analysis was done comparing survival of those with a total LCSS 3-item score at 6 weeks which had fallen by $> 20\%$ since baseline vs all other pts. Median survivals = 7.8 months vs 13.3 months (HR 1.91, p <.001). **Conclusions:** This 3-item index, based entirely on PROs, has strong predictive properties. It can help improve trial design and analysis. For all patients, a fall by $> 20\%$ in the total 3-item score after just 2 cycles of chemotherapy allows rapid, convenient and inexpensive identification of a large group of patients (28%) with poorer survival on their current chemotherapy, which can assist in clinical decision making.

| # of negative PRO factors | % of pts (N = 444) | Median survival: mos. | Survival: 1 year | HR* |
|---|---|---|---|---|
| **0** | 35% | 14.6 | 61% | 0.371 (p<.001) |
| **1,2** | 33% | 10.8 | 45% | 0.616 (p<.001) |
| **3** | 32% | 7.4 | 26% | -- |

*Reference group is 3 negative PRO factors.

**7589 General Poster Session (Board #197), Sat, 1:15 PM-5:00 PM**

**T-cell inflamed phenotype and PDL1 expression in malignant mesothelioma.** *Presenting Author: Hedy Lee Kindler, The University of Chicago, Chicago, IL*

**Background:** Malignant mesothelioma (MM), a universally lethal disease caused principally by asbestos exposure, develops in the pleura, peritoneum, pericardium and tunica vaginalis. MM is commonly associated with a prominent inflammatory reaction, though it remains unknown whether this relates primarily to asbestos-induced chronic inflammation or an anti-tumor immune response. We therefore evaluated markers of an anti-tumor immune response established for melanoma in MM. **Methods:** We analyzed gene expression data on 44 MM (Gordon et al 2005), applied a melanoma-derived signature of T-cell inflammation (Harlin 2009), and analyzed other immune response related genes. We also evaluated 8 MM tumors (7 epithelioid, 1 biphasic; 7 pleural, 1 peritoneal) by multi-color immunohistochemistry (IHC), staining for CD68 (macrophages), CD8 (tumor infiltrating lymphocytes), and PDL1 (immune checkpoint). **Results:** 14/44 (32%) of MM showed high CD8 gene expression; 11% demonstrated a T-cell inflamed phenotype similar to that observed for melanoma. IHC revealed prominent CD68 infiltration in all tumors. CD8 tumor infiltrating lymphocytes (TILs) were present in all epithelial tumors; the biphasic tumor was negative. Germinal centers surrounding and within the tumor were rich in CD8+ cells; 1 tumor showed accumulation of CD8+ lymphocytes along the tumor invasive front. Two patterns of PDL1 expression were observed: 1) PDL1 expression occurred in 6 MM tumor samples, which was 2-3+ in 3 tumors, and 1+ in 3 tumors; 2) Patchy higher level PDL1 expression was observed in stromal or CD68 cells located close to CD8+ cells in the germinal center or the invasive tumor front in 6 tumor samples (2+ in 4 samples; 1+ in 2 samples). **Conclusions**: Mesothelioma is an 'inflammatory' tumor, with prominent infiltration with CD68+ cells (macrophages). We describe the presence CD8+ tumor infiltrating lymphocytes and a T-cell inflamed expression pattern in a fraction of MM, characteristic of the T-cell inflamed phenotype found in other tumors such as melanoma that benefit from immune checkpoint blockade. These preliminary data suggest that agents that target PDL1 may be appropriate to evaluate in MM. Ongoing work will further characterize immune checkpoints in MM.

**7590 General Poster Session (Board #198), Sat, 1:15 PM-5:00 PM**

**Clinical and molecular profiling of surgically resected small-cell lung cancer: Intergroup study with FIGHT002 and HOT1301.** *Presenting Author: Hiroshi Yokouchi, Department of Pulmonary Medicine, Fukushima Medical University, Fukushima, Japan*

**Background:** NCCN and Japanese guidelines suggest surgery for patients with c-stage I small-cell lung cancer (SCLC). However, the clinical impact of surgery with other variables on patients with early-stage SCLC has yet to be determined. Thus clarification of the clinical and molecular profile of SCLC is required. **Methods:** We reviewed the clinical courses of 149 patients with SCLC who had undergone surgery at 16 institutes from January, 2003 through January, 2013. Eighty-nine paraffin-embedded tissue samples were subjected to immunohistochemistry using 8 antibodies, and to next-generation sequencing system (NGS) using MiSeq and TruSight Tumor Panel (Illumina) loading 26 genes (UMIN registration No. 000010116/10117). **Results:** Median relapse-free survival (RFS) and overall survival (OS) were 16.6 (95%CI=7.1-26.2), and 36.7 (17.3-56.2) months, respectively. Multivariate analysis revealed that OS was longer in patients without interstitial pneumonitis (IP) (HR=0.372, 95%CI=0.181-0.767, p=0.007), without history of malignancy (HR=0.446, 0.229-0.868, p=0.017), with preoperative diagnosis (HR=0.401, 0.210-0.767, p=0.006), with c-stage II and under (HR=0.204, 0.065-0.640, p=0.006), and with p-stage IA (HR=0.294, 0.142-0.605, p=0.001). Of the 89 patients whose samples were available, MED12 and TGF-$\beta$RII were highly expressed in nucleus and cytoplasm, respectively in 92% and 61%. Multivariate analysis demonstrated that high expression of either c-Kit or HER2 in tumors is an independent factor for longer OS (HR=0.396, 95%CI=0.209-0.752, p=0.005). None of the tumors expressed ALK. There was no relationship between the expression of c-Met, EGFR, and VEGFRII and either of RFS or OS. Thirty-five samples were subjected to NGS so far. However, no druggable mutations of *BRAF, EGFR, ERBB2, KRAS, KIT, PDGFRA, PIK3CA, FOXL2, GNAQ, GNAS*, and *FGFR2* were found. **Conclusions:** These results indicate that i) complication of IP and history of malignancy might be major decision factors of surgery, and: ii) patients with c-stage II should be considered for surgery in a prospective trial. Immunohistochemistry results assist us in gaining a better understanding of the biology of SCLC.

**7591 General Poster Session (Board #199), Sat, 1:15 PM-5:00 PM**

**Retrospective evaluation of prophylactic cranial irradiation in patients with limited-stage small cell lung cancer with stereotactic radiotherapy: A multi-institutional study.** *Presenting Author: Yuichi Ozawa, Department of Respiratory Medicine, Respiratory Disease Center, Seirei Mikatahara General Hospital, Hamamatsu, Japan*

**Background:** The benefits of prophylactic cranial irradiation (PCI) on survival time have been repeatedly reported especially in patients with limited stage small cell lung cancer (LS-SCLC). However, almost all such studies were performed decades ago and whether PCI is still beneficial in conjunction with pre-symptomatic brain screening and stereotactic radiotherapy (SRT) in patients with brain metastasis (BM) remains unknown. **Methods:** The data of all patients with pathologically proven SCLC from 1/1/2006 to 6/31/2013 were collected from 4 designated cancer care hospitals in Japan, all of which were equipped with or had access to SRT, and thoroughly reviewed. LS disease at diagnosis and who were estimated as CR or good PR after the first treatment were enrolled. All possible patients were periodically screened for BM by CT or MRI and patients with BM were preferentially considered for SRT. The effects of PCI and SRT were analyzed by Kaplan-Meier method and Cox proportional hazards model. **Results:** Of all 418 patients with SCLC, 124 matched our criteria. The 124 patients were divided into a PCI (P) group ($n$=29) and non-PCI (NP) group ($n$=95). Patient backgrounds were similar with the exception of median age (65 *v* 73; p<0.001) and stage (1/2/3) at diagnosis (1/4/24 *v* 31/15/49; p=0.001). Neither the cumulative occurrence of BM at 2 years (COB) (45.5 *v* 29.9%; p=0.250) nor the median survival time (MST) (25.5 *v* 34.5 months (m); p=0.312) showed statistically significant differences between the two groups. Even when only stage 3 cases were analyzed, no statistically significant differences in COB or MST were found between the two groups (43.1 *v* 53.7%; p=0.437, 25.5 *v* 26.5 m, p=0.546, respectively). 10 patients in P group and 25 in NP group developed BM. Survival time after BM detection was significantly longer in NP group (8.0 *v* 20.2 m, p=0.050). Furthermore, SRT was significantly associated with longer survival after BM detection when adjusted for age and stage (hazard ratio; 0.468, p=0.045). **Conclusions:** PCI does not benefit patients with LS-SCLC in conjunction with periodical brain screening and SRT. A prospective study is currently underway.

**7592 General Poster Session (Board #200), Sat, 1:15 PM-5:00 PM**

**Multiplex testing of potentially 'actionable' alterations in small cell lung cancer (SCLC).** *Presenting Author: Shirish M. Gadgeel, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

**Background:** Therapy and outcomes of SCLC patients have not changed for many years. Recently, driver mutations have been identified in many cancers and targeting these mutations can provide clinical benefit. Recent data from whole genome sequencing suggest that driver mutations may exist in SCLCs. We conducted multiplex testing of SCLCs to identify mutations potentially predictive of response to novel and established therapeutics. **Methods:** We identified tumor tissues of 30 SCLC patients collected as part of two different institutional review board approved studies. Using the Sequenom MassArray system and a multiplexed panel, we analyzed tumor DNA for 214 mutations in 26 genes associated with the pathogenesis of lung cancer. Gene copy number analysis utilized a 180K oligonucleotide microarray and comparative genomic hybridization assay. **Results:** The median age at diagnosis of patients was 63 years; 66 % of were males; 23% were African-Americans; 57% patients had extensive stage SCLC at diagnosis. Point mutations were identified in 5 (17%) patients, 2 patients had p53 mutations, 1 each had PI3K, EGFR and Kras mutation. Of the 21 tumors for which gene copy number analysis has been completed, the median number of genes, listed in the Sanger Institute Cancer gene census, that were altered was 135 (range 0-299). Only 1 tumor had no gene copy number alterations. Of the genes that are targets for novel anticancer agents, PI3K (76%) and DDR2 (48%) amplifications were the most frequent alterations. Among the 21 tumors analyzed for both point mutations and gene copy number variations, one or more potentially actionable alterations were identified in 19 (90%) tumors. **Conclusions:** Our analysis indicates that potentially "actionable" genome alterations can be identified in a high proportion of SCLCs by conducting point mutation and gene copy number variation analyses. We plan to initiate a clinical trial with prospective analyses of tumors of SCLC patients to identify "actionable" mutations and assess the clinical benefit of therapy based on these genome alterations.

**7593 General Poster Session (Board #201), Sat, 1:15 PM-5:00 PM**

**Pharmacokinetics (PK) and exposure-response (ER) of rilotumumab (Rmab) in patients (pts) with small-cell lung cancer (SCLC).** *Presenting Author: Yilong Zhang, Amgen, Inc., Thousand Oaks, CA*

**Background:** Rmab is a fully human monoclonal antibody against hepatocyte growth factor that was evaluated as a first-line treatment for extensive-stage SCLC in a phase 1b/2 trial (*J Thorac Oncol*. 2013;8(S2):021.05). That trial did not show meaningful improvements in progression-free survival (PFS) or overall survival (OS). We characterized Rmab PK in pts with SCLC and performed an ER analysis that related PK to tumor size (TS), PFS, and OS. **Methods:** Rmab population PK (PPK) and ER were assessed in 132 pts with SCLC who were randomized 1:1 to receive either Rmab (15 mg/kg) or placebo, with etoposide plus carboplatin/cisplatin every 3 weeks (Q3W). A PPK model was developed using data from phase 1 and earlier phase 2 studies. TS vs time was characterized using a tumor dynamic model, and time to tumor growth (TTG) and TS ratios (the ratios of TS at 6, 9, or 12 weeks to TS at baseline) were derived from this model. The relationships between PFS/OS and baseline pt characteristics, exposure metrics, and tumor response metrics were evaluated using Cox proportional hazards and parametric survival models. Pts were divided into high- and low-exposure groups based on median Rmab trough concentration at steady state (Cminss). Survival analyses were performed with R, and PPK and tumor dynamic analyses were performed with NONMEM. **Results:** Rmab PK was well characterized by a two-compartment PK model. Body weight (WT) affected clearance (CL) and central volume of distribution (Vc): a 10% increase in WT increased CL by 6% and Vc by 7%. Chemotherapy reduced TS, but Rmab did not have an additional effect on TS. OS was best described by a log-logistic distribution. Rmab improved OS relative to placebo in the high-exposure group (Cminss $>$ 155 mg/mL) but not in the low-exposure group (Cminss $\leq$ 155 mg/mL). Univariate analysis suggested that favorable predictive factors of OS included higher Rmab exposure, female sex, and longer TTG. There was no apparent PK-PFS relationship. **Conclusions:** High Rmab exposure was associated with improved OS in this ER analysis, but further studies will be needed to determine whether this association is causative and whether a combination of chemotherapy and Rmab at a dose $>$ 15 mg/kg Q3W leads to improved OS.

**7594 General Poster Session (Board #202), Sat, 1:15 PM-5:00 PM**

**Final results of a phase I study of amrubicin and cyclophosphamide in patients with advanced solid organ malignancies: HOG LUN 07-130.** *Presenting Author: Shadia Ibrahim Jalal, Indiana University School of Medicine, Indianapolis, IN*

**Background:** Relapsed small cell lung cancer (SCLC) has limited treatment options. Anthracyclines and cyclophosphamide have shown synergy in a wide variety of tumors. Amrubicin (AMR) and cyclosphosphamide both have single agent activity in SCLC. This phase I trial evaluated the combination of AMR and cyclophosphamide in refractory solid organ malignancies and in relapsed SCLC. **Methods:** Eligible patients (pts) had refractory solid organ malignancies, PS 0-1, and adequate organ function. The primary endpoint was MTD and dose limiting toxicities (DLTs). Secondary endpoint was to assess response. Pts were enrolled in sequential dose escalation cohorts in a standard 3+3 design. Treatment consisted of cyclophosphamide IV at 500mg/m$^2$ on day 1 with escalating doses of AMR IV on days 1-3 (25-40mg/m$^2$ with increments of 5mg/m$^2$ per cohort).Cycles were repeated every 21 days. **Results:** Thirty six patients (pts) were enrolled on the dose escalation portion with 18 patients with SCLC as the primary diagnosis. Remaining patients had NSCLC, extrathoracic small cell carcinoma or other malignancies. The median number of cycles was 4 (range 1-6). MTD was determined to be dose level 2 (cyclophosphamide 500mg/m$^2$, AMR 30mg/m$^2$) due to grade 4 thrombocytopenia. Incidence of grade 3-4 neutropenia, anemia, thrombocytopenia and febrile neutropenia was 33.3%, 19.4%, 25% and 5.56% respectively. Other grade 3-4 toxicities included nausea, vomiting, hyponatremia, hypokalemia and fatigue. Partial responses were only noted in patients with SCLC or extrathoracic small cell with PR noted in 7 pts, SD in 5 pts and PD in 7 pts. Of the pts achieving PRs on our study, 4 were platinum sensitive, 3 were refractory. The median duration of response was 4 months, median progression free survival was 3.06 months and the median overall survival was 9.1 months. Ten additional pts with relapsed SCLC were treated at the MTD on a compassionate cohort and 9 were evaluable for response. In this cohort SD was noted in 3 pts, PD in 6 pts with median OS of 6 months. **Conclusions:** AMR and cyclophosphamide can be safely combined with activity observed in a heavily pretreated SCLC population. Clinical trial information: NCT00890955.

**7595 General Poster Session (Board #203), Sat, 1:15 PM-5:00 PM**

**A randomized, multicenter phase III study of lobaplatin/etoposide versus cisplatin/etoposide as first-line therapy in patients with extensive-stage small-cell lung cancer and circulating tumor cells (CTCs) as an exploratory biomarker.** *Presenting Author: Ying Cheng, Jilin Provincial Cancer Hospital-(JPCH), Changchun, China*

**Background:** Cisplatin plus etoposide (EP) is conventional regimen to treat small cell lung cancer (SCLC), however the toxicities of cisplatin limited its efficacy. Here, we showed the results of a phase III clinical trial using lobaplatin, a third-generation platinum compounds, in combination with etoposide (EL) in comparison to EP for extensive SCLC (ES-SCLC). **Methods:** A total 234 Chinese patients with newly diagnosed ES-SCLC were randomized into two groups: (1) the EL Group (n=122): 6 cycles of lobaplatin (30 mg/m$^2$/day on day 1) and etoposide (100 mg/m$^2$/day on days 1-3, every 21 days) and (2) EP Group (n=112): 6 cycles of cisplatin (80 mg/m$^2$/day on day 1) and etoposide. The primary end point was progression-free survival (PFS); secondary end points included toxicity, QOL and overall survival (OS). Eighty five ES-SCLC patients were tested for circulating tumor cells (CTCs) (CELLSEARCHÒ) prior to treatment, at 2 cycles after therapy and disease progression. **Results:** For EL and EP group, the median PFS and the disease control rate (DCR) was 5.37 versus 5.99 months ($P$=0.1638), and 82.64% versus 83.78% ($P$=0.8618), respectively. In terms of toxicities, the incidence of nephrotoxicity in the EL group was significantly lower than that in the EP group (2.48% vs 11.71%, $P$=0.0079), as well as incidences of nausea and vomiting (22.31% vs 36.04%, $P$=0.0292, and 14.05% vs 25.23%, P=0.0453, respectively). At baseline as well as 2 cycles after chemotherapy, the median OS was significantly lower in patients with $\geq$5 CTCs than those with $<$5 CTCs (baseline: 23 months vs $>$26 months, $P<0.0028$ and 2 cycles: 23 months vs $>$26 months, $P<0.0124$). **Conclusions:** EL regimen is not inferiority to EP regimen in terms of PFS. The tolerance and QOL with EL regimen are better than that with EP regimen. Thus EL regimen provides an alternatively new choice for first-line ES-SCLC treatment in China. The study is the first worldwidely prospective clinical study using CTCs as a biomarker monitoring SCLC therapeutic effects. Clinical trial information: ChiCTR-TRC-10001047.

**7596 General Poster Session (Board #204), Sat, 1:15 PM-5:00 PM**

**Comparison of cisplatin- versus carboplatin-based concurrent chemoradiation for limited-stage small cell lung cancer using SEER-Medicare data.** *Presenting Author: Ellen Kim, Case Western Reserve University School of Medicine, Cleveland, OH*

**Background:** Small cell lung cancer (SCLC) accounts for 14% of lung cancers. Current standard therapy for limited stage (AJCC stages I-III) SCLC is concurrent chemoradiation (CCRT) with cisplatin/etoposide but carboplatin/etoposide is often used for patients with poor tolerance or contraindication to cisplatin. The aim of this retrospective cohort study is to compare survival of cisplatin (cis) and carboplatin (carb) based CCRT in limited stage SCLC. **Methods:** Cases were selected from the population-based SEER-Medicare lung cancer database if the patient's first cancer was limited stage SCLC diagnosed at age 66-80 in 1992-2007. CCRT was defined with radiation starting within 60 days of the start of the first cycle of cis/carb. Study endpoints were overall survival (OS, time from diagnosis until death) and cause specific survival (CSS, time from diagnosis until death from lung cancer). SAS v9.3 was used to select cases, and R v3.0.2 was used to calculate Kaplan-Meier survival analysis and log-rank tests for significance. **Results:** Study sample meeting inclusion criteria included 1603 patients, with median age 72 (66-81) and gender ratio 1.1. Majority were stage III (n=1342, 84%), with some stage I (11%) and II (5%). Cis was used in 617 cases (38%) while carb was used in 986 cases (62%). On average, cis group was younger ($p<0.001$). Median (OS, CSS) were (1.20, 1.34) and (1.17, 1.33) years for cis and carb groups, respectively. Five-year (OS, CSS) for cis and carb were (13.7%, 24.4%) and (11.1%, 20.5%), respectively. There was no statistically significant difference in OS ($p=0.163$) or CSS ($p=0.683$) between the groups. **Conclusions:** Cis vs carb based CCRT had comparable OS and CSS, even though cis group was younger. This suggests that if carb is better tolerated, it should be preferred for limited stage SCLC, though randomized trials are needed.

**7597 General Poster Session (Board #205), Sat, 1:15 PM-5:00 PM**

**Clinical outcomes of patients with recurrent small cell lung cancer receiving third-line chemotherapy.** *Presenting Author: Koichi Saruwatari, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** Patients with small-cell lung cancer (SCLC) that progress after first-line therapy have a dismal prognosis. Second-line chemotherapy is effective for some patients, but there is little evidence for third-line chemotherapy. The purpose of this study is to evaluate the efficacy of third-line chemotherapy and clarify prognostic factors for patients receiving it. **Methods:** Between November 2001 and October 2011, 202 of 648 patients who were consecutively diagnosed with SCLC at the National Cancer Center Hospital East received third-line chemotherapy. We performed multivariate Cox regression analysis to identify the prognostic factors of overall survival after third-line chemotherapy (OS). **Results:** At the start of third-line chemotherapy, median age was 66 years (range 38-83), male/ female: 168/34, ECOG performance status (PS) 0/1/2/3: 22/122/49/9, stage at diagnosis LD/ED: 88/114, response to second-line chemotherapy CR/PR/SD/PD: 3/95/56/48, and median progression free survival after second-line chemotherapy (PFS2) : 4.4 months. 155 and 47 patients received single-agent and platinum-based regimen, respectively. Overall response rate was 17.8%, which was significantly associated with response (CR/PR) to second-line chemotherapy (23.5% vs. 12.5%, $p=0.042$) and PFS2 (25.6% vs. 7.4%, $p=0.024$). Median PFS and OS from third-line chemotherapy were 2.7 months and 5.1 months, respectively. Multivariate Cox analysis identified PS 0-1 (hazard ratio [HR], 0.38; 95% confidence interval [CI], 0.27-0.55; $p < 0.001$) and PFS2 $\geq$5 months (HR, 0.59; 95%CI, 0.42-0.81; $p=0.001$) were the independent prognostic factors indicating better OS. An optimal threshold of 5 months of PFS2 ($\geq$5/<5 months: 82/120) was selected based on the concordance index adjusted by PS. **Conclusions:** PS 0-1 and PFS2 $\geq$5 months were associated with favorable prognosis among SCLC patients receiving third-line chemotherapy. These two factors would be worth considering as stratification factors when conducting future clinical trials.

**7598 General Poster Session (Board #206), Sat, 1:15 PM-5:00 PM**

**Limited-stage small cell lung cancer treated with cisplatin/irinotecan and concurrent thoracic radiation therapy.** *Presenting Author: Salini Sathya Naidu, Leo Jenkins Cancer Center, Brody School of Medicine at East Carolina University, Greenville, NC*

**Background:** Concurrent chemotherapy and radiation therapy (CRT) is a curative option for limited-stage small cell lung cancer (SCLC). The standard of care in the United States is concurrent etoposide-platinum CRT. In Asia, CRT with irinotecan and cisplatin has been shown to be an effective and tolerable regimen. (Han et al J Clin Oncol 2005 and Jeong et al Lung Cancer 2006) Irinotecan is a potent radiosensitizing agent (Tamura et al Jpn J Cancer Res 1997). Patients with limited-stage SCLC treated with irinotecan-platinum concurrent CRT were identified from our institutional thoracic oncology program database. **Methods:** 36 patients with limited stage SCLC from 2006-2013 were identified from our database. Ages 49-85. 17 females and 27 males. All patients were treated with cisplatin 30mg/m2 and irinotecan 65mg/m2 on day 1 and 8 every 21 days for a total of 4 cycles, along with concurrent radiation therapy commensurate with cycle 2. 29 patients received BID concurrent radiation therapy (45Gy), and 7 patients received daily dosing (54Gy). 25 patients received prophylactic cranial irradiation. Median follow-up two years; 22 patients followed for over 3 years. **Results:** Overall radiographic response rate 67% (18 CR, 8 PR). Median overall survival 19 months. 1 year survival 60%: 2 year survival 44%; 3 year survival 30%. No symptomatic pneumonitis with 13% of patients developing symptomatic esophagitis. **Conclusions:** Irinotecan and cisplatin with concurrent CRT achieved a 30% 3-year overall survival in an American patient population with limited stage SCLC.

**7599 General Poster Session (Board #207), Sat, 1:15 PM-5:00 PM**

**Trends in small cell lung cancer (SCLC) survival: Predictors and impact of systemic therapy.** *Presenting Author: Madhusmita Behera, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background**: The last 2 decades witnessed limited therapeutic advances in SCLC management. We evaluated trends in the use of systemic therapies and the impact on outcome in the US. **Methods**: We employed data from the SEER-MEDICARE database for SCLC patients diagnosed between 1985 and 2005. The 1985-1990 period served as a baseline for a temporal survival analysis conducted at 5-year intervals (1985-1990, 1991-1995, 1996-2000 & 2001-2005). Predictors of chemotherapy use were identified by logistic regression model with a backward variable selection method. Cox proportional hazards models were employed to estimate the effect of chemotherapy on survival by time of diagnosis with adjustment for significant predictors of chemotherapy use. **Results**: There were 47,351 eligible patients; M/F (52%/48%); median age (71 years); ethnicity (Whites-87%; Blacks- 7%; Hispanic: <0.4%; Asians: 1.4%; Others-2.8%); median OS overall, with and without chemotherapy (7.2, 9.6 and 3.6 months). Rate of chemotherapy use was very low but showed a significant increase over time (38, 55, 50, 53%, $p<0.001$). Females (51%), Asians (53%) and rural residents (60%) were more likely to receive chemotherapy. Race, comorbidity, year, age and location at diagnosis significantly predicted chemotherapy use. Linear trend analyses across the defined 5-year intervals showed improved survival in patients treated with chemotherapy over untreated patients (HR: 0.70; 0.66, 0.67, 0.64; $p<0.001$) after adjusting for significant predictors of chemotherapy use. While survival did not significantly change over time among patients treated with chemotherapy (HR: 1.0, 1.014, 1.035,1.033; $p=0.337$) it became worse in untreated patients (HR: 1.0, 1.047, 1.057, 1.071; $p=0.002$). Treatment with >1 type of chemotherapy was associated with improved survival (HR: 1.315; 0.941; 0.858; 0.827; $p<0.001$). Analysis in propensity score matched patients showed no survival difference between carboplatin and cisplatin (HR: 0.906 (0.761-1.078); $p=0.267$) or platinum doublet and CAV regimen (HR: 0.929 (0.847-1.019); $p=0.118$). **Conclusions**: Chemotherapy use was associated with an incremental survival benefit in MEDICARE-eligible SCLC patients treated in the real-world setting.

**7600 General Poster Session (Board #208), Sat, 1:15 PM-5:00 PM**

**Final outcome results of platinum-sensitive small cell lung cancer (SCLC) patients treated with platinum-based chemotherapy rechallenge: A multi-institutional retrospective analysis.** *Presenting Author: Giovenzio Genestreti, Medical Oncology Department, Bellaria-Maggiore Hospital, Azienda USL of Bologna - IRCCS Institute of Neurological Sciences, Bologna, Italy*

**Background:** Rechallenge might be used as rescue therapy in progressing platinum-sensitiveSmall Cell Lung Cancer (SCLC). This international multicenter retrospective analysis evaluates the clinical outcomes of SCLC patients treated with this strategy. **Methods:** We retrospectively collect each institutional data warehouse of platinum-sensitive SCLC treated with platinum/etoposide rechallenge. Primary endpoint was overall survival (OS) from diagnosis and from the rechallenge of chemotherapy (PPS). Secondary endpoints were response rate (RR) and Progression-Free Survival2 (PFS2) yielded by rechallenge. **Results:** We reviewed 2000 SCLC patients from 9 institutions. One hundred twelve (5.6%) with sensitive SCLC were treated with first-line platinum/etoposide rechallenge. There were 72 (64%) males and 40 (36%) females with a median age of 64 years (range 40–83). At diagnosis, 49 (44%) patients had limited disease (LD) whereas 63 (56%) had extensive disease (ED). ECOG Performance Score (PS) was $<1$ and $>1$ in 87% and 13% of patients, respectively. First-line chemotherapy yielded: 14 % complete response (CR), 84% partial response (PR) and 2% stable disease (SD). Mean number of cycles of rechallenging chemotherapy was 3.6 (range 1-7). Carboplatin and cisplatin were administered in 96 (86%) and 16 (14%) of the patients, respectively. There were 3% CR, 42% PR, 19% SD, 27% progressive disease and 9% not evaluable yielding a median PFS2 of 5.5 months (95% CI 4.4-6.3). Median OS and PPS were 21.4 months (95% CI 19.8-24.1) and 7.9 months (95% CI 6.9-9.7), respectively. Forty (36%) patients received further chemotherapy. At the multivariate analysis stage at diagnosis, PS and platinum (carboplatin or cisplatin) used in rechallenge were not prognostic factors, while time from diagnosis to first progression disease (PFS1) $>$ 150 days ($p<0.0001$) was. **Conclusions:** Rechallenge may be an efficacy option in patients with platinum sensitive disease with a PFS1 $>$ 150 days.

**7601 General Poster Session (Board #209), Sat, 1:15 PM-5:00 PM**

**Phase 1b of anticancer stem cell antibody OMP-59R5 (anti-Notch2/3) in combination with etoposide and cisplatin (EP) in patients (pts) with untreated extensive-stage small-cell lung cancer (ED-SCLC).** *Presenting Author: David R. Spigel, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** The Notch pathway plays a central role in embryonic development, the regulation of stem and progenitor cells, and is implicated centrally in many human cancers, including SCLC. OMP-59R5, a fully human IgG2 antibody, inhibits signaling of Notch2 and 3 receptors. Anti-tumor activity was noted in 7 of 8 pt-derived SCLC xenografts expressing Notch 2 and 3 with OMP-59R5 treatment. The maximum tolerated dose (MTD) of single agent OMP-59R5 was 7.5mg/kg IV every 3 weeks (Smith, EORTC 2012); the main dose-limiting toxicity (DLT) was Grade 3 diarrhea. This study is to determine the MTD, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary efficacy of OMP-59R5 in combination with EP in ED-SCLC. **Methods:** Cohorts of 3 to 6 pts were treated at each dose level of OMP-59R5. OMP-59R5 was given IV on Day 1 of each 21 day cycle along with etoposide 100 mg/m$^2$ on Days 1, 2, and 3 and cisplatin 80 mg/m$^2$ on Day 1. After 6 cycles, pts continued OMP-59R5 alone every 21 days in the absence of disease progression or unacceptable toxicities. **Results:** By Jan 17, 2014, 8 pts were treated. No DLTs have occurred. Frequently reported (>25%) adverse events (all grades, G) regardless of relationship were: fatigue(62.5%), nausea(62.5%), anemia(50%), diarrhea(50%), peripheral edema(50%), alopecia(37.5%), blood creatinine increase(37.5%), decreased appetite(37.5%), neutropenia(37.5%), and weight loss(37.5%); Of these, fatigue(50%), anemia(37.5%), diarrhea(37.5%), nausea(37.5%), alopecia(25%), decreased appetite(25%), and weight loss(25%) were considered related to OMP-59R5-treatment. The events were mostly G 1 or 2, and managed with supportive care. Additional data are below (see Table). **Conclusions:** OMP-59R5 with EP is well tolerated. The MTD has not been reached. Encouraging anti-tumor activity is observed. Updated Safety, PK/PD, and efficacy data will be presented. Clinical trial information: NCT01859741.

| OMP-59R5 Dose (mg/kg) | | 5 (n=3) | 7.5 (n=3) | 10 (n=2) |

**7602 General Poster Session (Board #210), Sat, 1:15 PM-5:00 PM**

**Phase I trial of the hedgehog (Hh) inhibitor, LDE225, in combination with etoposide and cisplatin (EP) for initial treatment of extensive stage small cell lung cancer (ES-SCLC).** *Presenting Author: Maria Catherine Pietanza, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** SCLC relies on the Hh developmental pathway for tumor initiation and progression. Pharmacologic blockade with Hh inhibitors blocks these processes. We performed a phase I study to determine the maximum tolerated dose (MTD) of LDE225, a selective, oral smoothened antagonist, in combination with EP in newly diagnosed ES-SCLC patients. **Methods:** Untreated patients with measurable disease, Karnofsky performance status ≥70, and asymptomatic brain metastases were eligible. All patients received 4 to 6 21-day cycles of EP (E, 120mg/m2 D1-3; P, 60mg/m2 D1) with daily LDE225. Patients with response or stable disease were continued on LDE225 until disease progression or unacceptable toxicity. Prophylactic cranial irradiation was performed after EP + LDE225, and LDE225 was held during that therapy. Two dose levels of LDE225 were planned: 400mg and 800mg daily, with 200mg daily de-escalation if necessary. Circulating tumor cells were quantified by Veridex Cell Search Platform at baseline and with disease evaluation. **Results:** 14 patients with ES-SCLC were enrolled (median age 56 (range, 46-68); 57% male). Patients were treated as follows: 200mg (n=2); 400mg (n=7); 800mg (n=5). The first 3 patients were enrolled at 400mg, and 2 experienced a dose limiting toxicity (DLT) (nausea, n=1; febrile neutropenia (FN), n=1), leading to dose de-escalation (200mg). The definition of DLT was changed to exclude FN. The 400mg dose level was expanded with 4 additional patients without any further DLTs. 800mg has been established as the recommended phase II dose in combination with EP. Toxicity led to removal of one patient from study (grade 3 colitis and acute kidney injury). Grade 3 toxicities included: anemia (n=1), thrombocytopenia (n=1), CPK elevation (n=1), fatigue (n=2), and fever (n=1). 3 patients had grade 4 neutropenia. One patient died of an unrelated myocardial infarction. 5 patients actively are being treated. Partial responses were confirmed in 50% (7/14; 95% CI: 27-73%); 3 received maintenance LDE225 ≥4 months. **Conclusions:** LDE225 800mg daily was the MTD when administered with EP. The phase II dose expansion of this regimen is underway. Clinical trial information: NCT01579929.

**7603 General Poster Session (Board #211), Sat, 1:15 PM-5:00 PM**

**Clinical characteristics and outcomes for patients with thymic carcinoma: Evaluation of Masaoka staging.** *Presenting Author: Anna Maria Litvak, Memorial Sloan Kettering Cancer Center, New York City, NY*

**Background:** Thymic carcinomas (TC) are rare cancers with limited data regarding outcomes, particularly for those patients (pts) with advanced disease. **Methods:** We identified pts with TC diagnosed between 1993-2012. Pt characteristics, recurrence free survival (RFS) from date of resection, and overall survival (OS) from date of diagnosis were analyzed. Pts were followed until death or last follow up. Time-to-event outcomes were determined using the Kaplan-Meier method. **Results:** 121 pts with TC were identified with 7 pts (6%) with Masaoka stage I, 13 (11%) with stage II, 25 (21%) with stage III, 13 (11%) with stage IVA, 61 (51%) with stage IVB, and 2 (2%) with unclear staging. Higher Masaoka stage was associated with worse OS and RFS (5-yr OS of 100%, 81%, 51%, 24%, and 17% for stage I, II, III, IV respectively, $p<0.001$ and 5-yr RFS of 80%, 28%, and 7% for stage I/II, III, and IV respectively, $p<0.001$). Stage IVB pts with lymph node involvement had a better 5-year OS as compared to stage IVB pts with distant metastasis (24% vs. 7%, $p=0.025$). Of the 61 pts with stage IVB disease, 22/29 pts (76%) with lymph node involvement underwent curative intent resection vs. 3/32 pts (9%) with visceral metastasis. Of the 29 stage IVB pts with lymph node involvement treated with surgery, chemotherapy, and radiation, 3 (10%) are currently free of disease with long-term follow-up (range: 3.4 years to 6.8 years). **Conclusions:** This is the largest review of the clinical features of pts with TC in North America. Stage IVB pts with lymph node positive disease have significantly better OS as compared to Stage IVB pts with distant metastasis. Stage IVB pts with lymph node positive disease treated with multi-modality therapies can have long term recurrence free survival. If validated, these data would support a revised Masaoka staging system with subclassification of stage IVB disease into two groups.

**7604 General Poster Session (Board #212), Sat, 1:15 PM-5:00 PM**

**Outcomes of thymic neoplasms after the 1999 WHO classification.** *Presenting Author: Yousif Yonan, Penn State College of Medicine, Hershey, PA*

**Background:** In 1999 the World Health Organization (WHO) published a histologic sub-typing system for thymoma that divided it in to six classes, which included one category for thymic carcinoma (WHO C, Group 1) and five categories of invasive thymoma (WHO A, AB, B1, B2 and B3, Group 2). **Methods:** The SEER database was used to retrospectively identify thymic neoplasms from 2000-2010 using the six-tier classification system. Only those patients having thymic neoplasia as their only cancer and undergoing complete ($R_0$) resection were included in the analysis. Overall survival (OS) and thymic-specific survival (TSS) were evaluated by Kaplan-Meier methods. Multivariate analysis(MVA) was performed including group, age, race, Masaoka stage, gender, and adjuvant radiation therapy as key variables. **Results:** 505 thymic neoplasms were identified including 96 (19%) in group 1 and 409 (81%) in group 2. Median follow-up was 38 months. For patients with early Stage(I/II) group 1 and group 2 tumors, OS at 2, 3, and 5 years was 90.5, 90.5, 67.9% for Group 1 and 98.2, 95.8, 95.8 for Group 2 respectively. Group 1 classication ($p<0.0001$, HR 1.82), advancing age ($p=0.003$, HR 1.03) and increasing stage ($p=0.04$, HR 1.37) were significant predictors of worse OS. TSS was excellent in the overall group with thymus-related death listed as cause of death in only 35 (6.9%) of patients. Any Group 1 and Stage III/IV Group 2 tumors had significantly worse TSS. Histologic sub-typing within Group 2 was not associated with OS, TSS or high-risk of lymph node involvement (all<5%). In early-stage Group 1 patients, 15/34 (44%) did not have a nodal exam and 6/19 (32%) had positive nodes. **Conclusions:** Early-stage Group 2 patients have an excellent OS and TSS may not benefit from adjuvant therapy. Trials of adjuvant therapy should be considered for advanced-stage Group 2 patients and all Group 1 patients. Thymic carcinomas may be understaged due to lack of lymph node examination and the high percentage with involved nodes.

**7605 General Poster Session (Board #213), Sat, 1:15 PM-5:00 PM**

**National multidisciplinary tumor board (MTB): Report of the first 526 questions raised within RYTHMIC, the network for thymic malignancies in France.** *Presenting Author: Benjamin Besse, Gustave Roussy, Villejuif, France*

**Background:** RYTHMIC (Réseau tumeurs THYMiques et Cancer) is a nationwide network for thymic malignancies, which was funded in 2012 by the French National Cancer Institute. The objectives of the network include a territorial coverage by regional expert centers, elaboration of recommendations, dissemination of knowledge and promotion of collaborative research. All patients diagnosed with thymic malignancy in France have to be discussed on a real-time basis at a reference web-based national MTB or regional MTB. Patient's data from the MTB were prospectively entered in a database. **Methods:** We report the patient's and tumor's characteristics and treatment modalities of the patients included during the first 2 years of MTB. Questions raised during the MTB were reviewed. **Results:** From January to December 2013, 383 patients were included in the RYTHMIC database. There were 197 (51%) men and 186 (49%) women. Among 304 cases, histology was thymoma for 198 (65%) patients (16 (5%) type A, 31 (10%) type AB, 38 (12%) type B1, 46 (15%) type B2, 35 (12%) type B3, 38 (12%) mixed type, 4 unknown), and thymic carcinoma for 34 (11%) patients, 7 (2%) carcinoïds; other histologies were diagnosed for 65 (21%) patients. Among 206 cases, Masaoka-Koga stage was I, IIA, IIB, III, IVA, and IVB in 46 (22%), 33 (16%), 28 (13%), 37 (18%), 44 (21%), and 18 (9%) patients, respectively. 71 (18%) patients presented with autoimmune disorder, consisting of myasthenia gravis in 60% of the cases. Surgery was performed for 229 patients, mostly using a median sternotomy approach (52% of cases), video-assisted surgery accounted for 9% of the cases. Among the 526 questions addressed during the MTB, the most frequent were the indication of post-operative radiotherapy (29%), recurrence management (18%) and indication of surgery of a mediastinal lesion (17%). **Conclusions:** The RYTHMIC prospective cohort demonstrates the feasibility of a national MTB for thymic malignancies. It provides with a comprehensive tool to monitor dedicated actions to improve the management of patients in the future, increase the quality-of-care (mostly regarding locoregional treatment), and screen patients for future clinical trials.

**7606 General Poster Session (Board #214), Sat, 1:15 PM-5:00 PM**

**Programmed death receptor ligand-1 (PD-L1) expression in a thymoma (T) tissue microarray (TMA).** *Presenting Author: Sukhmani Kaur Padda, Department of Medicine, Division of Oncology, Stanford Cancer Institute/ Stanford University School of Medicine, Stanford, CA*

**Background:** Thymomas (T) contain lymphocytic infiltrates, and as they arise from an immune organ confer a unique tumor microenvironment. Tumor expression of the immune checkpoint ligand, PD-L1, is a known mechanism for immune evasion. Here, we evaluated T expression of PD-L1. **Methods:** A TMA was constructed from 69 Ts, with 15 thymic controls (C) (including 8 paired normal thymuses adjacent to tumor), at Stanford University. The pathologist was blinded to clinical data and sample identity. The TMA was stained with a monoclonal antibody (clone 15, Sino Biological) to human PD-L1 using human placenta for staining titration. To distinguish PD-L1 expression on epithelial cells from that on lymphocytes, a CK5/6 cytokeratin stain was used. An intensity scale of 0, 1, 2, and 3 representing no, equivocal, weak, and intermediate-strong staining, respectively, was used. Positive PD-L1 expression was defined as ≥2 staining intensity on thymic epithelial cells. A two-sample Wilcoxon rank sum test was used to compare the average intensity between Ts and Cs, and a Kruskal-Wallis rank test was used to compare the average intensity between type A, B, and AB histologies. A two-sided p-value ≤0.05 was considered statistically significant. **Results:** Characteristics for 69 patients: 36M/33F; mean age 54 years (2-86); WHO histology: 7 A, 17 AB, 8 B unspecified, 9 B1, 18 B2, 4 B3, 3 C, and 3 NOS. There were no PD-L1 intensity scores of 0 or 1 in either Ts or Cs. The majority of lymphocytic infiltrates did not stain for PD-L1. Ts had a higher frequency of more intense PD-L1 staining compared to Cs [T: 22.4% (2)/77.6% (3) v. C: 58.1% (2)/41.9% (3); $p=0.007$]. PD-L1 staining intensity also varied between histologic subtypes: B>AB>A ($p=0.0002$). The difference between A v. B was the most striking [A: 66.7% (2)/33.3% (3) v. B: 9.2% (2)/90.8% (3); $p=0.0001$]. **Conclusions:** To our knowledge, Ts have not been previously examined for PD-L1 expression. Although both Ts and Cs expressed PD-L1, Ts generally stained more intensely than Cs. There was also higher PD-L1 staining intensity in lymphocyte dominant histologies (i.e. type B). This finding is highly translatable as several PD-1 and PD-L1 inhibitors are in clinical trials.

**7607 General Poster Session (Board #215), Sat, 1:15 PM-5:00 PM**

**Mesothelin expression in thymic epithelial tumors (TETs).** *Presenting Author: Yuanbin Chen, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

**Background:** Mesothelin (meso) is overexpressed in many solid tumors and has been used as a target for anticancer therapy. Limited data is available on meso expression in TETs and its clinical correlates. Standard treatments have limited efficacy for patients with advanced TETs, especially thymic carcinoma (TC) after failure of platinum-based chemotherapy. There is an urgent need to identify novel therapeutic targets. In view of early results demonstrating benefit in therapeutic targeting of meso, we characterized meso expression in TETs. **Methods:** Patients with histologically confirmed thymoma (T) or TC and available tumor tissue who were enrolled in clinical trials at the National Cancer Institute between December 2007 and December 2013 were included. Meso expression was assessed by immunohistochemistry (IHC) using monoclonal antibody 5B2 (Novocastra/Leica, Bannockburn, IL) by a pathologist who was blinded to histological subcategory (T vs. TC) and clinical outcome. IHC staining of > 50% was labeled as positive and ≤ 50% was considered negative. Associations between meso expression and patient characteristics were assessed. **Results:** 71 cases (42 TC; 29 T consisting of 3 WHO subtype AB, 2 B1, 13 B2 and 11 B3) were included in this series. Meso expression localized to tumor cell membrane was observed in 19 (45%) TC and 1 (3%) T. Median age and gender distribution of meso-positive vs. meso-negative TC was: 55 (21-73) vs. 50 (20-74) years and 11M/8F vs. 10M/5F respectively. Meso-expressing TC included 12 of 16 (75%) poorly differentiated carcinomas, 3 of 11 (27%) squamous cell carcinomas, 1 of 2 (50%) basaloid cancers and 0 of 8 neuroendocrine tumors (including atypical carcinoids). Median overall survival was significantly higher in meso-positive TC compared to meso-negative TC (not reached vs. 48 months; $p=0.03$). Extra-thoracic metastases were present in 13 of 19 (68%) meso-positive TC and 17 of 23 (74%) meso-negative TC. **Conclusions:** This is the largest series of meso expression in TC. Meso expression was detected in 45% of TC and associated with a significantly higher overall survival. Further studies are needed to assess the role of meso as a potential therapeutic target in TC.

**TPS7608 General Poster Session (Board #216A), Sat, 1:15 PM-5:00 PM**

**START2: Tecemotide in unresectable stage III NSCLC after first-line concurrent chemoradiotherapy.** *Presenting Author: Suresh S. Ramalingam, Emory University Winship Cancer Institute, Atlanta, GA*

**Background:** Tecemotide is an antigen-specific cancer immunotherapy targeting the mucinous glycoprotein MUC1, which is overexpressed and aberrantly glycosylated in a number of cancers including non-small cell lung cancer (NSCLC). The START study evaluated tecemotide after first-line concurrent or sequential chemoradiotherapy (CRT) for unresectable stage III NSCLC (Butts et al, *Lancet Oncol* 2013). Though the primary endpoint was not achieved for the overall patient population, the predefined subset of 806 patients treated with concurrent CRT showed improved overall survival (OS; adjusted HR 0.78, 95% CI 0.64–0.95; p=0.016). The pivotal phase III study START2 intends to confirm these results in patients having had initial concurrent CRT. **Methods:** START2 is a global, randomized, double-blind placebo-controlled phase III trial investigating tecemotide in patients with unresectable stage III NSCLC with stable disease or objective response after first-line concurrent CRT completed 4–12 weeks before randomization. Concurrent CRT is defined as ≥2 cycles of platinum-based chemotherapy that overlaps with radiotherapy (total tumor dose ≥60 Gy, single fraction dose ≥1.8 Gy); any other therapy for NSCLC constitutes an exclusion criterion. Patients will be stratified by response to CRT (stable disease or objective response) and region (North America and Australia; Western Europe; Rest of World), and randomized (1:1) to tecemotide (806 $\mu$g lipopeptide) or placebo. One low dose of i.v. cyclophosphamide (300 mg/m$^2$) or saline will be given 3 days prior to the first dose of tecemotide or placebo, respectively. Eight weekly subcutaneous injections will be given initially, followed by 6-weekly injections until disease progression or discontinuation. The primary endpoint is OS time. Secondary endpoints are: time to symptom progression (Lung Cancer Symptom Scale), progression-free survival, time to progression, and safety. Approximately 1002 patients will be enrolled. Sample size was calculated for a hazard ratio of 0.77 corresponding to an increase in median OS from 20 to 26 months in the placebo/tecemotide arm, respectively, a power of 90%, and 1-sided significance level of 2.5%. Clinical trial information: NCT02049151.

**TPS7609^ General Poster Session (Board #216B), Sat, 1:15 PM-5:00 PM**

**Randomized, double-blind, placebo-controlled study of tremelimumab for second- and third-line treatment of unresectable pleural or peritoneal mesothelioma.** *Presenting Author: Michele Maio, University Hospital of Siena, Siena, Italy*

**Background**: Mesothelioma is an uncommon cancer principally caused by asbestos exposure. After 1st-line pemetrexed/platinum, there are no approved or active agents. Novel approaches are clearly needed. Cytotoxic T lymphocyte-associated antigen 4 (CTLA-4) is expressed upon T-cell activation, modulating and eventually inhibiting the T-cell immune response. Tremelimumab is a fully human anti-CTLA-4 antibody that has been investigated in more than 1000 patients (pts) with various tumor types. A single-center, single-arm phase 2 trial of tremelimumab in 29 mesothelioma pts who progressed on 1 prior line of platinum-based therapy demonstrated encouraging activity, including durable partial responses lasting 6 and 18 mos, disease control in 31% of pts, median overall survival (OS) of 10.7 mos, and 1- and 2-y survival rates of 48% and 37%, respectively (Maio, *Lancet Oncol* 2013). **Methods**: This multicenter, international, phase 2b, randomized, double-blind, placebo-controlled study (NCT01843374) enrolls pts with unresectable pleural or peritoneal mesothelioma who progressed after 1–2 lines of treatment that must have included a prior anti-folate-platinum-based regimen. Pts, stratified by EORTC status (low vs. high risk), line of therapy (2nd vs. 3rd), and anatomical site (pleural vs. peritoneal) are randomized 2:1 to tremelimumab or placebo. The primary endpoint is OS; secondary efficacy end points include OS rate at 18 mos, patient-reported outcomes, disease control rate (DCR), progression-free survival (PFS), overall response rate (ORR), and duration of response, based on modified RECIST criteria for pleural mesothelioma and RECIST criteria v1.1 for peritoneal mesothelioma. Exploratory objectives include clinical outcomes (DCR, PFS, ORR, and duration of response) based on immune-related response criteria; health-related quality of life, disease-related symptoms, pain, and health status in pts with durable clinical activity; and biomarkers (cellular, protein, and nucleic acid) and their association with tremelimumab treatment and clinical outcome. Recruitment is ongoing to a total of 564 pts at approximately180 centers globally. Clinical trial information: NCT01843374.

**TPS7610 General Poster Session (Board #217A), Sat, 1:15 PM-5:00 PM**

**Phase I-Ib trial of tivantinib in combination with carboplatin and pemetrexed as first-line treatment in patients (pts) with advanced nonsquamous NSCLC or malignant pleural mesothelioma (MPM).** *Presenting Author: Paolo A. Zucali, Humanitas Cancer Center, Rozzano, Italy*

**Background:** Dysregulation of MET signalling has been reported as a key event in several malignancies and has been identified as a promising therapeutic target. Strong preclinical data on MPM and NSCLC showed that MET inhibition blocks tumor cell growth and migration (Jagadeeswaran et al, Cancer Res 2006; MA et al, Cancer Res 2005). Tivantinib (T) is a selective non-ATP competitive oral inhibitor of MET receptor. In a randomized phase III trial, the combination of T plus erlotinib improved overall survival in a subset of pts with non-squamous NSCLC and high MET expression (Scagliotti G, ESMO/ECCO 2013 abst. n°:3410). Adding T to first-line chemotherapy (CT) may improve efficacy. **Methods:** This Phase I-Ib study is designed to assess the maximum tolerated dose (MTD), pharmacokinetics, pharmacodynamics and preliminary anti-tumor activity of escalating doses of T in combination with fixed doses of carboplatin (AUC 5 i.v. d1-q21) and pemetrexed (500 mg/m$^2$ i.v. d1-q21) as first line treatment for pts with advanced MPM or non-squamous NSCLC. Eligible pts must be CT naïve with ECOG Performance Status <2 and adequate bone marrow, liver and kidney functions. Sequential cohorts of 3 pts per dose level are recruited according to a standard 3 + 3 dose-escalation design starting from level 0 (T 240 mg BID). In case of DLTs in the first 3 pts, a dose level -1 (T 120 mg BID) will be investigated; in absence of DLTs, dose escalation will continue at dose level +1 (T 360 mg BID). The MTD is defined as the highest dose level at which no more than 1 of 6 pts experiences a DLT during the first cycle. If the frequency of DLTs encountered at dose-level +1 will not fulfil the MTD definition it will be accepted as the recommended dose for phase II trials. Additional pts (in order to reach 13 pts with MPM and 18 with NSCLC) will be enrolled at the MTD in an expansion cohort, to evaluate the preliminary anti-tumor activity in terms of 3-month PFS% for MPM pts and 5-month PFS% for NSCLC pts. Enrollment has begun in October 2013. The first dose level has been completed without DLTs and the first pt at dose level + 1 started treatment in January 2014. Clinical trial information: NCT02049060.

**TPS7611 General Poster Session (Board #217B), Sat, 1:15 PM-5:00 PM**

**COMMAND: A phase II randomized, double-blind, placebo-controlled, multicenter study of defactinib as maintenance therapy in subjects with malignant pleural mesothelioma that has not progressed on at least four cycles of pemetrexed/platinum therapy.** *Presenting Author: Dean Anthony Fennell, University of Leicester, Leicester, United Kingdom*

**Background:** Malignant pleural mesothelioma (MPM) is an aggressive tumor in the pleural lining of the lung usually caused by asbestos exposure. Median OS following frontline chemotherapy with pemetrexed/cisplatin (pem/cis) is ~12 months. There is no established second line therapy. 40-50% of MPM tumors exhibit disruption of the NF2 tumor suppressor gene by mutation and/or deletion resulting in lack of expression of functional merlin protein. Mesothelioma cell lines that lack merlin are more sensitive to focal adhesion kinase (FAK) inhibitors than those with wild type merlin. Furthermore, pem/cis enrich cancer stem cells (CSCs) in tumors, while FAK inhibitors have been found to decrease CSCs in mesothelioma models. Given the sensitivity of mesothelioma cells lacking merlin and the effect on CSCs, the use of a FAK inhibitor in a maintenance setting after first line chemotherapy may be an attractive strategy to extend survival of MPM patients. Defactinib (VS-6063) is an oral inhibitor of FAK. **Methods:** A multinational, randomized, double-blind, placebo controlled, clinical trial will determine if defactinib provides superior clinical benefit compared with placebo as a maintenance treatment in patients with MPM following frontline therapy with pem/platinum therapy. Approximately 370 eligible patients with PR or SD following at least 4 cycles of pem/cis or pem/carboplatin will be enrolled. Patients will receive defactinib 400mg BID or matched placebo (1:1). Patients will continue treatment until disease progression. Randomization will be stratified by merlin status (high vs low) as determined by immunohistochemistry on archival tumor tissue. Primary endpoints will include OS and PFS. An adaptive enrichment design at the interim analysis may restrict patients to those with low merlin protein expression if benefit is observed among the subpopulation. Secondary endpoints include patient-reported outcomes, objective response and safety and tolerability. Twenty-eight sites are actively recruiting patients across 8 countries. Clinical trial: NCT01870609.

**TPS7612 General Poster Session (Board #218A), Sat, 1:15 PM-5:00 PM**

**Nintedanib plus pemetrexed/cisplatin followed by maintenance nintedanib for unresectable malignant pleural mesothelioma (MPM): An international, multicenter, randomized, double-blind, placebo-controlled phase II study.**

*Presenting Author: Giorgio V. Scagliotti, Department of Clinical and Biological Sciences, University of Turin, S. Luigi Hospital, Torino, Italy*

**Background:** MPM is a rare cancer originating from multipotent mesothelial cells capable of differentiating into epithelial, sarcomatoid, or biphasic (mixed) neoplasms. The only approved 1st-line chemotherapeutic regimen for unresectable MPM, combination pemetrexed/cisplatin extends OS to only approximately one year, illustrating a need for improved treatment strategies. In the present trial, we are investigating the efficacy and safety of nintedanib (BIBF 1120) combined with pemetrexed/cisplatin for the treatment of unresectable MPM. Nintedanib is an oral, twice-daily, angiokinase inhibitor targeting most prominently vascular endothelial growth factor receptors 1–3, platelet-derived growth factor receptors $\alpha/\beta$, and fibroblast growth factor receptors 1–3, as well as Src and Abl kinase signaling, which are involved in regulating tumor angiogenesis, growth, and metastasis of MPM. These signaling pathways are also implicated in the pathogenesis and maintenance of MPM. In previous studies, we demonstrated that nintedanib can be co-administered with various anti-cancer drugs to safely and significantly increase survival in patients (pts) with non-small cell lung cancer. **Methods:** A total of 86 pts—at least 18 years of age and with ECOG score of 0 or 1 and histologically confirmed epithelioid or biphasic MPM—will be randomized in a 1:1 ratio to receive either up to 6 cycles of 1st-line combination pemetrexed (500 mg/m$^2$)/cisplatin (75 mg/m$^2$) on day one administered along with nintedanib (200 mg bid) or placebo from days two to 21. Pts who do not develop progressive disease (PD) will continue to receive maintenance treatment with either nintedanib or placebo until PD. The primary endpoint is PFS. Secondary endpoints are OS and baseline change in forced vital capacity as a measure of pulmonary function. Frequency and severity of adverse events will also be evaluated as a measure of safety. All pts will attend an end-of-trial visit when they discontinue study treatment permanently, and return for follow-up visits until the end of trial, death, or loss to follow-up. Clinical trial information: NCT01907100.

**8000 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Onartuzumab plus erlotinib versus erlotinib in previously treated stage IIIb or IV NSCLC: Results from the pivotal phase III randomized, multicenter, placebo-controlled METLung (OAM4971g) global trial.** *Presenting Author: David R. Spigel, Sarah Cannon Research Institute, Nashville, TN*

**Background:** A placebo-controlled, phase II trial of erlotinib + onartuzumab, a humanized monovalent antibody to the MET receptor, demonstrated a benefit in progression-free survival (PFS) when compared with erlotinib in patients with MET-positive NSCLC (JCO 2013;31;4105). The aim of the METLung trial was to confirm the efficacy and safety of onartuzumab + erlotinib in MET-positive NSCLC. **Methods:** This prospective, randomized, double-blind, placebo-controlled trial enrolled patients with previously treated MET-positive stage IIIb/IV NSCLC. MET diagnostic status was determined by an immunohistochemistry (IHC) assay using the CONFIRM anti-total MET SP44 monoclonal antibody (Ventana). Eligibility criteria included: ECOG PS 0–1, 1–2 prior lines of chemotherapy, and normal organ function. Stratification factors: *EGFR* mutation status (activating mutation vs negative; cobas® *EGFR* assay), MET IHC (2+ vs 3+), number of prior treatments (1 vs 2), and histology (squamous vs non-squamous). Patients were randomized (1:1) to receive erlotinib 150mg PO daily + placebo or onartuzumab 15mg/kg IV every 21 days. Tumor assessments occurred every 6 weeks. The primary endpoint was overall survival (OS). The sample size (n=490) was based on the assumption that adding onartuzumab to erlotinib would improve OS by 41% with 90% power (one-sided alpha 0.025). An interim analysis was planned when 67% (244 events) of the final events were reached. **Results**: 499 patients were enrolled between Jan 2012 and Aug 2013. An independent data review committee recommended to stop the trial for futility, as the addition of onartuzumab to erlotinib did not improve OS (HR 1.27, p=0.068; median OS 6.8 mos vs 9.1 mos), PFS (HR 0.99, p=0.92; median PFS 2.7 mos vs 2.6 mos), or overall response rate (8.4% vs 9.6%; p=0.63). The most frequent adverse events that were higher in the combination arm were peripheral edema, hypoalbuminemia, back pain, dyspnea, nausea, acneiform dermatitis, and rash. **Conclusions:** The phase III study did not confirm the efficacy results observed in the phase II study. Exploratory analyses based on molecular subgroups are pending. Clinical trial information: NCT01456325.

**8001 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Efficacy and safety of crizotinib in patients with advanced *c-MET*-amplified non-small cell lung cancer (NSCLC).** *Presenting Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

**Background:** *c-Met*-amplified NSCLC defines a subset of NSCLC that may be sensitive to the small-molecule tyrosine kinase inhibitor crizotinib, approved multinationally for the treatment of advanced *ALK*-positive NSCLC. Efficacy and safety data are presented for crizotinib in patients with advanced *c-Met*-amplified NSCLC within 3 categories of amplification MET/CEP7 ratio ≥1.8-≤2.2 (Low), >2.2-<5 (Intermediate) and ≥5 (High). **Methods:** *c-MET*amplification status was determined by FISH, with 10-12 patients to be enrolled into each amplification category. If 2 or more objective responses occur in a category, 19 additional patients are to be enrolled. This study is part of an ongoing phase 1 crizotinib study (NCT00585195). Patients received crizotinib 250 mg BID. Responses were assessed using RECIST v1.0. **Results:** At data cut-off, 16 patients were enrolled; 3 were subsequently determined not to have an amplification meeting MET/CEP7 criteria. 13 patients with *c-MET*-amplified NSCLC [Low (n=1), Intermediate (n=6) and High (n=6)] enrolled and received crizotinib, with 12 evaluable for response. Median age was 63 years (range 42-79), 92% of patients were ECOG 0 or 1 and 77% were ex-smokers. To date 4 PRs (33%; 95% CI: 10,65) have been observed (Low (n=0), Intermediate (n=1; 20%) and High (3; 50%). Median duration of response was 35 weeks [95% CI: 16,112]. Median treatment duration was 15.7 weeks (range 4 -188), and 6 patients were on treatment at the data cut-off; 5 patients have died (all disease-related). 75% of the 16 patients enrolled had treatment-related adverse events (AEs): most commonly diarrhea (50%), nausea (31%), vomiting (31%), peripheral edema (n=25%) and visual impairment (25%). Most AEs were grade 1 in severity. There were no treatment-related serious AEs or treatment-related permanent discontinuations. Accrual of patients with *c-Met*-amplified NSCLC is ongoing. **Conclusions:** Crizotinib appears to have antitumor activity in patients with *c-Met*-amplified NSCLC and a generally tolerable and manageable AE profile. These findings warrant further study of crizotinib in advanced *c-MET*-amplified NSCLC and ongoing exploration of the MET/CEP7 ratio associated with clinical benefit. Clinical trial information: NCT00585195.

**8002 Poster Highlights Session (Board #52), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**First-line crizotinib versus pemetrexed–cisplatin or pemetrexed–carboplatin in patients (pts) with advanced *ALK*-positive non-squamous non-small cell lung cancer (NSCLC): results of a phase III study (PROFILE 1014)** *Presenting Author: Tony Mok, The Chinese University of Hong Kong, Hong Kong, China*

**Background:** The efficacy of the oral ALK inhibitor crizotinib as 1st-line treatment for advanced *ALK*-positive NSCLC compared with standard chemotherapy is unknown. A multicenter, randomized open-label phase III study was conducted to compare the efficacy and safety of crizotinib vs. pemetrexed–platinum chemotherapy (PPC) in this setting. **Methods:** Between Jan 2011 and Jul 2013, 343 pts with previously untreated advanced non-squamous *ALK*-positive NSCLC were randomized 1:1 to receive crizotinib 250 mg PO BID (n=172) or PPC (pemetrexed 500 mg/m$^2$ + either cisplatin 75 mg/m$^2$ or carboplatin AUC 5–6; all IV q3w for ≤6 cycles; n=171). Continuation of/crossover to crizotinib after PD (per independent radiologic review) was allowed for pts randomized to crizotinib or PPC, respectively. The primary endpoint was PFS. Secondary endpoints included ORR, OS, safety, and pt-reported outcomes. **Results:** Proportions of pts in the crizotinib and PPC treatment groups with each stratification factor were 45% and 47% Asians, 94% and 95% with ECOG PS 0/1, and 26% and 28% with previously treated brain metastases, respectively. The study met its primary objective, demonstrating superiority of crizotinib over PPC in prolonging PFS (median 10.9 vs. 7.0 mo; HR: 0.454; 95% CI: 0.346−0.596; P<0.0001). The ORR was significantly higher with crizotinib (74% vs. 45%; P<0.0001). With 68% of pts still in follow-up, a statistically significant improvement in OS was not demonstrated (HR: 0.821; 95% CI: 0.536−1.255; P=0.1804). At time of data cut-off 109 pts on PPC had crossed over to crizotinib. AEs with crizotinib and PPC were consistent with those previously reported in patients with advanced *ALK*-positive or unselected NSCLC, respectively. The most common all-causality AEs with crizotinib were vision disorder and GI symptoms. **Conclusions:** First-line crizotinib treatment showed significant improvements in PFS and ORR compared with standard chemotherapy and had an acceptable safety profile. These findings establish crizotinib as the standard of care for pts with previously untreated advanced *ALK*-positive non-squamous NSCLC. Clinical trial information: 2010-021336-33.

**8003^ Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Ceritinib in advanced anaplastic lymphoma kinase (ALK)-rearranged (ALK+) non-small cell lung cancer (NSCLC): Results of the ASCEND-1 trial.** *Presenting Author: Dong-Wan Kim, Seoul National University Hospital, Seoul, South Korea*

**Background:** ALK+ NSCLC is sensitive to crizotinib (CRZ) but patients (pts) invariably progress. Ceritinib (LDK378) is a novel ALK inhibitor (ALKi) more potent than CRZ in enzymatic and cell-based assays and CRZ-resistant animal models. Prior results from this Phase I study (ASCEND-1) established a MTD of 750 mg/d. **Methods:** Adult pts with advanced ALK+ cancers received oral ceritinib q.d. After MTD determination, pts were enrolled to expansion groups: ALKi pretreated (PT) NSCLC; ALKi naive NSCLC; non-NSCLC diseases. Results are reported for all NSCLC pts receiving ceritinib at the recommended dose (750 mg/d). **Results:** 255 pts from 11 countries were treated at 750 mg/d. 246 pts had ALK+ NSCLC, with 4.5 months' median follow-up; of these, 67% had received ≥2 anticancer therapies; ORR was ≥60% in each subgroup of pts with 0, 1, 2, and 3 prior anticancer regimens. 83 pts were ALKi naïve. All 163 ALKi PT pts had received CRZ – 78% as their last prior therapy – and 92% had progressive disease on prior ALKi. Investigator efficacy assessments are presented for 180 NSCLC pts who received first dose of ceritinib ≥18 wks prior to cut-off (2 Aug 2013). Of all 255 pts, the most common AEs were diarrhea (84%), nausea (77%), vomiting (57%), fatigue (36%), and ALT increased (36%). The most common Grade 3/4 AEs were ALT increased (21%), and AST increased (8%). Ceritinib treatment is ongoing for 58% of pts. During the dosing period dose reductions occurred in 133 pts (52.2%), all due to an AE. Only 24 (9.4%) pts discontinued ceritinib due to an AE. **Conclusions:** Ceritinib 750 mg/d has rapid, durable and high antitumor activity in ALK+ NSCLC pts, regardless of prior treatment with ALKi, providing effective treatment in this pt population. Clinical trial information: NCT01283516.

**8004^** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Overall survival (OS) in patients (pts) with advanced non-small cell lung cancer (NSCLC) harboring common (Del19/L858R) epidermal growth factor receptor mutations (EGFR mut): Pooled analysis of two large open-label phase III studies (LUX-Lung 3 [LL3] and LUX-Lung 6 [LL6]) comparing afatinib with chemotherapy (CT).** *Presenting Author: James Chih-Hsin Yang, National Taiwan University Hospital, Taipei, Taiwan*

**Background:** Afatinib (A) is an oral, irreversible ErbB family blocker of EGFR, HER2, ErbB3 and ErbB4 signalling. LL3 compared A with cisplatin/pemetrexed in 345 pts recruited globally and LL6 compared A with gemcitabine/cisplatin in 364 Asian pts. The primary analysis (2012) showed improved progression-free survival (PFS) with A versus CT in the overall EGFR mut positive population (HR=0.58 [LL3], HR=0.28 [LL6]) and pts with common (Del19/L858R) EGFR mut (HR=0.47 [LL3], HR=0.25 [LL6]). The FDA has approved A for the first-line treatment of pts with advanced NSCLC harboring common EGFR mut. Here we present a pooled analysis of mature OS data among such pts. **Methods:** Treatment-naïve pts with EGFR mut stage IIIB/IV NSCLC were randomized 2:1 to 40 mg A or up to 6 cycles of standard CT and stratified by EGFR mut and race (LL3). The primary endpoint was PFS, with OS as a key secondary endpoint. Adverse events were also recorded. **Results:** The pooled analysis included 631/709 pts randomized into LL3 and LL6 with common EGFR mut (Del19=355, L858R=276); 419 pts received A and 212 received CT. At the time of analysis (January 2014), 404 (64%) pts had died. Median follow-up for OS was 36.5 months. Following progression, 78% of pts received subsequent systemic therapies (median of 3 regimens); 68% in the CT group received EGFR TKIs and 70% in the A group received CT. OS was significantly improved with A versus CT (median 27.3 vs 24.3 months, HR=0.81 [CI 0.66, 0.99; p=0.037]). Individual HRs for OS in LL3 and LL6 were consistent with the pooled analysis. Among Del19 pts the HR=0.59 (CI 0.45, 0.77; p<0.001) and in L858R pts the HR=1.25 (CI 0.92, 1.71; p=0.160). Updated PFS and safety findings were consistent with earlier primary reports. **Conclusions:** This pooled analysis reveals that first-line A significantly improves OS in pts with advanced NSCLC harboring common EGFR mut (Del19/L858R) compared with CT. This is the first analysis to show that genotype-directed therapy for EGFR mut pts can improve survival. Clinical trial information: NCT00949650, NCT01121393.

**8005** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Erlotinib plus bevacizumab (EB) versus erlotinib alone (E) as first-line treatment for advanced EGFR mutation–positive nonsquamous non-small cell lung cancer (NSCLC): An open-label randomized trial.** *Presenting Author: Terufumi Kato, Department of Respiratory Medicine, Kanagawa Cardiovascular and Respiratory Center, Yokohama, Japan*

**Background:** Despite the development of EGFR tyrosine kinase inhibitors, median progression-free survival (PFS) is only about 13 months in patients with EGFR mutation–positive NSCLC. However, results from the BeTa Lung study for a subgroup of patients with EGFR mutation suggest that EB may prolong PFS in these patients. **Methods:** Open-label randomized trial. Patients with stage 3b/4 or recurrent non-squamous EGFR mutation–positive NSCLC, ECOG performance status 0/1, and no previous chemotherapy were randomly allocated to receive EB (E, 150 mg/day; B, 15 mg/kg every 3 weeks) or E (150 mg/day) until disease progression or unacceptable toxicity. The primary endpoint was PFS determined by blinded independent review committee. Secondary endpoints included overall survival, objective response rate (ORR), safety, and quality of life. The planned sample size was 150, with an alpha error of 0.2 and a power of 80% for a target hazard ratio (HR) of 0.7. **Results:** From February 2011 to March 2012, 154 patients were enrolled (EB group, $n = 77$; E group, $n = 77$). There were no major differences in patient characteristics, including age, gender, stage, and EGFR mutation type, between the two groups. Median PFS was 16.0 months for EB and 9.7 months for E (HR, 0.54; 95% CI, 0.36–0.79; log-rank $p = 0.0015$). In the EGFR exon 19 deletion subgroup, median PFS was 18.0 months for EB and 10.3 months for E. In the L858R subgroup, median PFS was 13.9 months for EB and 7.1 months for E. ORR was 69.3% for EB and 63.6% for E. There were 3 and 1 complete responses to EB and E, respectively. Grade 3 or 4 rash was more common in the EB group (25.3% versus 19.5%). Grade 3 or 4 bleeding was more common in the EB group (2.7% versus 0.0%). However, most adverse events were manageable, and no new safety signals arose. Five patients experienced grade 1–3 interstitial lung disease, but there was no difference between the groups. One treatment-related death occurred in the E group. **Conclusions:** EB results in significantly longer PFS than E in patients with EGFR mutation–positive NSCLC. Clinical trial information: JapicCTI-111390.

**REVEL: A randomized, double-blind, phase III study of docetaxel (DOC) and ramucirumab (RAM; IMC-1121B) versus DOC and placebo in the treatment of stage IV non-small cell lung cancer (NSCLC) following disease progression after one prior platinum-based therapy.** *Presenting Author: Maurice Perol, Léon-Bérard Cancer Centre, Lyon, France*

**The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 31, 2014, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2014, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.**

**8007** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Safety and clinical activity of MK-3475 as initial therapy in patients with advanced non-small cell lung cancer (NSCLC).** *Presenting Author: Naiyer A. Rizvi, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Programmed death-1 (PD-1) receptor-ligand interaction inhibits T cell activation against tumor cells. MK-3475 is a potent and highly selective humanized monoclonal antibody against PD-1 designed to directly block its interaction with its ligands, PD-L1 and PD-L2, thus removing the inhibition of T cell activation against cancer. MK-3475 led to prolonged anti-tumor activity in previously treated NSCLC patients. This Phase I study evaluated the safety, tolerability, and clinical activity of MK-3475 as initial therapy in patients with locally advanced or metastatic NSCLC. **Methods:** Patients with no prior systemic therapy for metastatic disease whose tumors expressed PD-L1 by a preliminary immunohistochemical assay were randomized to MK-3475 10 mg/kg every 2 or 3 wks (Q3W). The first 11 patients were randomized to 2 mg/kg and 10 mg/kg Q3W. At least 1 measurable tumor lesion, ECOG performance status of 0 to 1, adequate organ function and adequate tumor biopsy were required for enrollment. Prior adjuvant therapy was allowed if it preceded relapse by at least a year. Tumor response was assessed every 9 weeks until confirmed disease progression per immune related response criteria (irRC; investigator review); RECIST 1.1 by independent central review will also be performed. **Results:** 84 patients submitted tissue for PD-L1 assessment and 57 patients had tumors that expressed PD-L1. Between Feb 2013 and Oct 2013, 45 patients started treatment (n=6 2Q3W, n=23 10Q3W, n=16 10Q2W). Preliminary data indicate an ORR (confirmed and unconfirmed) of 36% (67% 2 mg/kg Q3W, 27% 10 mg/kg Q3W, 35% 10 mg/kg Q2W) by irRC. 25 patients (55%), including all but 2 responders, remain on treatment (treatment duration from 12+ to 48+ wks). 52% of patients experienced a drug-related adverse event (AE), usually grade 1-2 in severity, most commonly fatigue (14%), pruritus (8%), dermatitis acneiform (6%), diarrhea (6%) and dyspnea (6%). There was a single drug-related grade 3-5 AE, a grade 3 pericardial effusion. **Conclusions:** These data suggest that MK-3475 is generally well-tolerated and provides robust antitumor activity in a first-line setting in patients with locally advanced or metastatic NSCLC that expresses PD-L1. Clinical trial information: NCT01295827.

**8008^ Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**A randomized, multicenter, open-label, phase III study of gemcitabine-cisplatin (GC) chemotherapy plus necitumumab (IMC-11F8/LY3012211) versus GC alone in the first-line treatment of patients (pts) with stage IV squamous non-small cell lung cancer (sq-NSCLC).** *Presenting Author: Nick Thatcher, The Christie Hospital NHS Foundation Trust, Manchester, United Kingdom*

**Background:** Necitumumab (N), a human IgG1 anti-EGFR monoclonal antibody, inhibits ligand-binding and receptor activation. EGFR is detectable in the vast majority of advanced sq-NSCLC tumors. **Methods:** Pts with pathologically proven stage IV sq-NSCLC were randomized 1:1 to GC (G=1250 mg/m$^2$ iv, days 1 and 8; C=75 mg/m$^2$ iv, day 1) plus N (800 mg iv, days 1 and 8) (GC+N arm), or GC alone (GC arm) every 21 days for up to 6 cycles. GC+N pts with no progression continued on N alone until progressive disease or intolerable toxicity. The primary endpoint was overall survival (OS). Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), and safety. EGFR protein expression level by immunohistochemistry (H-score) in tumor tissue was an exploratory analysis. Planned sample size was 1080 pts, with 90% power and a 2-sided alpha level of 0.05. **Results:** 1,093 pts were randomized (n=545, GC+N; n=548, GC). Baseline characteristics were balanced between GC+N and GC, respectively, including males (82.6% and 83.6%), ECOG PS 0/1 (91.0% and 91.2%), and PS 2 (9.0% and 8.6%). Exposure to chemotherapy was similar in both arms; median dose intensity (DI) for G and C was 86% and 95%, respectively, and DI for N was 94%. 51% of GC+N pts continued N alone for a median of 4 additional cycles. The addition of N to GC statistically significantly improved OS (HR=0.84, $p$=0.012) and PFS (HR=0.85, $p$=0.020); mOS was 11.5 vs 9.9 mo in GC and mPFS was 5.7 vs 5.5 mo in GC. ORR was 31% vs 29% in GC ($p$=0.400), and the disease control rate (DCR) was 82% vs 77% in GC ($p$=0.043). Post-progression anticancer therapy was similar (47% vs 45%). Several prespecified subgroup analyses of OS and PFS showed a consistent treatment effect, including pts with ECOG PS 2. Grade ≥3 adverse events with GC+N (measured by preferred MedDRA terms) that showed a >2% increase over GC were hypomagnesemia (8.7% vs 1.1%) and skin rash (3.7% vs 0.2%). **Conclusions:** The addition of N to GC statistically significantly improved OS, PFS, and DCR. The safety profile of GC+N is acceptable. Clinical trial information: NCT00981058.

**8009^ Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Clinical activity of the mutant-selective EGFR inhibitor AZD9291 in patients (pts) with EGFR inhibitor–resistant non-small cell lung cancer (NSCLC).** *Presenting Author: Pasi A. Janne, Dana-Farber Cancer Institute, Boston, MA*

**Background:** AZD9291 is a selective, third generation EGFR-TKI, effective against both EGFR-TKI sensitizing and resistance T790M mutations in preclinical models. We are conducting a phase I study of AZD9291 in EGFR mutant (EGFRm+) NSCLC pts. **Methods:** EGFRm+ NSCLC pts, with acquired resistance to EGFR-TKIs, were enrolled in a multicenter trial (NCT01802632) into dose escalation and expansion cohorts. AZD9291 was administered orally, at doses of 20–240 mg once daily. Stable brain metastases were allowed. All pts were assessed for pharmacokinetics (PK), response to therapy, and adverse events (AEs). Prospective mandatory central T790M testing was required in the expansion cohorts and was optional for dose escalation cohorts. **Results:** As of 16 January 2014, 199 pts (62% female, median age 60, Asian/Caucasian 65%/32%, immediate prior EGFR-TKI therapy: 57%) were enrolled including 31 across 5 dose levels in the dose escalation and 168 in 8 dose expansion cohorts. Median number of prior EGFR therapies: 1 (range, 1-5). PK was dose proportional, median t1/2 ~50 h. Plasma exposures achieved at all doses are predicted to be efficacious in preclinical models. Among all evaluable pts to date, the confirmed+unconfirmed overall response rate (c+uORR) was 51% (91/177). RECIST responses were observed at all dose levels and in brain metastases. In 132 pts with centrally confirmed T790M, the c+uORR in 89 EGFR T790M+ pts was 64% (95% CI; 53%, 74%) and in 43 EGFR T790M- pts was 23% (95% CI; 12%, 39%).The overall disease control rate (CR+PR+SD) in T790M+ pts was 96% (85/89). Among the 60 pts with a confirmed response, 97% (58/60) were ongoing at data cut-off; longest duration of response to date >8 months. No dose limiting toxicities were observed. Most common AEs (≥15%), mostly CTCAE Grade 1, were: diarrhea (30%), rash (24%), and nausea (17%). Grade 3/4 AEs occurred in 16% of pts. Six pts (3%) had dose reductions. Five reports of ILD-like events are under investigation. **Conclusions:** AZD9291 has robust efficacy and is well tolerated in EGFRm+ NSCLC pts with acquired resistance to EGFR-TKIs. Pts with EGFR T790M+ tumors have higher ORR with AZD9291 compared with those with EGFR T790M- tumors. Clinical trial information: NCT01802632.

**8010^ Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**First-in-human evaluation of CO-1686, an irreversible, highly selective tyrosine kinase inhibitor of mutations of EGFR (activating and T790M).** *Presenting Author: Lecia V. Sequist, Massachusetts General Hospital, Boston, MA*

**Background:** Efficacy of existing EGFR tyrosine kinase inhibitors (TKIs) in NSCLC is limited by emergence of the T790M mutation in approximately 60% of patients, and significant skin rash and diarrhea, caused by wild-type (WT)-EGFR inhibition. CO-1686 is an oral, covalent TKI that targets common activating EGFR mutations and T790M, while sparing WT-EGFR. **Methods:** This is a completed dose finding study in patients with EGFR mutated advanced NSCLC. Patients were previously treated with EGFR TKI and had a tumor biopsy in screening for central EGFR genotyping. CO-1686 was administered twice daily. Endpoints included safety, pharmacokinetics (PK), and efficacy. **Results:** As of 17$^{th}$January 2014, 88 patients were treated: 57 with CO-1686 free base (up to 900 mg BID); 31 with CO-1686 HBr (500 to1000 mg BID). 10 transitioned from free base to HBr. 63% were T790M+, median age 61 years, 77% female, 76% white, and 72% ECOG 1. Median number of previous therapies was 3 (1- 7); 40% had >1 prior line of EGFR TKI. PK of the CO-1686 HBr formulation was dose proportional with three times greater exposure than the equivalent free base dose. The dose limiting toxicity (DLT) rate at all doses was <33%. Related AEs (all grades) in ≥ 20% patients were: nausea (25%), fatigue (21%), impaired glucose tolerance/hyperglycemia (21%). Hyperglycemia was well managed with oral hypoglycemics and/or dose reduction. A recommended phase 2 dose of 750 mg BID has been selected. Nine T790M+ patients treated with 900 mg BID (free base) were evaluable for response; 6 (67%) achieved PRs, 2 (22%) achieved SD, one of whom subsequently achieved a PR after transition to CO-1686 HBr. Eight of nine progressed on EGFR TKI immediately before CO-1686. PRs have occurred among patients treated with CO-1686 HBr, however the majority of patients have not reached the first restaging. Efficacy data for at least 41 patients on CO-1686 HBr will be presented at the meeting. **Conclusions:** CO-1686 has demonstrated promising efficacy against T790M+ EGFR mutant NSCLC. CO-1686 HBr delivered higher exposures than free base and was equally well tolerated. Dose-related WT-driven diarrhea and rash has not been seen. The phase 2/3 program will open in 2014. Clinical trial information: NCT01526928.

**8011 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Clinical activity and safety of HM61713, an EGFR-mutant selective inhibitor, in advanced non-small cell lung cancer (NSCLC) patients (pts) with EGFR mutations who had received EGFR tyrosine kinase inhibitors (TKIs).** *Presenting Author: Dong-Wan Kim, Seoul National University Hospital, Seoul, South Korea*

**Background:** HM61713 is a novel, oral, selective inhibitor for EGFR mutations including both activating mutations and T790M, but not EGFR wild-type. This phase 1 trial was conducted to evaluate the safety, pharmacokinetics, and preliminary efficacy of HM61713 in the pts with advanced NSCLC harboring EGFR mutations who had failed to previous EGFR-TKIs (NCT01588145). **Methods:** EGFR TKIs pre-treated, advanced NSCLC pts with EGFR mutation positive tumors were enrolled. The 3+3 dose-escalation scheme was used in dose-escalation cohort. Expansion cohort was implemented at the dose 300mg qd; pts were assigned to either arm A or B according to elapsed time interval after prior EGFR-TKIs (Arm A: <4 weeks; Arm B: ≥4 weeks) and underwent mandatory tissue biopsy at baseline to analyze EGFR T790M mutation status. **Results:** To date, a total of 93 pts have been enrolled in both dose escalation and expansion cohorts (35:58 respectively). These pts received HM61713 up to 500 mg/day and maximum tolerated dose has not been determined yet and subsequent dose escalation is ongoing. Drug-related adverse events (AEs) reported in ≥10% of pts were skin exfoliation, nausea, diarrhea, rash, decreased appetite and pruritus. Most of AEs were typically Gr 1/2, easily manageable and reversible without interruption of dosing. Two cases of Gr3 or more drug-related AEs were reported. A total of 7 unconfirmed partial responses (uPR) were observed so far out of 42 evaluable pts (arm A: 3/16; arm B: 4/26) in expansion cohort. Disease control rate was 76.5% and 73.1% in arm A and B, respectively. Among 27 patients who had T790M mutation at baseline biopsy, 18 pts showed decreased size in the target lesions and all the uPR observed were T790M mutation positive cases. **Conclusions:** HM61713 showed good safety profile and promising anti-tumor activity in pts with EGFR mutated NSCLC who failed to EGFR-TKIs, especially in pts with T790M mutation. Clinical trial information: NCT01588145.

**8012 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Overall response rate (ORR) as a potential surrogate for progression-free survival (PFS): A meta-analysis of metastatic non-small cell lung cancer (mNSCLC) trials submitted to the U.S. Food and Drug Administration (FDA).** *Presenting Author: Gideon Michael Blumenthal, U.S. Food and Drug Administration, Silver Spring, MD*

**Background:** Targeted therapies (TT) administered as single agents in molecularly defined mNSCLC subsets are yielding high ORR. Improvements in PFS of large magnitude with favorable benefit-risk have served as the basis of drug approval in mNSCLC. The relationship between ORR with PFS or Overall Survival (OS) in mNSCLC is not established. Therefore, we conducted a meta-analysis of mNSCLC trials submitted to the FDA, including 3 trials of TT in molecularly enriched populations with high ORR. **Methods**: We identified 15 trials of 12,534 patients (median N = 698) of 9 experimental agents (tyrosine kinase inhibitor = 5, chemotherapy = 2, monoclonal antibody = 2) submitted for treatment of mNSCLC in initial or supplemental New Drug or Biologics License Applications since 2003. Criteria for inclusion of the trials in this analysis were: randomized, active-controlled, multicenter, N ≥ 150. Three trials tested TT in defined populations (EGFR mutant = 2, ALK+ = 1). The estimated PFS hazard ratio (HR- ratio of hazard of treatment versus hazard of control group) and OS HR versus the estimated odds ratio (OR) of ORR (ratio of odds of response in controls to odds of response in treatment) on the log-scale was calculated. Weighted least square (WLS) regression analyses (weight equal to the number of patients) were performed on log-transformed effects. **Results**: For the PFS HR vs. ORR OR analysis, the $R^2 = 0.89$, the slope of the WLS = 0.41 (95% CI: 0.32, 0.49). For the OS HR vs. ORR OR analysis, $R^2 = 0.12$, slope = 0.05 (95% CI: -0.03, 0.13). Using trials ≥ 500 patients (n=12), $R^2 = 0.50$, slope = 0.16 (95% CI: 0.04, 0.3). For the OS HR vs. PFS HR analysis, $R^2 = 0.1$, slope = 0.1 (95% CI: -0.1, 0.3). Using trials with ≥ 500 patients, $R^2 = 0.39$, slope = 0.32 (95% CI: 0.04, 0.6). **Conclusions**: On a trial level, the meta-analysis of randomized, active-controlled trials indicates a strong correlation between ORR and PFS. A correlation between ORR or PFS and OS is not established and may be confounded by cross-over in the TT trials. At the trial level, a TT in a molecularly defined subset of mNSCLC with a large magnitude of effect on ORR will likely have a large effect on PFS.

**8013 Poster Highlights Session (Board #27), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Pan-Canadian rash trial with EGFR inhibitors.** *Presenting Author: Barbara L. Melosky, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** Erlotinib prolongs survival in advanced non-small cell lung cancer (NSCLC), as a first-line treatment for EGFR mutation, and second-/third-line upon progression on chemotherapy. Rash is a major side effect of erlotinib; studies have retrospectively illustrated a relationship between rash and efficacy. The primary objective of this study was to determine the optimal treatment of rash secondary to erlotinib **Methods:** The Pan Canadian Rash Trial studied rash in patients who received erlotinib for advanced NSCLC in the second or third-line setting. This trial was initiated before *EGFR* mutational testing was available. Patients were randomized to one of three arm: Prophylactic (Arm 1) minocycline (150 po bid) on day 1 of erlotinib; Reactive (Arm 2) treatment with topical clindamycin + hydrocortisone +/- minocycline upon rash occurrence depending on grade; Observation (Arm 3) no treatment of rash unless severe (Gr 3). Endpoints included the overall incidence and severity of rash and relationship to survival. **Results:** 150 patients were enrolled. 75% were Caucasian and 76% were current/former smokers. Overall incidence of rash was 83%. Time to occurrence of rash was significantly longer in Arm 1. (Table) Prophylactic minocycline reduced the probability of rash by 39.8% compared to Arms 2 and 3 combined (odds ratio 0.602, p = 0.3210). The incidence of Grade 3 rash was greater in Arm 3 (34.1%) versus Arms 1 (14.3%) and 2 (9.5%). Patients in Arm 1 were on erlotinib 50% longer than in arms 2 and 3 (6.34 months vs 4.02 and 4.16 respectively). Although not statistically significant, Arm 1 had the longest overall survival. **Conclusions:** Incidence of rash secondary to erlotinib treatment is common. Prophylactic minocycline reduced occurrence and severity of rash, was well tolerated and conferred a non-significant survival advantage. This may reflect improvement in patient compliance. Observation until severe rash (Gr 3) led to the worst outcome. Prophylactic treatment did not reduce erlotinib efficacy, and should be considered in patients upon initiation of erlotinib therapy. Clinical trial information: NCT00473083.

**Time to first presentation of rash, all grades.**

| | Incidence of rash n (%) | Median (days) | Mean (days) | P value |
|---|---|---|---|---|
| **ARM 1 (N=50)** | 42 (84) | 12.0 | 17.4 | p 0.0147 |
| **ARM 2 (N=50)** | 42 (84) | 9.0 | 13.3 | |
| **Arm 3 (N=50)** | 41 (82) | 8.0 | 12.0 | |

**8014 Poster Highlights Session (Board #28), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II trial of XL184 (cabozantinib) plus erlotinib in patients (pts) with advanced EGFR-mutant non-small cell lung cancer (NSCLC) with progressive disease (PD) on epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) therapy: A California Cancer Consortium phase II trial (NCI 9303).** *Presenting Author: Karen L. Reckamp, City of Hope National Medical Center, Duarte, CA*

**Background:** MET and VEGF are important in mediating NSCLC tumorigenesis and EGFR TKI resistance. We hypothesized that treatment with the dual MET-VEGF inhibitor cabozantinib plus erlotinib in EGFR mutation-positive NSCLC following PD on EGFR TKI therapy may allow for tumors to overcome this resistance or restore sensitivity to therapy. **Methods:** Eligible pts were required to have known EGFR mutation and PD on an EGFR TKI immediately prior to enrollment without intervening therapy. Pts received erlotinib 150 mg daily + cabozantinib 40 mg daily on a 28 day cycle. This was a single-arm study to distinguish between a promising response rate of 20% and a discouraging response rate of 5% (requiring at least 4/37 responders). There was a pre-planned analysis of the percent of patients with at least a 30% increase in the tumor doubling time (DT), reflecting a reduction in the tumor growth rate with the addition of cabozantinib using each patient's tumor growth rate during prior TKI treatment as their own control. Secondary endpoints include the evaluation of specific EGFR mutations and MET amplification in pre-treatment tissue. **Results:** 37 patients were registered between 5/2013 and 1/2014 in 4 centers; 35 have been treated. Median age was 63 years, 63% female and 51% ECOG PS 0. 4 pts had a PR (2 confirmed, 2 unconfirmed), with 13 patients remaining on treatment. In addition, 20/23 demonstrated significant growth rate reduction corresponding to a greater than 30% increase in DT. Diarrhea (10/35, 29%) was the most common grade 3 AE; 2 patients (6%) had a grade 3 maculopapular rash. Grade 4 AE's include vomiting (1), elevated lipase (2), elevated amylase (1). Ongoing correlative studies are to determine correlation of response with MET amplification and T790M mutation. **Conclusions:** Combination erlotinib and cabozantinib demonstrates anti-tumor activity in pts with EGFR mutation and PD on EGFR TKI. Supported by NCI N01CM2011-00038 and U01CA062505. Clinical trial information: NCT01866410.

**8015 Poster Highlights Session (Board #29), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II study of the AKT inhibitor MK-2206 plus erlotinib (E) in patients (pts) with advanced non-small cell lung cancer (NSCLC) who progressed on prior erlotinib: A California Cancer Consortium Phase II trial (NCI 8698).** *Presenting Author: Primo Lara, University of California, Davis Medical Center, Sacramento, CA*

**Background:** Preclinical modeling in NSCLC cell lines shows that in some E-sensitive cells (whether epidermal growth factor receptor [EGFR] mutated or wild type), stimulation with HGF reverses the cytostatic and cytotoxic effects of E. Inhibitors of AKT signaling mitigated this HGF-mediated resistance, partially restoring E activity. We conducted a phase II trial of E plus MK2206, a highly selective inhibitor of AKT, in NSCLC pts previously benefiting from E. **Methods:** Eligible pts must have had progression (PD) following prior benefit from E [response or stable disease > 12 weeks]. Treatment consisted of E 150 mg po QD + MK-2206 45 mg po QOD on a 28-day cycle. Pts were accrued into 2 strata: 1) presence of EGFR activating mutation; and 2) EGFR wild type. Primary endpoints: RECIST response rate (RR) > 30% (stratum 1) and disease control rate (DCR) > 20% at 12 weeks (stratum 2). Up to 41 pts per stratum were planned in a two-stage design. **Results:** Eighty pts were enrolled with median age 64 years (range 40-86); tumor EGFR status: mutant – 46, wild type-34; females - 51 (64%); performance status 90-100% - 53 (66%); and median time from diagnosis – 2.3 years (range 0.2-11.1). Most common attributable adverse events (all grade 3) were rash (12), diarrhea (11), fatigue (7), and mucositis (5). There was one treatment-related death (pneumonia). Efficacy results are shown in the Table. **Conclusions:** Combination MK2206 and E met its primary endpoint (DCR 47%) in E-pretreated pts with EGFR wild type NSCLC while its activity in EGFR mutants appears modest (RR 9%). Treatment was generally tolerable and toxicities manageable. AKT pathway inhibition merits further clinical evaluation in pts with E-refractory EGFR wild type NSCLC (N01-00038). Clinical trial information: NCT01294306.

| Stratum | RR, N (%) | DCR at 12 weeks, N (%) | Median progression-free survival, months (95% CI) |
|---|---|---|---|
| **1: EGFR mutant (N=46)** | 4 (9%) | 18 (39%) | 4.4 (2.7,6.6) |
| **2: EGFR wild-type (N=34)** | 1 (3%) | 16 (47%) | 4.6 (2.9, 8.5) |

**8016 Poster Highlights Session (Board #30), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized phase II study of concurrent gefitinib and chemotherapy versus sequential alternating gefitinib and chemotherapy in previously untreated non-small cell lung cancer (NSCLC) with sensitive *EGFR* mutations: NEJ005/TCOG0902.** *Presenting Author: Satoshi Oizumi, First Department of Medicine, Hokkaido University School of Medicine, Sapporo, Japan*

**Background:** The first-line combination of an epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) plus platinum-based doublet chemotherapy has yet to be sufficiently evaluated for patients with *EGFR*-mutant NSCLC. This randomized phase II trial was designed to identify an effective combined regimen of gefitinib (G) plus carboplatin/pemetrexed (CP) for subsequent use in phase III study. **Methods:** Chemotherapy-naïve patients with advanced non-squamous *EGFR*-mutated NSCLC were randomly assigned to receive either a concurrent regimen (C group) or a sequential and alternating regimen (S group). Patients in the C group received concurrent G (250 mg daily) and CP (AUC = 6 and 500 mg/m$^2$, day 1) of a 3-week cycle for 6 cycles, followed by concurrent G and P maintenance. Patients in the S group initially received G (days 1 to 28) and then CP (day 29 and 51); the cycle was repeated for 3 cycles, followed by alternating G and P maintenance. The primary endpoint was progression-free survival (PFS). **Results:** All 80 patients enrolled were eligible and evaluable for efficacy. Median PFS was 17.2 months in the C group and 15.1 months in the S group (p = 0.41). Although overall survival data are immature (with a median follow-up time of 24.6 months, 10 and 19 death events), median survival times were not reached in the C group, and were 30.0 months in the S group (p = 0.049). Response rates were similar in both groups (87.8% in the C group and 82.1% in the S group). The most common grade 3 or greater adverse events were neutropenia (48.8% and 46.2%), thrombocytopenia (41.5% and 28.2%), and anemia (34.1% and.12.8%). G-related skin rash or diarrhea was not severe, and interstitial lung disease was not frequent (two cases in each group; 5% of all patients). No treatment-related deaths occurred. **Conclusions:** To the best of our knowledge, this is the first randomized study to investigate the efficacy of a combination of EGFR-TKI and chemotherapy in the *EGFR*-mutated setting. Both regimens had promising efficacy with predictable toxicities, although concurrent regimens might provide better overall survival. Clinical trial information: UMIN000002789.

**8017 Poster Highlights Session (Board #31), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Safety and efficacy of INC280 in combination with gefitinib (gef) in patients with *EGFR*-mutated (mut), MET-positive NSCLC: A single-arm phase Ib/II study.** *Presenting Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

**Background:** Despite high response rates to EGFR tyrosine kinase inhibitors (TKIs), most patients (pts) with *EGFR*-mut NSCLC ultimately relapse. Dysregulation of the MET pathway is implicated as a therapeutically tractable resistance mechanism, occurring in 15–20% of cases. INC280 is a highly selective, oral MET inhibitor with preclinical activity in *EGFR*-mut/MET-activated NSCLC when combined with EGFR TKIs. **Methods:** This Ph Ib/II, open-label, dose-escalation study of INC280 plus gef was performed in pts (age ≥18 yrs, ECOG PS ≤2) with *EGFR*-mut NSCLC who progressed after prior EGFR TKI, and have confirmed MET dysregulation (amplification [FISH ≥5 CN] or overexpression [IHC 2/3+]). The primary objective (Ph Ib) was to determine the MTD/recommended Ph II dose (RP2D) of INC280 plus gef; secondary objectives were safety, efficacy, pharmacodynamics and PK. An adaptive Bayesian logistic regression model with overdose control guided dose escalation to establish the MTD. **Results:** As of December 2, 2013, 41 pts were enrolled in the ongoing Ph Ib part of the study (59% female, median age 58 years). Pts were treated with INC280 at 7 dose cohorts of 100–800 mg QD and 200–600 mg BID, in combination with gef 250 mg QD. Dose-limiting toxicities (DLTs) occurred in 2 pts: dizziness (800 mg QD) and dyspnea (600 mg BID). The most frequent drug-related AEs (any grade [Gr]) were nausea (27 %), vomiting, diarrhea, and rash (all 22%). The most common drug-related Gr 3/4 AEs were increased lipase (7 %), and increased amylase (5%). For one death, causality to INC280 was not ruled out. INC280 exposure increased with dose from 100–800 mg QD and 200–400 mg BID; preliminary data show no PK interactions with gef. Partial responses were seen in 6/41 (15%) evaluable pts; 5 confirmed, 1 unconfirmed, including 3/7 pts (43%) on 400 mg BID; 5/6 responders had EGFR TKIs as a last treatment prior to study entry. All responders had high MET status. **Conclusions:** Oral INC280 in combination with gef is well tolerated; the RP2D has not yet been defined. Preliminary clinical activity supports further evaluation of INC280 combined with gef in MET-positive NSCLC resistant to EGFR TKIs. Clinical trial identifier: NCT01610336. Clinical trial information: NCT01610336.

**8018 Poster Highlights Session (Board #32), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized, double-blinded study of dacomitinib, an irreversible pan-human epidermal growth factor receptor (HER) inhibitor, versus erlotinib for second-line/third-line therapy of locally advanced/metastatic non-small cell lung cancer (ARCHER 1009).** *Presenting Author: Suresh S. Ramalingam, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Dacomitinib, an irreversible pan-HER kinase inhibitor, has demonstrated anti-cancer activity in phase 2 studies for patients with EGFR activating mutation and in those with EGFR and K-RAS wild-type (WT) NSCLC. **Methods:** Patients (pts) with locally advanced/metastatic NSCLC were randomized following progression with 1 or 2 prior chemotherapy regimens to treatment with Dacomitinib (D) (45 mg PO QD) or Erlotinib (E) (150 mg PO QD) with placebo control for both arms. Archived tumor tissue, ECOG performance status (PS) of 0-2, adequate organ function and informed consent were required. The primary endpoint was progression-free survival (PFS) per independent review in the co-primary populations [all patients and those with KRAS WT]. The estimated sample size was 800 pts, using 1-sided stratified log rank test for all pts to detect HR≤ 0.75, at significance = 1.5% with 90% power and to detect HR≤ 0.69 for KRAS WT at significance = 1% with 80% power. Secondary endpoints: overall survival, objective response (OR), safety, and patient reported outcomes. **Results:** 878 pts with the following baseline characteristics were enrolled; approximate median age of 63 years, 64% males, 76% Caucasians, 90% with PS 0/1, 69% adenocarcinoma and 18% never-smokers. Activating EGFR mutation was present in 41 pts in each arm. Discontinuation for treatment-related toxicity was more frequent with D (8% vs. 4.8%). Diarrhea, stomatitis, paronychia, and mucositis were more common with D. **Conclusions:** Irreversible EGFR inhibition with Dacomitinib is not superior to Erlotinib in the second-/third-line therapy of advanced NSCLC. Overall survival and outcomes for pts with EGFR mutation are not mature. Clinical trial information: NCT01360554.

**8019^ Poster Highlights Session (Board #33), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Continuation of afatinib beyond progression: Results of a randomized, open-label, phase III trial of afatanib plus paclitaxel (P) versus investigator's choice chemotherapy (CT) in patients (pts) with metastatic non-small cell lung cancer (NSCLC) progressed on erlotinib/gefitinib (E/G) and afatanib—LUX-Lung 5 (LL5).** *Presenting Author: Martin H. Schuler, West German Cancer Center, University Duisburg-Essen, Essen, Germany*

**Background:** Improved disease control with continuation of EGFR inhibition beyond progression has been suggested in retrospective/non-randomized studies, however, this has yet to be prospectively evaluated in a randomized trial. LL5 is a randomized trial, which assessed the efficacy of continuation of the irreversible ErbB family blocker, afatinib (A), beyond progression with the addition of P in NSCLC pts with prior benefit from reversible EGFR tyrosine kinase inhibitors (E/G) and A. **Methods:** In this open-label, global phase III trial, pts with NSCLC who had failed ≥1 line of CT and E/G (after ≥12 wks treatment) were treated with A (50 mg/day) in Part A (n=1154). Upon progression, those with ≥12 wks on A were eligible to be randomized 2:1 to A+P (40 mg/day; 80 mg/m$^2$/week) or single agent investigator's choice CT in Part B. Primary endpoint was progression-free survival (PFS). Secondary endpoints included objective response rate (ORR), overall survival (OS), and safety. **Results:** 202 pts were randomized (A+P, n=134; CT, n=68) and baseline characteristics were well balanced (median age 60 yrs, females 49%, ECOG PS 0–1 91% overall). A statistically significant improvement in PFS was observed on A + P vs CT arm (median 5.6 vs 2.8 months, hazard ratio (HR) 0.60 (95% CI 0.43, 0.85; p=0.003). ORR was also significantly higher in A+P arm vs CT (32.1% vs 13.2%; p=0.005). OS was similar in both arms 12.2 vs. 12.2 months, HR 1.00 (95% CI 0.70, 1.43; p=0.994). Most common related adverse events (AEs) with A+P vs CT were diarrhea (53.8% vs 6.7%), alopecia (32.6% vs 15.0%) and asthenia (27.3% vs 28.3%). **Conclusions:** ContinuedErbB family blockade with A with the addition of P significantly improved PFS and ORR vs CT alone in heavily pretreated pts with acquired resistance to E/G and progression on A monotherapy. AEs were considered manageable. Our data support that tumors progressing on E/G and A continue to depend on signalling through the receptors of the ErbB family and can benefit from continuous ErbB family blockade with A. Clinical trial information: NCT01085136.

**8020 Poster Highlights Session (Board #34), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Safety and clinical activity of MK-3475 in previously treated patients (pts) with non-small cell lung cancer (NSCLC).** *Presenting Author: Edward B. Garon, University of California, Los Angeles, Los Angeles, CA*

**Background:** This Phase I study evaluated the safety, tolerability, and clinical activity of MK-3475, a selective anti-PD-1 antibody that blocks the interaction between programmed death-1 (PD-1) on T-cells and PD-L1 and PD-L2 on tumor cells in pts with previously-treated, progressive locally advanced or metastatic NSCLC. **Methods:** Previously-treated pts with NSCLC whose tumors expressed any detectable PD-L1 using a preliminary immunohistochemical assay were randomized to MK-3475 at 10 mg/kg every 2 weeks (Q2W) or 3 weeks (Q3W). Some pts with tumors without PD-L1 expression who had received ≥2 prior lines of therapy were treated with MK-3475 at 10 mg/kg Q2W. At least 1 measurable tumor lesion, ECOG performance status of 0-1, adequate organ function, and new tumor biopsy ≤60 days prior to study entry were required. Tumor response was assessed every 9 wks until disease progression by investigator review using immune-related response criteria (irRC) and independent central review using RECIST 1.1. **Results:** 450 pts provided tissue for PD-L1 assessment; 305 were eligible based on PD-L1 tumor staining. 221 pts (n=102, Q2W [including 43 whose tumors did not express PD-L1]; n=119, Q3W) began treatment between Feb 2013 and Oct 2013. 48% of pts experienced drug-related adverse events (AEs), usually grade 1-2 in severity, most commonly fatigue (13%), decreased appetite (6.5%), arthralgia (6.1%), pruritus (5.4%), rash (4.7%), and pyrexia (3.6%). The incidence of grade 3/4 drug-related AEs was 6%. There were 3 cases of drug-related grade 3/4 pneumonitis. The preliminary ORR (confirmed & unconfirmed by irRC/RECIST) in all pts was 15%/21% (16%/24% for pts with PD-L1 expressing tumors [19%/31% 10 mg/kg Q2W, 15%/22% 10 mg/kg Q3W], 10%/8% for pts without PD-L1 tumor expression. 40% of pts had <18 wks of follow-up and 69 pts (33%) remain on treatment. A mature dataset will be available for presentation, including correlation between level of tumor PD-L1 expression and response rates. **Conclusions:** In this cohort of over 200 pts, treatment with MK-3475 was generally well tolerated and provided robust antitumor activity in previously-treated pts with progressive locally advanced or metastatic NSCLC that expressed PD-L1. Clinical trial information: NCT01295827.

**8021^ Poster Highlights Session (Board #35), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Clinical activity and biomarkers of MEDI4736, an anti-PD-L1 antibody, in patients with NSCLC.** *Presenting Author: Julie R. Brahmer, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background**: Lung cancer is the leading cause of cancer death in both men and women. PD-L1 is upregulated in NSCLC and may be associated with a poor prognosis. MEDI4736 is a human IgG1 antibody which binds specifically to PD-L1 preventing binding to PD-1 and CD80. **Methods**: An ongoing phase 1, multicenter, open-label study (NCT01693562) is evaluating the safety and efficacy of MEDI4736 administered IV every 2 wks (q2w) or every 3 wks (q3w) using a 3+3 dose escalation followed by expansion cohorts. NSCLC pts were assigned to expansion cohorts by histology and line of therapy (including treatment- naïve pts). Retreatment was permitted for progression after 12 mos of therapy. Response is assessed by immune-related response criteria (irRC) in escalation and RECIST v1.1 in expansion. **Results**: As of Jan 17, 2014, 13 NSCLC pts in dose escalation (median age 65 yrs; 40-76), all PS 0-1, with a median of 4 prior treatments, received a median of 7 doses (1-25) of MEDI4736 across 6 cohorts (0.1 – 10 mg/kg q2w; 15 mg/kg q3w). Treatment-related AEs occurred in 43% of pts, all of which were Grade 1-2; none led to discontinuation of study drug. No pneumonitis or colitis was reported in dose escalation. Of 13 pts, 3 PRs were observed, with 2 additional pts achieving tumor shrinkage not meeting PR per irRC (46% and 48% decreases). Tumor shrinkage was reported as early as first assessment (6 wks) and benefit was durable; 4/13 pts remain on study (10+, 10+, 11.1+, 14.9+ mos) as of the data cutoff. Expansion cohorts opened Sep 2013; 43 pts (including treatment-naïve pts) have been dosed, with the opportunity to enroll > 300 NSCLC pts in total. Preliminary clinical activity has been observed with acceptable safety, no ≥ grade 3 pneumonitis, and no apparent differences in toxicity between treatment-naïve vs pretreated pts. Assessment of clinical activity by PD-L1 expression, underlying mutation, smoking history, and line of therapy patient-reported outcomes is ongoing. **Conclusions:** The preliminary safety and durable clinical efficacy profile of MEDI4736 in NSCLC supports continued clinical development; AEs are manageable, even in highly pretreated pts. Recruitment continues and development of MEDI4736 in NSCLC as monotherapy and in combination is ongoing. Clinical trial information: NCT01693562.

**8022 Poster Highlights Session (Board #36), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Safety and response with nivolumab (anti-PD-1; BMS-936558, ONO-4538) plus erlotinib in patients (pts) with epidermal growth factor receptor mutant (EGFR MT) advanced NSCLC.** *Presenting Author: Naiyer A. Rizvi, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** Erlotinib is FDA-approved for the first-line treatment of EGFR MT NSCLC, with a median progression free survival (PFS) of 10.4 months. Nivolumab, a fully human IgG4 programmed death-1 (PD-1) immune checkpoint inhibitor antibody, demonstrated encouraging safety and survival outcomes as monotherapy in advanced NSCLC pts. Preclinical data support EGFR pathway activation of PD-L1 expression and immune escape in EGFR driven lung tumors. Interim results from a phase I study evaluating nivolumab + erlotinib in an EGFR MT advanced NSCLC cohort are reported. **Methods:** Stage IIIB/IV EGFR MT chemotherapy-naïve NSCLC pts (EGFR TKI naïve or progression post prior TKI therapy) received nivolumab 3 mg/kg IV Q2W + erlotinib 150 mg PO daily until progression/unacceptable toxicity. Objective response rate (ORR) and PFS were evaluated by RECIST 1.1. **Results:** All pts (n=21) began study treatment ≥10 months prior to data analysis; only 1 pt was EGFR TKI naïve. Any-grade treatment-related AEs were reported in all 21 pts; treatment-related grade 3–4 AEs (4 pts) were increased AST (n=2) or ALT (n=1), weight decrease and diarrhea (1 pt each); 2 pts discontinued due to treatment-related AEs (grade 3 AST increase and grade 2 nephritis). No pneumonitis (any grade) was observed. ORR was 19% (4/21 pts) and 24 wk PFS rate was 47%; median duration of response (DOR) was not reached (range 6.1+ to 27.1+ wks). Of the 20 pts with acquired erlotinib resistance, 3 (15%) achieved partial response (PR, all ongoing; DOR 6.1+, 16.3+ and 27.1+ wks); 9 pts (45%) had stable disease with 3/9 (33%) ongoing (time to progression/death 9.9+, 15.7, 21, 22.3, 24.4+, 31.1+, 35.9, 52.7 and 53 wks), and 1 pt had an unconventional "immune related" response (ongoing), with 46% reduction in target lesions after progression in non-target lesions. The EGFR TKI-naïve pt achieved PR with DOR 24.3+ wks (ongoing). **Conclusions:** These interim results suggest that nivolumab + erlotinib may provide durable clinical benefit and an acceptable safety profile in TKI refractory, EGFR MT advanced NSCLC, supporting further evaluation of nivolumab in pts with EGFR MT NSCLC. Additional follow up will be presented. Clinical trial information: NCT01454102.

**8023 Poster Highlights Session (Board #37), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Nivolumab (anti-PD-1; BMS-936558, ONO-4538) and ipilimumab in first-line NSCLC: Interim phase I results.** *Presenting Author: Scott Joseph Antonia, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Nivolumab, a fully human IgG4 programmed death-1 (PD-1) immune checkpoint inhibitor antibody, and ipilimumab, an IgG1 CTLA-4 checkpoint receptor blocking antibody, have shown activity in advanced NSCLC; clinical data in melanoma showed improved responses and a manageable safety profile when combined. We report interim results from a phase I study evaluating first-line nivolumab + ipilimumab (N+I) in advanced NSCLC patients (pts). **Methods:** Chemotherapy-naive pts (n=46) with squamous (sq) or non-sq NSCLC received the 3 + 1 mg/kg or 1 + 3 mg/kg combination dose IV Q3W for 4 cycles followed by nivolumab 3 mg/kg IV Q2W until progression/unacceptable toxicity. Objective response rate (ORR; RECIST 1.1) was evaluated overall and by baseline tumor PD-L1 status (Dako immunohistochemistry assay). After an amendment, a 1 + 1 mg/kg cohort was added (n=30, data immature at Dec 2013 analysis). **Results:** In the 4 cohorts with ≥4 months follow up, any-grade treatment-related adverse events (managed with protocol algorithms) were reported in 39 pts (85%; grade 3–4 in 22 pts [48%]) and led to discontinuation in 16 pts. Treatment-related deaths (n=3) were due to respiratory failure, bronchopulmonary hemorrhage and toxic epidermal necrolysis. Responses occurred in all 4 cohorts (Table); overall ORR[b] was 22% (median duration of response [mDOR] not reached [NR]) and stable disease (SD) 33% (range 13 – 34.1+ wks); 2 pts exhibited unconventional "immune related" responses. In 29 evaluable tumor samples from the study, ORR did not correlate with PD-L1 status. **Conclusions:** These interim data in pts with advanced NSCLC suggest that a nivolumab + ipilimumab immunotherapy regimen is feasible and demonstrates antitumor activity in both PD-L1+ and PD-L1– pts. Safety will be further assessed at the 1 + 1 mg/kg dose. The recommended combination dose for phase II/III evaluation has not been determined. Clinical trial information: NCT01454102.

**8024 Poster Highlights Session (Board #38), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**First-line nivolumab (anti-PD-1; BMS-936558, ONO-4538) monotherapy in advanced NSCLC: Safety, efficacy, and correlation of outcomes with PD-L1 status.** *Presenting Author: Scott N. Gettinger, Yale Cancer Center, New Haven, CT*

**Background:** The fully human IgG4 programmed death-1 (PD-1) immune checkpoint inhibitor antibody nivolumab has demonstrated durable responses and tolerability in patients (pts) with previously treated advanced NSCLC. Tumor PD-1 ligand (PD-L1) expression is being studied as a potential biomarker for nivolumab. We report interim phase I results of first-line nivolumab in chemotherapy-naïve advanced NSCLC pts. **Methods:** Pts with squamous (sq) or non-sq advanced NSCLC received nivolumab 3 mg/kg IV Q2W until progression or unacceptable toxicity (post-progression treatment allowed based on protocol-defined criteria). Responses (RECIST 1.1) were evaluated overall and according to tumor PD-L1 status (PD-L1+ = ≥5% tumor cells expressing PD-L1 [Dako immunohistochemistry assay]). Results on the first 20 pts are included. **Results:** After ≥6 months follow up, 17 pts (85%) experienced any-grade treatment-related adverse events (AEs), managed with standard algorithms. Treatment-related grade 3-4 AEs (3 pts, 15%) were AST or ALT elevations, hyperglycemia, and rash (n=1 each). No pneumonitis (any grade) was observed. Objective response rate (ORR) was 30% (Table); 5/6 responders (83%) achieved response by first scan (wk 11). Two pts had >80% target lesion reduction at 18 wks. Of 15 evaluable tumor samples, 9 were PD-L1+. ORR was 67% in PD-L1+ pts; no responses were observed in the 6 PD-L1- pts. Responses were durable (median duration of response [mDOR] not reached [NR]; 5 ongoing responses). **Conclusions:** In this phase I study, nivolumab led to early, durable responses in advanced NSCLC pts, with a tolerable safety profile. PD-L1 status appeared to correlate with ORR/progression-free survival (PFS). Follow up and responses of 30 additional treated pts will be reported. These data support further studies of first-line nivolumab monotherapy in advanced NSCLC. Clinical trial information: NCT01454102.

**Molecular characterization of an extensive lung cancer patient-derived xenograft (PDX) resource.** *Presenting Author: Philip C. Mack, UC Davis Comprehensive Cancer Center, Sacramento, CA*

**Background:** A large series of non-small cell lung cancer (NSCLC) PDX models has been established through direct implantation of patient tumor material into immune compromised mice. Here we report the molecular characterization of this resource, reflecting the biologic diversity and heterogeneity inherent to NSCLC with implications for drug development. **Methods:** Patient tumor acquired from biopsy, resection or pleural effusion was implanted subcutaneously into the flank of NOD.Cg-Prkdc$^{scid}$ Il2rg$^{tm1Wjl}$/SzJ (NSG) mice. The contributing patient tumor (PT) and the resultant PDX were analyzed for driver mutations (Response Genetics Inc., and Illumina TSCAP); copy number variants (CNV) and global RNA expression (Affymetrix arrays). Normalized gene expression across all PDX models was analyzed using Principal Component Analysis (PCA). Clustering was performed based on shared patterns of gene expression, analyzed using Gene Set Enrichment Analysis to identify biological themes. **Results:** At time of submission, 55 NSCLC models from 53 patients were fully established & characterized. Contributing patients: Median age 62 (36-82); 62% female; 22% stage IV; 32 adenocarcinoma, 19 squamous cell carcinoma (SCC), 2 large cell. All driver mutations detected in PTs were retained in resultant PDXs: 10 EGFR, 11 KRAS, 1 ALK, 1 NRAS. PCA revealed 6 clusters with subgroups differentiated by genes associated with signal transduction, epithelial-mesenchymal transition and DNA repair. SCC models predominantly populated two clusters, with one group almost exclusively comprised of PI3KCA amplified models with upregulated/amplified FGFR1-3 signaling components. KRAS mutants showed divergent cluster patterns, with several models grouping with EGFR/ALK mutants, potentially influenced by PI3K mutation status. **Conclusions:** The UC Davis Cancer Center/The Jackson Laboratory NSCLC PDX resource is one of the largest, most characterized collections currently in use for advanced therapeutic development. PCA subgrouping, along with mutation and CNV status, suggest strategies to refine patient selection and treatment algorithms.

**8026 Poster Highlights Session (Board #41), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Clinical activity of LY2835219, a novel cell cycle inhibitor selective for CDK4 and CDK6, in patients with non-small cell lung cancer.** *Presenting Author: Jonathan Wade Goldman, UCLA Santa Monica Hematology-Oncology, Santa Monica, CA*

**Background:** LY2835219, a novel cell cycle inhibitor selective for the cyclin-dependent kinases CDK4 and CDK6 (CDK4/6), has shown antitumor activity in human NSCLC xenograft models. Importantly, KRAS mutant xenografts exhibit greater sensitivity to LY2835219 compared to KRAS wildtype xenografts. To evaluate the safety and clinical activity of LY2835219, we conducted a Phase I study with cohorts for multiple cancers. Here, we report results for a cohort of 49 NSCLC patients: 19 KRAS wildtype, 26 KRAS mutant, and 4 with unknown KRAS status. **Methods:** Patients with advanced NSCLC that progressed or relapsed after standard treatments received continuous therapy with LY2835219 orally every 12 hours (Q12H) on Days 1-28 of a 28-day cycle. RECIST v1.1 was used to assess tumor response. Progression-free survival (PFS) was described using the Kaplan-Meier method. **Results:** In the NSCLC cohort, 49 patients with a median of 4 prior systemic therapies received single-agent LY2835219 either at the maximum tolerated dose of 200 mg Q12H (n=25) or, to gain additional safety and efficacy data, at 150 mg Q12H (n=24). The most common possibly related treatment-emergent adverse events across all grades were diarrhea (including 2% G3), nausea (4% G3), fatigue (2% G3), vomiting (2% G3), and anemia (2% G3); there were no Grade 4 events. The disease control rate (DCR = complete response [CR] + partial response [PR] + stable disease [SD]) was 51% with 1 confirmed PR. The median duration of SD was 5.6 months and the median PFS (n=49) was 2.1 months. Among the 49 NSCLC patients, 20 (41%) reached at least 4 cycles and 13 reached at least 6 cycles, with 5 of these 13 patients still receiving LY2835219 therapy (range: 7-12 cycles). Consistent with NSCLC xenograft studies, the DCR in this clinical trial was 37% for KRAS wildtype (n=19) and 54% for KRAS mutant (n=26) NSCLC. **Conclusions:** In a cohort of patients with advanced NSCLC and a median of 4 prior systemic therapies, single-agent LY2835219 demonstrated acceptable safety and achieved an overall DCR of 51%, reflecting in part the higher DCR of 54% for KRAS mutant NSCLC. Thus, LY2835219 merits further clinical investigation for NSCLC, including KRAS mutant disease. Clinical trial information: NCT01394016.

**8027 Poster Highlights Session (Board #42), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Rictor amplification to define a novel and unique subset of lung cancer patients.** *Presenting Author: Haiying Cheng, Department of Medical Oncology, Montefiore Medical Center, Bronx, NY*

**Background:** Recent advances in molecularly tailored therapy have shifted the treatment paradigm in lung cancer. We recently identified amplification of *RICTOR*, a key component of the mTORC2 complex, as a new and sole genomic alteration in an 18-year-old never smoker with lung adenocarcinoma. We hypothesizethat *RICTOR* amplification, unlike previously reported molecular changes in the PI3K/AKT/mTOR pathways, may identify a new subgroup of lung cancer patients amenable to molecularly targeted therapy. **Methods:** The index patient had *RICTOR* amplification identified by next generation sequencing (NGS)- genomic profiling of 182 cancer-related genes performed with extracted DNA from FFPE specimens. We then reviewed the database of 1128 lung cancer patients who had profiling performed by Foundation Medicine. Additionally, we examined the *in vitro* cytotoxicity of 6 classes of drugs against different components of the PI3K/AKT/mTOR pathways in *RICTOR*-amplified H23 lung cancer cells. **Results:** *RICTOR* amplification in the index case was confirmed by FISH and IHC of RICTOR and its downstream targets. *RICTOR* amplification was found in 8.2% (92/1128) lung cancer patients from the NGS database. In 11% (10/92) of cases, *RICTOR* amplification was the only potentially actionable target. Additionally, 13% (12/92) and 27% (25/92) of these patients had concomitant alterations in *KRAS* and *EGFR*, exclusively in lung adenocarcinomas. One third of the patients (29/92) had alterations in other genes within the PI3K/AKT/mTOR pathway. Among all the examined agents targeting the PI3K/AKT/mTOR pathways, BEZ235 (dual PI3K/mTOR inhibitor) and AZD2014 (dual mTOR1/2 inhibitor) were the most active in *RICTOR*-amplified H23 lung cancer cells. As a proof of concept, our index patient has been treated on a phase I clinical trial with a dual mTOR1/2 inhibitor (CC223) and has had stable disease for over 8 months. **Conclusions:** *RICTO*R amplification may define a novel and unique molecular subset of lung cancer patients. Our observation provides the rationale for testing *RICTOR* amplification as a potential biomarker for targeted therapy with mTOR1/2 inhibitors in lung cancer patients.

**8028 Poster Highlights Session (Board #43), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Extended cohort study of OPB51602, a novel inhibitor of STAT3/5 activation, in non-small cell lung carcinoma.** *Presenting Author: Joline Si Jing Lim, National University Cancer Institute, Singapore, Singapore, Singapore*

**Background:** STAT3, a signal transduction protein of growth factor receptors including EGFR, is constitutively activated in many solid malignancies, leading to tumor angiogenesis, cell proliferation and immune tolerance. Inhibition of STAT3 in vitro and in vivo induces apoptosis in STAT3-activated tumor cells. OPB51602 is an oral small molecule inhibitor of STAT3 phosphorylation with favorable preclinical profile that has entered clinical development. **Methods:** We analyzed a subgroup of patients with non-small cell lung cancer (NSCLC) from a phase I study of OPB51602 including an extension cohort at the recommended dose of 4mg daily in NSCLC. Dosing included dosing daily for 2 weeks every 3 weeks, and continuous dosing of 4mg daily. Archival tissue was analyzed for oncogenic mutations and STAT3/5 phosphorylation. Patients were evaluated for treatment response, and pharmacodynamic effects of STAT3 phosphorylation assessed in peripheral blood mononuclear cells by flow cytometry (PBMCs). **Results:** 25 patients were treated at doses of 2mg, 4mg and 5mg. 23 patients (92%) had adenocarcinoma, and 11 (44%) had tumor EGFR mutations. Two patients treated at doses of 4mg and 5mg had partial response(PR), with progression free survival of 5 and 7 months respectively; both had EGFR mutations that responded and then progressed on EGFR TKIs. Overall disease control rate was 12.5% at 3 months, and duration of disease control was longer in EGFR mutant patients. Patients who achieved PR/stable disease (n=6) had a higher incidence of *EGFR* mutations compared to those with PD (n=8), (83% *vs* 50%). 12 patients had repeat FDG PET CT during cycle 1, with metabolic response by EORTC criteria observed in 5 patients(42%). Immunohistochemistry showed pSTAT3($Ser^{727}$) overexpression in 44% of patients, and PBMC analysis revealed downregulation of pSTAT3 with treatment (mean decrease 22.1±14.1%), with maximal effect at 4h post-dosing. There was no correlation between extent of downregulation of pSTAT3 and tumor response. **Conclusions:** OPB51602 demonstrates evidence of clinical activity in treatment refractory NSCLC, particularly for EGFR mutants. Further evaluation of its efficacy and biomarker exploration is warranted in NSCLC.

**8029 Poster Highlights Session (Board #44), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Next-generation sequencing (NGS) to identify actionable genomic alterations (GA) in "pan-negative" lung adenocarcinomas (ADC) from patients with no smoking or a light smoking (NS/LS) history.** *Presenting Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Testing for an increasing number of biomarkers has become essential to the care of lung ADC patients (pts). This commonly requires multiple technologies and often is limited by inadequate tissue. Hybrid capture-based targeted NGS has the ability to identify relevant GAs in a single test. We undertook this study to estimate the frequency of GAs in "pan-negative" lung ADC pts with NS/LS history. **Methods:** Eligible pts had ≤15 pack-year smoking history (high likelihood of undetected GA) and advanced lung ADC that were "pan-negative" for mutations (*EGFR, ERBB2, KRAS, NRAS, BRAF, MAP2K1, PIK3CA,* and *AKT1* by hotspot testing and/or multiplex sizing assays) and fusions (*ALK, ROS1,* and *RET* by break apart FISH). Tumor required contained ≥20% tumor nuclei on FFPE material yielding ≥50 ng of DNA. NGS was performed by hybridization capture of coding exons in 287 cancer-related genes and 47 introns in 19 frequently rearranged genes (Foundation Medicine). **Results:** 34 pts were eligible. Previous testing required additional biopsies in 71% (n=24/34). Tissue exhaustion precluded testing in 9 of 34 pts (26%) and NGS was successfully performed in 25 pts. NGS uncovered ≥1 GA in 92% (n=23/25) of cases [median 3; 42% base substitution, 35% amplification (amp), 10% fusions, 9% in/del, 4% homozygous loss]. NGS uncovered an actionable GA with a targeted agent based on NCCN guidelines in 36% (n=9/25: *EGFR* G719A, *EGFR* L747P, *ERBB2* exon 20 ins, *BRAF* V600E, *SOCS5-ALK, CD74-ROS1*, *KIF5B-RET, CCDC6-RET, MET* amp), and a targeted agent available on a clinical trial in 32% (n=8/25: 2 *EGFR* exon 18 del, *FGFR1* T141R, *KRAS* Q61H, *BRCA1* E1011K, *MDM2* amp, *CDK4* amp, *CDKN2A* loss) of pts. A GA not previously detected in lung ADCs (*SHC2-ERBB2*) was found in 1 pt. Reasons why non-NGS testing had not detected these GAs include lower sensitivity, test failure, use of different biopsies, technical issues, and complex or intrachromosomal rearrangements undetectable by FISH. **Conclusions:** NGS identified actionable GAs in 68% of NS/LS pts with "pan-negative" lung ADCs. This suggests that initial profiling of lung ADCs using NGS may be a more efficient and sensitive strategy.

**8030^ Poster Highlights Session (Board #45), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase I trial of X-396, a novel ALK inhibitor, in patients with advanced solid tumors.** *Presenting Author: Leora Horn, Vanderbilt-Ingram Cancer Center, Nashville, TN*

**Background:** X-396 is a novel, potent anaplastic lymphoma kinase (ALK) small molecule TKI with significant anti-tumor activity in both ALK TKI naive and crizotinib resistant models of *ALK* fusion-positive NSCLC. **Methods:** In this multicenter phase I study, patients with advanced solid tumors were enrolled and given X-396 on a continuous 28-day schedule. This was an accelerated titration design with the dose starting at 25 mg once daily. At the first DLT cohorts were expanded to the classic 3+3 design up to 250 mg daily. All pts were assessed for adverse events (AEs) using CTCAE version 4.0, response to therapy was assessed using RECIST 1.1, and pharmacokinetics (PK) were measured. **Results:** As of the January 23, 2014 cutoff, 30 patients enrolled (21 NSCLC patients, 13 ALK+ - 3 crizotinib naïve and 10 crizotinib resistant), 4 H&N, 2 SCLC, 2 colorectal,1 breast). Median age 58, 12 ECOG PS 0 and 18 PS 1. The most common drug related AEs include rash (36%, G1-G3), fatigue (30%, G1-G2), nausea (27%, G1), vomiting (27%, G1) and edema (20%, G1-G2). Grade3/4 treatment related AEs were rash (2patients), edema (1patient). X-396 exhibited linear PK at doses 25 – 250mg. At 200mg QD, the $t_{1/2}$ is ~23 hours, and the trough level (~300nM) is sufficient to inhibit most crizotinib resistant mutations in vitro. To date, 18 patients are evaluable for response; SD is 28% and PR 28%. Among 8 evaluable ALK+ NSCLC cases, responses occurred in crizotinib naïve and crizotinib treated patients. In the 6 ALK+ patients treated at doses ≥ 200 mg SD is 17% and PR 83%; 2 PRs were observed in patients treated with prior crizotinib. CNS responses have been observed in 2 patients, 1 crizotinib naïve and 1 crizotinib resistant. The median duration of treatment in evaluable ALK+ patients is 20+ weeks with the longest being 58+ weeks. **Conclusions:** X-396 is generally well tolerated at doses up to 250 mg daily and induces responses in both crizotinib naïve and crizotinib resistant ALK+ NSCLC patients. Enrollment is ongoing. Clinical trial information: NCT01625234.

**8031 Poster Highlights Session (Board #46), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Evolution of resistance in ALK-positive patients treated with ALK tyrosine kinase inhibitors (TKIs).** *Presenting Author: Justin F. Gainor, Massachusetts General Hospital, Boston, MA*

**Background:** Lung cancers harboring ALK rearrangements are sensitive to treatment with ALK TKIs. Ceritinib (LDK378) is a novel, highly potent ALK TKI that has shown promising anti-tumor activity in crizotinib-resistant patients (pts); however, resistance invariably develops. **Methods:** To determine molecular mechanisms of resistance to ceritinib, we identifiedpts with ALK-positive lung cancer who underwent biopsies of progressing lesions following treatment with ceritinib. Specimens underwent ALK FISH and sequencing of the ALK tyrosine kinase domain. Similar analyses were performed in a subset of pts with pre-ceritinib/post-crizotinib biopsy specimens available. Biopsies were performed under an IRB-approved protocol. **Results:** We identified 10 ALK-positive pts who underwent biopsies at the time of resistance to ceritinib. Median duration of treatment (DOT) on ceritinib was 7.5 months (range 2.5 – 15.4 months). Nine of 10 pts had previously received crizotinib with a median DOT of 8.1 months (range 2.8 – 35.1 months). Pre-ceritinib/post-crizotinib biopsies were available for comparison in 8 pts. ALK resistance mutations were identified in 5/11 (45%) post-ceritinib biopsies (1 pt had 2 separate procedures performed). Resistance mutations included: G1202R (3), F1174C (1) and F1174V (1). Notably, 2 pts had ALK resistance mutations (S1206Y and G1269A) identified in pre-ceritinib/post-crizotinib samples. These mutations were no longer present in ceritinib-resistant biopsies performed at the same anatomic sites; however, the G1202R mutation emerged in both pts. One of these pts was also found to have an F1174V mutation at a separate post-ceritinib biopsy site. ALK FISH was positive for ALK rearrangement in 8/8 ceritinib-resistant specimens, but ALK gene amplification was not identified, including in 1 pt with high-level ALK amplification in a pre-ceritinib/post-crizotinib biopsy. Additional genetic data will be presented at the meeting. **Conclusions:** Mechanisms of acquired resistance are heterogeneous and may evolve dynamically in response to different ALK TKIs. Consistent with preclinical data, ALK mutations in two residues, G1202 and F1174, can mediate resistance to ceritinib in the clinic.

**8032 Poster Highlights Session (Board #47), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Differential expression of LKB1, PD-L1, and PD-L2 in KRAS-mutant non-small cell lung cancer in never-smokers.** *Presenting Author: Antonio Calles, Dana-Farber Cancer Institute, Boston, MA*

**Background:** *KRAS* mutation is the most common oncogenic alteration in lung adenocarcinoma and is detected in smokers and up to 15% of never smokers. The tumor suppressor LKB1 is commonly mutated in NSCLC and LKB1 mutations occur concurrently in 30% of *KRAS* mutant NSCLC. In murine models, *KRAS* mutant tumors with concurrent LKB1 loss did not respond to docetaxel/selumetinib treatment. Immune checkpoint blockade by anti-PD-1/PD-L1 monoclonal antibodies (MoAb) is being clinically evaluated. Clinical responses to these agents correlate with PD-L1 expression and smoking status. We aimed to determine the expression of LKB1, PD-L1 and PD-L2 in *KRAS* mutant NSCLC from smokers (KS) and never smokers (KNS). **Methods:** We evaluated the clinical and molecular characteristics of *KRAS* mutant NSCLC patients (pts) using an institutional database. We examined LKB1, PD-L1, PD-L2 tumor expression by immunohistochemistry (IHC). IHC was performed using the murine MoAbs Ley37D/G6 (LKB1), 9A11 (PD-L1) and 9E5 (PD-L2). LKB1 staining was scored as intact or lost, with any degree of expression qualifying as intact, PD-L1 positive if >5% of cells were stained and PD-L2 positive if >10%. **Results:** Between 8/09 and 1/14 we identified 514 *KRAS* mutant NSCLC pts (stage I 22%/II 10%/III 19%/IV 49%) of which 39 were never smokers (incidence 7.6%) We analyzed 114 pts with available tissue using IHC (30 KNS and 84 KS). LKB1 loss was detected in 29% of cases (95%CI, 21-38%) and was significantly less frequent in KNS pts (KS 34% vs KNS 13%; $P$= 0.035). *KRAS* transversion mutations were more frequent in KS vs KNS pts (78% vs 37%; $P$= 0.0001). LKB1 staining was intact in 95% of KNS pts with transition mutations. Pts with LKB1 loss had more metastatic sites and brain involvement (47% vs 24%, $P$= 0.0472). PD-L1 was expressed in 19% of *KRAS* mutant cases and PD-L2 in 45% and were inversely correlated (r=-0.86, $P$ <0.0001). PD-L1/PD-L2 expression was not related to either LKB1 status or type of *KRAS* mutation. PD-L1/PD-L2 IHC 3+ vs 1+/2+ staining was more frequent in KS vs KNS pts (50% vs 20%; 40% vs 13% respectively). **Conclusions:** *KRAS* mutant NSCLC is a heterogeneous disease. Our findings may have implications for choosing *KRAS* mutant pts for ongoing trials of MEK and PD-1/PD-L1 inhibitors.

**8033 Poster Highlights Session (Board #48), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Concurrent molecular alterations in KRAS-mutant lung adenocarcinomas and effects on overall survival.** *Presenting Author: Gregory J. Riely, Memorial Sloan Kettering Cancer Center, New York City, NY*

**Background:** *KRAS* mutations define the largest subset of oncogene-driven lung adenocarcinomas (25-30%). Among patients with *KRAS* mutations, their clinical course during treatment is heterogeneous. The presence of concurrent genetic alterations in other oncogenes and tumor suppressors, such as *TP53* or *STK11* may affect outcomes for patients with *KRAS* mutant lung cancers. We sought to use a next-generation sequencing-based assay to comprehensively describe concurrent genetic alterations present in *KRAS* mutant lung cancers and explore the effect of such alterations on patient outcomes. **Methods:** We studied tumor DNAs from 102 patients with stage IV/recurrent *KRAS* mutant lung cancers enriched for cases with longer and shorter overall survivals. All patients received standard therapies for advanced lung cancer. We performed massively parallel sequencing (Ion Torrent PGM) of all exons from 65 cancer genes using a custom AmpliSeq panel. The sequence data were analyzed for point mutations and small insertions and deletions using a custom pipeline. We collected clinical characteristics, survival, and concurrent mutations. The association of concurrent mutations and overall survival was evaluated using Kaplan-Meier methodology with log rank test for comparisons. **Results:** Among these 102 samples in which the *KRAS* (G12C=47, G12D=23, G12V=12, G12A=9, Other=11) mutation was confirmed by Ion Torrent PGM sequencing, we found 0 to 11 concurrent mutations with a majority of the patients having 1 (24), 2 (30), or 3 (16) mutations in addition to *KRAS*. The most frequent concurrent mutations included *TP53* (21), *KEAP1* (13), *SMARCA4* (7), and *ARID1A* (6). There was no difference in median overall survival between patients with or without a concurrent mutation in *TP53* (21 vs 25 mos, p=0.84), *KEAP1* (19 vs 25 months, p=0.86), *SMARCA4* (12 vs 25 months, p=0.14) or *ARID1A*(22 vs 25 months, p=0.5). **Conclusions:** This study is the largest reported series of *KRAS* mutant lung cancers with a broad analysis of concurrent molecular alterations and survival. There was no significant effect on survival for concurrent mutations in the identified cancer associated genes.

**8034 Poster Highlights Session (Board #49), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Targeting *FGFR1*-amplified lung squamous cell carcinoma with the selective pan-FGFR inhibitor BGJ398.** *Presenting Author: Lucia Nogova, Lung Cancer Group Cologne, Center for Integrated Oncology, University Hospital Cologne, Cologne, Germany*

**Background:** Identifying molecular drivers in lung squamous cell carcinoma (SCC) is a major medical need since no targeted therapy is available yet for this subtype. Fibroblast growth factor receptors (FGFRs) are physiologically involved in cell proliferation and survival. Genetic alteration of *FGFR* genes leads to deregulated activation in various cancers, and *FGFR1* amplification has been detected in lung SCC. Here, we report on patients (pts) with *FGFR1*-amplified lung SCC treated in a phase 1 study of BGJ398, a potent, selective pan-FGFR inhibitor. **Methods:** While this phase 1 dose-escalation study enrolled pts ≥ 18 years of age with any *FGFR* genetically altered tumor, we report here on the subgroup of pts with *FGFR1*-amplified advanced or metastatic lung SCC treated with 100 or 125 mg BGJ398 once daily in 28-day cycles. Pts who had progressed following at least 1 line of therapy, including platinum, were eligible for enrollment. *FGFR1*-amplified tumors were identified by fluorescent/chromogenic in situ hybridization (FISH/CISH) using, in most pts, a score recently established for lung SCC (Schildhaus, Mod Path 2012). Radiologic evaluation was performed every 8 weeks. **Results:** As of November 22, 2013, 21 pts with lung SCC were treated at the maximum tolerated dose of 125 mg/day (n = 19) or 100 mg/day (n = 2). Screening for *FGFR1* amplification was most commonly performed locally (n = 17) vs centrally (n = 4) and was assayed by FISH in all but 1 case (CISH). Of 17 evaluable pts at data cutoff, 2 achieved partial responses (PR; 1 confirmed by RECIST). PRs were durable, lasting about 8 and 3 months, respectively. Of note, 2 additional pts achieved PR (1 confirmed) after the data cutoff date. Additionally, 3 pts had stable disease with tumor regressions noted (up to 11% reduction). The adverse event profile for pts in this study with lung SCC included manageable and reversible hyperphosphatemia, as well as stomatitis, alopecia, decreased appetite, and fatigue. **Conclusions:** Here we report on the first molecularly targeted therapy in lung SCC demonstrating clinical efficacy. These data encourage further development of BGJ398 in *FGFR1*-amplified lung SCC and efforts to optimize predictive biomarkers for FGFR inhibitor sensitivity. Clinical trial information: NCT01004224.

**8035 Poster Highlights Session (Board #50), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase 1b open-label multicenter study of AZD4547 in patients with advanced squamous cell lung cancers: Preliminary antitumor activity and pharmacodynamic data.** *Presenting Author: Paul K. Paik, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Squamous cell lung cancers (SQCLC) account for 25% of all NSCLCs. Prognosis is poor with few treatment options. Amplified *FGFR1* is one of the most common oncogenic events in SQCLCs and occurs in ~20% of cases. AZD4547 is a potent and selective FGFR1-3 inhibitor with activity in *FGFR1* amplified SQCLC cell lines and patient-derived xenografts. Prior work identified a recommended dose of 80mg po bid. **Methods:** This was a multicentre Phase 1 expansion of AZD4547 in patients with previously treated stage IV *FGFR1* amplified SQCLCs (NCT00979134). *FGFR1* amplification (*FGFR1:CEP8*≥ 2) was confirmed through central FISH (N=13) or review of local results (N=2). Primary endpoint was safety/tolerability. Secondary endpoints were preliminary anti-tumor activity, PK, and PD. CT scans were performed at baseline and every 6 weeks. **Results:** 15 patients were treated. Median age=66 (48-72); female=46%; former/current smoker=100%; WHO restricted PS=69%. 8 patients had FISH ratios between 2-2.8 (low amplification). 7 patients had FISH ratios > 2.8 (high amplification). Mean relative dose intensity= 97%. The most common related AEs were GI and dermatologic. Grade ≥ 3 related AEs occurred in 3 patients (20%) (central serous retinopathy (CSR), hyponatremia, dehydration). Related SAEs occurred in 3 patients (CSR,dehydration, asthenia and dyspnea). There were 3 discontinuations due to AEs and no deaths due to drug. 14 patients were evaluable for tumor response assessment. There were: 1 PR, 4 SD, 9 PD (7 progressions and 2 deaths). The 1 PR was observed in a patient with high *FGFR1*amplification. Preliminary analysis found an increase in serum phosphate following treatment with AZD4547. Exon-sequencing of 283 cancer-related genes in 6 patient tumors, including 1 with a PR, showed no clear response modifiers. **Conclusions:** AZD4547 was well-tolerated in patients with *FGFR1* amplified SQCLC but did not meet its pre-specified efficacy endpoint in terms of overall response rate for continuation. The increase in serum phosphate concentration observed in this study provides evidence that AZD4547 at this dose and schedule causes pharmacologic target inhibition. Clinical trial information: NCT00979134.

**8036^ Poster Highlights Session (Board #51), Tue, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**NCIC CTG BR.26: A phase III randomized, double blind, placebo controlled trial of dacomitinib versus placebo in patients with advanced/metastatic non-small cell lung cancer (NSCLC) who received prior chemotherapy and an EGFR TKI.** *Presenting Author: Peter Michael Ellis, Juravinski Cancer Centre, Hamilton, ON, Canada*

**Background:** Dacomitinib (D) is an irreversible pan-HER inhibitor with evidence of activity in previously treated NSCLC patients (pts). **Methods:** BR26, a phase III randomized double blind placebo (P) controlled trial of D (45mg daily oral) vs P in NSCLC pts after one to three lines of chemotherapy and an EGFR TKI, randomized pts 2:1 to D or P. Response was assessed at 4, 8 then every 8 weeks during treatment. The primary endpoint was overall survival (OS). Secondary endpoints included OS in pts with *KRAS* wild type (WT) NSCLC, progression free survival (PFS), response rate (RR), toxicity, quality of life, biomarker analyses and resource utilization. **Results:** 720 pts were randomized: median age 64 yrs (range 32-90), male 51%, PS 0/1 75%, adenocarcinoma 73%, never smokers 36%. D did not improve OS compared with P (median OS 6.8m v 6.3m, HR 1.0, 95%CI 0.83-1.21, p=0.99). There was significant improvement in PFS favoring D (median PFS 2.7m v 1.4m, HR 0.66, 95%CI 0.55 – 0.79, p<0.0001). The RR was 7% v 1%, p=0.001. *EGFR* /*KRAS* status were known in 531/418 pts, respectively. The effect of D on OS was similar in pts with *EGFR* WT and *EGFR* mutation positive NSCLC (HR 0.93 vs 0.98, interaction p=0.69). The effect of D on OS appeared to differ by *KRAS* status: improving OS in pts with *KRAS* WT tumors (7.0m v 5.2m, HR 0.79, 95%CI 0.61 – 1.03), but worsening OS in pts with *KRAS* mutation positive NSCLC (5.8m v 8.3m, HR 2.1, 95%CI 1.05 – 4.22, interaction p=0.08). Pts on D had significantly longer time to deterioration of cough (p<0.0001), dyspnea (p=0.049) and pain (p=0.041). Pts treated with D vs. P [%] experienced more diarrhea (80 vs. 20), acneiform rash (60 vs. 10), oral mucositis (43 vs. 3), paronychia (30 vs. 0), dry skin (36 vs. 11), nausea/vomiting (36/28 vs. 25/16). Systemic therapy use after PD was 37% in pts. on D vs. 41% on P. **Conclusions:** D has activity in heavily pretreated pts with NSCLC. Although there was no improvement in OS, BR26 demonstrated a significant improvement in RR, PFS and time to symptom deterioration, and a trend to improved OS in pts with *KRAS* WT NSCLC. Further evaluation of D in biomarker defined subgroups appears warranted. Clinical trial information: NCT01000025.

**8037 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Randomized phase III trial of stereotactic radiosurgery (SRS) versus observation for patients with asymptomatic cerebral oligo-metastases in non-small cell lung cancer (NSCLC).** *Presenting Author: Sung Hee Lim, Department of Medicine, Division of Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** In patients with non-small cell lung cancer (NSCLC) with asymptomatic cerebral oligo-metastases, it is unclear whether treating brain metastasis before starting systemic chemotherapy is beneficial effects on survival compared with upfront systemic chemotherapy. This study was aimed to determine if early treatment with stereotactic radiosurgery (SRS) improve overall survival (OS) in NSCLC patients with asymptomatic oligo-brain metastases. **Methods:** We undertook a randomized controlled trial of 105 patients with asymptomatic oligo (1 to 4) brain metastases, each less than 3 cm in diameter, enrolled at Samsung Medical Center between 2008 and 2013. Patients older than 18 years with NSCLC and synchronous asymptomatic brain metastasis were randomly assigned to receive SRS initially (53 patients) followed by systemic chemotherapy or upfront systemic chemotherapy alone group (52 patients). The primary end point was OS and secondary end points included time to CNS disease progression, salvage brain treatment. **Results:** The median age of all patients was 58 years (range, 29-85) with good ECOG performance status(0,1), and most patients had adenocarcinoma (87%). The median overall survival time was 15.8 months (95% CI, 8.1-23.5) in SRS group and 17.6 months (95% CI, 12.4-22.8) for observation group (P=0.346). There was no significant difference in time to CNS disease progression (median, 9.4 months vs. 8.7 months, P=0.579). Salvage treatment for progression of CNS disease was required more frequently in observation group (52.8%) than SRS group (47.2%) which did not show statistical significance (P=0.201). The multivariate analysis revealed that higher extra-cranial disease activity, number of brain metastases (≥2), age older than 65 years, non-adenocarcinoma histology were independent risk factors associated with poor OS. **Conclusions:** These results suggest that SRS treatment followed by systemic chemotherapy did not improve overall survival in asymptomatic oligo-brain metastases NSCLC patients compared with upfront chemotherapy alone.

**8040 General Poster Session (Board #221), Sat, 1:15 PM-5:00 PM**

**Sunitinib (S) switch maintenance in advanced non-small cell lung cancer (NSCLC): An ALLIANCE (CALGB 30607), randomized, placebo-controlled phase III trial.** *Presenting Author: Mark A. Socinski, University of Pittsburgh, Pittsburgh, PA*

**Background:** This study compared switch maintenance with S versus placebo (P) in patients (pts) with advanced NSCLC following four cycles of first-line chemotherapy. The primary endpoint was progression-free survival (PFS) after randomization. Overall survival (OS) was a secondary endpoint. **Methods:** Stage IIIB/IV pts, PS 0-1 with stable/responding disease after 4 cycles of platinum-based therapy were randomized to S (37.5 mg po qd) vs P. Pts were assessed for progression every 6 weeks. PFS and OS were measured from the time of randomization. The trial was designed to have 90% power to detect a 6 week improvement in PFS using a log rank test at a 2-sided significance level of 0.05. Planned accrual was 244 pts. All p values are 2-sided. **Results:** The trial crossed the superiority boundary on the primary endpoint at an interim analysis. 210 pts were randomized (106 S, 104 P). Median age 66 yrs (range 25-89), 55.7% male, 60.5% ECOG PS 1, 87.6% stage IV, 22.4% received bevacizumab (which had to be discontinued at randomization), 91.7% current/past smokers. 45.9% had adenocarcinoma, 33.2% squamous, 13.7% undifferentiated NSCLC and 4.4% large cell. PFS was 4.3 mos on the S arm vs 2.8 mos on the P (HR 0.59, p=0.0008). PFS was improved for both squamous (4.3 S vs 2.4 P mos, HR=0.55, p=0.02) as well as non-squamous histology (4.3 S vs 2.8 P mos, HR=0.64, p=0.02). OS was not different (11.2 mos S vs 11.2 mos P, HR 1.05, p=0.77). Protocol treatment discontinuation was most commonly due to disease progression for P (90.6% for P vs 51.1% on S) and adverse event for S (28.7% for S vs 4.2% for P). Grade 3/4 toxicities (%) occurring in >5% of patients (S vs P) were anemia (6 vs 0), neutropenia (6 vs 1), thrombocytopenia (12 vs 0), hypertension (8 vs 0), fatigue (25 vs 4), rash (11 vs 0) and mucositis/stomatitis (11 vs 0). The rate of subsequent therapy was 74% on the P arm vs 61% on the S arm (p=0.049). **Conclusions:** CALGB 30607 met its primary endpoint by demonstrating a significant improvement in PFS for S switch maintenance therapy in advanced NSCLC. No effect on the secondary endpoint of OS was seen. Clinical trial information: NCT00693992.

**8041 General Poster Session (Board #222), Sat, 1:15 PM-5:00 PM**

**Randomized phase III study comparing gefitinib (G) with erlotinib (E) in patients (pts) with previously treated advanced lung adenocarcinoma (LA): WJOG 5108L.** *Presenting Author: Nobuyuki Katakami, Division of Integrated Oncology, Institute of Biomedical Research and Innovation, Kobe, Japan*

**Background**: Second-line therapy for advanced LA pts after progression on platinum-based regimens typically employs chemotherapy (CT) or EGFR-TKIs. Both G and E improved progression free survival (PFS) in pts with activating *EGFR*-mutation. We conducted a multicenter randomized phase III study designed to demonstrate noninferiority of G to E. **Methods**: Eligible pts were those with pathologically proven LA with stage IIIB/IV (AJCC version 6) or recurrence, previously treated with at least one chemotherapy regimen, evaluable disease, age ≥20 years and ECOG PS 0-2. Pts were randomized 1:1 to E (150 mg, daily), or G (250mg, daily) according to gender, stage, *EGFR* mutation status, performance status, smoking history, CT line, and institution. Target sample size was 560 based on the assumption that G was not inferior to E in PFS (2 – 4 months, $\alpha$ =0.025 [one sided], $\beta$ =0.80).Noninferiority was to be concluded if the upper CI limit was < 1.30. The primary endpoint was PFS, and secondary endpoints included overall survival (OS), response rate (RR), disease control rate (DCR), safety, and time to treatment failure (TTF). **Results**: From 2009/7 to 2012/10, 561 pts were accrued, and 280 and 279 were randomly assigned to E and G in FAS, respectively, including 185 (66.1%, E) and 186 (66.7%, G) with *EGFR* activating mutation tumors. Other baseline factors were balanced between arms except PS: median age 67/68 years; % female 54/55; % PS=0, 50/40; PS=1, 43/54; % stage IV, 69/69; % 2nd line, 69/71, % smoker, 50/50; for E v G. Median PFS, TTF and OS for E v G were 7.5 m v 6.5 m (p=0.257, HR=1.125, 95% CI: 0.940-1.347), 5.3 m v 5.6 m (HR=1.032, 95% CI: 0.866-1.231), and 24.5 m v 22.8 m (HR=1.038, 95% CI: 0.833-1.294), respectively. RR and DCR for E v G were 43.9% v 46.1%, and 75.0% v 71.2%, respectively. Median PFS and OS in pts with activating mutation for E v G were 10.1 m v 8.9 m (p=0.532), and 32.0 m v 26.6 m (p=0.111), respectively. Main grade 3/4 toxicities were rash (18.1% [E] v 2.2% [G]) and elevation of AST/ALT (2.2%/3.3% [E] v 6.1%/13.0% [G]). **Conclusions**: Noninferiority in PFS between E and G was not demonstrated according to predefined criteria, however, there was no statistically significant difference in PFS. Clinical trial information: UMIN000002014.

**8042 General Poster Session (Board #223), Sat, 1:15 PM-5:00 PM**

**BATLLE-2: *KRAS* mutation and outcome in a biomarker-integrated study in previously treated patients (pts) with advanced non-small cell lung cancer (NSCLC).** *Presenting Author: Vassiliki Papadimitrakopoulou, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** BATTLE-2 is building on the personalized medicine approach pioneered in the Biomarker-integrated Approaches of Targeted Therapy for Lung Cancer Elimination (BATTLE-1) trial, and is designed to address mutant *KRAS* and identify predictive biomarkers for targeted therapies in chemo-refractory pts. **Methods:** Pts refractory to at least 1 prior therapy, were adaptively randomized (AR), in this phase II, multi-center study, after tumor biopsy and exclusion of sensitizing *EGFR* mutations (mut+) or *ALK* fusions to 4 arms: erlotinib (E) 150 mg qd, E plus the AKT inhibitor MK-2206 (M) 135 mg q week, M 100 mg q week plus the MEK inhibitor AZD6244 (A) 100 mg qd, and sorafenib (S) 400 mg bid. The primary objective is 8-week disease control rate (DCR). In Stage 1, 200 pts are randomized and in Stage 2, AR of 200 pts will incorporate the best predictive biomarkers from Stage 1, to be derived from protein expression, gene expression profiling, 16-gene Sequenom mutation analysis and next generation sequencing (NGS) of 182 genes by Foundation Medicine. **Results:** From 6/2011 to 11/2013, 198 pts randomized to E (22 pts), EM (42 pts), MA (73 pts), S (61 pts). Demographics: Median age 62 (range 22-82); male 48%; ECOG PS 0-1 83%, PS 2 17%; Caucasian 89%, Asian 3%, other 8%; never/former/current smokers 33%/60%/7%; adenocarcinoma 73%, squamous 19%, other NSCLC 8%; prior E 37%, *KRAS* mut+ 23%, median prior therapies for metastatic NSCLC: 2 (range 1-9). Treatment was well tolerated. With 167 pts evaluable, overall 8-week DCR was 47%, worse with E (20%) than with EM (51%), MA (53%) and S (43%) (Fisher's exact test p= 0.06, 0.02, and 0.14). For *KRAS* wild type pts, DCR was worse for E (25%) than all other 3 arms (53%, 50%, and 44%, for EM, MA and S). For *KRAS* mut+ pts, DCR was highest for MA (61%) (0%, 40%, and 43% for E, EM, and S).Partial responses to MA were seen in 2 pts (*KRAS* mut+/ *ARAF* mut+, and *CDKN2A/FBXW7/TP53*mut+). **Conclusions:** Improved DCR was observed with EM and MA compared with E. The MA combination is active in KRAS mut+ NSCLC and merits further study. Biomarker analysis is ongoing to define better predictive markers and Stage 2 of BATTLE-2 is being redesigned. (Supported by NCI RO1CA155196-01A1). Clinical trial information: NCT01248247.

**8044 General Poster Session (Board #225), Sat, 1:15 PM-5:00 PM**

**Tivantinib plus erlotinib versus placebo plus erlotinib in Asian patients with previously treated nonsquamous NSCLC with wild-type *EGFR*: First report of a phase III ATTENTION trial.** *Presenting Author: Koichi Azuma, Division of Respirology, Neurology and Rheumatology, Department of Internal Medicine, Kurume University School of Medicine, Kurume, Japan*

**Background:** A randomized phase II study suggested that adding a c-Met inhibitor tivantinib (T) to an EGFR-TKI erlotinib (E) may prolong PFS in non-squamous NSCLC patients (pts) with 1-2 prior chemotherapy. Furthermore, the subset analysis suggested that survival benefit was more prominent in pts with wild-type *EGFR* (WT-*EGFR*) than in those with *EGFR* mutation. Therefore we conducted the phase III ATTENTION trial to compare overall survival (OS) between T+E vs. placebo (P)+E, in Asian pts with pretreated NSCLC with WT-*EGFR*. **Methods:** Four-hundred-and sixty Asian (Japan, Korea, and Taiwan) pts who had been treated with 1-2 chemotherapy for non-squamous NSCLC with WT-*EGFR* were planned to be randomized between T+E and P+E. The doses of T were 360mg BID and 240mg BID, for CYP2C19 extensive metabolizers (EM) and poor metabolizers (PM), respectively, whereas that of E was 150 mg QD for both EM and PM. The primary endpoint was OS, and secondary endpoints included PFS, ORR, and safety. Exploratory analysis tested biomarkers including c-Met expression and *KRAS* mutation. **Results:** New enrollment was stopped when 307 pts had been randomized, following the Safety Review Committee's recommendation based on an observed imbalance in interstitial lung disease (ILD) between the groups. Accordingly,153 and 154 pts were treated with T+E and P+E, respectively. Patient backgrounds including CYP2C19 genotype were well balanced. Results are summarized below. Typical ≥Gr.3 adverse events in T+E were anemia (13.2 %), neutropenia (10.5 %), and leukopenia (6.6 %). Fourteen pts (including 3 deaths) and 6 pts (0 deaths) developed ILD in T+E and P+E, respectively. **Conclusions:** Although this trial lacked a statistical power due to the prematurely termination owing to toxicity concern, our results indicated some sign for benefit for adding T to E in this population. OS was numerically prolonged but this did not reach statistical significance. Exploratory biomarker analysis may identify subsets in which benefit and risk from this treatment is well balanced. Clinical trial information: NCT01377376.

**8045 General Poster Session (Board #226), Sat, 1:15 PM-5:00 PM**

**Phase 2 HERALD study of patritumab (P) with erlotinib (E) in advanced NSCLC subjects (SBJs).** *Presenting Author: Joachim Von Pawel, Asklepios-Fachkliniken München-Gauting, Gauting, Germany*

**Background:** P is a fully human anti-HER3 antibody that inhibits HER3 binding with its ligand heregulin (HRG). Preclinically, P enhances anti-tumor activity with EGFR inhibitors, prevents HER3 reactivation after anti-EGFR treatment, and inhibits HRG-dependent activation. Phase Ib showed that P, with E (150mg/day PO), was tolerated at 18mg/kg IV q3w. **Methods:** This Ph2 randomized, placebo-controlled double-blind study assessed safety and efficacy of P+E vs. placebo (Pbo)+E in E-naïve sbjs with advanced NSCLC (2nd or later line). 215 sbjs were randomized to: 1) High Dose [HD]: P 18 mg/kg IV q3w; 2) Low Dose [LD]: P: 18 mg/kg IV X 1, 9 mg/kg IV q3w maintenance; or 3) Pbo q3wk. All subjects received E 150 mg/day PO. Endpoints included PFS (primary), and OS and safety (secondary). HRG, measured as mRNA, was prospectively hypothesized to be the primary predictive biomarker before database lock. High/Low HRG cutoff was set at the median of the blinded data. **Results:** 212 sbjs comprised the ITT. Median (m) PFS for ITT for HD, LD, and Pbo arms was 1.4 mos (HR 0.98), 2.5 mos (HR 0.77), and 1.6 mos, respectively (p=NS). 101 sbjs (51 HRG high) had adequate tissue for HRG testing. PFS was significantly improved in the HRG high subgroup (Table). HRG low subgroup showed no improvement in PFS (HR 0.92) and OS (HR 1.05) vs. Pbo. Grade >3 AE's (HD, LD, Pbo) included: diarrhea (11.4%, 8.5%, 4.2%) and rash (5.7%, 7.0%, 2.8%). **Conclusions:** P showed improved PFS in the HRG high, but not in the ITT population. P safety was similar to Pbo with the exception of manageable rash and gastrointestinal effects. HRG appears to be a predictive biomarker for P, confirming preclinical findings (Schneider et al, Yonesaka et al, ASCO 2014). HERALD is the first randomized Pbo controlled trial in NSCLC to report a predictive biomarker for HER3. Based on these results, a 2-part (A, confirmation of HRG predictive value; B, pivotal HRG high only) Phase 3 study was initiated. Clinical trial information: NCT01211483.

**8046 General Poster Session (Board #227), Sat, 1:15 PM-5:00 PM**

**Efficacy and safety results from CurrentS, a double-blind, randomized, phase III study of second-line erlotinib (150 mg versus 300 mg) in current smokers with advanced non-small cell lung cancer (NSCLC).** *Presenting Author: Egbert F. Smit, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Pts with NSCLC who are active smokers may have increased erlotinib metabolism v non-smokers, which reduces exposure. **Methods:** Pts with stage IIIB/IV NSCLC (failed first-line platinum-based chemotherapy, current smokers) were randomized to receive standard dose erlotinib (150 mg/day; E150) or an experimental dose (300 mg/day; E300) until progression/death/unacceptable toxicity. Pts were assessed every 6 wks. Primary endpoint: progression-free survival (PFS). Secondary endpoints included: overall survival (OS), disease control rate (DCR), and safety. Planned sample size: 300 randomized pts; 277 PFS events needed to show a HR of 0.714 (median PFS improvement from 10 to 14 wks; E300 was expected to provide a longer median PFS v E150) with 80% power (5% 2-sided $\alpha$). **Results:** Baseline characteristics were balanced (Table). Efficacy and safety results are reported (Table). **Conclusions:** CurrentS, the first and largest trial in active smokers with NSCLC to date, did not show a statistically significant increase in PFS (primary endpoint) when erlotinib was given at 300 mg v 150 mg. OS (secondary endpoint) was not different between the arms. There was a numerical increase in AESIs with the higher dose. PK data will be presented. Clinical trial information: NCT01183858.

**Updated efficacy and safety of the ALK inhibitor AP26113 in patients (pts) with advanced malignancies, including ALK+ non-small cell lung cancer (NSCLC).** *Presenting Author: Scott N. Gettinger, Yale University, New Haven, CT*

**Background:** AP26113 is a novel orally-active tyrosine kinase inhibitor with preclinical activity against ALK and all 9 clinically-identified crizotinib-resistant mutants tested. **Methods:** The Phase (Ph) 2 portion of a Ph1/2 single arm, multicenter study in pts with advanced malignancies is underway. We report updated safety for all treated pts and efficacy data for ALK+ NSCLC pts previously treated with crizotinib. NCT01449461. **Results:** As of 16 Dec 2013, 114 pts were enrolled: 65 in Ph1 (30-300 mg) and 49 in Ph2 (180 mg). Baseline characteristics: 59% female, median age 57 yr; diagnoses: NSCLC n=106, other n=8. 66 pts remain on study; median follow-up for all pts is 3.6 mo (max= 21.4 mo, ongoing). The most common treatment-emergent AEs (≥20%) were nausea (38%), diarrhea (31%), fatigue (31%), cough (23%), and headache (20%), which were generally grade 1/2 in severity. Early onset of pulmonary symptoms (dyspnea with hypoxia and/or findings on imaging) observed in 6/45 (13%) pts at 180mg QD. These symptoms, requiring immediate medical attention, were not observed at 90mg QD (n=8) or in the lead-in dose cohort (n=19; initiated at 90mg QD, escalated to 180mg QD after 1 wk). Pts continue to be enrolled with this dose escalation scheme, and an additional cohort of 90mg QD without escalation will be added. Among 38 evaluable ALK+ NSCLC pts with prior crizotinib, 24 (63%) responded (23 partial response, 1 complete response). Duration of response was 1.6 - 14.7 mo (ongoing). 15 pts had confirmed responses; 5 await confirmation, 4 are unconfirmed. Among 42 evaluable pts with ALK+ NSCLC, median progression free survival is 47 wk. Independent radiological review conducted on 10 pts enrolled with untreated or progressing brain metastases showed 6/10 pts with response in brain, including 4 with undetectable brain metastases following AP26113; 2 pts had stable disease, 2 pts progressed; 8/10 remain on study (range 5-17 mo). **Conclusions:** AP26113 has promising anti-tumor activity in pts with crizotinib-resistant ALK+ NSCLC, including pts with brain metastases. A randomized Ph2 trial evaluating 90 mg QD vs. 90mg QD escalating to 180mg QD in crizotinib-resistant ALK+ NSCLC will begin shortly. Clinical trial information: NCT01449461.

**8048 General Poster Session (Board #229), Sat, 1:15 PM-5:00 PM**

**Analysis of *NTRK1* gene fusion incidence in an unselected cohort of non-small cell lung cancer patients.** *Presenting Author: Robert Charles Doebele, University of Colorado Cancer Center, Aurora, CO*

**Background:** The identification and therapeutic targeting of oncogenic drivers in lung adenocarcinoma has led to significant clinical improvements for patients with *EGFR* mutations or *ALK* fusions. We recently discovered a new oncogenic fusion involving *NTRK1* that can be targeted by kinase inhibitors against the TRK family of receptor tyrosine kinases. We therefore investigated *NTRK1*cytogenetic patterns of tumor samples from NSCLC patients to determine the incidence and clinical characteristics of patients in this unselected cohort. **Methods:** A tumor microarray (TMA) previously analyzed by *ALK (12/445=2.7%)*, *ROS1 (5/429=1.2%)* and *RET* (6/348=1.7%) FISH containing 447 tumor samples from patients with NSCLC was analyzed. Clinical characteristics of the TMA have been reported previously. Fluorescence in situ hybridization (FISH) screening using a novel dual color *NTRK1* break-apart assay was performed. RT-PCR was performed on RNA extracted from corresponding tumor blocks to confirm the presence and identify of the *NTRK1*fusion partner. A novel proximity-ligation assay (PLA) to detect TRKA activation by detecting TRK-SHC1 protein complexes was developed as a complimentary, proteomic method for the detection of TRK activation, regardless of the mechanism of activation. **Results:** *NTRK1* FISH analysis was successfully performed on 443 of 447 tumor samples (99.1%). Five of 443 (1.1%) tumor samples exhibited patterns indicating an *NTRK1* rearrangement with split (n=1), single 3' (n=1), or single 5' (n=3) signals. Clinical characteristics of the 5 *NTRK1*+ patients are as follows: 3 female; 2 never-smokers; and 3 adenocarcinoma, 1 squamous cell carcinoma, and 1 large cell neuroendocrine carcinoma histology. An additional 5 samples had atypical cytogenetic patterns and 7 samples demonstrated focal *NTRK1*gene amplification warranting further exploration by alternate methodologies. **Conclusions:** *NTRK1* gene rearrangements were detected in 1.1% of tumor samples from an unselected cohort of NSCLC patients. Additional *NTRK1* cytogenetic patterns were observed and warrant further evaluation. Confirmatory testing by PCR to evaluate the specific *NTRK1* fusion transcripts and a novel TRK PLA method will be presented.

**8049 General Poster Session (Board #230), Sat, 1:15 PM-5:00 PM**

**Identifying *ALK* rearrangements that are not detected by FISH with targeted next-generation sequencing of lung carcinoma.** *Presenting Author: Siraj M. Ali, Foundation Medicine, Inc., Cambridge, MA*

**Background:** Genomic rearrangements of *ALK* are the defining feature of a subset of lung non-small cell carcinomas (NSCLC), and predict response to ALK-targeted therapies. We reviewed our experience with *ALK* rearranged lung carcinomas (LC) as detected by a clinical next generation sequencing (NGS)-based assay. **Methods:** Genomic profiling of 1,070 lung carcinomas was performed on >50 ng of DNA extracted from formalin fixed, paraffin embedded specimens, from either primary tumors or metastatic sites. Libraries constructed from such DNA were subjected to hybrid capture of all exons of 236 cancer related genes and 47 introns of 19 genes frequently rearranged in cancer, and followed by clinical NGS with high uniform coverage to a median exon coverage depth exceeding 700x. Data regarding prior diagnostic studies for genomic alterations and response to targeted therapies was provided by treating physicians. **Results:** Of 1.070 total lung carcinomas profiled, 47 harbored *ALK* rearrangements (4.4%); including lung adenocarcinomas (n=39/724), NSCLC (n=4/146), adenosquamous carcinomas (n=2/12), and mucoepidermoid and large cell neuroendocrine carcinomas (n=1/3 and n=1/23). The median age of the patients was 52 years, with an equal sex ratio, and 38 patients had Stage IV disease. Of the 28 *ALK* rearranged specimens also tested by *ALK* FISH, 9 (32%) were negative, and 19 were positive. Of the 47 *ALK* rearranged cases, all fusions had a breakpoint in intron 19 of *ALK*. Six cases harbored non-*EML4* 5' partners. Of the 41 *EML4-ALK* fusions, there were 17 cases with a breakpoint in intron 13 of *EML4* (variant1), 2 cases in intron 18, 2 cases in intron 2(v5), 4 cases in intron 20 (v2), and 16 cases in intron 6 (v3). Twenty-two patients were treated with crizotinib and had response data available; 19 responded by investigator assessment. Of the 9 cases negative by FISH, 5 patients responded to crizotinib, 2 patients did not, and the response data for the remaining 2 patients is unavailable. **Conclusions:** Targeted NGS may be more sensitive for the detection of *ALK* rearrangements than FISH. In light of the responsiveness of *ALK* NGS+/FISH- tumors to crizotinib, the use of FISH as the gold standard for *ALK* detection in LC warrants prospective study.

**8050 General Poster Session (Board #231), Sat, 1:15 PM-5:00 PM**

**A randomized phase 2 study of a human antiplatelet-derived growth factor $\alpha$ (PDGFR$\alpha$) monoclonal antibody (olaratumab, IMC-3G3) with paclitaxel/carboplatin or paclitaxel/carboplatin alone in previously untreated patients with advanced non-small cell lung cancer (NSCLC).** *Presenting Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** In NSCLC, the PDGF-PDGFR axis mediates angiogenesis, local invasion, and tumor interstitial pressure. Olaratumab (IMC-3G3), a fully human monoclonal antibody, selectively binds human PDGFR$\alpha$ and blocks ligand binding. This open-label phase 2 study assessed the safety and efficacy of olaratumab added to paclitaxel/carboplatin (P/C) versus P/C alone in previously untreated patients (pts) with advanced NSCLC. **Methods:** Pts were randomized to receive up to 6 cycles of P 200 mg/m$^2$and C AUC 6 (day 1) with (Arm A) or without (Arm B) olaratumab 15 mg/kg on days 1 and 8. The primary endpoint was progression-free survival (PFS), estimated by the Kaplan-Meier method. Olaratumab maintenance therapy was continued in Arm A until disease progression. At the time of progression, pts in Arm B could cross over to olaratumab monotherapy. **Results:** A total of 131 pts were randomized to Arm A (n=67) or Arm B (n=64). Demographics were similar between arms (57% male, 84% white, and median age 65 years). Most pts (74%) had nonsquamous NSCLC. Median PFS (Arm A: 19.1 weeks, Arm B: 19.0 weeks; p=0.21; hazard ratio [HR]: 1.29 [0.86–1.93]), median overall survival (OS) (Arm A: 51.3 weeks, Arm B: 50.1 weeks; p=0.87; HR: 1.04 [0.68–1.57]), and objective response rate (ORR) (Arm A: 42%, Arm B: 34%; p=0.47) were similar between arms. The 2 arms had similar toxicity profiles (Table). Adverse events leading to death occurred in 4 pts in Arm A (dyspnea, sepsis, disease progression, and myocardial infarction) and 2 pts in Arm B (respiratory failure and pneumonia). **Conclusions:** Adding olaratumab to P/C did not result in significant prolongation of PFS, OS, or ORR among previously untreated pts with advanced NSCLC. Clinical studies of olaratumab in other pt populations and biomarker analyses are underway. Clinical trial information: NCT00918203.

**A randomized phase 2 trial of MM-121, a fully human monoclonal antibody targeting ErbB3, in combination with erlotinib in EGFR wild-type NSCLC patients.** *Presenting Author: Lecia V. Sequist, Massachusetts General Hospital, Boston, MA*

**Background:** Heregulin induced activation of ErbB3 has been implicated as a mechanism of resistance to many targeted therapies such as EGFR-TKIs in preclinical models. MM-121 is a monoclonal antibody designed to interfere with this mechanism of resistance. **Methods:** This Phase 2 trial was a global, multi-center, open-label, parallel cohort study of MM-121 and erlotinib in 3 predefined NSCLC patient groups. Here we report final results from one of the 3 groups: EGFR WT patients. This group comprised 132 patients with WT EGFR who progressed on ≥1 platinum-based SOC therapy and were EGFR TKI-naive. Patients were randomized 2:1 to receive MM-121 20 mg/kg every other week plus daily erlotinib at 100 mg (M) or daily erlotinib alone at 150 mg (E). The primary objective was to compare the progression-free survival (PFS) between M and E. Fresh tissue biopsies were mandatory for evaluation of a pre-specified set of biomarkers mechanistically-linked to ErbB3 signaling. **Results:** 121 patients (85 (M), 36 (E)) were included in the safety and efficacy analyses. PFS was analyzed after 105 events (73 (M), 32 (E)). Median PFS was 8.1 weeks for arm M and 7.7 weeks for arm E with a HR of 0.898 (95%CI [0.592, 1.363]), log-rank p=0.6129. The objective response rate was 4.7% (95%CI [1.85 - 11.48]) on arm M, and 5.6% (95%CI [1.54 - 18.14]) on arm E. The median overall survival estimate was 27.3 weeks for arm M and 37.3 weeks for arm E, with a HR of 1.499 (95% CI [0.855, 2.629]). The majority of adverse events were reported as mild to moderate in severity and included the following (M vs. E): rash (74% vs. 37%), diarrhea (59% vs. 27%), dermatitis acneiform (28% vs. 11%), dry skin (54% vs. 47%), nausea (29% vs. 14%), fatigue (31% vs. 13%), stomatitis (20% vs. 5%), decreased appetite (37% vs. 16%), weight decreased (27% vs. 11%), and dyspnea (22% vs. 9%). The adverse events were overall manageable and did not impact compliance on treatment. **Conclusions:** Addition of (M) to (E) was not effective at prolonging PFS in this study population. Overall survival favored the control arm. The observed safety profile is consistent with the expected adverse events associated with ErbB-family inhibitors. Biomarker data will be presented. Clinical trial information: NCT00994123.

**8052 General Poster Session (Board #233), Sat, 1:15 PM-5:00 PM**

**Phase II study of erlotinib plus tivantinib in patients with *EGFR*-mutation–positive NSCLC who failed in immediately previous EGFR-TKI therapy.** *Presenting Author: Tomonori Hirashima, Department of Thoracic Malignancy, Osaka Prefectural Hospital Organization Osaka Prefectural Medical Center for Respiratory and Allergic Diseases, Osaka, Japan*

**Background:** Although driver mutations in *EGFR* gene are often associated with initial dramatic response to EGFR-TKI, those patients inevitably develop acquired resistance. It is suggested that dual inhibition of EGFR and c-Met may overcome or delay emergence of this resistance. Therefore, we conducted a multicenter, open-label, single arm Phase II combining erlotinib and a c-Met inhibitor tivantinib, in *EGFR*-mutated NSCLC patients with EGFR-TKI resistance. **Methods:** NSCLC patients who developed progressive disease during their immediately previous treatment with either erlotinib or gefitinib were enrolled. Fresh tumor biopsy was mandatory prior to starting the combination. All patients received daily oral erlotinib and tivantinib, until discontinuation criteria were met. Tumor response was evaluated by the independent radiological committee. The biopsy specimens were used for a comprehensive biomarker analysis, such as IHC assay of c-Met and HGF, and for multiplex mutation analysis (LungCarta Panel) of lung cancer associate genes including *KRAS*, *c-MET*, *PTEN*, *EGFR* and *TP53*. Plasma concentration of soluble c-Met and 8 angiogenic cytokines were also determined by ELISA and Luminex assay, respectively. **Results:** Forty-five patients were treated. The Table below shows objective response rate (ORR) and progression free survival (PFS) in the overall population, and in a subpopulation defined by c-Met expression or resistance mutations in *EGFR* (i.e. T790M or Exon 20 ins). Most of AEs were similar to the previous trials. **Conclusions:** In patients with *EGFR*-mutated NSCLC with EGFR-TKI resistance, erlotinib/tivantinib combination therapy may be beneficial to those with high c-Met expression or in those without resistance mutations in *EGFR*. The more detailed multivariate analyses regarding biomarkers will also be reported. Clinical trial information: NCT01580735.

| Population | N | ORR (%) | Median PFS (days) |
|---|---|---|---|
| Overall | 45 | 4.4 (95% confidence interval [CI]; 0.5-15.1) | 83 (CI; 43-128) |
| c-Met high | 22 | 9.1 (CI; 1.1-29.2) | 125 (CI; 43-212) |
| c-Met low | 22 | 0.0 (CI; 0.0-15.4) | 43 (CI; 42-127) |
| Resistance mutations positive | 23 | 0.0 (CI; 0.0-14.8) | 44 (CI; 42-129) |
| Resistance mutations negative | 22 | 9.1 (CI; 1.1-29.2) | 86 (CI; 43-132) |

**8053 General Poster Session (Board #234), Sat, 1:15 PM-5:00 PM**

**Variation in mechanisms of acquired resistance (AR) among EGFR-mutant NSCLC patients with more than one post-resistant biopsy.** *Presenting Author: Zofia Piotrowska, MGH Cancer Center, Boston, MA*

**Background:** AR typically develops after 9-12 mos of EGFR TKI therapy among EGFR-mutant patients (pts). Here we report a unique series of 42 EGFR mutants who had >1 post-resistant biopsy (bx) that illustrates the heterogeneity of AR within individual pts. **Methods:** We analyzed prospective data from 126 EGFR mutants with advanced NSCLC who had ≥1 bx after AR developed on EGFR TKI therapy. All biopsies underwent multiplexed CLIA-certified SNaPshot genotyping. Some pts consented to provide tissue for patient-derived cell-line (PDCL) establishment. 42 pts had >1 post-AR bx. We collected data on EGFR TKI therapy, mechanisms of AR observed over multiple biopsies, bx safety and correlations between clinical and PDCL data. **Results:** Among 42 pts with multiple post-AR biopsies, median age= 57 (range 39-88), 73% were female, 62% had EGFR exon 19 deletion and 31% had L858R. The median number of post-AR biopsies was 2 (range 2-5). While the original EGFR mutation was uniformly maintained, we observed variation in AR mechanisms among 20/42 pts, with changes in T790M status over time in 10 pts. Notably, both gain and loss of T790M were observed on serial biopsies, without a clear correlation to the timing of EGFR TKI therapy or bx site. Changes in histology (8), development of EMT (1) and EGFR amp (1) were also seen. 22/42 pts had no variations in detected mechanisms of AR on serial biopsies, including T790M (n=11), MET amp (2), EGFR amp (1), both MET and EGFR amp (1), SCLC transformation (1), BRAF mutation (1), and no AR mechanism identified (5). Repeat biopsies were safe, with 2.4% bx-related complications and no serious complications. **Conclusions:** We observed frequent and unexpected changes in the mechanism of AR, particularly T790M status, in pts undergoing serial biopsies, suggesting heterogeneity of resistant clones in these pts. Among pts with T790M, 48% gained or lost the mutation over time. Relationship of AR mechanisms to therapy at the time of bx, bx location and correlations with PDCL data to understand their biologic implications will be presented. Our data suggest serial biopsies in EGFR pts are informative and safe, and may become increasingly important as T790M-specific TKIs become available.

**8054 General Poster Session (Board #235), Sat, 1:15 PM-5:00 PM**

**Randomized phase 2 trial of plinabulin (NPI-2358) plus docetaxel in patients with advanced non-small cell lung cancer (NSCLC).** *Presenting Author: Rebecca Suk Heist, Division of Hematology and Oncology, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA*

**Background:** Plinabulin (N) inhibits tumor growth by targeting both angiogenesis and tumor vasculature as well as directly by inducing apoptosis via the Ras-JNK pathway. This trial compared the combination of N and docetaxel (DN) to docetaxel alone (D). **Methods:** Patients (pts) with advanced NSCLC previously treated with standard chemotherapy (ChRx) were randomized between D (75 mg/m$^2$ IV) on Day 1 plus N 30 mg/m$^2$ IV on Days 1 and 8 in 21-day cycles (DN) vs D (75 mg/m$^2$ ) (30 Cohort). Pts with Stage IIIB/IV NSCLC and 1 or 2 prior ChRx were eligible. Prior D or vascular disrupting agent (VDA) were not allowed. A 2nd dose cohort (DN 20 mg/m$^2$) of pts with 1 prior ChRx (20 Cohort) was enrolled. The primary end point was overall survival (OS). **Results:** 172 pts were randomized into 2 dosing cohorts with 163 treated: 30 Cohort (50 DN; 55 D) and 20 Cohort (40 DN; 18 D). For 30 Cohort, OS (months (M)), 90% confidence interval [90% CI]) was 8.7 (6.6, 12.6) for DN and 7.5 (6.3, 10.5) for D; response rate was 14.0% for DN and 14.5% for D; and duration of response (M, 90% CI) for DN was 12.7 (4.0, 13.9) and 1.5 (1.1, 3.1) for D (p=0.049). Results appeared better for the DN 30 Cohort vs 20 Cohort. Post hoc subset analysis identified pts with large, lung tumors (>3 cm) and 1 prior ChRx as having better survival with DN. OS (M, 95% CI) for this subset was 11.5 (7.1, 15.1) DN vs 7.8 (4.1, 17.4) D. The most common adverse events were nausea, fatigue, diarrhea, constipation, and anorexia. There were fewer dose reductions of D among DN pts (10%) vs D pts (18.2%). There was a lower incidence of neutropenia in patients in the DN 30 Cohort compared to D (8.0% vs 36.4%, p<0.001) and the DN 20 Cohort compared with its companion D (7.5% vs 22.2%). A post hoc analysis showed that the DN 30 Cohort (n=50) had a significantly lower incidence of ≥ Grade 3 neutropenia vs the pooled D (n=73) at 8.0% vs 27.4%, respectively (p=0.010). **Conclusions:** Pts with large, lung tumors (>3 cm) and 1 prior ChRx may be more likely to have an increased survival with DN as compared to D. This finding is consistent with the mechanism of action of a VDA with anti-angiogenesis and apoptotic properties. A Phase 3 trial in pts with large, lung tumors is planned. Clinical trial information: NCT00630110.

**8055 General Poster Session (Board #236), Sat, 1:15 PM-5:00 PM**

**The Lung Cancer Genomic Screening Project for Individualized Medicine in Japan (LC-SCRUM-Japan): Screening for *RET* and *ROS1* fusions in advanced *EGFR* mutation-negative nonsquamous lung cancer and development of molecular targeted therapy.** *Presenting Author: Kiyotaka Yoh, Division of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** *EGFR* mutations and *ALK* fusions have emerged as important oncogenic drivers in non–small cell lung cancer (NSCLC). *RET* and *ROS1* fusions have identified as new drivers of lung adenocarcinomas and these fusions are reported to be promising druggable targets. However, these gene fusions are encountered rather rarely, that is observed in only 1-2% of all lung adenocarcinomas. **Methods:** This study was established in February 2013 as a new nationwide genomic screening project for developing individualized medicine of advanced NSCLC patients in Japan. Tumor samples of advanced *EGFR* mutation-negative non-squamous lung cancer patients were eligible for submission. The specimens were screened for *RET*, *ROS1* and *ALK* fusions by RT-PCR and FISH methods. **Results:** As of January 22th in 2014, The LC-SCRUM-Japan is under way with the participation of 158 institutions in Japan, under aid from the public research fund of the Ministry of Health, Labour and Welfare of Japan. 507 patients were enrolled to this study and 444 tumor samples of enrolled patients (88%) were screened. A gene fusion was detected in 52 (12%) of the 444 patients as follows; *RET* 21 (5%), *ROS1* 17 (4%), and *ALK* 14 (3%). We have synchronously initiated a phase II trial of vandetanib for advanced *RET* fusion-positive NSCLC patients (LURET study) (UMIN000010095). Eight of 21 patients with positive for *RET* fusion determined in the LC-SCRUM-Japan have been already enrolled and just treated with vandetanib in the LURET study. In addition, we enrolled 5 of 17 patients with *ROS1* fusion-positive NSCLC determined in the LC-SCRUM-Japan onto a global phase II trial of crizotinib for advanced *ROS1* fusion-positive NSCLC patients (OO12-01) (NCT01945021). **Conclusions:** The prevalence of *RET* and *ROS1* fusions in our enriched population was relatively higher compared with that reported in non-selected NSCLC population. This innovative screening project in Japan leads to the activation of screening for lung cancer with rare driver mutations and developing targeted therapy trials. Clinical trial information: UMIN000010234.

**8056 General Poster Session (Board #237), Sat, 1:15 PM-5:00 PM**

**An international, multicenter, randomized, double-blind phase III study of maintenance belagenpumatucel-l in non-small cell lung cancer (NSCLC): Updated analysis of patients enrolled within 12 weeks of completion of chemotherapy.** *Presenting Author: Lyudmila Bazhenova, UC San Diego Moores Cancer Center, La Jolla, CA*

**Background:** Belagenpumatucel-L (Lucanix) is a therapeutic vaccine comprised of 4 TGF-$\beta$2 antisense gene-modified, irradiated, allogeneic NSCLC cell lines. **Methods:** The trial enrolled patients (pts) without progression after completion of frontline chemotherapy (IIIA-42, IIIB/IV-490). Pts were randomized 1:1 between 4 and 17.4 weeks (w) from the end of frontline chemotherapy. Pts were treated until disease progression or withdrawal. The primary endpoint was overall survival (OS). Secondary endpoints were PFS, RR and safety. **Results:** 532 pts were enrolled (270 vaccine and 262 placebo), 57% adenocarcinoma (non-SCC), 27% squamous (SCC). Median OS results and safety profile of belagenpumatucel-L was previously reported. A predefined Cox regression demonstrated that the time elapsed between the end of frontline chemotherapy and randomization had a significant impact on survival outcomes (p=0.002). 318 (59.8%) of pts were randomized within 12 w of the completion of chemotherapy (IIIA=13, IIIB/IV=305, 162 vaccine, 143 placebo). Pts with pretreatment radiation (XRT) enrolled within 12 w had median OS of 40.1 m (belagenpumatucel-L) vs. 10.3 m (placebo) (HR 0.45, p=0.014). Median OS of pts treated with concurrent XRT and enrolled within 12 w was not reached (belagenpumatucel-L) and 10.3 m (placebo) (HR 0.34, p=0.04). **Conclusions:** Although,trial did not meet its predefined end point, a non-statistically significant increase in OS was observed in several subsets of pts who began belagenpumatucel-L within 12 w of the completion of frontline chemotherapy. These data support another Phase III trial with IIIB/IV patients to be randomized within 12 weeks of the completion of frontline chemotherapy. Clinical trial information: 00676507.

| Stage/time from randomization (< 12 w) | N | Median OS (m) | | P | HR |
|---|---|---|---|---|---|
| | Belagenpumatucel-L | Placebo | | | |
| All | 318 | 20.7 | 13.3 | 0.092 | 0.77 |
| IIIB/IV | 305 | 20.7 | 13.3 | 0.083 | 0.76 |
| IIIB | 83 | 24.7 | 13.4 | 0.303 | 0.71 |
| IV | 230 | 19.7 | 12.7 | 0.165 | 0.76 |
| IIIB/IV SCC | 78 | 20.7 | 12.3 | 0.092 | 0.58 |
| IIIB/IV non-SCC | 227 | 22.3 | 16.4 | 0.189 | 0.66 |

**8057 General Poster Session (Board #238), Sat, 1:15 PM-5:00 PM**

**Molecular profiling of non-small cell lung cancer by histologic subtype.** *Presenting Author: Solange Peters, University Hospital of Lausanne (CHUV), Lausanne, Switzerland*

**Background:** A substantial proportion of NSCLC has been shown to harbour specific molecular alterations affecting tumour proliferation and resulting in sensitivity to inhibition of the corresponding activated oncogenic pathway by targeted therapies. Comprehensive tumor profiling can diagnose such alterations and may identify new alterations opening additional treatment options for all distinct NSCLC subtypes. **Methods:** Over 6,700 non-small cell lung cancer cases referred to Caris Life Sciences between 2009 and 2014 were evaluated; clinical diagnoses and detailed tumor pathology were collected from referring physicians. Specific profiling was performed per physician request and included a combination of sequencing (Sanger, NGS or pyrosequencing), protein expression (IHC), gene amplification/rearrangement (CISH or FISH), and/or RNA fragment analysis within potential cancer-related genes and pathways. **Results:** Patients were grouped into cohorts according to histological subtype – adenocarcinoma (AD) (n=4,286), squamous cell carcinoma (SCC) (n=1,280), large cell carcinoma (LCC) (n=153) and bronchioalveolar carcinoma (BAC) (n=94). Protein overexpression of cMET (>2+ in >50% cells) was higher in AD (35.9%) compared to other subgroups (12-20%) while RRM1 and TOP2A levels were lower in AD. ALK or ROS1 were rearranged in 5.3% of patients with AD compared to 3.7% of patients with LCC and 1.2% of patients with SCC. EGFR mutations were found at low prevalence in both the LCC (0%) and SCC cohorts (2.8%) compared to 21% in AD. Similar lower rates of BRAF mutations were observed in the LCC and SCC cohorts compared to AD (0%, 1.1% and 5.1%). Pathway analysis showed activating mutations in the ERK pathway in 40% of patients with AD. Only 10-12% of patients with LCC or SCC had activating mutations in the ERK pathway. **Conclusions:** Despite the limitations of this retrospective series, we report comprehensive profiling of the largest cohort of NSCLC. Tumor profiling reveals that ADs may be more addicted to the ERK pathway than other histological subtypes. Drugs which target cMET may also have most utility in AD. Full analysis by histological subtype and additional correlative data on protein expression, gene copy number and mutations will be presented.

**8058 General Poster Session (Board #239), Sat, 1:15 PM-5:00 PM**

**The use of improved and complete enrichment co-amplification at lower denaturation temperature (ICE COLD-PCR) method for the detection of *EGFR* and *KRAS* mutations from cell-free plasma DNA of non-small cell lung cancer (NSCLC) patients.** *Presenting Author: Hai T. Tran, MD Anderson Cancer Center, Houston, TX*

**Background:** Identification of specific molecular alterations from cell free plasma DNA (cfpDNA) holds tremendous potential as a noninvasive method to assess tumor genotype. We evaluated whether ICE COLD-PCR(ICP) can be used to identify *EGFR* and *KRAS* mutations from cfpDNA in patients enrolled in the BATTLE research clinical trial. **Methods:** Tissue genotyping of *KRAS* (Exons 2, 3) and *EGFR* (Exons 18 - 21) on DNA extracted form paraffin-embedded tumor tissue was determined using PCR-based sequencing analysis, with lower limit of sensitivity of detection of 20%. Genotyping of cfpDNA was determined using ICP for mutation enrichment followed by Sanger sequencing for mutation detection, with limit of detection of 0.05%. **Results:** DNA was isolated and extracted from 154 available plasma samples with matched tumor genotype; with volumes ranging 0.2–0.7 mL. For the overall population with or without mutations, a concordance of 92%, 91%, and 81% was observed with tissue genotypes for *EGFR* Exon 19, *EGFR* Exon 21 and *KRAS* Exon 2, respectively. Mutation specific sensitivities were 80% for *EGFR*-19del, 42.9% for *EGFR*-21-L858R, and 34.4% for *KRAS*-2. **Conclusions:** The use of cfpDNA for the determination of important *EGFR* and *KRAS* mutations provides a non-invasive method which may assist physicians with clinical care for cancer patients. The results from this analysis are encouraging, but, regardless of the methodology used for mutation detection in cfpDNA; additional assay standardization such as initial plasma volume for extraction, amount of extracted DNA and the influence of tissue heterogeneity versus cfpDNA in mutation detection are needed prior to routine clinical use. Overall, these results demonstrate the feasibility in the use of ICP for mutation determination from cfpDNA of NSCLC patients. Clinical trial information: NCT00409968, NCT00411671, NCT00411632, NCT00410059, and NCT00410189.

**8059 General Poster Session (Board #240), Sat, 1:15 PM-5:00 PM**

**Prediction of lung cancer genotype noninvasively using droplet digital PCR (ddPCR) analysis of cell-free plasma DNA (cfDNA).** *Presenting Author: Adrian G. Sacher, Dana-Farber Cancer Institute, Boston, MA*

**Background**: Noninvasive plasma genotyping has the potential to accelerate delivery of targeted therapies to genotype-defined cancer populations and obviate repeat biopsies, particularly following drug resistance. We recently reported on a new assay for plasma genotyping using ddPCR of cfDNA (Oxnard et al., Clinical Cancer Research, 2014). Here, we aimed to predict the genotype of tumor biopsies using plasma genotyping. **Methods**: We identified patients (pts) with advanced NSCLC and acquired resistance to erlotinib that underwent rebiopsy and plasma collection on three IRB-approved protocols. Rebiopsy specimens underwent clinical *EGFR* genotyping. Plasma was collected in EDTA tubes, cfDNA extracted, and *EGFR* genotype quantified using ddPCR assays for L858R, exon 19 del and T790M. Serial plasma genotyping on treatment was performed for a subset of pts. This assay was then piloted in pts with advanced NSCLC who had not yet undergone tumor genotyping. **Results**: A total of 32 pts undergoing rebiopsy had plasma available for analysis. Sensitivity of plasma genotyping for *EGFR* exon 19 del and L858R was 57%; sensitivity increased to 91% among 11 pts with symptomatic bone or visceral metastases. One additional pt with no tumor *EGFR* sensitizing mutation but response to erlotinib had high levels of plasma exon 19 del, suggesting that plasma genotyping may identify mutations missed by tumor genotyping. T790M was detected on rebiopsy in 16 pts (50%); plasma genotyping was concordant with rebiopsy T790M status in 27 of 32 pts (84%). Post-treatment plasma specimens were available for 12 pts; the 5 pts with a partial response on imaging had a significant decrease in plasma concentration compared to the 7 pts without a response (median 895 copies/mL decrease vs 2 copies/mL increase, p=0.01). In 17 NSCLC pts without a known genotype, we identified *EGFR* mutations in 3 pts with a median 3 day turnaround time, up to 19 days before tumor genotyping confirmed the result. **Conclusions**: Plasma genotyping of cfDNA with ddPCR can predict tumor genotype rapidly and quantitatively with a high degree of accuracy, potentially obviating the need for re-biopsy in some circumstances. Clinical development of this assay is ongoing.

**8060 General Poster Session (Board #241), Sat, 1:15 PM-5:00 PM**

**HER2 mutations in lung adenocarcinoma: A report from the Lung Cancer Mutation Consortium (LCMC).** *Presenting Author: Rathi Narayana Pillai, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** A variety of somatic mutations and gene rearrangements have been described in patients with lung adenocarcinoma. The Lung Cancer Mutation Consortium (LCMC) tested for the presence of 10 driver mutations in over 1,000 patients with metastatic adenocarcinoma of the lung. **Methods:** Tumor specimens were assessed for diagnosis and adequacy; multiplexed genotyping utilizing SNaPshot or Sequenom was performed, and mutations were recorded in GeneInsight database. We reviewed the LCMC database for patients tested for *HER2* mutations and accessed clinical characteristics, including age and stage at diagnosis, sex, smoking status, treatment history, sites of metastatic disease, and vital status. We conducted an exploratory analysis to compare survival of *HER2* mutated patients treated with HER2 targeted therapies to those who did not receive targeted therapies. **Results:** Of the 920 patients tested for human epidermal growth factor receptor-2 (*HER2*) mutation, 24 patients (2.6%) had exon 20 insertion mutations. The mutation was located at exon 20 insertion at codon 775 in all patients; 1 patient also had concurrent *MET* amplification. The median age was 62 (37-84) and the majority were never smokers (71%). Nearly 70% had advanced stage disease at the time of diagnosis. There was a slight predominance of females (n=14) over males (n=10). The median survival for patients that received HER2 targeted therapies (n=12) or not (n=12) was 18.3 months and 16.4 months respectively. *HER2*- targeted therapies included dacomitinib (n=5), dacomitinib and crizotinib (n=1), neratinib (n=2), trastuzumab (n=1), lapatanib and trastuzumab (n=1), and STA-9090 (n=1). At last assessment of vital status, 50% (6/12) of the patients treated with targeted therapy were alive as compared to only 33% (4/12) of the remainder. The overall survival for *HER2* mutated patients was worse than that for overall LCMC cohort in which median survival with genotype directed therapies was 3.5 years versus 2.4 years without targeted therapy. **Conclusions:** *HER2* mutations were detected in 2.6% of patients with lung adenocarcinoma. There was a favorable survival trend among patients that received HER2 targeted therapies.

**8061 General Poster Session (Board #242), Sat, 1:15 PM-5:00 PM**

**Retrospective analysis of type of *KRAS* mutation (mut) and response to first-line platinum-based chemotherapy (PC) in non-small cell lung cancer (NSCLC) patients (pts).** *Presenting Author: Wouter Willem Mellema, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Improving clinical outcome of pts with advanced NSCLC with a *KRAS* mut is challenging. Previous research indicated that different types of *KRAS* mut respond differently to chemotherapy regimens. This may impact treatment strategy in this group of pts. **Methods:** Consecutive pts with advanced NSCLC and known *KRAS* mut status, treated with first-line PC were retrieved from different hospital databases. Primary objective: Differences in overall response rate (ORR), progression free survival (PFS) and overall survival (OS) between different types of PC per type of *KRAS* mut. $X^2$-test and log rank test were used and pts were stratified by *KRAS* amino acid substitution (sub). **Results:** 305 pts (92% stage IV) from 10 hospitals, treated between 2008 and 2013, were included. Most common mut were G12C (47%), G12V (20%) and G12D (10%); 90% of pts had a codon 12 mut. Pts were treated with cisplatin (n=155) or carboplatin (n=150), combined with pemetrexed (PEM; n=194), gemcitabine (GEM; n=50), taxanes (TAX; n=27) or paclitaxel plus bevacizumab (CPB; n=34). Treatment with CPB resulted in significant better ORR compared to other regimen (61% vs. 33% (TAX), 29% (GEM), 22% (PEM); p<0.001). The median OS for pts with codon 13 mut (n=20) was 6.4 months and for codon 12 mut (n= 262) 9.8 months (p=0.38). Pts with codon 12 mut were clustered into groups according to sub. Results are summarized in Table. **Conclusions:** CPB had best ORR in KRAS mut pts. G>A sub pts showed a trend to poor OS. PC treatment was comparable per type of *KRAS* mut. These observations encourages study in a larger group of patients.

| *KRAS* sub codon 12 (n) | ORR | Median PFS in months (95% CI) | Median OS in months (95% CI) |

**8062 General Poster Session (Board #243), Sat, 1:15 PM-5:00 PM**

**Description of ALK+ NSCLC patient characteristics and ALK testing patterns.** *Presenting Author: Heather A. Wakelee, Stanford Cancer Institute, Stanford, CA*

**Background:** Anaplastic lymphoma kinase (ALK) gene rearrangements are seen in 4-8% of non-small cell lung cancer (NSCLC) patients (pts). Historically these pts have been reported to be predominantly young never-smokers with adenocarcinoma histology. ALK translocations have also been more frequently reported in Asian pts. This study investigated ALK+ NSCLC pts' characteristics and physicians' ALK testing practices in the US. **Methods:** A panel of US community oncologists was surveyed about their ALK testing practices for NSCLC pts and key considerations and challenges encountered in ALK testing. Also, ALK+ NSCLC pts' medical charts were reviewed by the responding physicians to collect pt-level information. **Results:** A total of 27 physicians participated and pt-level data was collected for 273 ALK+ NSCLC pts. In this sample, ALK+ NSCLC pts were older, racially diverse, had mixed smoking histories, and 81% had adenocarcinoma. Not all pts received ALK testing upon NSCLC diagnosis; 47 (16%) pts received one systemic therapy while 7 (14%) received 2 systemic therapies prior to ALK testing. After detection of ALK rearrangements, 181 (66%) pts received crizotinib as next-line therapy, 80 (29%) received chemotherapy, and 12 (4%) did not receive further anticancer treatment. Participating physicians reported an average ALK testing rate of 67% of pts in the past 12 months. When asked about issues encountered when testing for ALK, physicians reported inadequate tissue sample (63%), delay in reporting results (41%), and inconclusive results (37%) as the top three challenges. **Conclusions:** In this retrospective chart review in a sample of US oncology practices, ALK+ NSCLC pts were older and racially diverse with mixed smoking histories and cancer histologies. These results challenge preconceived notions of the phenotype of ALK+ NSCLC pts.

**Regulation of tumor cell PD-L1 expression by microRNA-200 and control of lung cancer metastasis.** *Presenting Author: Don Lynn Gibbons, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Tumor cell regulation of the activity of diverse inflammatory cells creates an immunosuppressive microenvironment that favors tumor growth and metastasis. However, the mechanistic basis of how tumor cells trigger intra-tumoral immunosuppression has not been fully defined. Here we show that metastasis-prone lung adenocarcinoma cells suppress the proliferation and activity of intra-tumoral $CD8^+$T cells through a PD-L1 dependent mechanism and that PD-L1 expression is regulated by microRNA-200 (miR-200), a known mediator of tumor cell EMT. **Methods:** Publically available TCGA datasets were analyzed, along with a large MDACC cohort of resected tumors. Experimentally we utilized genetic and syngeneic mouse models of metastatic lung adenocarcinoma. **Results:** In lung adenocarcinomas from The Cancer Genome Atlas (TCGA) (n=230) and a large MDACC cohort of resected tumors (N>150), those with a mesenchymal gene expression signature displayed repression of the miR-200 family and higher levels of PD-L1. These findings were confirmed experimentally in human and murine NSCLC cell lines. In vivo experiments with a *Kras/p53* mutant mouse model of lung adenocarcinoma showed that decreased miR-200 led to increased tumor cell expression of PD-L1, causing profound $CD8^+$ T cell suppression. Upon suppression of $CD8^+$T cell activity tumors acquired a growth advantage and became metastatic. Confirmation of these results with the Lewis lung cancer model in PD-L1 knockout mice also demonstrated that PD-L1 expression on the tumor cells, rather than other cells in the tumor microenvironment, was critical to tumor immunity and metastastic ability. Genetic and pharmacologic blockade of PD-L1 suppressed metastasis. **Conclusions:** Our findings demonstrate a novel biological role for miR-200 in cancer cells by simultaneous control of the cell-intrinsic EMT program and the cell-non-autonomous PD-L1-mediated immune evasion. These findings support the conclusion that EMT-associated immunosuppression promotes metastasis and the potential use of EMT-related biomarkers to select immunomodulatory therapies.

**8064 General Poster Session (Board #245), Sat, 1:15 PM-5:00 PM**

**Domain-specific PD-L1 protein measurement in non-small cell lung cancer (NSCLC).** *Presenting Author: Joseph Francis McLaughlin, Department of Medical Oncology, Yale University, New Haven, CT*

**Background:** PD-L1 protein expression is being explored as a companion predictive test for anti-PD-1 therapies. Studies from our group, however, reveal limitations of available antibodies and indicate that different immunohistochemical (IHC) methods yield discordant results. Differential results have been seen when comparing antibodies targeting the extracellular (EC) versus intracellular (IC) domains. Here, we studied the specificity of anti-PD-L1 antibodies using quantitative fluorescence (QIF) and the performance of two of them in NSCLC. **Methods:** We measured PD-L1 protein expression using antibody clones E1L3N (IC) and E1J2J (EC) in 509 NSCLC tumor samples represented in two tissue microarrays (YTMA79, n=204 and YTMA250, n=305). Antibody specificity was tested using QIF in formalin-fixed paraffin-embedded (FFPE) samples from human placenta and Mel624 transfectants. PD-L1 signal was determined in the tumor compartment using the AQUAmethod. In YTMA79, scores were compared with previous data using 5H1 antibody (EC). Reproducibility was assessed by staining serial cuts, and the correlation coefficient ($R^2$) was calculated. For survival analysis, PD-L1 signal was used as a continuous score, or binarized with cutoffs defined by X-tile. **Results:** Of eight antibodies tested, only three (5H1, E1L3N, and E1J2J) validated. The serial section reproducibility was high for 5H1 ($R^2$>0.9), and lower for E1L3N and E1J2J ($R^2$ range 0.54-0.93). The regression coefficient of scores and dynamic range of the antibodies were dissimilar. The EC domain antibodies E1J2J and 5H1 showed no correlation with the IC antibody E1L3N. There were trends toward association with better outcome with each antibody, but the level of significance was a function of the experimental cutpoints and is only considered exploratory. **Conclusions:** Evaluation of PD-L1expression in NSCLC samples using validated antibodies targeting different protein domains produced discordant results. This could be due to different antibody affinities, cross reactivity, or distinct target epitopes. Evaluation of the predictive value of these antibodies for anti-cancer immunotherapies is currently underway.

**8065 General Poster Session (Board #246), Sat, 1:15 PM-5:00 PM**

**Improving clinical prognostic categories beyond performance status: Enhancing accuracy in survival prediction with a three-item patient-reported outcome (PRO) index from the LCSS in lung cancer and mesothelioma.** *Presenting Author: Richard J. Gralla, Albert Einstein College of Medicine, Bronx, NY*

**Background:** Accurate prediction of survival of patient groups is required for appropriate trial design. Performance status (PS) is often used both for trial eligibility and for stratification. Three global PRO items (quality of life, activity level, symptom distress) from the LCSS (Lung Cancer Symptom Scale) apply to all patients. We tested whether an index of the 3 items would predict survival in patients with lung cancer or mesothelioma, and if major differences were found within the same PS groups (with either ECOG or KPS). **Methods:** This study analyzed data from the prospective mesothelioma EMPHACIS study comparing pemetrexed + cisplatin (DDP) with DDP in 444 patients, and from the prospective AP-QL trial of 622 patients treated with docetaxel + DDP or carboplatin. Each of the 3 global items at baseline in NSCLC predicted improved survival if the value was above the median (positive factor) compared with below (negative factor) ($p < 0.003$). An index was created using the number of negative factors, 0 to 3. The LCSS can be completed in < 3 minutes. **Results:** As seen in the table, survival varied significantly for those with 0 vs 3 negative factors and for 1 or 2 vs 3 factors, at baseline in both NSCLC and mesothelioma. When we tested only for the subgroup of patients with ECOG PS =1 in NSCLC, or for KPS 80-90 (similar to ECOG 1) in mesothelioma, major survival differences were still identified by the PRO index. **Conclusions:** This analysis demonstrates that large survival differences exist within the same PS groups for both ECOG 1 and KPS 80-90. The 3-item PRO index can be rapidly and inexpensively obtained and can assist in more accurate stratification of patients in randomized trials in thoracic malignancies.

| # of negative PRO factors | Med survival: months – all patients | Median survival: months KPS 80-90 | Survival: 1 year | Survival: 1 year |
|---|---|---|---|---|
| **Mesothelioma** | (N = 444) | (n = 368) | All patients | KPS 80- 90 |
| **0** | 14.6 ** | 12.9 ** | 61% | 59% |
| **1,2** | 10.8 * | 10.1 * | 45% | 42% |
| **3** | 7.4 | 7.6 | 26% | 30% |
| **NSCLC** | (N = 622) | ECOG 1 (n = 413) | All patients | ECOG 1 |
| **0** | 16 ** | 15.4 ** | 64% | 62% |
| **1,2** | 13 * | 11.5 | 54% | 48% |
| **3** | 9 | 9.4 | 38% | 36% |

Reference group is 3 negative PRO factors. ** $p < 0.001$ by log-rank; * $p < 0.05$ by log rank.

**8066 General Poster Session (Board #247), Sat, 1:15 PM-5:00 PM**

**PD-L1 expression and survival in patients with non-small cell lung cancer (NSCLC) in Korea.** *Presenting Author: Jong-Mu Sun, Department of Medicine, Division of Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** Data are limited on whether programmed cell death ligand-1 (PD-L1) expression is a prognostic factor among patients (pts) with NSCLC. **Methods:** We evaluated the relationship between PD-L1 expression and overall survival (OS) in 779 NSCLC pts treated at Samsung Medical Center, Seoul, Korea, between 2001 and 2010. Tumor expression of PD-L1 was measured by immunohistochemistry, and PD-L1-positivity was defined as staining in ≥1% of cells. Kaplan-Meier methods, log-rank test, and Cox proportional hazards models were used for survival analysis, adjusting for age, gender, smoking, and stage. **Results:** Median pt age was 64 years (range, 21-86 years), and 74% of pts were male. 49% of pts had adenocarcinoma, 39% squamous cell carcinoma (SCC), and 12% large cell carcinoma or other. Disease stage was I/II in 71% and III/IV in 29%. All pts underwent surgery, and 411 pts received chemotherapy. Median follow-up time was 4.2 years. Overall, 50% of pts were PD-L1-positive. A statistically significant higher prevalence of PD-L1-positivity was observed in males and in pts with SCC or advanced-stage disease ($P < 0.001$). Overall, PD-L1-positivity was associated with worse OS, with a 5-year OS rate of 55% (95% CI, 50%-60%) for the PD-L1-positive group and 67% (62%-72%) for the PD-L1-negative group (log rank $P = 0.02$). Further analysis suggested that this association was driven mainly by the pts with adenocarcinoma. The 5-y OS rates for the PD-L1-positive and PD-L1-negative groups were 57% (50%-65%) and 59% (49%-68%), respectively, in SCC pts (log rank $P = 0.60$), and 52% (42%-61%) and 73% (66%-78%), respectively, in adenocarcinoma pts (log rank $P < 0.001$; adjusted hazard ratio [AHR] of PD-L1-positive vs PD-L1-negative, 1.47; 95% CI, 1.03-2.11). Similar trends of association between PD-L1-positivity and OS were observed among adenocarcinoma pts who received chemotherapy (log rank $P = 0.03$; AHR, 1.32; 95% CI, 0.84-2.09) and those who did not (log rank $P< 0.01$; AHR, 1.88; 95% CI, 1.03-3.43). **Conclusions:** Based on a preliminary assay and cutoff, our results suggest that PD-L1 expression may be a negative prognostic factor among non-SCC pts with NSCLC, particularly those with adenocarcinoma.

**8067 General Poster Session (Board #248), Sat, 1:15 PM-5:00 PM**

**Spatiotemporal T790M heterogeneity in individual patients with non-small cell lung cancer (NSCLC) after acquired resistance to EGFR-tyrosine kinase inhibitor (TKI).** *Presenting Author: Akito Hata, Division of Integrated Oncology, Institute of Biomedical Research and Innovation, Kobe, Japan*

**Background:** The secondary *EGFR* mutation T790M accounts for approximately half of acquired resistances to EGFR-TKI. A favorable prognosis was demonstrated in patients (pts) with NSCLC harboring T790M compared to those without T790M. Since T790M is mediated by TKI exposure, poor TKI penetration to central nervous system (CNS) and TKI withdrawal may affect T790M status and prognosis. **Methods:** We retrospectively reviewed T790M status and clinical course of pts who had undergone multiple rebiopsy in our institutes. Postprogression survival (PPS) after initial TKI failure was analyzed according to T790M status. **Results:** Between May 2008 and January 2014, 132 pts with *EGFR*-mutant NSCLC received rebiopsy after acquired resistance to EGFR-TKI. Of 132 pts, 22 underwent rebiopsy at multiple sites, and 14 received repeated rebiopsies of the same lesion. Of 19 pts who underwent rebiopsy from both CNS (18 cerebrospinal fluids [CSF] and 1 brain tumoral tissue) and thoracic lesions (5 lung tissues and 14 pleural effusions), 10 were thoracic-T790M-positive. Of these 10 pts, 9 were CNS-T790M-negative. Conversely, all 10 thoracic-T790M-negatives were CNS-T790M-negative. Median PPS of thoracic/CNS-T790M-negative was 20.1 months, and thoracic-T790M-positive/CNS-T790M-negative were 11.2 months (p=0.3798). PPS was 40 months in the only thoracic/CNS-T790M-positive. In 14 pts who received repeated rebiopsies at the same lesion (7 lung tissues, 4 CSFs, and 3 pleural effusions), T790M status of lung lesions varied in 3 pts after TKI-free interval. In all 3 pts whose T790M status changed from positive to negative, EGFR-TKI rechallenge was effective. The 2 of these pts, after progression of TKI rechallenge therapy, T790M status changed from negative to positive again. There was also a pt whose CSF T790M status changed from negative to positive after high-dose erlotinib therapy. **Conclusions:** T790M status in an individual pt can be spatiotemporally heterogeneous due to selective pressure from TKI. Our data support personalized therapeutic strategies after acquired resistance, such as local ablation for oligoprogressive CNS metastases and EGFR-TKI rechallenge.

**8068 General Poster Session (Board #249), Sat, 1:15 PM-5:00 PM**

**A phase 1 study evaluating the safety and efficacy of DKN-01, an investigational monoclonal antibody (Mab) in patients (pts) with advanced non-small cell lung cancer.** *Presenting Author: Jeff Edenfield, GHS Institute of Transitional Oncology Research, Greenville, SC*

**Background:** DKN-01 is a high affinity neutralizing humanized Mab targeting extracellular dickkopf-1 (Dkk-1). Dkk-1 inhibits the canonical Wnt/β-catenin signaling pathway and modulates other biological pathways required for cell growth/ differentiation. Prior studies have demonstrated elevated Dkk-1 expression in lung, esophageal and gastric cancer tissue. Preclinical studies have demonstrated that a reduction of free Dkk-1 led to clinical benefit in xenograft models. **Methods:** A two-part (A and B) phase I, dose-finding study determined safety, maximum tolerated dose and antitumour activity infusing DKN-01 to pts with advanced malignancies with emphasis on pts with non-small cell lung cancer (NSCLC). Other endpoints were progression free survival [PFS], overall response rate [ORR], and overall survival [OS]. Part A of the study tested intravenous (IV) DKN-01 at dose levels between 75 and 600 mg administered weekly or biweekly in a 28 day cycles. For Part B, DKN-01 was administered to refractory NSCLC pts at 300 mg IV on days 1 and 15 of every 28 day cycle. **Results:** 32 pts enrolled in Parts A and B; 24 with NSCLC. NSCLC pts: median age 64.5 yrs, 54% male, 75% ECOG PS1, 4 median prior therapies (1-7), and 63% adenocarcinoma. DKN-01 was well tolerated with no dose limiting toxicities (DLT) or related serious adverse events (SAE). All of the treatment related AEs were ≤ Grade 2. Treatment emergent adverse events (TEAE) ≥ 15% in decreasing frequency: nausea, fatigue, decreased appetite, dyspnea, vomiting and constipation. No TEAE led to study discontinuation. Responses in 22 evaluable NSCLC pts included partial response 4.2% and stable disease 42%. One NSCLC patient had confirmed complete resolution of target disease. Median PFS in 23 evaluable NSCLC pts was 2.2 months [95% CI 1.8-2.9]. NSCLC median OS was 6.6 months (95% CI 4.1-10.1). **Conclusions:** DKN-01 may be a promising innovative targeted treatment for NSCLC. DKN-01 monotherapy was extremely well tolerated and demonstrated clinical activity in pts with refractory NSCLC. The median PFS and safety profile suggest that further NSCLC development in combination with other agents is warranted. Clinical trial information: NCT01457417.

**8069 General Poster Session (Board #250), Sat, 1:15 PM-5:00 PM**

**Effect of angiotensin system inhibitors on survival in patients receiving chemotherapy for advanced non-small cell lung cancer.** *Presenting Author: Alex R. Menter, Kaiser Permanente, Lone Tree, CO*

**Background:** Several retrospective studies have identified an association between angiotensin system inhibitors (ASI) and improved survival for patients with advanced stage malignancies including non-small cell lung cancer (NSCLC). We examined this association in Kaiser Permanente's (KP's) integrated practice settings. **Methods:** Data from four KP regions (Colorado, Northern California, Southern California, Northwest) contributed to the analysis. The cohort (n=2,723) included patients with stage IIIb-IV non-squamous NSCLC diagnosed between 2005 and 2011 who were treated with carboplatin and paclitaxel (CP) or CP with bevacizumab (CPB). Patients were followed from chemotherapy initiation until death, disenrollment from the health plans, or December 31, 2012. Demographic, tumor, chemotherapy, comorbidity, pharmacy, and mortality data were extracted from each region's clinical databases. Exposure to ASI was defined as any angiotensin converting enzyme inhibitor or angiotensin receptor blocker dispensing between 30 days before to 90 days after the start of chemotherapy. Cox proportional hazard models adjusted for age, gender, weight, stage, smoking status, tumor grade, and comorbidity were used to estimate hazard ratios (HR) for overall survival (OS) comparing those who used an ASI to those who did not. **Results:** Of 2,277 patients treated with CP, 524 (23%) received an ASI; of 446 patients treated with CPB, 116 (26%) received an ASI. ASI patients were older and had more comorbidity. Median OS for patients receiving CP and CPB were 8.7 and 12.9 months, respectively. For CP patients with and without concomitant ASI exposure, median OS were 10.5 and 8.3 months, respectively (crude HR 0.81, 95% confidence interval (CI) 0.73-0.90). For CPB patients with and without concomitant ASI exposure, median OS was 14.9 and 12.3 months, respectively (crude HR 0.81, 95% CI 0.64-1.03). For CP and CPB patients with concomitant ASI exposure, the multivariate-adjusted HRs were 0.79 (95% CI 0.70-0.89) and 0.84 (95% CI 0.62-1.13), respectively. **Conclusions:** Concomitant ASI use during CP or CPB chemotherapy for NSCLC was associated with improved survival.

**8070 General Poster Session (Board #251), Sat, 1:15 PM-5:00 PM**

**Canadian ALK (CALK): A multicenter, prospective study of concurrent ALK immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) in NSCLC.** *Presenting Author: Jean Deschenes, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada*

**Background:** : FISH has been considered the "gold standard" for identification of ALK rearranged (ALK+) NSCLC, but its cost-effectiveness as a screening method for ALK+ lung cancer is debated. Recent reports suggest that ALK IHC may be an alternative screening/diagnostic method. However, most studies evaluating IHC performance were retrospective or from a single-institution. ALK IHC screening and FISH confirmation have been validated across Canadian centers in a prior CALK study. This follow-up study was initiated to prospectively assess the accuracy of IHC compared to FISH in cases requiring ALK status determination. **Methods:** 3 centres conducted parallel IHC (5A4 antibody) and FISH (Abbott kit) testing of 411 consecutive clinical cases using previously validated and optimized protocols. 4 um unstained sections were used as well as published criteria for FISH scoring. The centres scored cases showing diffuse cytoplasmic staining of tumor cells clearly greater than background as ALK IHC + (2+, 3+,as well as diffuse 1+ in previously published ALK scoring systems), cases showing only focal faint staining above background (focal 1+) were scored as IHC equivocal, and cases with no tumor staining above background as IHC(-) . In almost all cases, background staining was completely absent. **Results:** Among the 411 cases, 373 (90.8%) were informative by both methods and 38 (9.2%) failed FISH testing. Of the dual informative cases, 18 (4.8%) were both IHC + and FISH +, 326 (87.4%) tested IHC (-) and FISH (-), 29 (7.8%) tested as IHC equivocal and FISH (-). 2/411 cases were initially discordant (i.e. IHC (-) and FISH borderline+). After rescoring by 2 blinded experienced readers, FISH was negative. When considering equivocal cases as positive, IHC sensitivity and specificity were 100% and 91.8 %, respectively. From the informative cases, FISH (-) / IHC (-) had 3.2% ± 3.2% abnormal FISH signal counts vs. 48.6% ± 18.7% for FISH+/IHC+ and 4.1% ± 3.7% in IHC equivocal cases. **Conclusions:** Results of this prospective study support IHC as a reliable method to screen for ALK-rearranged lung cancers. They also suggest that a clearly positive IHC result may be used to determine ALK status.

**8071 General Poster Session (Board #252), Sat, 1:15 PM-5:00 PM**

**Observational study of treatment with epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKI) in activating EGFR-mutation–positive (EGFRm+) advanced or recurrent non-small cell lung cancer (NSCLC) after radiologic progression to first-line therapy with EGFR-TKI.** *Presenting Author: Yukio Hosomi, Department of Thoracic Oncology and Respiratory Medecine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan*

**Background:** NSCLC with activating EGFR mutation is generally sensitive to EGFR-TKIs, but resistance is inevitable. The clinical course after radiological (RECIST-based) "progressive disease" (PD) judgment is variable and yet to be fully elucidated. **Methods:** Thirty-one institutions in Japan participated in the survey of patients with EGFRm+ advanced or recurrent NSCLC who received first-line EGFR-TKIs between 2009 and 2011. The primary endpoint was the time from RECIST-based radiological PD (R-PD) to clinical PD (C-PD) in patients who continuously received TKI beyond R-PD. C-PD was defined as one or more of the following: 1) symptomatic PD; 2) worsening performance status due to PD; 3) threat to major vital organ(s); or 4) multi-organ unequivocal PD. Durations of TKI administration, reasons for discontinuation, therapies concomitantly given with TKI, "flare" phenomenon after TKI stoppage, and overall survival were also recorded. **Results:** At the time of submission, 578 cases were registered; 412 were analyzed, of whom 38 were still on TKI without R-PD (Group E). The remaining 374 were sub-classified into the following groups: Group A, TKI stopped at R-PD concurrently occurring with C-PD (n=140); Group B, TKI stopped at R-PD without C-PD (n=104); Group C, TKI continued beyond R-PD (n=63); and Group D, TKI stopped due to other reasons (n=67). Therefore, 63/167 patients (38%) continued to receive TKI beyond clinically stable R-PD. Median time from R-PD to C-PD or TKI discontinuation in Group C was 4.2 months. Median survival time for Groups A, B, C and D were 20.6, 23.3, 27.4 and 13.6 months, respectively, whereas median periods on TKIs were 8.8, 9.9, 18.3 and 2.7 months, respectively. Disease flare was observed in 6 cases. **Conclusions:** Clinical courses and pattern of care after resistance to EGFR-TKI varied. Some 38% of the patients without clinical deterioration at R-PD were continued on TKI, for a median period to C-PD of 4.2 months. Supported by the Public Health Research Center Foundation, with fund from AstraZeneca.

**8072 General Poster Session (Board #253), Sat, 1:15 PM-5:00 PM**

**Effect of BIM and mTOR expression on clinical outcome to erlotinib in EGFR-mutant non-small cell lung cancer (NSCLC) patients (p).** *Presenting Author: Niki Karachaliou, Quirón Dexeus University Institute, Barcelona, Spain*

**Background:** Sixty percent of EGFR-mutant NSCLC p respond to erlotinib, but overall survival (OS) is the same for upfront chemotherapy. Priming BIM, a pro-apoptotic signaling BH3-only protein, induced sensitivity to erlotinib in EGFR-mutant cell lines (Costa el at. PLoS Med 2007). BIM was related to response and progression-free survival (PFS) in clinical tumor samples, but OS was not reported (Faber et al. Cancer Disc 2011). Mammalian target of rapamycin (mTOR) negatively regulates apoptosis and could influence response to erlotinib. **Methods:** We assessed static levels of total BIM, BIM-extra long (BIM-EL – a main isoform of BIM), and mTOR mRNA expression and correlated findings with response and OS in 57 erlotinib- or chemotherapy-treated EGFR-mutant NSCLC p in the EURTAC trial. **Results:** Median age 65; 70.2% female; 59.6% never-smokers; 91.2% adenocarcinoma. Response rate 88.9% for erlotinib-treated p with high total BIM levels, compared to 22.2% with low/intermediate total BIM levels (P=0.0027). Sensitivity/specificity of total BIM as a predictor of response to erlotinib was highly significant (AUC=0.80; P=0.0056). OS was 35.8 months (m) for p with high and 17.7 m with low/intermediate total BIM (P=0.023). Notably, among p with high total BIM, OS was 35.8 m for p with low/intermediate mTOR levels, compared to 20.3 m with high mTOR levels (P=0.4848). In contrast, mTOR did not affect OS in p with low/intermediate BIM (17.5 m vs 25.1 m; P=0.9498). BIM-EL assessment was only possible in 31 p, due to insufficient tumor sample in the remaining p. However, in this subset, BIM-EL seemed to have greater predictive power than total BIM. **Conclusions:** Our findings highlight the potential usefulness of BIM mRNA as a predictive biomarker of response in EGFR-mutant NSCLC p. Those with low BIM expression could derive only meager benefit from treatment with EGFR TKIs alone but could benefit from synthetic lethality combinations, including BcL-2 inhibitors. Those with high BIM expression could benefit from erlotinib or similar EGFR TKIs, but analysis of mTOR could further improve outcome by selecting p with high mTOR for combination therapy with EGFR TKIs and mTOR inhibitors.

**8073 General Poster Session (Board #254), Sat, 1:15 PM-5:00 PM**

**Exploring therapeutic targets in pulmonary sarcomatoid carcinoma by comprehensive genomic profiling.** *Presenting Author: Xuewen Liu, State Key Laboratory of Oncology in Southern China and Department of Radiology, Sun Yat-sen University Cancer Center, Guangzhou, China; Division of Hematology/Oncology, Columbia University Medical Center, New York, NY*

**Background:** Pulmonary sarcomatoid carcinoma (SC) is a rare and highly aggressive lung tumor, and it is associated with poor prognosis and high rate of resistance to conventional chemotherapy. The molecular basis of the unique dual differentiation pattern is poorly defined. New therapeutic strategies based on better knowledge of the molecular pathogenesis for pulmonary SC are needed. We used SNP array and high-throughput sequencing technology to identify novel therapeutic molecular targets. **Methods:** Ten pairs of genomic DNA samples were extracted from fresh frozen tumor tissues and paired normal tissues of patients with pulmonary SC. Whole-exome sequencing at a median of 120× coverage for tumor samples and 60× coverage for normal samples was performed at the Columbia Genome Center. Validation by Illumina TruSeq panel was performed on DNA from formalin-fixed paraffin-embedded (FFPE) tissue from these tumors. In addition, ten of the top ranked genes were chosen for validation by Sanger sequencing on DNA from these 10 cases and an additional cohort of 18 FFPE extracted DNA samples of pulmonary SC. Isolated DNA was hybridized to Affymetrix 6.0 SNP arrays and compared to a control group of 689 lung adenocarcinomas from two cohorts. **Results:** Mutations in TP53 (7/10, 70%), KRAS (2/10, 20%) and PIK3CA (2/10, 20%) were detected by whole exome sequencing and separately validated by TruSeq Illumina panel. Eight of the 10 genes at the top of the rank list, including RASA1(2/10, 20%), RYR2 (2/10, 20%), CDH4 (2/10, 20%), CDH7 (2/10, 20%), LAMB4 (3/10, 30%), MET (2/10, 20%), SCAF1 (2/10, 20%), and LMTK2 (2/10, 20%), were validated using Sanger sequencing. The validation of these genes in the cohort of 18 DNA samples extracted from FFPE tumor tissues is ongoing and functional validation of novel actionable targets will be pursued. SNP array results clearly distinguished SC from adenocarcinoma samples with significant copy number increases in chromosome 3q,7, 8q, 11p, 11q and 17q. **Conclusions:** Our study has identified novel molecular events in pulmonary SC tumors via high-throughput sequencing and SNP array analysis. The findings will be helpful for the development of new therapeutic strategies for pulmonary SC.

**8074 General Poster Session (Board #255), Sat, 1:15 PM-5:00 PM**

**Alterations in two oncogenic drivers: Impact of concurrent *PIK3CA* or *AKT1* mutations in patients with oncogene-driven lung adenocarcinomas.** *Presenting Author: Juliana Eng, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Little is known of prognosis and the efficacy of targeted therapies in patients whose lung adenocarcinomas harbor two oncogenic drivers. **Methods:** We identified patients treated at MSKCC from 2009-2013 whose lung adenocarcinomas harbored two oncogenic drivers. Molecular diagnostic testing was performed via an institutional algorithm involving ≥1 of the following: mutational hotspot testing (91 mutations in *EGFR, HER2, KRAS, NRAS, BRAF, MAP2K1, PIK3CA* and *AKT1)*, multiplex sizing assays (insertions/deletions in *EGFR* and *HER2*), and break apart FISH tests (fusions involving *ALK, ROS1* and *RET*). Overall survival (OS) and duration of response to EGFR tyrosine kinase inhibitor (TKI) therapy (*EGFR*-mutant subgroup) were assessed using Kaplan-Meier estimates. Outcomes were compared between double-driver and single-driver stage-matched control groups from the Lung Cancer Mutation Consortium study (log-rank test). **Results:** 49 patients (55% *KRAS*-mutant, 39% *EGFR*-mutant, 2% *BRAF*-mutant, 2% *MAP2K1*-mutant, 2% *ALK* fusion-positive) were found to have a driver in a second gene (*PIK3CA* 94% or *AKT1* 6%). In patients with advanced disease (stage IIIB/IV), the median OS was worse if their tumors harbored a concurrent *PIK3CA* or *AKT1* mutation (n=31, 11 mo, 95%CI 8.9-23.1) vs a single-driver (n=87, 24 mo, 95%CI 16.2-31.1, p=0.017). Median OS in subgroups (concurrent *PIK3CA* or *AKT1* vs not) were as follows: *KRAS*-mutant (8 vs 12 mo, p=0.032), *EGFR*-mutant (18 vs 34 mo, p=0.066), and *PIK3CA*-mutant (concurrent driver vs not; 14 vs 21 mo, p=0.840). In patients with *EGFR*-mutant lung cancers who received single-agent EGFR TKIs, while the median duration of therapy was similar between groups (15 vs 15 mo, single vs double, p=0.157), 33% (95% CI 19-59%) of patients with *EGFR*-mutant-only tumors versus 0% with concurrent *PIK3CA* or *AKT1*-mutated tumors remained on therapy at 2 and 3 years. **Conclusions:** In patients with metastatic oncogene-driven lung adenocarcinomas, the presence of a concurrent *PI3KCA* or *AKT1* mutation is a negative prognostic factor for OS. In *EGFR*-mutant lung cancers, continued EGFR TKI benefit at ≥2 yrs was observed only in patients without concurrent *PIK3CA* or *AKT1* mutations.

**8075 General Poster Session (Board #256), Sat, 1:15 PM-5:00 PM**

**Clinicopathologic features of lung cancer patients harboring de novo *EGFR* T790M mutation.** *Presenting Author: Young Joo Lee, National Cancer Center, Goyang, South Korea*

**Background:** *EGFR* T790M mutation drives acquired drug resistance to EGFR tyrosine kinase inhibitors (EGFR-TKI) in lung cancer harboring sensitive *EGFR* mutations. However, several studies reported the preexistence of this resistant mutation before EGFR-TKI exposure is not rare event when identified by more sensitive sequencing methods. This study aimed to evaluate clinicopathological features of lung cancer with de novo *EGFR*T790M mutations. **Methods:** We collected pretreatment tissues from 124 advanced non-small cell lung cancer patients with sensitizing *EGFR* mutations (exon 19 deletion and exon 21 L858R) that had been detected by direct sequencing at our institute between January 2009 and August 2011. Genotyping for *EGFR*T790M mutation was further performed using matrix-assisted laser desorption/ionization-time of flight/mass spectrometry. **Results:** The T790M mutation was found in 31 (25.0%) patients. The patients with T790M-positive tumor had shorter time to progression (TTP) after EGFR-TKI than those with T790M-negative tumor (median 6.3 months vs. 11.5 months; $P < 0.001$). The T790M mutation frequency at which the risk of progression to EGFR-TKI begins to increase was estimated to be 3.2%. The T790M-positive group harboring ≥3.2% of T790M (n= 24) had higher proportion of never smoker (83% vs 62%; $P = 0.047$), *EGFR* exon 21 L858R mutation (75% vs 25%; $P = 0.051$), and ≥3 of metastatic organ (71% vs 50%; $P = 0.066$) compared to the opposite group (n= 100). However, there was no significant difference in age, gender, histology, stage, and anatomical location. Peak SUV value of tissue sample sites on PET scan was not different between two groups (6.0 vs 7.9; $P = 0.317$). In terms of chemotherapy response, there was no difference in response to platinum (20% vs 33%; $P = 0.529$) and pemetrexed (10% vs 21%; $P = 0.470$) but taxane (33% vs 7%; $P = 0.057$). In the T790M-positive group, first-line EGFR-TKI users did not show longer TTP than second-line or more EGFR-TKI users (median 6.0 months vs. 3.9 months; $P = 0.197$). **Conclusions:** Lung cancer patients with 3.2% or more of de novo T790M mutation frequency showed decreased efficacy to EGFR-TKI. De novo T790M mutation are significantly associated with never smoking history and *EGFR* exon 21 L858R mutations.

**8076 General Poster Session (Board #257), Sat, 1:15 PM-5:00 PM**

**Clinicopathologic features of advanced *RET* fusion-positive lung cancers and outcomes in comparison to other fusion-positive lung cancers.** *Presenting Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Recurrent gene rearrangements are important drivers of lung cancer growth. While *RET* fusions are recognized as actionable targets, the clinicopathologic features of these drivers in advanced (stage IIIB/IV) disease and survival in comparison to *ALK* and *ROS1* fusion-positive lung cancers are less well-characterized. **Methods:** A FISH study using dual-color break-apart probes was performed to screen for *RET* fusions in patients (pts) with advanced lung ADCs that tested negative for mutations in *EGFR, KRAS, NRAS, BRAF, MAP2K1, ERBB2, PIK3CA,* or *AKT,* and fusions of *ALK* or *ROS1*. In pts with sufficient tissue, fusion partners were identified (RT-PCR/next-generation sequencing). Pathologic review of available tumor specimens and assessment of radiographic response via RECIST v1.1 were conducted. Overall survival (OS) and progression-free survival (PFS) were determined using Kaplan-Meier estimates. Comparisons to control groups of *ALK* and *ROS1* fusion-positive lung cancers were performed (Mantel-Haenszel/log rank tests). **Results:** 17% (n=18/104, 95%CI 9-22%) of tumors from screened pts harbored a *RET* fusion (56% male, median age 61). Majority of pts had no history of chest RT [89%, n=16] and were never smokers [72% (n=13) <1, 22% (n=4) 1-15, and 6% (n=1) >15 pack-years]. In 8 pts with sufficient tissue, known upstream partners were identified in 7 pts (*NCOA4*, *TRIM33,* 6 *KIF5B*). An upstream partner not previously described in lung cancers (*CLIP1*) was found. Morphology in surgical specimens (n=8) was as follows: 63% (n=5) predominantly solid, 25% (n=2) predominantly cribriform, 13% (n=1) predominantly papillary. OS of *RET* (n=18) vs *ALK* (n=45; HR 0.84, 95%CI 0.34-2.08, p=0.71) and *ROS1* (n=10; HR 1.59, 95%CI 0.34-7.31, p=0.55) fusion-positive lung cancers was similar. In patients who received first-line chemotherapy, PFS of *RET* (n=12) vs *ALK* (n=22; HR 0.53, 95%CI 0.25-1.13, p=0.10) and *ROS1* (n=8; HR 1.19, 95%CI 0.34-4.17, p-0.78) fusion-positive lung cancers was similar. **Conclusions:** Advanced *RET* fusion-positive lung cancers represent a distinct group of tumors with clinical outcomes comparable to *ALK* and *ROS1* fusion-positive lung cancers.

**8077 General Poster Session (Board #258), Sat, 1:15 PM-5:00 PM**

**A phase II clinical trial of the CDK 4/6 inhibitor palbociclib (PD 0332991) in previously treated, advanced non-small cell lung cancer (NSCLC) patients with inactivated *CDKN2A*.** *Presenting Author: Priya Kadambi Gopalan, University of Florida, Gainesville, FL*

**Background:** The Retinoblastoma pathway is targeted for mutational or epigenetic inactivation in more than 70% of NSCLC. The most common event is loss of *CDKN2A* expression (p16 protein), usually by hypermethylation, resulting in deregulated CDK4/6 activity and cell cycle progression. Palbociclib is a highly specific CDK4/6 inhibitor and has been shown to inhibit cell cycle progression and promote cellular senescence. **Methods:** We conducted a phase II, single arm trial of palbociclib in 19 previously-treated patients with recurrent or metastatic NSCLC. Only patients whose tumors were negative for p16 expression by immunohistochemistry were eligible. The primary endpoint was response rate. A Simon's 2-stage design was employed, with 2 or more responses required to proceed to the second stage. Palbociclib at 125 mg daily was given orally on days 1-21 of a 28-day cycle. Tumors were assessed by RECIST every 2 cycles. Secondary endpoints included overall survival, progression-free survival, toxicity and biomarker analysis. **Results:** Of the 16 evaluable patients who received at least one month of therapy, there were no responses, and the trial was closed to accrual. However, 8 patients with previously progressive NSCLC had stable disease (SD) lasting 16, 17, 20, 24, 35, 38, 41 and 42 weeks. The remaining 8 patients had progressive disease within 8 weeks. The median PFS was 12.5 weeks. There was no correlation between SD and histology or EGFR mutation status. One patient experienced grade 3 and 4 toxicities as a result of transaminitis and rhabdomyolysis (generalized muscle weakness and increased CPK) thought to be due to concomitant use of high-dose (80 mg) simvastatin. Three patients developed grade 3 or 4 neutropenia, and one patient developed grade 3 thrombocytopenia. All other toxicities were grade 1 or 2. **Conclusions:** Palbociclib therapy alone was well-tolerated, and stable disease (SD) was achieved in 50% of evaluable patients, suggesting the induction of cellular senescence. PFS was comparable to other second-line chemotherapeutic agents. Molecular predictors of clinical benefit (SD) are currently under investigation. Clinical trial information: NCT01291017.

**8078^ General Poster Session (Board #259), Sat, 1:15 PM-5:00 PM**

**Ceritinib in Asian versus Caucasian patients (Pts) with advanced anaplastic lymphoma kinase (ALK)-rearranged (ALK+) NSCLC: Subgroup analysis of the ASCEND-1 trial.** *Presenting Author: Daniel Shao-Weng Tan, National Cancer Centre, Singapore, Singapore*

**Background:** Prior results from the first-in-human phase I study (ASCEND-1) of the novel ALK inhibitor (ALKi) ceritinib (LDK378), demonstrated high response rates in crizotinib (CRZ)-naïve and CRZ-resistant patients, and established 750 mg/day as maximum tolerated dose. As inter-ethnic variations can lead to differences in treatment response in Asian vs Caucasian pts, we report here a subgroup analysis of the data for pts with ALK+ NSCLC receiving ceritinib at 750 mg/day. **Methods:** In ASCEND-1, adult pts with advanced ALK+ cancers received oral ceritinib once daily. Investigator assessment of efficacy is presented for pts who received a first dose of ceritinib ≥18 wks prior to the cut-off date (2 Aug 2013). **Results:** 246 pts with ALK+ NSCLC (82 Asian, 156 Caucasian, 8 other) received ceritinib 750 mg/day with median follow-up of 4.5 months (mos). 67% of patients had received ≥2 prior anticancer therapies. Between Asian and Caucasian pts baseline demographics were similar but ALKi pretreatment had been received by 47 (29%) and 108 (66%) pts, respectively. Among Asian vs Caucasian pts, 42.7% vs 51.9% had no dose reductions while 29.3% vs 38.5% and 24.4% vs 7.1% had 1 and 2 dose reductions, respectively. Duration of ceritinib exposure was similar between groups. A modest increase (<30%) in the pharmacokinetic parameters AUCtau and Cmax at steady-state was observed in Asian vs Caucasian pts. Grade 3/4 AEs were reported in 55% Asian pts and 72% Caucasian pts; 4 (5%) and 18 (12%) pts, respectively, discontinued due to AEs. Of 173 pts analyzed for efficacy the ORR was 69% (95% CI: 55.2, 80.9) in Asian pts (38/55) and 57% (95% CI: 47.3, 65.9) in Caucasian pts (67/118). The median duration of response (DOR) among responders was 10.1 mos (95% CI: 7.3, not reached) and 6.9 mos (95% CI: 4.5, 11.4) in the Asian and Caucasian pts, respectively. The observed differences between Asians and Caucasians for ORR and DOR were not explained by differences in ALKi pretreatment. **Conclusions:** Ceritinib 750 mg/day resulted in high and durable antitumor activity and manageable tolerability with low discontinuation rates in both Asian and Caucasian pts with ALK+ NSCLC. Clinical trial information: NCT01283516.

**8079 General Poster Session (Board #260), Sat, 1:15 PM-5:00 PM**

**Phase IB study to evaluate efficacy and tolerability of olaparib (AZD2281) plus gefitinib in patients (P) with epidermal growth factor receptor (EGFR) mutation positive advanced non-small cell lung cancer (NSCLC) (NCT=1513174/GECP-GOAL).** *Presenting Author: Rosario Garcia Campelo, CHUAC, A Coruña, Spain*

**Background:** Progression-free survival (PFS) and response rate (RR) to EGFR tyrosine kinase inhibitors (TKIs) vary in P with NSCLC driven by EGFR mutations, suggesting that other genetic alterations may influence oncogene addiction. High BRCA1 mRNA expression negatively influenced PFS among EGFR mutant P treated with erlotinib. We hypothesized that since olaparib can attenuate and/or prevent BRCA1 expression, the addition of olaparib to gefitinib could improve PFS in these P. **Methods:** This is a Phase IB dose escalation study (standard 3+3 design) to identify the maximum tolerated dose (MTD), dose limiting toxicity (DLT), pharmacokinetics (PK), and clinical activity of orally administered olaparib in combination with gefitinib in EGFR mutant advanced NSCLC. P were treated with gefitinib 250mg once daily plus olaparib at escalating doses ranging from 100mg BID to 250mg TDS during a 28-day cycle. **Results:** Twenty-two P were included across four dose levels of olaparib: 100mg BID (3), 200mg BID (6), 200mg TDS (6) and 250mg TDS (7). Most common toxicities were G1-2, including anemia, leucopenia, nausea, diarrhea, asthenia, rash and anorexia; G3 drug-related events included lymphopenia (1) and anemia (3). No DLT at dose levels 1 and 2; 1 DLT at dose level 3, and 2 at dose level 4 (G3 anemia and repeated blood transfusion within 4-6 weeks). Thirteen P harbored concomitant sensitizing mutation (exon 19 del or L858R mut) plus T790M (5 previously treated, and 7 untreated P). Twenty-one P were evaluated for response: for those not previously treated, complete responses (CR) were observed in 1 r75966P (7.1%) partial responses (PR) in 9 P (69.2%), stable disease (SD) in 3 P (23%) and no progressive disease (PD) (0%). In P previously with TKI, 3 (37.5%) had PR, 3 (37.5%) SD, and 2 (25.5%) PD. Durable PR and SD were observed in both EGFR TKI-naïve and previously treated P. **Conclusions:** This phase IB trial of gefitinib plus olaparib confirms tolerability of the combination and the activity seen warrants further exploration in treatment-naïve patients. MTD of olaparib was 200mg TDS. Clinical trial information: NCT01513174.

**8080 General Poster Session (Board #261), Sat, 1:15 PM-5:00 PM**

**A prospective, multicenter phase II trial of low-dose erlotinib monotherapy for patients with previously treated non-small cell lung cancer (NSCLC) with activating mutation of epidermal growth factor receptor (EGFR): Thoracic Oncology Research Group (TORG) 0911.** *Presenting Author: Yoshiro Nakahara, Department of Thoracic Oncology and Respiratory Medecine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan*

**Background:** Erlotinib and gefitinib have been shown to have similar activity for EGFR mutation-positive (EGFRm+) NSCLC. Since the steady-state plasma trough concentration of erlotinib is approximately 3.5 times higher than that of gefitinib when administered at the respective approved dose, treatment with low-dose erlotinib may be as effective as full-dose therapy, with less toxicity and cost. **Methods:** Eligible patients had advanced EGFRm+ NSCLC with 1 to 3 prior chemotherapy treatments. Erlotinib with the initial daily dosage of 50 mg was administered. Dose was escalated to 150 mg in case of not achieving CR or PR by RECIST criteria at the evaluation after the first 4 weeks of treatment. Erlotinib was continued until disease progression or unacceptable toxicities. The primary endpoint was independent committee-determined objective response rate (ORR) to the low-dose erlotinib, with target ORR of 70% and threshold of 50%. The sample size was calculated to be 40, and the primary endpoint was met if 26 or more patients responded. **Results:** Thirty-four patients were enrolled between Apr. 2010 and Nov. 2012. Males/females 20/14; median age 67 (range 38-81); PS 0/1 16/18; Ad/Sq 33/1. One patient was excluded from evaluation due to absence of active tumor. The study was closed early according to the protocol definition when 15 of 33 evaluable patients failed to achieve CR/PR, making it impossible to meet the primary endpoint. ORR was 54.5% (95% C.I.: 36.4% to 71.9%), with disease control rate of 84.8%. Median progression free survival and overall survival were 9.5 months and 28.5 months, respectively. Grade 3 toxicities were 2 cases with transient neutropenia, and 1 with reversible AST/ALT elevation. No grade 4 toxicity or treatment-related death was observed. **Conclusions:** This trial is the first prospective study evaluating low-dose erlotinib. Although it appeared to have a certain efficacy, the primary endpoint was not met. Because of its low toxicity, it may be worth further evaluation in elderly and/or frail patients. Trial registry UMIN #000003313.

**8081 General Poster Session (Board #262), Sat, 1:15 PM-5:00 PM**

**EGFR mutation status in cerebrospinal fluid of NSCLC patients who developed leptomeningeal metastasis after EGFR-TKI treatment.** *Presenting Author: Jing Zhao, Department of Respiratory Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Science, Beijing, China*

Background: Prognosis for these patients with leptomeningeal metastasis (LM) is very poor due to the lack of therapeutic options. It was suggested that the leptomeningeal space is protected from the systemic chemotherapy as well as EGFR-TKIs. Therefore, it would be interesting to explore the EGFR mutation status in CSF of the NSCLC patients who developed LM after the initial response to EGFR-TKI. In this study, we attempted to address two questions: 1. what is the EGFR mutation status in CSF of this group of patients? 2. what is the difference of EGFR mutation status in CSF as compared to that in the concurrent plasma samples? **Methods:** A highly sensitive droplet digital PCR (ddPCR) method was used to detect EGFR mutation in 7 CSF samples which were collected from seven patients with NSCLC who initially responded to EGFR-TKI and developed LM afterwards. Concurrent plasma samples were collected and analyzed as well for comparison. **Results:** EGFR-sensitive mutations were detected in CSF of all 7 patients (4 of 19-del and 3 of L858R), one of which (1/7, 14.3%) carried T790M mutation as well (19-del&T790M). EGFR mutations were not detected in plasma from 5 of these 7 patients (5/7, 71.4%). In additional plasma samples from remaining 2 patients, who were positive for EGFR E19-del in CSF, E19-del and T790M double mutations were detected. **Conclusions:** With development of LM after EGFR-TKI treatment, CSF remained positive for EGFR mutations dominant by sensitive mutations only, even though the plasma were either negative for EGFR mutations or carried TKI-resistant T790M mutation. This is supportive of the protection of EGFR mutation positive tumor cells within leptomeningeal space from the exposure to current EGFR-TKIs.

**EGFR mutation status of matched CSF and plasma samples from NSCLC patients who developed LM after initial response to EGFR-TKI treatment.**

**Clinical significance of TILs subtypes in non-small cell lung cancer.** *Presenting Author: Kurt A. Schalper, Department of Pathology, Yale School of Medicine, New Haven, CT*

**Background:** Tumor infiltrating lymphocytes (TILs) are associated with better outcome in diverse neoplasms including non–small cell lung cancer (NSCLC). TILs are usually determined using subjective semi-quantitative methods. Studies suggest that TILs subtypes have independent roles and their contribution to prognosis remains unknown. Here, we measured TILs subtypes in NSCLC using objective methods and determined their relationship with clinico-pathologic characteristics and survival. **Methods:** Using the AQUA method of quantitative fluorescence**,** we measured the levels of CD3, CD8 and CD20 in 554 stages I-IV NSCLC represented in two tissue microarrays (YTMA79 n=204 and YTMA140 n=350). TILs subtypes were simultaneously measured in different tumor compartments using multiplexed immunofluorescence for epithelial tumor cells (cytokeratin), T lymphocytes (CD3), cytotoxic T cells (CD8), B lymphocytes (CD20) and nuclei (DAPI). Associations were determined using uni/multivariate analyses with per-unit adjustments. **Results:** In both NSCLC collections CD3, CD8 and CD20 signals showed a positive non-linear relationship (R=0.3-0.7, P<0.001). CD3 levels were not correlated with age, gender, smoking, tumor size, stage and histology. High levels of CD8 and CD20 (> median) were significantly associated with adenocarcinoma histology. Using proportional hazard models and continuous scores, CD3 and CD8 were significantly associated with longer survival in YTMA79 (HR=0.59 [CI:0.41-0.81] P=0.0003 for CD3 and HR=0.34 [CI:0.12-0.74] P=0.003 for CD8) and YTMA140 (HR=0.44 [CI:0.20-0.88] P=0.01 for CD3 and HR=0.437 [CI:0.20-0.81] P=0.007 for CD8). The contribution of CD20 was less pronounced (HR=0.86 P=0.05 and HR=0.93 P=0.29, respectively). In multivariate analysis, the prognostic effect of CD3 and CD8 were independent from age, tumor size, histology and stage. **Conclusions:** Increased CD3 and CD8 positive TILs are independent prognostic factors in NSCLC.Despite the positive relationship between TILs subtypes, only CD8 and CD20 show association with adenocarcinoma histology. Objective measurement of TILs subpopulations could be useful to predict response or monitor the off-target effect of anti-cancer immunostimulatory therapies.

**8083 General Poster Session (Board #264), Sat, 1:15 PM-5:00 PM**

**Integrated genomic analysis for revealing broad remodeling of EGFR-targeted therapy resistant lung cancers.** *Presenting Author: Petros Giannikopoulos, Cancer Therapeutics Innovation Group, San Francisco, CA*

**Background**: Patients with EGFR-mutant NSCLC often respond initially to EGFR kinase inhibitor therapy but ultimately relapse. The spectrum of clinical resistance mechanisms and mechanistically appropriate therapeutic strategies to enhance EGFR inhibitor treatment responses remains incompletely defined. **Methods**: We used whole exome and transcriptome deep sequencing analysis of tumors obtained from 16 EGFR-mutant NSCLC patients both prior to EGFR inhibitor therapy and at clinical resistance to identify the spectrum and biological basis of molecular alterations that could drive therapy resistance and be targeted to enhance clinical responses. **Results**: Tumors with acquired EGFR TKI resistance harbored individual and concurrent established resistance-conferring alterations, including $EGFR^{T790M}$ and upregulation of several receptor kinases, and other molecular alterations not previously associated with this resistance, including activating KRAS mutations. Pathway analysis of the transcriptome data revealed upregulation of ERBB2 and FGFR signaling broadly in the therapy-resistant tumors and that the $EGFR^{T790M}$ positive resistant tumors exhibited therapy-induced upregulation of biological pathways underlying cell cycle progression and genome maintenance. The evolution of $EGFR^{T790M}$-positive resistance was also associated with increased genetic divergence and genomic instability. Genomic amplification and increased levels of the NF-kB inhibitor NFKBIA correlated with improved EGFR TKI response. **Conclusions**: This genome-scale characterization of the molecular landscape of EGFR inhibitor resistance uncovered biological programs and molecular events underlying the evolution of resistance, establishes the utility of whole exome and transcriptome deep sequencing in repeat biopsy specimens from NSCLC patients, and provides rationale for serial, comprehensive tumor molecular profiling in individual cancer patients to enhance therapeutic precision and response. Our findings also uncovered new molecular biomarkers of therapy response and provide new insight into the biological basis and complexity underlying the evolution of resistance.

**8085 General Poster Session (Board #266), Sat, 1:15 PM-5:00 PM**

**A phase II trial of first-line *nab*-paclitaxel/carboplatin versus gemcitabine/carboplatin in advanced squamous cell carcinoma of the lung (CTONG1002).** *Presenting Author: Jinji Yang, Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China*

**Background:** The administration of *nab*-paxlitaxel/carboplatin (*nab*-PC) as first-line therapy in patients with advanced non-small-cell lung cancer was efficacious and resulted in a significantly improved objective overall response rate (ORR) versus solvent-based PC in a phase III trial. Subgroup analysis showed the squamous histology appeared to be a predictive factor to *nab*-paclitaxel treatment. This phase II trial (NCT01236716; CTONG1002) compared the efficacy and safety of first-line *nab*-PC with gemcitabine/carboplatin (GC) in advanced squamous cell carcinoma of the lung. **Methods:** From November 2010 to June 2013, 127 untreated patients with locally advanced and metastatic squamous cell carcinoma of the lung were randomly assigned 1:1 to receive first-line *nab*-PC (*nab*-P, 135 mg/m$^2$, d1, d8, q3w; C, AUC = 5, d1, q3w ) or GC (G, 1,250 mg/m$^2$, d1, d8, q3w; C, AUC = 5, d1, q3w). The primary end point was ORR. **Results:** There were 110 cases evaluable for ORR (*nab*-PC, 54; GC, 56), 119 evaluable for survival (*nab*-PC, 57; GC, 62) and 124 evaluable for safety (*nab*-PC, 59; GC, 65), respectively. ORR was 46.3% (25/54) for the *nab*-PC arm and 30.4% (17/56) for the GC arm respectively, $P = 0.085$. There was an approximately 18.8% improvement in progression-free survival (median, 5.7 *v* 4.8 months; hazard ratio [HR], 0.907; 95% CI, 0.588 to 1.399; $P = 0.657$) in the *nab*-PC arm versus the GC arm. Overall survival was not mature. Significantly more grade $\geq$ 3 leucopenia and neutropenia occurred in the *nab*-PC arm. **Conclusions:** First-line *nab*-PC in advanced squamous cell carcinoma of the lung was efficacious and resulted in a marginally improved ORR versus GC, but not achieving the primary end point. *nab*-PC produced more leucopenia and neutropenia than GC. Clinical trial information: NCT01236716.

**8086 General Poster Session (Board #267), Sat, 1:15 PM-5:00 PM**

**Genomic characterization of non-small cell lung cancer by targeted massively parallel sequencing in African Americans.** *Presenting Author: Luiz H. Araujo, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

**Background:** Technological advances have enabled the comprehensive analysis of genetic perturbations in non-small cell lung cancer (NSCLC), but African-Americans (AA) have often been underrepresented. This ethnic group presents higher lung cancer incidence and mortality, and some studies have suggested a lower incidence of EGFR mutations. Herein we used a targeted massively parallel sequencing approach to assess NSCLC samples resected from AAs. **Methods:** We designed and validated a NSCLC-specific panel comprising 80 genes of potential interest for therapy. Libraries were constructed using a custom Agilent Haloplex kit, and sequenced on an Illumina HiSeq 2500. Cell lines and clinical formalin-fixed paraffin-embedded samples with known mutation status were used for validation. NSCLC archival tissues derived from AAs were retrospective collected, and medical charts were reviewed to assess clinical data. ALK translocations were evaluated by fluorescence in situ hybridization (FISH). **Results:** Targeted capture probes covered 15,473 amplicons comprising 310,720 base pairs, with 99.29% coverage. Our platform successfully identified all known mutations in the validation samples. Ninety-nine AAs were included, with a median age of 61 years (41-76). Sixty-one percent were males, and 94% were current/former smokers. Sixty percent of samples had an adenocarcinoma component, and 31% were squamous cell carcinomas. We detected 1,465 non-silent variants in the coding sequence, after excluding known germline polymorphisms. Classic recurrent mutations were found in KRAS (16%), EGFR (5%), PIK3CA (1%), and NRAS (1%). We also identified known somatic mutations in TP53 (48%), BRAF (4%), KEAP1 (3%), PDGFRA, FBXW7, CDKN2A, and CTNNB1 (1% each). In addition, several variants of unknown significance were found and may deserve further investigation. One case was positive for ALK-FISH. EGFR and ALK-positive cases were adenocarcinomas, and no overlap was identified between major drivers. **Conclusions:** We demonstrated a relatively low frequency of classic driver mutations in NSCLC among AAs. This group may benefit from the identification of novel drivers through comprehensive genomic approaches.

**8087 General Poster Session (Board #268), Sat, 1:15 PM-5:00 PM**

**Further molecular profiling of tumors harboring therapeutic targets within non-small cell lung cancer.** *Presenting Author: Solange Peters, University Hospital of Lausanne (CHUV), Lausanne, Switzerland*

**Background:** Treatment of NSCLC has been revolutionized in recent years with the introduction of several targeted therapies for selected genetically altered subtypes of NSCLC. A better understanding of molecular characteristics of NSCLC, which features common drug targets, may identify new therapeutic options. **Methods:** Over 6,700 non-small cell lung cancer cases referred to Caris Life Sciences between 2009 and 2014. Diagnoses and history were collected from referring physicians. Specific testing was performed per physician request and included a combination of sequencing (Sanger, NGS or pyrosequencing), protein expression (IHC), gene amplification/rearrangement (CISH or FISH), and/or RNA fragment analysis. **Results:** Tumors profiles from patients with hormone receptor positive disease (HER2, ER, PR, or AR positive by IHC) (n=629), HER2 mutations (n=8) ALK rearrangements (n=55), ROS1 rearrangement (n=17), cMET amplification or mutation (n=126), and cKIT mutation (n=11) were included in this analysis and compared to the whole cohort. Tumors with ALK rearrangement overexpressed AR in 18% of cases, and 7% presented with concomitant KRAS mutation. Lower rates of PTEN loss, as assessed by IHC, were observed in ALK positive (20%), ROS1 positive (9%) and cKIT mutated tumors (25%) compared to the overall NSCLC population (58%). cMET was overexpressed in 66% of ROS1 translocated and 57% of HER2 mutated tumors. cKIT mutations were found co-existing with APC (20%) and EGFR (20%) mutations. Pathway analysis revealed that hormone receptor positive disease carried more mutations in the ERK pathway (32%) compared to 9% in the mTOR pathway. 25% of patients with HER2 mutations harbored a co-existing mutation in the mTOR pathway. **Conclusions:** Pathway profiling reveals that NSCLC tumors present more often than reported with several concomitant alterations affecting the ERK or AKT pathway. Additionally, they are also characterized by the expression of potential biological modifiers of the cell cycle like hormonal receptors, representing a rationale for dual inhibition strategies in selected patients. Further refining of the understanding of NSCLC biomarker profile will optimize research for new treatment strategies.

**8088 General Poster Session (Board #269), Sat, 1:15 PM-5:00 PM**

**A multicenter randomized phase II trial of erlotinib with and without hydroxychloroquine (HCQ) in TKI-naive patients (pts) with epidermal growth factor receptor (EGFR) mutant advanced non-small cell lung cancer (NSCLC).** *Presenting Author: Joel W. Neal, Stanford Cancer Institute, Stanford, CA*

**Background:** Erlotinib (E) is widely used in the treatment of advanced EGFR mutant NSCLC, with a historical progression free survival of about 9 months. Preclinical data showed HCQ prevented the development of resistance to E putatively via chromatin state modulation, and a prior phase I trial established safety of E+HCQ (EQ). This randomized phase II trial tested the efficacy of EQ in delaying acquired resistance to E. **Methods:** EGFR-TKI naïve pts with metastatic or recurrent EGFR mutant NSCLC were randomized to E (150 mg daily) with or without HCQ (1,000 mg daily). Tumor assessments were performed every 8 weeks until disease progression. With a sample size of 76 pts, the study was powered for a primary endpoint of improvement in 9-month progression free survival (PFS) from 50% in the E arm compared with 77% in the EQ arm. **Results:** 76 pts were enrolled at 4 sites between 12/09 and 1/13, 38 on each arm. Age, sex, race, histology, and prior chemotherapy were well balanced between the arms, but an excess of patients with a smoking history (26% E vs 47% EQ) and brain metastases (29% E vs 42% EQ) was observed on the EQ arm. E-related toxicities were mostly balanced among treatment arms, but EQ patients had an excess of grade (G) 3 fatigue (3% E vs 18% EQ) and nausea (28% G1/2 + no G3 for E, and 53% G1/2 + 3% G3 for EQ). No drug-attributed G4/5 toxicities were observed. Among 37 evaluable pts on arm E and EQ, respectively, confirmed response rates were 65% and 57% and disease control rates were 92% and 84%. 9-month PFS was 71% for E and 52% for EQ (p=NS), but median PFS was identical in each arm (10.8 months). Preliminary median overall survival (OS) was 33.5 months on E and 27.8 months on EQ (p=0.06) though OS data are not yet mature. **Conclusions:** EQ did not improve 9 month PFS compared with arm E. OS numerically favored the E arm, which may reflect imbalances between the arms. Despite strong preclinical evidence, hydroxychloroquine does not appear to delay the development of resistance to erlotinib in pts with EGFR mutant NSCLC. Clinical trial information: NCT00977470.

**8089 General Poster Session (Board #270), Sat, 1:15 PM-5:00 PM**

**A randomized phase II study of paclitaxel-carboplatin-bevacizumab (PCB) with or without nitroglycerin patches (NTG) in patients (pts) with stage IV nonsquamous non-small cell lung cancer (NSCLC): Nvalt 12 (NCT01171170).** *Presenting Author: Anne-Marie C. Dingemans, University Hospital Maastricht, Maastricht, Netherlands*

**Background:** NTG increases tumor blood flow and thereby may augment drug delivery to the tumor and inhibits HIF-1a, a major regulator of hypoxia. In mouse models addition of HIF-1$\alpha$ inhibitors to B significantly impairs tumor growth. A randomized phase II study has shown improved clinical outcome when NTG patches were added to vinorelbine/cisplatin in pts with advanced NSCLC (Yasuda, 2006). We hypothesized that adding NTG to PCB improves progression free survival (PFS), response rate (RR) and overall survival (OS) in pts with stage IV non-squamous NSCLC. **Methods:** This open-label multicenter phase II trial randomized chemo-naive pts with stage IV non-squamous NSCLC 1:1 to PCB with or without NTG. Main other inclusion criteria: performance score 0-2; measurable disease (RECIST 1.1); adequate bone marrow, liver and renal function; written informed consent; no clinical significant cardiovascular disorders; no significant bleeding. Pts were treated with P 200 mg/m2 day (d) 1-C AUC 6 d1-B 15 mg/kg d1 every 3 weeks (wks) without (Arm A) or with (Arm B) NTG 15 mg/24 h for 5 d (d -2 to +3) every cycle for 4 cycles and B and NTG until progression. Tumor measurements were assessed every 2 cycles. The study was powered (80%) to detect a decrease in the hazard of progression of 33% in arm B at $\alpha = 0.05$ with a two-sided log rank test when 222 pts were enrolled and followed until 195 events were observed. **Results:** Between 01-2011 and 01-2013 223 pts were randomized; 112 arm A and 111 arm B; 50% males; median (range) age 62 years (39-81); 85% adenocarcinoma. Pts characteristics were balanced between both arms. RR was 45% in arm A and 30% in arm B. Median (95% CI) PFS in arm A was 6.8 months (m) (5.6-7.3) and 5.0 m (4.2-5.8) in arm B, HR 1.22 (95% CI 0.91-1.63). OS was 11.6 m (8.7-14) in arm A and 9.5 m (7.8-11.9) in arm B, HR 1.12 (95% CI 0.76-1.67). In arm B no additional toxicity was observed except headache (14% arm A and 57% arm B). **Conclusions:** Adding NTG to first line PCB does not improve PFS and OS in pts with stage IV non-squamous NSCLC. No further study with this regimen is warranted. Clinical trial information: NCT01171170.

**8090 General Poster Session (Board #271), Sat, 1:15 PM-5:00 PM**

**Implementation of clinical next-generation sequencing (NGS) of non-small cell lung cancer (NSCLC) to identify EGFR amplification as a potentially targetable oncogenic alteration.** *Presenting Author: Geoffrey R. Oxnard, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Tumor genotyping has become fundamental in the care of NSCLC. Targeted NGS can simultaneously test for oncogenic mutations, rearrangements, and amplifications using one platform and specimen. Using an institute-wide prospective trial, we aimed to evaluate feasibility of NGS and clinical impact for patients (pts). **Methods:** Testing commenced in our CLIA-certified lab in 7/13. NSCLC pts were identified for whom NGS was ordered as a supplement to routine genotyping. All pts provided informed consent. A minimum of 50ng DNA was analyzed by massively parallel sequencing on an Illumina HiSeq 2500, using hybrid capture to target exonic and/or intronic sequences in 305 cancer genes. Coverage was normalized to a panel of normals and expressed as a log2ratio, with high amplification defined as log2ratio >2. **Results:** As of 12/2013, NGS was ordered on 191 NSCLC pts: 45 (24%) were screened out due to insufficient tissue, and results from another 33 are pending at time of submission. Testing was completed on 113 with a turnaround time (TAT) as short as 12 days: 86% non-squamous NSCLC, 14% squamous NSCLC, 19% never-smokers, 54% female. Using this single assay, key targetable alterations were identified in 77% of non-squamous and 50% of squamous cases (Table). Three cases showed high *EGFR* amplification; one of these, a 61 yo never-smoker, initiated second-line erlotinib 150mg daily and had a response sustained for 23 weeks, interrupted by CNS progression. One *ALK* FISH positive case showed no rearrangement by NGS and a *KRAS*Q61L mutation, potentially indicating false positive FISH. **Conclusions:** Clinical NGS of NSCLC can efficiently identify targetable mutations, rearrangements, and amplifications, with acceptable specimen requirements and TAT. This assay has now been adopted for routine clinical genotyping. *EGFR* amplification may represent a rare targetable oncogenic alteration with sensitivity to erlotinib.

**Randomized, controlled, multicenter, multinational phase 2 study of docetaxel (DCT) or AXL1717 treatment in patients with squamous cell carcinoma (SCC) or adenocarcinoma (AC) of non-small cell lung cancer (NSCLC).** *Presenting Author: Michael Bergqvist, Department of Oncology, Uppsala University Hospital, Uppsala, Sweden*

**Background:** AXL1717 (picropodophyllin) is small molecule that inhibits the IGF-1R signaling pathway as well as suppresses tumor cell division by arresting cells in mitosis through a non-IGF-1R dependent mechanism. Preclinical data have shown extensive anti-tumor effects includingcomplete regressionsin xenograft studies against a range of tumors. **Methods:** A total of 101 patients (99 treated, ITT population) with locally advanced or metastatic NSCLC (Stage IIIB or IV, SCC or AD) with 1-2 lines of previous treatmentwere randomized. Patients had ECOG PS 0–2 and a life expectancy ≥ 3 months. The patients were randomized to either AXL1717 or DCT as monotherapy, in a 3:2 ratio for each NSCLC subtype. AXL1717 was administrated as an oral suspension given twice daily ata dose of 400 mg (later changed to 300 mg) and DCT was administered at 75 mg/m2 on Day 1 of every 21-day cycle. The treatmentduration was 12 weeks. **Results:** The primary objective was to compare the rate of progression-free survival (PFS) at 12 weeks between the treatment groups. The 12-week PFS rate for the ITT population was 25.9% in the AXL1717 and 39.0% in the DCT group (p=0.19). The median follow-up time was 27 weeks. Updated data will be presented at ASCO. The median OS was 38.7 weeks (w) for AXL1717 treated patients compared with 39.6 w for DCT patients (HR 1.063, p=0.813 [log rank test]). The median OS for the 49 patients with AC was 57.3 w for AXL1717 treated and 24.8 w for DCT patients(HR 0.932, p=0.846). The main side effects were hematological, mainly reduced neutrophil counts: 22.4% of the AXL1717 treated patients reported at least one event of CTCAE grade 3/4 neutropenia compared with 53.7% of the DCT treated patients. Some of the early neutropenic episodes in the AXL1717 group developed into serious events and some of these were fatal. The side effects were managed with a dose reduction of AXL1717 coupled with increased supervision of the patients. **Conclusions:** The phase 2 data in 99 patients did not show statistically confirmed difference between the two treatment groups for all patients or any of the histological subgroups for OS or PFS. Clinical trial information: NCT01561456.

**8092 General Poster Session (Board #273), Sat, 1:15 PM-5:00 PM**

**EGFR mutation detection in ctDNA from NSCLC patient plasma: A cross-platform comparison of technologies to support the clinical development of AZD9291.** *Presenting Author: Kenneth Thress, AstraZeneca, Waltham, MA*

**Background:** EGFR tyrosine kinase inhibitors are highly effective in treating EGFR mutant+ NSCLC. Patients invariably relapse and resistance is most often associated with an EGFR T790M mutation. AZD9291 is currently in clinical development to address this primary T790M-mediated resistance. Several highly sensitive technologies have been described for detection of EGFR mutations from tumor DNA (ctDNA) shed into the circulating plasma. ctDNA may provide an option for patients unable to provide tissue biopsies for AZD9291 patient selection and disease monitoring purposes. **Methods:** Using plasma from patients enrolled on the AZD9291 clinical study (NCT01802632), we undertook a cross-platform comparison of 4 methods for the detection of EGFR mutations in ctDNA: ARMS-based detection using 1) Roche Cobas and 2) Qiagen Therascreen EGFR mutation detection kits, and digital PCR-based (dPCR) approaches using 3) BioRad ddPCR (MolecularMD) and 4) BEAMing (Inostics). **Results:** To date, 38 pre-dose plasma samples have been evaluated. ctDNA was tested for 3 EGFR mutations (T790M, L858R, Exon 19 del). Matched tumor biopsies were available for most plasma samples to enable ctDNA-tumor concordance testing. Overall, concordance of mutation status was high for all ctDNA detection methods. The false positive rate was low across platforms with specificities >90%. In contrast, dPCR methods showed increased sensitivities for T790M compared with the ARMS-based methods (67-71% vs. 29-41%) whereas sensitivity for activating mutations was equivalent between dPCR and ARMS (80-90%). The sensitivity of dPCR for T790M allowed for preliminary correlations of baseline plasma T790M levels with clinical characteristics and AZD9291 response (unvalidated). T790M was more frequently detected in the plasma from patients with metastatic vs. local disease (77% vs. 25%). Moreover, patients with quantifiable T790M at baseline showed a 71% response rate (RR) compared to a 31% RR for patients with undetectable levels of T790M. **Conclusions:** The detection of EGFR mutations from ctDNA using sensitive dPCR methods will help to inform alternative patient selection strategies for AZD9291.

**8093 General Poster Session (Board #274), Sat, 1:15 PM-5:00 PM**

**Detection of sensitizing and resistance *EGFR* mutations from circulating tumor DNA (ctDNA) in blood using multiplexed next-generation sequencing in patients with advanced *EGFR*-mutant lung adenocarcinoma.** *Presenting Author: Sarah B. Goldberg, Department of Medical Oncology, Yale University School of Medicine, New Haven, CT*

**Background:** Analysis of tumor biopsies obtained after the development of acquired resistance (AR) to EGFR tyrosine kinase inhibitors can contribute to the understanding of resistance mechanisms, but requires an invasive procedure and only provides data on a single site of disease at one timepoint. We developed a next-generation sequencing method that employs novel error-suppression techniques to measure tumor-specific mutations in plasma at levels as low as 1 variant in 5,000. Here we report on the detection of sensitizing *EGFR* mutations and the emergence of the T790M resistance mutation in ctDNA and in tumor specimens. **Methods:** We collected plasma samples from patients (pts) with advanced *EGFR*-mutant lung adenocarcinoma. When feasible, serial plasma samples were collected during treatment and repeat tumor biopsies were performed at AR. Plasma was analyzed using error-suppressed deep sequencing to quantify point-mutations and insertions/deletions in multiple genes that are commonly mutated in lung cancer, including *EGFR*. **Results:** Plasma samples were obtained from 52 pts with known activating *EGFR* mutations. Thirty-two pts had serial samples, allowing monitoring of mutant DNA levels and detection of the emergence of new mutations in the plasma. Of the 31 pts who had a repeat biopsy, the T790M mutation was found in 15 (48%) in the tumor at AR. Data for the ctDNA and repeat tumor biopsy results for the first 5 pts tested in this cohort are presented in the Table. **Conclusions:** Detection of *EGFR* sensitizing and resistance mutations in ctDNA from the plasma using multiplexed next generation sequencing is feasible and shows a high concordance with results from tumor biopsy. This novel method using plasma may allow for earlier identification of resistance in pts treated with targeted therapy without the need for invasive biopsies.

**Randomized, open-label trial evaluating the preventive effect of tetracycline on afatinib induced-skin toxicity in non-small cell lung cancer patients.** *Presenting Author: Oscar Arrieta, Instituto Nacional de Cancerologia - INCAN, Mexico City, Mexico*

**Background:** Afatinib has shown high objective response rates and prolonged progression-free survival in patients with metastatic non-small cell lung cancer (NSCLC). The most common toxicity of this agent is acneiform rash, which may have a negative impact on quality of life. Tetracyclines are used as treatment for this adverse event (AE). No randomized trial have evaluated the prophylactic efficacy treatment of tetracycline in afatinib induced-skin toxicity. **Methods:** We performed an open-label, randomized, controlled trial to assess the preventive effect of tetracycline for reducing afatinib skin toxicity. Patients receiving afatinib treatment (40mg/day) were randomly assigned to pre-emptive or reactive treatment (after skin toxicity developed). Pre-emptive comprised tetracycline 250 mg/d for 4 weeks and reactive treatment included the use of skin moistures, sunscreen, topical steroids and tetracycline according to the severity of toxicity. All patients were blindly monitored for rash and other adverse events at baseline, 2 weeks and 4 weeks. Cutaneous toxicity was reported according to the Common Terminology Criteria for Adverse Events v4.0 (CTCAE). The protocol is registered on ClinicalTriasl.gov with the number NCT01880515 **Results:** We included 90 patients. No differences were found in clinical and dermatological baseline characteristics. The incidence of adverse events of any grade and grade ≥2 were lesser in the pre-emptive arm versus the control arm (55.6 *vs.* 75.6%, RR 0.4 [95% CI 0.17-0.99, $p$=0.046 and 15.6 *vs.* 35.6%, RR 0.35 [0.12-0.91], $p$=0.030; respectively). No difference was found in other dermatologic adverse events like paronychia, xerosis, mucositis, folliculitis and skin fissure. Nor the presence of rash or pre-emptive treatment with tetracycline impact on response rate, progression-free survival and overall survival. No adverse events were associated with tetracycline. **Conclusions:** The incidence and severity of rash associated with afatinib was reduced by 60% in the tetracycline group compared with the control group. Its use can positively impact quality of life in patients who are candidates for afatinib treatment. Clinical trial information: NCT01880515.

**8095 General Poster Session (Board #276), Sat, 1:15 PM-5:00 PM**

**Multiplex genomic profiling of non-small cell lung cancer patients enrolled in the LETS phase III trial of first-line S-1/carboplatin versus paclitaxel/carboplatin (WJOG6611LTR).** *Presenting Author: Hiroshige Yoshioka, Department of Respiratory Medicine, Kurashiki Central Hospital, Kurashiki, Japan*

**Background:** High-throughput genotyping tests to evaluate large numbers of genetic abnormalities in non–small cell lung cancer (NSCLC) are needed. **Methods:** Archival formalin-fixed, paraffin-embedded (FFPE) tumor specimens were collected from patients with advanced NSCLC enrolled in the LETS phase III trial. With the use of the multiplex platform of Sequenom's MassARRAY assays, we performed high-throughput genotyping for 214 somatic hotspot mutations in 26 genes (LungCarta Panel) and 20 major variants of *ALK*, *RET*, and *ROS1* fusion genes (LungFusion Panel). We also evaluated *MET* amplification by fluorescence in situ hybridization. **Results:** The numbers of evaluable patients were 275 for somatic gene mutations, 240 for fusion genes, and 229 for *MET* amplification. A somatic mutation in at least one gene was identified in 105 (48%) of the 217 patients with nonsquamous cell carcinoma (non-SCC) and in 26 (45%) of the 58 patients with SCC. Overall, we identified *EGFR* mutations in 46 patients (17%), *TP53* mutations in 30 (11%), *STK11* mutations in 27 (9.8%), *MET* mutations in 21 (7.6%), *KRAS* mutations in 17 (6.2%), *PIK3CA* mutations in 6 (2.2%), and *BRAF* and *NRAS* mutations in 3 each (1.1%). Median overall survival of *EGFR* mutation–positive patients was significantly longer than that of those without *EGFR* mutations (23.7 vs. 12.6 months, $P$ = 0.004). Conversely, patients with *KRAS* mutations had a significantly shorter survival time than did those with wild-type *KRAS* (9.9 vs. 15.3 months, $P$ = 0.04). *ALK* fusions were detected in six cases (2.5%), *ROS1* fusions in five (2.1%), and *RET* fusions in one (0.4%), with these three types of rearrangement being mutually exclusive. Median overall survival was 19.5 versus 13.8 months for fusion gene–positive and –negative patients, respectively ($P$ = 0.89). De novo *MET* amplification was identified in 9 patients (3.9%). **Conclusions:** This first multiplex genotyping of NSCLC accompanying a phase III study demonstrates that MassARRAY-based testing performs well with nucleic acid derived from FFPE tissue obtained from patients with advanced NSCLC.

**8096 General Poster Session (Board #277), Sat, 1:15 PM-5:00 PM**

**Immunohistochemically determined EGFR mutations in NSCLC.** *Presenting Author: Nina Turnsek, University Clinic Golnik, Golnik, Slovenia*

**Background:** ActivatingEGFR mutations (EGFRmu), especially exon 19 deletions (del 19) and L858R point mutation in exon 21 are best predictors of response to TKI therapy in advanced non-small cell lung cancer (NSCLC) and are routinely detected by PCR. Data on immunohistochemically (IHC) determined EGFRmu are scarce. We evaluated the concordance between PCR and IHC determined del 19 and L858R EGFRmu and their predictive value in a Slovenian cohort of NSCLC patients. **Methods:** IHC using mutation specific antibodies for E746-A750 deletion in exon 19 and for L858R in exon 21 (Ventana Medical Systems) was performed on 137 formalin-fixed tissue specimens. These specimens had PCR predetermined EGFRmu status: 37/137 (27.0%) specimens with del 19, 40/137 (29.1%) with L858R, 31/137 (22.6%) with other mutations, and 29/137 (21.2%) EGFRwt specimens (Therascreen EGFR 28 Mutation Kit Qiagen). IHC staining reaction was assessed by two independent evaluators as positive or negative. 81 EGFRmu patients that received EGFR TKI for advanced disease were included in the survival analysis. **Results:** With PCR results set as gold standard, the sensitivity, specificity, positive and negative predictive value for the del 19-specific antibody were 67.6%, 99.0%, 96.2%, and 89.2%, respectively, while for the L858R-specific antibody were all 100% (Table). The median overall survival (mOS) of patients treated by TKI differs significantly for PCR+ and IHC+ patients (n=50) compared to PCR+ alone patients (n=31) (33.8 months vs. 17.1 months, respectively; p= 0.024). **Conclusions:** Both mutation-specific antibodies are highly specific, and could be used as a first-step method for EGFRmu screening. Results, including survival (mOS), are indicating that IHC positive patients could directly receive TKI therapy, while IHC negative cases should be submitted for further molecular testing.

**8097 General Poster Session (Board #278), Sat, 1:15 PM-5:00 PM**

**Molecular testing prior to first-line therapy in patients with stage IV nonsquamous non-small cell lung cancer (NSCLC): A survey of U.S. medical oncologists.** *Presenting Author: Mark R. Green, Xcenda, Palm Harbor, FL*

**Background:** Current ASCO, CAP/IASLC/AMP, and NCCN guidelines recommend testing tumor specimens from all patients with advanced non-squamous NSCLC for EGFR mutation status and ALK fusion gene rearrangement. Clearly defining actual rates of oncogene mutation testing among US medical oncologists (MO's) has been challenging. During 2013, we used a live, case-based, market-research vehicle to document estimated rates of oncogene testing for patients with advanced non-squamous NSCLC. **Methods:** Using unaided recall estimates, we quantitated testing rates of 385 US MO's. Response options included specified intervals between 0 and 100%. Assessments were done at 4 research events throughout 2013. Each MO participated in only one research assessment. Three questions were posed: 1) Think about the last 20 patients with stage IV non-squamous NSCLC seen by you for consideration of 1st line therapy. In what percentage of those 20 patients did you prescribe a 1stline anti-tumor therapy? 2) In thinking about those same patients, in what percentage did you (or someone prior to you) order testing for EGFR mutation status? 3) In those same patients, in what percentage did you or someone prior to you, order testing for ALK fusion gene rearrangement? **Results:** Shown in the Table are the results averaged across all events for treatment and testing for EGFR mutation status and ALK. No trends for increased rates of testing were seen over the assessment interval. **Conclusions:** Approximately 20% of US MO's estimated their EGFR and ALK testing rates as being < 40% in patients with advanced non-squamous NSCLC. Our findings demonstrate an urgent need to educate physicians on the role of molecular testing in NSCLC.

**8098 General Poster Session (Board #279), Sat, 1:15 PM-5:00 PM**

**Effect of reflex testing by pathologists on molecular testing rates in lung cancer patients: Experience from a community-based academic center.** *Presenting Author: Cengiz Inal, Montefiore Medical Center Department of Medical Oncology, Bronx, NY*

**Background:** IASLC/CAP and NCCN guidelines recommend molecular testing for non-squamous non-small cell lung carcinoma (NSCLC) patients. Testing is usually performed upon request by medical oncologist. Reflex testing by pathologists for ER/PR/HER-2 is routinely done in breast cancer patients. We instituted reflex molecular testing at Montefiore Medical Center (MMC) on all non-squamous NSCLC patients in Jan 2012. **Methods:** We retrospectively reviewed our cancer registry database from Jan 2009 to July 2013 and analyzed all non-squamous NSCLC patients with pathology in our system. We examined annual molecular testing rates as well as testing rates before and after institution of reflex testing. Integrated Oncology (Labcorp) performed EGFR and KRAS testing by PCR-based technology. For patients with wild type EGFR and KRAS, the MMC cytogenetics laboratory performed ALK testing by FISH (Vysis assay). **Results:** From 2009 to July of 2013, 1,910 patients with lung cancer were identified in our cancer registry and 874 of these had non-squamous NSCLC with pathology diagnosed at MMC. At least 1 set of molecular tests was performed in 14, 25, 46, 64, and 69 % of patients in 2009, 2010, 2011, 2012 and 2013 respectively. The molecular testing rates pre (prior to 2012) and post (after 2012) reflex testing were 28% (166/598) vs 64% (177/276). The testing rates pre and post-reflex testing for EGFR, KRAS and ALK are 26 vs 62%, 6 vs 43% and 7 vs 23% respectively. Among the tested patients, the incidence of EGFR, KRAS and ALK positivity were 14% (46/326), 40% (61/152), and 1.9% (2/106) respectively. Of 276 patients post reflex testing, 52 (19%) had cytology-only NSCLC diagnoses; 75% (39/52) of these patients did not have any molecular testing. **Conclusions:** Reflex testing by pathologists increased the rate of molecular testing in a community based academic center. Despite the institution of reflex testing, ~30% of patients still do not have guideline recommended molecular testing. The reason for this is unclear; it may be in part due to lack of tissue available for molecular testing, particularly for cytology-only cases. We will further examine factors that influence the lack molecular testing in these patients.

**8099 General Poster Session (Board #280), Sat, 1:15 PM-5:00 PM**

**Lung cancer in never-smokers from the Princess Margaret Cancer Centre.** *Presenting Author: Grzegorz Korpanty, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Lung cancer in never smokers accounts for ~15-20% of cases, and globally is a growing clinical problem. **Methods:** We identified 570 never-smokers with lung cancer diagnosed from 1988-2013 at the Princess Margaret Cancer Centre. Clinical and demographic data were retrieved from the electronic patient record with the aim of characterizing the epidemiology, demographics, pathology, molecular profile, treatment, and survival in these patients. **Results:** There were 409 females (72%) and 161 males (28%), median age 62.1 years (18– 94), 46% Caucasian, 34% Asian, 6% Black, 4% South Asian, 4 % Filipino, 6% Other/Unknown. Environmental tobacco exposure was identified in only 17%. A history of prior malignancy was present in 89 (14.2%) patients (1 cancer 81; multiple cancers 8 patients). Most patients (87.3%) had adenocarcinoma and most presented in stage IV - 54.9%, followed by I - 26%, III - 12.8% and II - 6.3%. In stage IV patients, 88% were ECOG PS 0-1. Among 310 patients with molecular results to date, the mutation rate was 71% (*EGFR* mutation [mut] 76%, *ALK* 10%, *KRAS* 4%, *HER2* 1.4% *BRAF* 0.5%, other 1.8%, multiple mut 6.3%. Brain metastases at presentation occurred in 18.4% stage IV patients (77/419): 67% (52/77) with *EGFR* mut *vs* 22% (17/77) with *EGFR* WT vs 10% (8/77) with other mut (P=0.0023). Median overall survival (OS) of *EGFR* mut patients *vs EGFR* WT with brain metastases at presentation was 57 vs 16 mo (P=0.031). Stage IV patients with *EGFR* and *ALK* mut received targeted treatment in 88% (121/138) and 89% (16/18) cases, respectively, with 65% (92/138, 66% for EGFR and 14/18, 82% for ALK) staying on TKI >6 months. Overall, 68% (285/419) of patients received 1-3 lines of systemic therapy (range 0-8 lines). Median OS was 47 mos. Median OS for patients with known vs unknown mutation status was 59 mo vs 34 (P<0.001). Early stage (P<0.0001), PS 0-1 (P<0.0001), presence of *EGFR* (P=0.003) or *ALK* mut (P=0.035) were associated with longer survival, but *not* Asian ethnicity (P=0.6) or female sex (P=0.1). **Conclusions:** Lung cancer in never-smokers represents a distinct clinical and molecular entity characterized by a high incidence of targetable mutations and long survival. Updated molecular profiling results will be presented for the entire cohort.

**8100 General Poster Session (Board #281), Sat, 1:15 PM-5:00 PM**

**Antiangiogenic-specific adverse events (AEs) in patients with non-small cell lung cancer (NSCLC) treated with nintedanib (N) and docetaxel (D).** *Presenting Author: Martin Reck, Department of Thoracic Oncology, Lung Clinic Grosshansdorf, Member of the German Center for Lung Research (DZL), Grosshansdorf, Germany*

**Background:** Antiangiogenic treatments, including monoclonal antibodies and TKIs, have shown activity in tumors; however, their use is limited in part by their characteristic side effects (eg, bleeding, thrombosis, perforation, serious skin reactions, hypertension). N is an oral, twice-daily, triple angiokinase inhibitor. Here we extend our investigation of the LUME-Lung 1 study (ClinicalTrials.gov NCT00805194) and evaluate whether adding N to standard second-line D increases the frequency of characteristic adverse events (AEs) associated with antiangiogenic agents and whether these AEs restrict the use of N. **Methods:** LUME-Lung 1, a randomized, placebo-controlled Phase III trial investigating N + D in patients with advanced NSCLC after failure of first-line chemotherapy, demonstrated significant PFS improvement regardless of histology and showed significant survival improvement for patients with adenocarcinoma histology. The incidence and intensity of antiangiogenic-associated AEs according to the common terminology criteria for AEs (CTCAE version 3.0) were evaluated in all patients who received at least one dose of N, D, or Placebo (Pl). **Results:** AEs linked to VEGF inhibition that were more common (≥2% difference) in the N vs Pl arm were bleeding (all grades: 14.1% vs 11.6%; grade ≥3: 2.3% vs 1.8%) and hypertension (all grades: 3.5% vs 0.9%; grade ≥3: 0.6% vs 0.2%). When we compared histologic differences in antiangiogenic-associated AEs, we found nominal differences. More bleeding events were reported for N- treated squamous cell carcinoma (SCC) patients (all grades: 17.1% vs 10.9%; grade ≥3: 2.9% vs 1.3%) than for those with adenocarcinoma (all grades: 10.9% vs 11.1%; grade ≥3: 1.5% vs 1.3%). Fatal bleeding events, serious skin reactions, thrombosis, and perforations occurred at a low frequency and were balanced between both arms, regardless of histology. **Conclusions:** We demonstrated that adding N to standard second-line D for NSCLC therapy did not increase the frequency of AEs associated with antiangiogenic treatment to a relevant extent, except for grade 1-2 bleeding events in SCC patients. These AEs were balanced regardless of histology in LUME-Lung 1. Clinical trial information: NCT00805194.

**8101 General Poster Session (Board #282), Sat, 1:15 PM-5:00 PM**

**A meta-analysis of smoking status on clinical outcomes of non-small cell lung cancer patients harboring activating epidermal growth factor receptor (EGFR) mutations receiving first-line EGFR tyrosine kinase inhibitor.** *Presenting Author: Yoshikazu Hasegawa, Department of Medical Oncology, Izumi Municipal Hospital, Izumi, Osaka, Japan*

**Background:** In several univariate analyses from randomized phase 3 trials, ever-smokers with advanced EGFR mutated (m) NSCLC did not seem to benefit from improved progression-free survival (PFS) even when EGFR TKIs were is used compared to doublet chemotherapy as first-line treatment. **Methods:** We performedpooled analysis of PFS outcome of six published randomized phase 3 trials comparing EGFR TKI to doublet chemotherapy in EGFRm NSCLC patients (WJTOG3405, NEJ002, EURTAC, OPTIMAL, LUX Lung-3, LUX Lung-6). Hazard ratio (HR) and corresponding 95% confidence interval (CI) were collected from each study published in the literature and pooled. We computed a pooled HR and its 95% CI using random-effect model. **Results:** 1,432 EGFRm NSCLC patient data were analyzed, 1,163 (81.2%) were Asians and 430 (30.0%) were ever-smokers. A total of 592 patients, including 178 ever-smokers (30.1%), received doublet chemotherapy and 840, including 252 (30.0%) ever-smokers, received EGFR TKI. The pooled HR for never-smokers was 0.29 (95%CI: 0.21-0.39) while the pooled HR for ever-smokers was 0.54 (95%CI: 0.38-0.76). The p-value comparing HR for never-smokers and ever-smokers by meta-regression analysis was 0.007. The pooled HR for exon 19 was 0.26 (95%CI: 0.19-0.36) while it is 0.45 for exon 21 substitution (95%CI: 0.32-0.64) with a significant difference ($p = 0.019$) between the two pooled HRs. The pooled HR was 0.33 (95%CI: 0.24-0.46) for Asians and 0.48 (95%CI: 0.27-0.85) for non-Asians. Asians did not derive significantly more PFS benefit than non-Asians ($p = 0.256$). The pooled HR for erlotinib was 0.25 (95%CI: 0.16-0.41), 0.38 (95%CI: 0.24-0.59) for gefitinib, and 0.41 (95%CI: 0.24-0.68) for afatinib. No significant differential PFS benefit was noted in any one specific EGFR TKI. **Conclusions:** In this meta-analysis analysis EGFRm NSCLC patients derived significant PFS benefit from TKI over chemotherapy regardless of smoking status but the PFS benefit from EGFR TKIs over chemotherapy is significantly higher in never-smokers than ever-smokers by meta-regression analysis.

**8102 General Poster Session (Board #283), Sat, 1:15 PM-5:00 PM**

**A phase II trial of cabazitaxel in patients with metastatic NSCLC progressing after docetaxel-based treatment.** *Presenting Author: Athanasios Kotsakis, Hellenic Oncology Research Group (HORG), Athens, Greece*

**Background:** Cabazitaxel, a semi-synthetic microtubule inhibitor has shown antitumor activity in models resistant to paclitaxel and docetaxel. It has been approved for the treatment of docetaxel-resistant prostate cancer. We investigated its activity in patients with metastatic NSCLC progressing under or after docetaxel-based regimens. **Methods:** Pre-treated patients with documented, measurable, stage IV NSCLC, with an ECOG performance status 0-2 were enrolled; patients had to have up to 2 prior chemotherapy regimens for the treatment of metastatic disease from which one containing docetaxel. Treatment consisted of cabazitaxel (25 mg/m$^2$ iv, every 21 days) until disease progression. G-CSF was administered to the physician's discretion. Primary endpoint was the objective response rate. A 2-stage design was followed. **Results:** Among the 46 evaluable patients, 28% had squamous cell carcinoma, 54% adenocarcinoma and 18% low differentiated carcinoma. Eight (17.4%) patients had received one and 38 (82.6%) two prior chemotherapy regimens. Treatment compliance was 95%; 26 (16%) cycles were delayed because of toxicity (n=13) or other reasons (n=13); dose reduction was required in 6 (13%) patients because of hematologic toxicity. Six (13%) patients achieved partial response and 17 (39.5%) stable disease [Disease Control Rate of 52.5%; 95% CI: 3.6-24.3%]. The median response duration was 2.9 months. The median PFS and OS were 2.1 (95% CI: 1.0- 3.2) and 7.8 (95% CI: 5.3- 10.3) months, respectively. Grade 4 adverse events (AEs) included: neutropenia (n=8pts; 17%), febrile neutropenia (n=6; 13%); thrombocytopenia (n=3; 6.5%); anemia (n=4; 9%); infection (n=3; 6.5%) and fatigue (n=2; 4%). One patient experienced bowel obstruction and another hemorrhagic cystitis; both resolved with conservative treatment. There was no treatment-related death. **Conclusions:** Cabazitaxel monotherapy is an active agent in NSCLC patients pre-treated with docetaxel-based chemotherapy. The toxicity profile of the drug was acceptable and manageable. Further development of cabazitaxel in this indication is needed. Clinical trial information: NCT01852578.

**8103 General Poster Session (Board #284), Sat, 1:15 PM-5:00 PM**

**Antitumor activity of alectinib (CH5424802/RO5424802) for ALK-rearranged NSCLC with or without prior crizotinib treatment in bioequivalence study.** *Presenting Author: Kazuhiko Nakagawa, Department of Medical Oncology, Kinki University Faculty of Medicine, Osaka-Sayama, Japan*

**Background:** Alectinib, a potent highly selective ALK inhibitor, shows good efficacy and safety for crizotinib-naïve and -resistant patients (pts) with ALK-rearranged non-small cell lung cancer (NSCLC). However, each dose required 8 capsules (caps). Thus, a higher strength formulation was developed. **Methods:** This 2-arm crossover study (JP28927) evaluated the bioequivalence of alectinib 300 mg b.i.d. with 20 and 40 mg caps vs. 150 mg caps at steady state in ALK-rearranged NSCLC pts. Primary objectives were to evaluate bioequivalence between drug formulations and food effect with 150 mg caps; secondary objectives were to evaluate efficacy and safety. Arm 1 of Cycle 1 (30 d) consisted of 300 mg b.i.d. with 20/40 mg caps for 10 d, 150 mg caps for the next 10 d, and 150 mg caps after meals for the last 10 d. The order was different in arm 2: 150 mg caps for 10 d, 20/40 mg caps for the next 10 d, and 150 mg caps after meals for the last 10 d. After Cycle 1, to evaluate bioequivalence, pts continued alectinib 300 mg b.i.d. with 150 mg caps until the investigator determined lack of clinical benefit. Tumors were assessed on Day 31 and 59, and then every 56 d. **Results:** As of Dec 16, 2013, 35 ALK-rearranged NSCLC pts were enrolled. The exposure between formulations was similar, and no food effect was seen with 150 mg caps. Safety (median follow-up period, 4 months) was acceptable: no pt discontinued treatment due to AEs; AEs were mostly Grade 1 or 2. Preliminary efficacy was observed with 63.3% partial response (PR) (including 9 unconfirmed PR) by investigator's assessment in the 30 pts with target lesions. Among 20 crizotinib-resistant pts with target lesions (median duration from last dose of crizotinib, 18.5 d [15–361]), response rate was 60.0% (including 5 unconfirmed PR) and median time to response was 36 d (29–119). In 2 pts, non-irradiated brain metastases over 10 mm had complete response at first assessment (Day 34 and 36). **Conclusions:** The exposure of 20/40 mg and 150 mg caps was similar, and no food effect was seen with 150 mg caps. Alectinib in 150 mg caps was efficacious for ALK-rearranged NSCLC pts regardless of crizotinib treatment history, with quick and high efficacy and good safety. Clinical trial information: JapicCTI-132186.

**8104 General Poster Session (Board #285), Sat, 1:15 PM-5:00 PM**

**An updated systematic review and meta-analysis of randomized controlled trials on duration of chemotherapy for advanced non-small cell lung cancer.** *Presenting Author: Yu Yang Soon, National University Cancer Institute, Singapore, Singapore*

**Background:** We previously published a meta-analysis which identified a survival benefit with extended duration of chemotherapy in patients with advanced non-small cell lung cancer. We have updated our meta-analysis with results from new or updated randomized trials presented in June 2008 to Oct 2013. **Methods:** Biomedical literature databases and conference proceedings were searched for randomized controlled trials (RCTs) comparing: (i) a defined number of cycles versus continuation of the same chemotherapy until disease progression; (ii) a defined number of cycles versus a larger defined number of cycles of identical chemotherapy, and (iii) a defined number of cycles of identical initial chemotherapy versus the addition of cycles of alternative chemotherapy. Meta-analysis was performed using the fixed effect model. The primary outcome was overall survival (OS) and secondary outcomes included progression-free survival (PFS), adverse events (AE), and health-related quality of life (HRQL). **Results:** We identified updated results of two trials from the previous meta-analysis and found four new trials, resulting in a total of 17 trials including 5069 patients. Extending chemotherapy improved PFS substantially (hazard ratio [HR], 0.70; 95% CI 0.66 to 0.75; $P < 0.00001$, $I^2 = 72\%$, $Chi^2$ $P < 0.0001$) and OS modestly (HR, 0.91, 95% CI 0.85 to 0.96, $P = 0.001$, $I^2 = 14\%$, $Chi^2$ $P = 0.29$). Subgroup analysis revealed that the effects on PFS were greater for trials extending chemotherapy with third generation chemotherapy regimens, non-platinum regimens and maintenance therapy trial design. There was no evidence of difference in the effects on overall survival between subgroups defined by use of third generation chemotherapy regimens or platinum regimens and trial design. Extending chemotherapy was associated with more frequent AE in all trials where it was reported and impaired HRQL in two of 12 trials. **Conclusions:** This updated meta-analysis continues to demonstrate improvement in both progression- free and overall survival benefit with extended duration of chemotherapy in patients with advanced non-small cell lung carcinoma.

**8105 General Poster Session (Board #286), Sat, 1:15 PM-5:00 PM**

**PIK3CA as a prognostic marker in non-small cell lung cancer of squamous cell carcinoma type.** *Presenting Author: Odd Terje Brustugun, Oslo University Hospital - The Norwegian Radiumhospital and University of Oslo, Oslo, Norway*

**Background:** Genetic aberrations are regarded both prognostic and predicitive in NSCLC, and are found with various frequency and different significance in the subtypes. Mutation in the *PIK3CA* gene is reported frequent in squamous cell carcinomas, but little if anything is known of its potential prognostic role which is important for treatment strategy using PI3K inhibitors. We have studied the frequency and prognostic importance of *PIK3CA*mutations in a large number of early stage lung cancers of squamous carcinoma subtype. **Methods:** Tumor tissue was obtained from 156 consecutively operated lung cancer patients with squamous cell carcinoma in the period 2006-2012. Tissue was taken from the excised tumours, snap frozen in liquid nitrogen in the operation room, and stored at -80ºC until DNA isolation. The tumour cell content in the specimens was found to be more than 70% in most samples. DNA was isolated according to standard procedures, and mutation analysis was done with either the SnapShot method (Life Technologies), or using the Cobas® PIK3CA Mutation Test (Roche). Several samples were analysed on both platforms with identical results. After thorough follow-up (median 20.7 months, range 6.3-91.9), relapse-free survival was calculated with the Kaplan-Meier method using Chi-Square for significance assessment. **Results:** Tissues from 55 females and 101 males were analyzed. 92 (59%) were in stage I, 44 (28%) II and 20 (13%) stage III. 1 (0.6%) was never-smoker, and median number of pack-years was 36 (range 0-145). Overall, 15 patients (9.6%) harbored a *PIK3CA*mutation. There was a significant relapse-free survival difference (p=0.0299) in favor of the mutated group. In fact none of the mutated patients have relapsed after a median follow up of 27.5 months, whereas 39 (28%) of non-mutated patients have relapsed. **Conclusions:** *PIK3CA* mutations confer a survival advantage in non-small cell lung cancers of the squamous cell carcinoma type. This effect might have implications in therapy strategies.

**8106 General Poster Session (Board #287), Sat, 1:15 PM-5:00 PM**

**Characterization of heart rate (HR) changes during crizotinib treatment: A retrospective analysis of 1,053 ALK+ NSCLC patients.** *Presenting Author: Sai-Hong Ignatius Ou, Chao Family Comprehensive Cancer Center, Orange, CA*

**Background:** Decreases in HR have been described in patients receiving crizotinib. We performed a large retrospective analysis of HR changes during crizotinib therapy. **Methods:** Subjects with *ALK*+ NSCLC enrolled in PROFILE 1005 and in the crizotinib arm of PROFILE 1007 were included in this analysis. Sinus bradycardia (SB) was defined as HR <60 beats per min (bpm). Magnitude and timing of HR changes and changes in systolic (SBP) and diastolic blood pressure (DBP) were assessed. Subjects with no baseline or no on-treatment HR were excluded. Potential risk factors including age, gender, and race were investigated by chi-square tests of association. **Results:** 1,053 subjects were analyzed. For all subjects, median duration of therapy was 24.4 wk (range 0.6–108.3), meanHRdecrease on treatment was 25 bpm (standard deviation [SD] 15.8), and median time to within 5 bpm of the lowest HR recorded was 6.1 wk (range 0.7–60.3).441 (41.9%) subjects had ≥1 lowest HR that qualified as SB, of which 5.9% had a lowest HR of <45 bpm, 18.8% had a lowest HR of 45–49 bpm, and 75.3% had a lowest HR of 50–59 bpm. Mean decrease in HR was 30 bpm (SD 13.8) for the 441 SB subjects with a median time to within 5 bpm of the lowest HR of 9.3 wk (range 1.7–60.3). Of 4900 paired BP and HR recordings from 542 subjects without relevant concomitant medication, a ≥40-mmHg decrease in SBP was observed in 0.3% (0.6%) of recordings in the presence (absence) of SB, and a ≥30-mmHg decrease in DBP was observed in 0.6% (0.7%). Of 963 paired BP and HR recordings from 117 subjects who had concomitant beta blockers (BBs), a ≥40-mmHg decrease in SBP was observed in 0.9% (1.7%) of recordings in the presence (absence) of SB, while a ≥30-mmHg decrease in DBP was observed in 1.8% (2.0%). Only 66 instances of SB were recorded as AEs: n=55 for grade 1, n=9 for grade 2, and n=2 for grade 3. Significant associations between age (P=0.003) as well as ethnicity (P=0.039) with SB were noted in this study, with higher proportions of subjects ≥65 y as well as non-Asians developing SB. **Conclusions:** HR decreaseis common with crizotinib. Age ≥65 y and non-Asian ethnicity may predispose to the development of SB with crizotinib. Concomitant use of BBs may accentuate BP decrease with crizotinib.

**8107 General Poster Session (Board #288), Sat, 1:15 PM-5:00 PM**

**Exon 19 deletion association with progression-free survival compared to L858R mutation at exon 21 in treatment with first-line EGFR-TKIs: A meta-analysis of subgroup data from eight phase III randomized controlled trials.** *Presenting Author: Wenhua Liang, Cancer Center, Sun Yat-Sen University, Guangzhou, China*

**Background:** The superior efficacy of epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) compared with cytotoxic chemotherapy in patients harboring sensitive EGFR mutations has been extensively proved by a well-known series of eight phase III randomized controlled trials (RCT). However, the question of whether the efficacy of EGFR-TKIs differs between EGFR exon 19 deletions and exon 21 L858R mutations has not been statistically answered. **Methods:** Subgroup data on hazard ratio (HR) for progression free survival (PFS) in these RCTs were extracted and were synthesized based on random-effect model. Comparison of outcomes between specific mutations was estimated through indirect methods. All calculations were performed using STATA version 11.0. **Results:** A total of 7 randomized RCTs (IPASS, WJTOG3405, EUTRAC, OPTIMAL, LUXLUNG3, and LUXLUNG6, as well as NEJ002 being included in sensitivity analysis) involving 1489 patients with either 19 or 21 exon alteration receiving first-line EGFR-TKIs were included. First-SIGNAL study was not eligible without reporting PFS on specific mutations. The pooled $HR_{TKI/chemotherapy}$ for PFS were 0.276 (95% CI 0.200 to 0.382, P<0.001) in patients with 19 exon deletion and 0.470 (95% CI 0.346 to 0.637, P<0.001) in those with exon 21 L858R mutations. Indirect comparison revealed that patients with exon 19 deletions had more favorable outcome for PFS than those with exon 21 L858R mutations ($HR_{19\ exon\ deletion/exon\ 21\ L858R\ mutations}$=0.587, 95% CI 0.376 to 0.917; P=0.02). Sensitivity analysis by incorporating direct comparison result from NEJ002 study did not affect the overall outcome. **Conclusions:** Exon 19 deletions might be associated with longer PFS compared with L858 mutation at exon 21.

**8108 General Poster Session (Board #289), Sat, 1:15 PM-5:00 PM**

**Clinical impact of gastric acid suppressing medication use on the efficacy of elrotinib and gefitinib in patients with advanced non-small cell lung cancer harboring EGFR mutations.** *Presenting Author: Yoshitaka Zenke, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** Gastric acid suppressing medications (AS), namely, proton pump inhibitors (PPIs) and histamine 2 receptor antagonists (H2RA), increase the gastric pH, which may reduce the absorption of the EGFR tyrosine kinase inhibitors (EGFR-TKIs) erlotinib and gefitinib. The aim of this study was to evaluate the clinical impact of the use of AS on the efficacy of erlotinib and gefitinib in NSCLC patients harboring EGFR mutations. **Methods:** From 2008 to 2011, 130 consecutive patients with advanced NSCLC harboring EGFR mutations were treated with the EGFR-TKIs erlotinib or gefitinib at our institution. The clinical characteristics of the patients were reviewed, and the efficacy and toxicity of erlotinib and gefitinib were compared between patients receiving and not receiving AS. **Results:** Among the 130 patients treated with erlotinib or gefitinib, 47 were receiving AS (AS group), while the remaining 83 patients were not receiving AS (non-AS group). The overall response rate (ORR) and median progression-free survival (PFS) in the subject population were 60.9% and 10.0 months, respectively. In the sub-analysis carried out in the AS and non-AS groups, the ORR was 61.7% in the AS group and 60.5% in the non-AS group ($p = 0.89$), and the median PFS was 8.7 in the AS group and 10.7 months in the non-AS group ($p = 0.13$). Thus, no significant difference in the ORR or PFS was observed between the AS and non-AS groups. The median overall survival in the subject population was 31.2 months. In regard to the toxicity, the frequencies of rash (83% vs. 86%, $p = 0.60$) and diarrhea (34% vs. 29%, $p = 0.55$) were similar in the AS and non-AS groups. There were no deaths that were deemed to be treatment-related in either group. **Conclusions:** Concurrent use of AS did not affect the efficacy or toxicity of the EGFR-TKIs erlotinib and gefitinib in patients with NSCLC harboring EGFR mutations.

**8109 General Poster Session (Board #290), Sat, 1:15 PM-5:00 PM**

**TRY: A phase II study to evaluate safety and efficacy of combined trastuzumab and AUY922 in advanced non-small cell lung cancer (NSCLC) with HER2 overexpression or amplification or mutation.** *Presenting Author: Lucia Nogova, Lung Cancer Group Cologne, Center for Integrated Oncology, University Hospital Cologne, Cologne, Germany*

**Background:** HER2 amplifications and/or mutations are rare genetic alterations in NSCLC accounting for approximately 4%. Preliminary clinical data suggested efficacy of trastuzumab (Herceptin) in patients with HER2 immunochemistry 3+ (IHC3+) status or positive fluorescence in situ hybridization (FISH). The heat shock protein HSP90 is a molecular chaperone modulating stability and/or transport of intracellular client proteins including HER2. In breast cancer HSP90 inhibition showed anticancer activity in HER2-positive patients after trastuzumab failure. Here we are investigating the efficacy of the combination of trastuzumab and the HSP90 inhibitor AUY922 in lung cancer patients with aberrant HER2. **Methods:** This phase II study recruits metastatic NSCLC patients with HER2 overexpression (IHC DAKO-score 3+) or amplification (FISH positive) or activating mutation after failure of at least one previous standard treatment. In the first part of the study, patients are treated with trastuzumab only (initially 4mg/kg, followed by 2 mg/kg weekly). CT scan is scheduled every 6 weeks during treatment. In case of disease progression, AUY922 (70 mg/m2) is given additionally. Patients are recruited in two German centers: in Cologne and Essen. **Results:** Within the Network of Genomic Medicine in Cologne, 3,863 NSCLC patients of all stages were screened. Patients with overexpression were tested for amplification and mutation. HER2 amplification was seen in 4% and HER2 mutations in 1.6% of all adenocarcinomas. Patients in Essen are screened separately. The study is ongoing. Five patients with HER2 amplifications were treated in the study. Two patients progressed after 6 and 12 weeks on the combination. One patient showed clinical progression within first 6 weeks on trastuzumab. Two patients are still ongoing on trastuzumab monotherapy. The best CT response was -29.3% in patient on trastuzumab and AUY922 at week 6. **Conclusions:** HER2 overexpression, amplification or mutation is a rare genetic alteration in NSCLC patients. Data on treatment with HER2 antibody trastuzumab and HSP90 inhibitor AUY922 will be presented Clinical trial information: DRKS00003301.

**8110 General Poster Session (Board #291), Sat, 1:15 PM-5:00 PM**

**Phase I trial of icotinib combined with whole brain radiotherapy for EGFR-mutated non-small cell lung cancer patients with brain metastases.** *Presenting Author: Lin Zhou, Department of Thoracic Cancer, Cancer Center, West China Hospital, Sichuan Univeristy, Chengdu, China*

**Background:** Icotinib has been demonstrated to provide similar efficacy to gefitinib in non-small cell lung cancer (NSCLC) patients. This phase I trial (NCT01516983) evaluated the dose-escalation toxicity of icotinib combined with whole brain radiotherapy (WBRT) in EGFR-mutated NSCLC patients with brain metastases, and cerebrospinal fluid (CSF) penetration rates of icotinib were assessed in the dose-escalation. **Methods:** The cohorts were constructed with a 3 + 3 design, and the dose-escalation schedule of icotinib was set as 125mg tid, 250mg tid, 375mg tid, 500mg tid, and 625mg tid. Icotinib was started 7 days before and continued during WBRT (37.5Gy/15f/21d), and maintained until disease progression or intolerable toxicities occurred. The blood and CSF samples were obtained at 7:30-8:00 a.m. just before the administration of icotinib on day 7 (before WBRT), day 29 (after WBRT) and day 57 of therapy. **Results:** Fifteen patients were enrolled in this trial. The treatment-related toxicities were generally mild (CTC AE grade 1-2), and the most frequent treatment-related toxicities were alopecia (15/15), acne-like rash (14/15) and nausea (11/15). At dose level of 500mg tid, 3 out of 6 patients experienced dose-limiting toxicity including 1 grade 3 alanine aminotransferase elevation and 2 grade 3 nausea, after reducing the dose of icotinib to 250mg tid, these toxicities disappeared. The mean icotinib CSF penetration rate was 4.04% (range: 1.23%-9.71%), and there was a good correlation between plasma and CSF concentrations ($R^2$=0.577, P<0.001). There were no statistical differences in plasma concentrations, CSF concentrations, and penetration rates of icotinib between day 7, day 29, and day 57. However, CSF concentration and penetration rate of icotinib were much higher at dose of 375mg tid (mean CSF concentration: 154.09ng/ml, $P<0.001$; mean penetration rate: 7.06%, $P<0.001$). **Conclusions:** WBRT with concurrent and maintenance icotinib (125mg tid-375mg tid) were well tolerated in EGFR-mutated NSCLC patients with brain metastases. WBRT might not increase penetration rate of icotinib, however, there were the highest CSF concentration and penetration rate at dose of 375mg tid. Clinical trial information: NCT01516983.

**8111 General Poster Session (Board #292), Sat, 1:15 PM-5:00 PM**

**Stage at diagnosis as a prognostic marker for patients with KRAS-mutant metastatic lung adenocarcinomas.** *Presenting Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Stage at diagnosis, age, gender, mutation status, and performance status are recognized prognostic factors in lung cancers. These variables are independently associated with survival, and are fundamental to clinical trial design and data interpretation. Stage at the time of initial diagnosis has not previously been evaluated as a prognostic factor in patients (pts) with metastatic lung cancers, and is not controlled for in prospective trials. In order to adjust for the potential impact of tumor histology and presence of a driver oncogene, we evaluated the impact of stage at initial diagnosis on survival using a cohort of patients with KRAS-mutant, metastatic lung adenocarcinomas. **Methods:** We identified all pts with KRAS-mutant metastatic lung adenocarcinomas from Feb 2005 to Aug 2011. Stage at diagnosis, age, gender, smoking history, and Karnofsky performance status (KPS) were obtained from the medical record. Overall survival (OS) from date of diagnosis of recurrent/metastatic disease was estimated using Kaplan-Meier method and compared across groups in a multivariable Cox proportional hazards model. **Results:** 635 pts with KRAS-mutant lung adenocarcinomas and known stage at diagnosis were identified. Median age: 66 (range 31-89), women: 61%, never smokers: 7%. KPS was available in 471 pts, median KPS: 80%. When compared to pts with stage IV lung cancers at initial diagnosis, patients with early stage lung cancers that later recurred/metastasized had a longer OS from date of advanced disease (18 vs 13 mo, p=0.003). Advanced stage at diagnosis (4 vs 1-3, HR 1.5 [1.2-1.8], P<0.001) and lower KPS ($\leq$70% vs $\geq$80%, HR 2.5 [2.0-3.2], P<0.001) were independently associated with shorter overall survival after adjusting for gender and smoking history in a multivariable analysis. **Conclusions:** In KRAS-mutant lung adenocarcinomas, stage at initial diagnosis was strongly associated with OS from diagnosis of recurrent/metastatic disease, with a 5 month difference in overall survival in patients with recurrent versus de novo stage IV lung cancers. Stage at diagnosis is a prognostic variable that should be accounted for in prospective randomized studies of new therapies in pts with metastatic lung cancers.

**8112^ General Poster Session (Board #293), Sat, 1:15 PM-5:00 PM**

**Nivolumab (anti-PD-1, BMS-936558, ONO-4538) in patients (pts) with advanced non-small-cell lung cancer (NSCLC): Survival and clinical activity by subgroup analysis.** *Presenting Author: Julie R. Brahmer, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Nivolumab, a fully human IgG4, PD-1 immune-checkpoint inhibitor antibody, has shown durable clinical activity in a large phase I trial of pts with advanced solid tumors. For NSCLC pts in this trial, we report overall survival (OS) by dose and histology and clinical activity of pt subgroups including PD-L1 tumor status. **Methods:** Previously treated pts with advanced NSCLC received IV nivolumab (1, 3, or 10 mg/kg) Q2Wk for ≤96 wk with tumor evaluation by RECIST v1.0. Clinical activity by key prognostic factors was assessed. PD-L1 tumor cell membrane expression was measured in archival specimens (n=68) by a Dako immunohistochemistry assay (positive ≥5% tumor cells). **Results:** Across doses and histologies, NSCLC pts (N=129, 54% with ≥3 prior therapies) hadmedian overall survival (mOS) of 9.2-14.9 mo and 1- and 2-y OS rates of 32-56% and 12-45%, respectively (Table). At the 3 mg/kg dose, mOS was 14.9 mo; 1- and 2-y OS rates were 56% and 45%. Objective response rate was 17% (22/129); median response duration was 17 mo. Clinical activity was observed across all pt subgroups, including <3 and ≥3 prior therapies and with/without *EGFR* or *KRAS* mutations. For pts with PD-L1(+) and (–) tumors, mOS was 7.8 mo (95% CI: 5.6, 21.7) and 10.5 mo (5.2, 21.2), respectively; mPFS was 3.6 mo (1.8, 7.5) and 1.8 mo (1.7, 2.3). Grade 3-4 treatment-related adverse events occurred in 14% of pts; most common was fatigue (3%). **Conclusions:** Nivolumab continues to demonstrate an encouraging survival profile and clinical activity across NSCLC pt subgroups with a manageable safety profile. Ongoing phase III trials are evaluating 3 mg/kg nivolumab in NSCLC pts and PD-L1 as a potential predictor of clinical outcomes. Clinical trial information: NCT00730639.

**Nivolumab (anti-PD-1; BMS-936558, ONO-4538) in combination with platinum-based doublet chemotherapy (PT-DC) in advanced non-small cell lung cancer (NSCLC).** *Presenting Author: Scott Joseph Antonia, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** First-line PT-DC has demonstrated 1-yr overall survival (OS) rates of up to 54% in NSCLC; however, there remains a need for therapies with improved long-term survival. We report an updated analysis of a phase I multi-cohort study evaluating nivolumab, a fully human IgG4 programmed death-1 (PD-1) immune checkpoint inhibitor antibody, plus PT-DC in chemotherapy-naive patients (pts) with advanced NSCLC, with longer follow up and additional pts. **Methods:** Pts (N=56) with advanced NSCLC were assigned based on histology to 4 cohorts to receive nivolumab 10 mg/kg IV Q3W plus concurrent IV gemcitabine 1250 mg/m$^2$ + cisplatin 75 mg/m$^2$ (squamous [sq]) or pemetrexed 500 mg/m$^2$ + cisplatin 75 mg/m$^2$ (non-sq), or nivolumab 5 or 10 mg/kg IV Q3W plus IV paclitaxel 200 mg/m$^2$+ carboplatin AUC6 (sq + non-sq), in a phase I dose de-escalation trial to assess dose-limiting toxicity (DLT). PT-DC was given for 4 cycles, followed by nivolumab until progression or unacceptable toxicity. Objective response rate (ORR) was assessed by RECIST 1.1. **Results:** No DLTs were seen during the first 6 wks of treatment. Grade 3-4 treatment-related adverse events were reported in 45% of pts (25-73% across arms), including pneumonitis (4 pts, 7%; managed by protocol algorithm), and fatigue and acute renal failure (3 pts [5%] each). Across arms, ORR (≥10 months follow up) was 33–50% and progressive disease (PD) as best overall response (BOR) was infrequent (Table). One-year OS rates were 59–87% (Table). **Conclusions:** Nivolumab combined with standard PT-DC regimens used for first-line treatment of NSCLC demonstrated antitumor activity, with encouraging 1-yr OS and an acceptable tolerability profile. Clinical trial information: NCT01454102.

**Tumor regression as a continuous variable and survival in advanced non-small cell lung cancer (NSCLC).** *Presenting Author: David J. Stewart, University of Ottawa and The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

**Background:** Tumor response is generally reported categorically by RECIST criteria as complete response (CR), partial response (PR), stable disease (SD) or progressive disease (PD). SD includes patients with minor tumor growth (1-19% increase in tumor diameter) and minor tumor regression (1-29% decrease in tumor diameter). Recent publications indicate that change in tumor size correlates linearly with survival in phase I studies (R Jain et al. J Clin Oncol 30:2684, 2012) and that change in tumor size as a continuous variable might be a useful endpoint in phase II trials (T Karrison et al. JNCI 99:1455, 2007). **Methods:** We used serial tumor measurements from 130 patients receiving platinum-based therapy for advanced NSCLC to further assess the correlation of change in tumor size with overall survival and time to progression (TTP). **Results:** Median survival was 10.6 months (range, 1-60 months) for the 125 patients who had died and median follow-up was 54 months (range, 45-57 months) for the 5 who remained alive. Median TTP was 4.2 months (range, 0.5-54 months). 32 patients had tumor growth by first follow-up scan (median 19% increase in tumor diameter, range 1%-49%). For the 98 with tumor regression, maximum regression over the course of therapy was 1-76% (median 27%). Maximum tumor regression correlated with overall survival (Spearman r = 0.46, p<0.0001) and with TTP (r = 0.69, p<0.0001). (For these correlations, % tumor growth at first follow-up scan was coded as "negative tumor regression".) Median overall survival was 15 months in patients with any tumor regression at first follow-up scan vs 5.9 months with any growth (p<0.0001), and for patients with RECIST confirmed PR (23% of patients), minor tumor regression (52% of patients), minor tumor growth (13% of patients) and PD (13% of patients) was 16.9, 13.6, 9.8 and 4.0 months, respectively (P<0.0001). **Conclusions:** Change in tumor size as a continuous variable correlated strongly with both overall survival and TTP in patients with advanced NSCLC receiving platinum-based therapy. Within the SD RECIST category, patients with minor tumor regression do better than patients with minor growth. Response as a continuous variable (% change in tumor size) warrants further assessment.

**8115 General Poster Session (Board #296), Sat, 1:15 PM-5:00 PM**

**Advanced NSCLC: Finding the right prescription for oncologist education.** *Presenting Author: Tara Herrmann, Medscape Education, New York, NY*

**Background:** Lung cancer is the leading cause of cancer related death in the United States. The objective of this study was to evaluate the impact of a personalized education curriculum on narrowing gaps in clinical practices of oncologists who care for patients with advanced NSCLC. **Methods:** A pre-education assessment tool designed to identify relevant knowledge and practice gaps in individual oncologist learners was made available online to healthcare providers without monetary compensation or charge. The assessment consisted of 10 knowledge and case-based multiple-choice questions. Upon completion of the survey, each oncologist learner was directed to a personalized learning plan, which included up to 5 distinct activities. Confidentiality of survey respondents was maintained and responses were de-identified and aggregated prior to analyses. The case vignettes and questions were based on current standards of care and evidence-base in the treatment of advanced NSCLC. The pre-assessment survey and corresponding activities launched on January 31, 2013 and participant responses were collected over the following 6 months. **Results:** In total, 92 oncologists completed their individualized educational curriculum. The intervention was associated with an effect size of 0.70, exceeding the recognized medium effect size standard of 0.45-0.50. After the education activity, there was a significant increase in the number of oncologists able to identify the rationale for determining the histological subtype of NSCLC (68% at baseline to 81% post education), prevalence of specific genetic abnormalities (76% to 97%, $P = 0.04$), and awareness of who should be considered for maintenance therapy (55% to 86%, $P = 0.01$). There was also a significant improvement in the identification of the most appropriate treatment regimen for squamous cell carcinoma (19% increase, P = 0.003) and adenocarcinoma (44% increase, $P< 0.001$). **Conclusions:** Our study demonstrates the feasibility of a personalized, targeted educational intervention for improving practice patterns of oncologists treating patients with advanced NSCLC. Novel personalized educational programs need to be developed to improve physician learning experience in an era of personalized medicine.

**8116 General Poster Session (Board #297), Sat, 1:15 PM-5:00 PM**

**Validation study of graded prognostic assessment (GPA) of non-small cell lung cancer (NSCLC) patients with brain metastasis (BM).** *Presenting Author: Eberechi Sandra Agwa, Cleveland Clinic Foundation, Cleveland, OH*

**Background:** NSCLC is the most common cause of BM and GPA is used as a prognostic index (PI) for BM. We evaluated its validity in a contemporary large cohort treated at a single tertiary care institution. Preliminary data was presented at ASCO 2013. **Methods:** IRB approved. NSCLC BM treated between 2000 and 2012 was identified from the Cleveland Clinic Brain Tumor and Neuro-Oncology Center's database. OS from the diagnosis of NSCLC BM was the primary end point.Cox proportional hazards models were used for data analysis. **Results:** 958 (54% male) patients were included for final analysis. Median age at BM diagnosis was 62 years (29-92). Karnofsky performance scale (KPS) was 90-100 in 345 (39%), 70-80 in 415 (47%) and <70 in 116 (13%) patients. Single BM was noted in 448 (47%), 2 BM in 169 (18%), 3 BM in 92 (10%), 4 BM in 49 (5%), 5 BM in 56 (6%) and >5 in 136 (14%) patients. Initial therapy included stereotactic radiosurgery (SRS) in 186 (20%) patients, whole brain radiation (WBRT) in 420 (44%), surgery (S) + WBRT in 132 (14%), WBRT + SRS in 138 (15%) and S + SRS in 23 (2%) patients, while 20 patients underwent only S, 11 patients received medical therapy alone, 17 were observed, 1 patient had S, WBRT + SRS. Median OS from diagnosis of BM was 7.8 months (95% C.I. 7.1-8.9).GPA for lung cancer is derived from KPS, number of BM, the presence/absence of extracranial metastases and age. GPA was prognostic for survival with very good separation between each of the groups (p<.0001). **Conclusions:** Even in the modern era GPA is still a valid PI for OS in NSCLC patients with BM.

| Factor | N (%) | Median survival (months) | P* |
|---|---|---|---|
| **KPS** | | | |
| **90-100** | 345 (39%) | 12.0 | <0.001 |
| **70-80** | 415 (47%) | 7.5 | |
| **< 70** | 116 (13%) | 2.8 | |
| **Number of brain metastases** | | | |
| **1** | 448 (46%) | 10.0 | <0.001 |
| **2-3** | 261 (27%) | 7.4 | |
| **>3** | 241 (25%) | 6.3 | |
| **Extracranial metastases** | | | |
| **No** | 434 (46%) | 12.1 | <0.001 |
| **Yes** | 502 (54%) | 5.6 | |
| **Age (years)** | | | |
| **<50** | 122 (13%) | 11.9 | <0.001 |
| **50-60** | 291 (30%) | 9.8 | |
| **>60** | 544 (57%) | 6.4 | |
| **GPA** | | | |
| **0 - 1.0** | 209 (24%) | 3.4 | <0.001 |
| **1.5 - 2.0** | 312 (36%) | 7.0 | |
| **2.5 - 3.0** | 275 (32%) | 13.0 | |
| **3.5 - 4.0** | 62 (7%) | 23.2 | |

*Proportional hazards model stratified by when brain metastases were diagnosed.

**8117 General Poster Session (Board #298), Sat, 1:15 PM-5:00 PM**

**Final overall survival results of WJTOG 3405, a randomized phase 3 trial comparing gefitinib (G) with cisplatin plus docetaxel (CD) as the first-line treatment for patients with non-small cell lung cancer (NSCLC) harboring mutations of the epidermal growth factor receptor (EGFR).** *Presenting Author: Hiroshige Yoshioka, Department of Respiratory Medicine, Kurashiki Central Hospital, Kurashiki, Japan*

**Background:** WJTOG3405 has proven that chemotherapy-naïve patients with postoperative recurrent or stage IIIB/IV NSCLC harboring activating *EGFR*mutation have longer progression free survival (PFS) when treating with G than treating with CD. (9.2 months (mos.) for G vs. 6.3 mos. for CD, hazard ratio (HR) 0.489, 95% confidence interval (CI): 0.336-0.710). (Mitsudomi et al., Lancet Oncol. 2010) Although we reported updated overall survival results of this study after 34 mos. median follow-up period, the impact on overall survival (OS) was still unclear because of lack of survival events. (Mitsudomi et al, ASCO 2012). **Methods:** Overall survival (OS) was re-evaluated using updated data (data cutoff, 30 Sep, 2013, median follow-up, 59.1 mos.) for 172 patients. **Results:** One hundred twenty-seven events had occurred (73.8%). Median survival time (MST) for G arm was 34.8 mos. (95% CI: 26.0 – 39.5) which was not significantly different from 37.3 mos. (95% CI: 31.2 – 45.5) for CD arm (HR 1.252, 95% CI 0.883-1.775). Multivariate analysis using Cox proportional hazards model revealed that postoperative recurrence or IIIB/IV significantly affected OS among assessed covariates (treatment arm, smoking status, sex, age, postoperative recurrence or IIIB/IV, and mutation type). The overall survival of patients with postoperative recurrence was better than that of those with IIIB/IV stage disease (HR 0.459, 95% CI 0.312-0.673, p < 0.001). In the CD arm, 8 patients (9%) never received EGFR-TKI in their whole courses of therapy, whereas 31 patients (36%) never received chemotherapy in the G arm. MST for the former and the latter group were 13.5 months (95% CI: 6.5 -) and 44.5 months (95% CI: 21.3 - 51.8), respectively. **Conclusions:** This five-year follow-up OS analysis confirmed that G for advanced NSCLC with *EGFR* mutation offers survival benefit of 3 years. There was no difference in OS whether the initial treatment was G or CD, probably due to high cross over rate. Clinical trial information: 000000539.

**TPS8118^ General Poster Session (Board #299A), Sat, 1:15 PM-5:00 PM**

**Galaxy-2 trial (NCT01798485): A randomized phase 3 study of ganetespib in combination with docetaxel versus docetaxel alone in patients with advanced lung adenocarcinoma.** *Presenting Author: Suresh S. Ramalingam, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Hsp90 is a molecular chaperone recognized as a key facilitator of cancer cell growth and survival. Ganetespib is a resorcinolic Hsp90 inhibitor that has shown single-agent activity in patients with lung, breast, and other cancers after progression on standard treatments. Ganetespib in combination with docetaxel induces synergistic efficacy in human non-small-cell lung carcinoma (NSCLC) tumor xenografts. Ganetespib is well tolerated and has not shown severe liver or common ocular toxicities reported for other Hsp90 inhibitors. Transient diarrhea is the most common adverse event, and is manageable with appropriate supportive care. A large randomized Phase 2 study of ganetespib in combination with docetaxel in advanced NSCLC patients (GALAXY-1 Trial) indicated good tolerability of the combination, and improvement in efficacy, including OS. **Methods:** GALAXY-2 is a randomized (1:1), international, open-label Phase 3 study enrolling patients who received and progressed on 1 prior systemic platinum-based combination therapy for advanced NSCLC of adenocarcinoma histology, were diagnosed ≥6 months before study entry, and whose tumors are negative for both EGFR mutations and ALK translocation (Target Patient Population [TPP]). Patients (N=700 TPP) are prospectively stratified for ECOG PS, total screening LDH, and geographic region (North America and Western Europe vs Rest of World). The primary endpoint is OS in the TPP. Key secondary endpoints include PFS, ORR, DCR, and DOR in the TPP. OS will also be analyzed in 3 subpopulations of the TPP: mKRAS, elevated LDH, and elevated LDH5. Patients in the control arm are treated with docetaxel 75 mg/m$^2$ on Day 1 of a 3-week cycle. In the combination arm, ganetespib 150 mg/m$^2$ is given on Day 1 with 75 mg/m$^2$ docetaxel, and ganetespib 150 mg/m$^2$ alone is given on Day 15 of each 3-week cycle. Two interim analyses for OS will be performed. Tumor tissue and blood samples will be collected for planned translational studies. Clinical trial information: NCT01798485.

**TPS8119^ General Poster Session (Board #299B), Sat, 1:15 PM-5:00 PM**

**A single arm, open-label, phase II study to assess the efficacy of lucitanib in patients with *FGFR1*-amplified squamous NSCLC (sqNSCLC).** *Presenting Author: David R. Spigel, Sarah Cannon Research Institute, Nashville, TN*

**Background:** Lucitanib, a potent, oral inhibitor of the tyrosine kinase activity of Fibroblast Growth Factor Receptors 1/2 (FGFR1/2), Vascular Endothelial Growth Factor Receptors 1-3 (VEGFR1-3) and Platelet-Derived Growth Factor Receptors A/B (PDGFRA/B), is being developed for the treatment of lung cancer and breast cancer. *FGFR1*-amplification is a hallmark genomic alteration in sqNSCLC, observed at a frequency of 10-20%. As such, inhibition of the FGF-axis represents a promising potential target for therapy of sqNSCLC. **Methods:** The current study evaluates daily oral lucitanib monotherapy in patients (pts) with *FGFR1*-amplified sqNSCLC. This is an international, multicenter, open-label, single-arm study. The primary endpoint is objective response rate (ORR; RECIST1.1) with secondary endpoints of response duration, clinical benefit rate, progression-free survival, and safety evaluation. Exploratory objectives include volumetric assessment of tumor growth kinetics, serial circulating tumor DNA measurement, and identification of additional biomarkers of lucitanib activity including determination of FGFR1 or FGF ligand RNA or protein expression using *in-situ* hybridization or immunohistochemistry. A Simon's minimax two-stage design will be used to provide 80% power to test the hypothesis $H_0$: p ≤ 10% versus $H_1$: p ≥ 25%, with a type I error at 5% (one sided). A minimum of 22 and maximum 40 pts will be enrolled. Key inclusion criteria include: pts aged ≥ 18 years with stage IV sqNSCLC and tumor *FGFR1*-amplified, tumors that are not invading or abutting a major vessel and/or tumors that are not cavitary. *FGFR1* amplification will be assessed centrally by FISH but local *FGFR1* testing is sufficient for enrollment. Pts should have measurable disease and have had at least one previous treatment for advanced disease. This study will begin enrolling pts in the United States and Europe in early 2014 at a network of centers skilled in the identification of pts with relatively uncommon tumor characteristics. Clinical trial information: 2013-003874-29.

**TPS8120 General Poster Session (Board #300A), Sat, 1:15 PM-5:00 PM**

**Multiarm, nonrandomized, open-label phase IB study to evaluate FP1039/GSK3052230 with chemotherapy in NSCLC and MPM with deregulated FGF pathway signaling.** *Presenting Author: Pilar Garrido Lopez, Hospital Ramón y Cajal, Madrid, Spain*

**Background:** FP1039/GSK3052230 (GSK230) is a soluble fusion protein that acts as a ligand trap by sequestering fibroblast growth factors (FGFs) involved in tumor growth. FGF ligand-dependent signaling plays an important role in cancer development and growth through autocrine production of FGFs from cancer cells, or paracrine production of FGFs from local stroma, or by tumor overexpression of FGF receptors (FGFRs) or amplification of FGFR genes. *FGFR1* amplification has been identified in ~15-20% of squamous non-small cell lung cancers (NSCLC) and is associated with shorter disease-free and overall survival. Efficacy was observed with GSK230 + chemotherapy in *FGFR1* amplified in NSCLC xenograft models and in xenograft models of malignant pleural mesothelioma (MPM) where FGF2 mRNA levels were overexpressed. In a phase I study, no maximum tolerated dose (MTD) was identified and 20 mg/kg weekly was the maximum feasible dose (MFD) achieving the desired target concentration. Toxicities associated with small-molecule FGFR inhibition, namely hyperphosphatemia and retinal, nail, and skin changes, were not observed. **Methods:** This is a multi-arm, nonrandomized, open-label phase IB study designed to evaluate the safety and preliminary efficacy of GSK230 in combination with paclitaxel + carboplatin in previously untreated *FGFR1* amplified metastatic squamous NSCLC (Arm A), in combination with docetaxel in *FGFR1* amplified metastatic squamous NSCLC that has progressed after 1 line of chemotherapy (Arm B), or in combination with pemetrexed + cisplatin in patients with untreated and unresectable MPM (Arm C). Approximately 70 patients will be enrolled. Each arm involves a dose escalation phase utilizing the 3+3 design, followed by a cohort expansion phase of at least 12 patients treated at either MTD or MFD. GSK230 will be administered as a 30-minute intravenous infusion once a week in a 21-day cycle. The starting dose is 5 mg/kg and will be dose escalated until MTD or MFD in combination with chemotherapy is reached. Endpoints include the combination dose of GSK230 with chemotherapy, safety, response rates and their duration, and translational objectives (NCT01868022). Clinical trial information: NCT01868022.

**TPS8121 General Poster Session (Board #300B), Sat, 1:15 PM-5:00 PM**

**Phase I/II multicenter, randomized, open-label trial of the c-Met inhibitor MSC2156119J and gefitinib versus chemotherapy as second-line treatment in patients with MET-positive (MET+), locally advanced, or metastatic non-small cell lung cancer (NSCLC) with epidermal growth factor mutation (EGFRm+) and progression on gefitinib.** *Presenting Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong General Hospital (GGH) and Guangdong Academy of Medical Sciences, Guangzhou, China*

**Background:** Resistance to EGFR tyrosine kinase inhibitors (eg, gefitinib) in EGFRm+ NSCLC patients (pts) is mainly caused by a secondary mutation in the EGFR (ie, T790M) or by activation of the c-Met/HGF signaling pathway (eg, protein overexpression and/or amplification). MSC2156119J, a highly selective small-molecule c-Met inhibitor, displayed promising antitumor activity in pts with advanced solid tumors in a Phase I trial (Falchook et al. *J Clin Oncol* 2013:31(Suppl):2506). This Phase Ib/II, multicenter, open-label trial investigates the antitumor activity of MSC2156119J + gefitinib in pts with MET+ advanced EGFRm+ NSCLC (NCT01982955). **Methods:** Primary objectives are determination of the recommended phase II dose (RP2D) for the combination (Phase Ib), and progression-free survival (PFS) per investigator read (Phase II). Secondary objectives include safety, pharmacokinetics, and antitumor activity of MSC2156119J (PFS per independent read, overall survival, objective response, and disease control). Adults with advanced NSCLC with activating EGFR mutation, ECOG status 0–1, and resistance on 1st-line gefitinib (Phase II only) are recruited in mainland China, South Korea, Taiwan, and other Asian countries. Patients must have confirmed MET+ status, defined as either strong or moderate protein overexpression by immunohistochemistry, or *MET* gene amplification by in situ hybridization. Main exclusion criteria: life expectancy <3 mo, or prior EGFR targeting therapy other than gefitinib (Phase II only). For the Phase Ib part (3+3 design), 15–18 pts are planned to receive 300 or 500 mg MSC2156119J p.o. + 250 mg gefitinib p.o./d (21-d cycle); for the Phase II part, up to 200 pts are planned to be enrolled into 2 predefined subgroups according to their T790M mutation status and subsequently randomized 1:1 to RP2D MSC2156119J p.o. + 250 mg gefitinib p.o./d or 500 mg/m$^2$ pemetrexed i.v. + 75 mg/m$^2$ cisplatin i.v. on day 1 (max. of six 21-d cycles). Enrollment for Phase Ib began on Dec 23, 2013. Clinical trial information: NCT01982955.

**TPS8122 General Poster Session (Board #301A), Sat, 1:15 PM-5:00 PM**

**A phase II cluster study of single agent AUY922, BYL719, INC280, LDK378, and MEK162 in Chinese patients with advanced non-small cell lung cancer (NSCLC).** *Presenting Author: Qing Zhou, Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China*

**Background:** Advanced NSCLC management has evolved toward individual tumor subtyping based on targetable oncogenic drivers. Most molecularly characterized lung adenocarcinoma patients (pts) could thus potentially benefit from targeted treatment. This study investigates the innovative paradigm of allocating pts to specific treatment arms based on their genetic profile. The targeted therapies AUY922 (HSP90 inhibitor[i]), BYL719 (PI3Ki), LDK378 (ALKi), INC280 (METi), and MEK162 (MEKi) will be evaluated in different pt subgroups with appropriate confirmed molecular aberrations, in a single cluster study. **Methods:** This Phase II, multiple arm, open-label study will enroll pts (aged ≥18 years, ECOG PS ≤2) with advanced (stage IIIB/IV) lung adenocarcinoma bearing different molecular alterations, who have failed prior treatment or are unsuitable for chemotherapy, and have received ≤2 prior lines of therapy. Pts must have locally obtained documentation of a relevant molecular alteration from either a new or the most recent archival tumor sample, using primary genetic profiling. Pts will be allocated to a specific treatment arm accordingly (AUY922, 70 mg/m$^2$ QW: activating *EGFR* mutation and resistant to EGFR inhibitors; BYL719, 350 mg QD: *PIK3CA* mutation/amplification [other PI3K pathway alterations may be eligible]; INC280, 600 mg BID: *MET*-positive tumors [by IHC or FISH]; LDK378, 750 mg QD: *ALK* or *ROS1* rearrangement; MEK162, 45 mg BID: *KRAS, NRAS* or *BRAF* mutation). Sample size was calculated based on a Bayesian approach using either a minimally informative prior (BYL719, INC280 and MEK162; N=20 for each) or an informative prior using relevant historical data (AUY922 [N=30] and LDK378 [N=25]). The sample size will allow detection with high likelihood, of statistically and clinically relevant antitumor activity. Each treatment arm is independent from one another and will be analyzed separately. Study treatment is given until disease progression or discontinuation. The primary endpoint is overall response rate; secondary endpoints are overall survival, progression-free survival, disease control rate, duration of response, safety, and pharmacokinetics.

**TPS8123 General Poster Session (Board #301B), Sat, 1:15 PM-5:00 PM**

**Clinical trials of MPDL3280A (anti-PDL1) in patients (pts) with non-small cell lung cancer (NSCLC).** *Presenting Author: Naiyer A. Rizvi, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** Blocking the PD-L1/PD-1 immune inhibitory signals can reinvigorate preexisting anticancer immunity and can lead to durable responses in NSCLC. MPDL3280A is a human anti-PD-L1 monoclonal antibody that contains an engineered Fc-domain. MPDL3280A targets PD-L1, preventing binding to its receptors PD-1 and B7.1, thus restoring tumor-specific T-cell immunity. MPDL3280A does not disrupt the PD-L2/PD-1 interaction, which is potentially implicated in autoimmune lung toxicity. In a Phase I study, MPDL3280A led to antitumor responses, with an overall response rate (ORR) of 23% (12/53) in previously-treated NSCLC pts, 46% (6/13) in those pts with a PD-L1 IHC score of 2 or 3 and 83% (5/6) in those pts with a PD-L1 IHC score of 3. Based on these results, we initiated a clinical program examining unselected and PD-L1-positive pts with locally advanced or metastatic NSCLC. Here, we describe the BIRCH and OAK trials. **Methods:** Both studies require pts aged ≥ 18 y with an ECOG status of 0 or 1 and measurable disease (RECIST v1.1). Pts receive MPDL3280A (1200 mg IV) q3w for up to 16 cycles (or 12 months) in the absence of overt toxicity or deteriorative progressive disease. Pts with autoimmune disease, active CNS metastases and/or prior immune checkpoint blockade are excluded. For BIRCH, a Phase II, single-arm study, ≈ 300 pts (3 cohorts; chemo-naive, single prior platinum-based regimen and ≥ 2 prior therapies) with PD-L1-positive tumors receive MPDL3280A. Chemo-naive pts with a sensitizing *EGFR* mutation or an *ALK* rearrangement are excluded. The primary end-point is ORR (RECIST v1.1). Recruitment is ongoing (NCT02031458). OAK is a global Phase III, multicenter, randomized, open-label, efficacy and safety evaluation of MPDL3280A compared with docetaxel after failure of a platinum-containing chemotherapy. Pts (≈ 850) receive docetaxel (75 mg/m$^2$ IV) or MPDL3280A. Eligible pts are enrolled regardless of PD-L1 status but stratified by PD-L1 expression levels. The primary objective is a comparison of OS. Secondary objectives include ORR, PFS and other efficacy criteria. Recruitment begins Q1 of 2014 (NCT02008227). Clinical trial information: NCT02031458, NCT02008227.

**TPS8124 General Poster Session (Board #302A), Sat, 1:15 PM-5:00 PM**

**A phase II/III randomized trial of two doses of MK-3475 versus docetaxel in previously treated subjects with non-small cell lung cancer.** *Presenting Author: Roy S. Herbst, Department of Medical Oncology, Yale University School of Medicine, New Haven, CT*

**Background:** Docetaxel is a standard second line treatment for patients with advanced non-small cell lung cancer (NSCLC). It yields a low response rate (~10.5%), limited 1-year survival rate (~37%), and median overall survival (OS) of ~ 7.5 months. MK-3475 is a highly selective anti-PD-1 monoclonal antibody exerting dual ligand blockade (DLB) of the PD-1 pathway, a major pathway hijacked by tumors to suppress immune control. Preclinical and clinical data suggest that this pathway plays an important role in NSCLC. Upon interaction with its ligands, PD-L1 and PD-L2, the activation of PD-1 may lead to suppression of antitumor immunity. This randomized phase II/III trial was designed to assess the clinical activity of MK-3475 monotherapy compared with standard docetaxel in patients with advanced NSCLC whose disease has progressed after platinum-containing therapy. **Methods:** Eligibility stipulates minimum age of 18 years; ECOG performance status of 0-1, and diagnosis of advanced PD-L1-positive NSCLC with documented progression after platinum-containing systemic therapy. Patients are stratified by ECOG performance status, geographic location of the site, and degree of PD-L1 expression and randomized in a 1:1:1 ratio to receive intravenous MK-3475 (2 mg/kg, every 3 weeks [Q3W] or 10 mg/kg, Q3W) or docetaxel (75 mg/m$^2$, Q3W) for 2 years or until disease progression, unacceptable toxicity, intercurrent illness or investigator decision. Response to treatment will be evaluated every 9 weeks by investigators using the immune-related response criteria (irRC) and centrally by RECIST 1.1. Adverse events (AEs) will be monitored throughout the trial. Primary objectives include OS and PFS per RECIST 1.1 in patients with strong expression of PD-L1, and safety, including incidence and time to first Grade 3-5 AE. Secondary objectives include OS, PFS and ORR per RECIST 1.1 in patients with PD-L1 positive tumors. Fifty of approximately 920 pts targeted for accrual have enrolled. Clinical trial information: NCT01905657.

**TPS8126 General Poster Session (Board #303A), Sat, 1:15 PM-5:00 PM**

**A phase 2 study of defactinib (VS-6063), a cancer stem cell inhibitor that acts through inhibition of focal adhesion kinase (FAK), in patients with KRAS-mutant non-small cell lung cancer.** *Presenting Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** *KRAS* mutations have been associated with poor prognosis in NSCLC and resistance to epidermal growth factor (EGFR) tyrosine kinase inhibitors. FAK represents a therapeutic target in *KRAS* mutant NSCLC. The RHOA-FAK axis is a critical downstream mediator of RAS signal transduction and FAK inhibition results in growth suppression in *KRAS* mutant but not KRAS wild type (wt) cancers both in vitro and in vivo. Interestingly, loss of function of the tumor suppressors CDKN2A/INK4a/ARF (p16) and/or p53 appears requisite for efficacy of FAK inhibition in KRAS-driven cancers. Specifically, in vitro and in vivo studies in xenograft and transgenic *KRAS* mutant NSCLC adenocarcinoma models carrying *INK4a/Arf* and/or *p53* mutant genotypes demonstrated susceptibility to FAK inhibition evidenced by tumor inhibition and prolonged survival. Furthermore, treatment with FAK inhibitors reduces the proportion of cancer stem cells (CSCs) compared to treatment with standard chemotherapy which enriches for CSCs. Defactinib is an oral inhibitor of FAK and proline-rich tyrosine-kinase-2 currently in clinical development in a number of indications including mesothelioma and ovarian cancer. **Methods:** Pts with *KRAS* mutant advanced NSCLC ($>$ 1 prior platinum based doublet) are enrolled into 1 of 4 cohorts (A-D): wt *INK4a/Arf*, wt *p53* (A); *INK4a/Arf* mutation, wt *p53* (B); wt *INK4a/Arf*, *p53* mutation (C), or *INK4a/Arf* mutation, *p53* mutation (D). Defactinib is administered continuously at 400 mg PO BID in 21 day cycles until disease progression. The primary endpoint is the Progression Free Survival (PFS) rate at week 12. In the Simon 2 stage design, if $\geq$ 4 of 11 pts have PFS at week 12, enrollment in that cohort will be expanded to a total of 34 pts. PFS at 12 weeks of $\geq$ 50% will be deemed clinically important and $\leq$ 25% will be deemed not clinically valuable. Response rate (RR), PFS, overall survival (OS), and comparisons between Cohort A to B, C, and D will also be measured. Associations between pharmacodynamic biomarkers (including pFAK) and clinical outcomes (RR, PFS, OS) will be evaluated. The study is currently enrolling at 8 US centers. Clinical trial information: NCT 01951690.

**TPS8127 General Poster Session (Board #303B), Sat, 1:15 PM-5:00 PM**

**Open, phase II randomized trial of gefitinib alone versus olaparib (AZD2281) plus gefitinib in advanced non-small cell lung cancer (NSCLC) patients (P) with epidermal growth factor receptor (EGFR) mutations: Spanish Lung Cancer Group trial (NCT=1513174/GECP-GOAL).** *Presenting Author: Bartomeu Massuti, Hospital General de Alicante, Alicante, Spain*

**Background:** EGFR tyrosine kinase inhibitors (TKIs) are considered the treatment of choice for p with advanced NSCLC harboring EGFR mutations, with higher response rate (RR) and longer progression free survival (PFS). However, the majority of p develop resistance to TKIs via several mechanisms. Our previous experience in the EURTAC trial showed that high BRCA1 mRNA expression levels cause shorter PFS for erlotinib-treated p. Olaparib, a PARP-inhibitor, can reduce BRCA1 expression and could improve PFS in this subset of patients when added to an EGFR TKI. A phase IB study confirmed activity and tolerance of olaparib plus gefitinib in the absence of pharmacokinetic interactions. Recommended dose for the combination was gefitinib 250 mg daily + olaparib 200 mg TDS. **Methods:** Stage IV EGFR-mutated NSCLC p, previously untreated for metastatic disease, with PS 0-2 and evaluable disease (RECIST criteria) are randomly assigned in a 1:1 ratio to single agent gefitinib or gefitinib+olaparib. Primary planned endpoint is PFS. Secondary endpoints: Overall survival (OS), RR, toxicity (CTC criteria), detection of initial presence of T790M resistant mutation, influence of BRCA1 and EGFR mutations on PFS, parallel analysis of EGFR mutations in serum, and ancillary molecular analyses. Statistical hypothesis: Median PFS of 10 months (m) in the gefinitib arm could be increased to 16 m in the combination arm; two-sided alpha error = 0.05 and power 80%. One hundred and sixteen events are required to test the superiority hypothesis. Total planned number of inclusions: 186 p. Pre-planned interim analysis at 58 PFS events (progression or death). Current status: Study opened on July 2013 in 38 Spanish centers; recruitment ongoing. Fifty-nine p screened; 14 included. Clinical trial information: NCT1513174.

**TPS8128 General Poster Session (Board #304A), Sat, 1:15 PM-5:00 PM**

**A phase III, randomized, open-label trial of nivolumab (anti-PD-1; BMS-936558, ONO-4538) versus investigator's choice chemotherapy (ICC) as first-line therapy for stage IV or recurrent PD-L1+ non-small cell lung cancer (NSCLC).** *Presenting Author: David Paul Carbone, Ohio State University Wexner Medical Center, Columbus, OH*

**Background:** The majority of NSCLC patients (pts) present at the time of diagnosis with advanced disease. Subsets of pts are eligible for therapies targeted at mutated oncogene drivers; however, the majority of pts have few effective options beyond standard platinum-based chemotherapy. Preclinical data suggest that immune dysfunction, including T-cell downregulation through increased tumor expression of programmed death-1 ligand (PD-L1), plays a role in NSCLC. Nivolumab, a fully human IgG4 PD-1 immune checkpoint inhibitor antibody, has shown clinical activity against several solid tumors including NSCLC. Preliminary data suggest that nivolumab's activity in first-line NSCLC is accentuated in pts with positive tumor PD-L1 expression (PD-L1+). This phase III, randomized, open-label trial will compare the clinical activity of first-line nivolumab monotherapy vs ICC in treatment-naïve pts with stage IV or recurrent NSCLC with PD-L1+ tumor expression. **Methods:** Chemotherapy-naïve pts with ECOG performance status $\leq$1 and without known EGFR mutations or ALK translocations will be randomized 1:1 to nivolumab (3 mg/kg IV Q2W) or ICC, and stratified by tumor PD-L1 expression level (Dako immunohistochemistry assay) and NSCLC histology. Pts randomized to ICC (maximum of six 3-week cycles) will receive gemcitabine 1250 mg/m$^2$ + cisplatin 75 mg/m$^2$, gemcitabine 1000 mg/m$^2$ + carboplatin AUC 5, or paclitaxel 200 mg/m$^2$ + carboplatin AUC 6 (squamous [sq]), or pemetrexed 500 mg/m$^2$ + either cisplatin 75 mg/m$^2$ or carboplatin AUC 6 (non-sq); with optional crossover to nivolumab. The primary objective is to assess progression-free survival (PFS) with nivolumab vs ICC in pts with strong PD-L1 expression. Secondary objectives are objective response rate and overall survival in strongly PD-L1+ pts, PFS in pts with any PD-L1 expression level, and disease-related symptom improvement. Exploratory objectives include safety, correlation of PD-L1 expression with PFS, pharmacokinetics, pharmacodynamics, pt-reported outcomes, and potential biomarkers. Clinical trial information: NCT02041533.

**TPS8129 General Poster Session (Board #304B), Sat, 1:15 PM-5:00 PM**

**Stimulating an immune response through bavituximab in a phase III lung cancer study.** *Presenting Author: David E. Gerber, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Escape from immune surveillance is a frequent mechanism of tumor initiation, proliferation, and resistance to treatment. Bavituximab is a chimeric monoclonal antibody with immune modulating properties. Bavituximab targets exposed phosphatidylserine (PS) on tumor vascular endothelium, tumor cells and tumor derived exosomes. Exposed PS in the tumor microenvironment suppresses immune and inflammatory responses by binding to PS receptors on myeloid derived suppressor cells (MDSC) and M2 macrophages, which leads to production of anti-inflammatory cytokines such as TGF-$\beta$ and IL-10which inhibits the development of an adaptive immune response. In preclinical models, PS-targeting antibodies counter these effects, resulting in production of pro-inflammatory cytokines such as TNF-$\alpha$ and IL-1$\beta$, maturation of dendritic cells and induction of tumor specific cytotoxic T lymphocyte immunity. Administration of docetaxel increases PS exposure within the tumor microenvironment and also suppresses MDSCs, thereby enhancing bavituximab's effects. In a double-blind Phase II clinical trial, bavituximab 3 mg/kg plus docetaxel was well-tolerated and demonstrated 60% improvement (11.7 vs 7.3 month) in median overall survival (OS) compared to control. **Methods:** In this randomized, double-blind, global Phase III clinical trial, approximately 600 pts with second-line stage IIIb/IV non-squamous NSCLC will be randomized 1:1 to receive up to six 21-day cycles of docetaxel 75 mg/m2 with placebo or bavituximab 3 mg/kg weekly until disease progression or unacceptable toxicity. Patients must have one progression on platinum doublet therapy for advanced disease. Prior maintenance or targeted therapy is allowed if only 1 progression occurred. Within each geographic region, patients will be stratified by disease stage and prior maintenance/targeted therapy. The primary endpoint is overall survivaland secondary endpoints include overall response rate (modified RECIST 1.1), progression free survival (PFS) and safety. Clinical trial information: NCT01999673.

**TPS8130 General Poster Session (Board #305A), Sat, 1:15 PM-5:00 PM**

**A randomized, double-blind, multicenter phase 2 trial of denosumab in combination with chemotherapy as first-line treatment of metastatic non-small cell lung cancer.** *Presenting Author: David R Spigel, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** Non-Small Cell Lung Cancer (NSCLC) is a heterogeneous disease forwhich patients (pts) may benefit from targeted therapies. RANK ligand (RANKL) and its receptor RANK are expressed in a subset of NSCLC tumors (Branstetter, 2013). Results from preclinical models show that RANKL acts directly on RANK-expressing tumor cells to promote tumor progression and metastases (Gonzalez-Suarez, 2010; Tan, 2011). Denosumab is a fully human monoclonal antibody that binds RANKL, approved for the prevention of skeletal-related events in pts with solid tumors and bone metastases. In a study of pts with solid tumors receiving standard treatment, post hoc analysis of those with stage IV NSCLC (n = 702) showed that pts who received denosumab had improved median overall survival (OS) vs those who received zoledronic acid (ZA; HR [95% CI] 0.78 [0.65–0.94], p = 0.01; Scagliotti, 2012). The current trial will correlate tumor RANK and RANKL expression and OS in pts with metastatic NSCLC receiving denosumab in combination with standard chemotherapy vs those receiving chemotherapy alone. The trial is sponsored by Amgen Inc. and registered with ClinicalTrials.gov (NCT01951586). **Methods:** ~216 pts with untreated stage IV NSCLC will receive 4–6 cycles of standard of care chemotherapy and be randomized (2:1) to denosumab 120 mg or placebo SC Q3W or Q4W plus a loading dose on day 8. ZA or placebo IV may be offered in a blinded manner if requested. The sample size is powered to test the interaction between treatment effect and RANK or RANKL expression under various reasonable scenarios. Pts will receive calcium and vit D daily. Randomization will be stratified based on bone metastasis (yes or no), histology (squamous vs nonsquamous), and region (North America, Western Europe/Australia, rest of world). The primary endpoint is tumor RANK expression correlated with OS. Primary analysis will occur when ~149 deaths have occurred. Eligible pts will have ECOG status 0–1 and radiographically evaluable disease. Pts with known EGFR-activating mutations, EML-4-ALK translocations, or brain metastasis will be excluded. Pt screening and enrollment is planned or underway in ~10 countries. Clinical trial information: NCT01951586.

**TPS8131 General Poster Session (Board #305B), Sat, 1:15 PM-5:00 PM**

**NEJ009 trial: A randomized phase III study of gefitinib (G) in combination with carboplatin (C) plus pemetrexed (P) versus G alone in patients with advanced nonsquamous non-small cell lung cancer (NSCLC) with EGFR mutation.** *Presenting Author: Akira Inoue, Department of Respiratory Medicine, Tohoku University Hospital, Sendai, Japan*

**Background:** Based on the previous phase III studies including our NEJ002 study comparing G with platinum doublet, G alone has been accepted as the standard first-line treatment for patients with EGFR-mutated NSCLC. To improve the survival in this population, we had investigated subsequent randomized phase II study (NEJ005) that evaluate the efficacy and safety of two patterns of combined regimen with G, C, and P, and selected one regimen with concurrent use of G, C, and P according to the results of interim monitoring. **Methods:** This randomized phase III trial was designed to compare the efficacy and safety of G alone with combined regimen with G, C, and P in patients with advanced EGFR-mutated NSCLC. Eligible patients (N=340) have pathologically confirmed stage IIIB/IV NSCLC with activating EGFR mutation including exon 18 G719A, C, or S mutation, exon 19 deletion, exon 21 L858R, or L861Q mutation. Concurrent mutation in exon 20 T790M is ineligible. Patients must have radiologically measurable disease, ECOG PS 0–1 and no prior systemic therapy. Patients will be randomized (1:1) to receive G 250 mg alone once daily or same schedule of G with C (AUC 5.0) plus P (500 mg/m2) on day1, every 3 weeks, up to 4-6 cycles, followed by maintenance P with concurrent G. The primary endpoint is overall survival (OS) and secondary endpoints include progression-free survival, best overall response, toxicity profile, and quality of life. A minimum of 168 OS events is required for 80% power to detect a OS improvement of GCP regimen versus G alone using the intent-to-treat (ITT) analysis population (HR $\leq$0.7). A significant (0.025 significance level) 2-sided stratified log-rank test for OS at the final analysis will be indicative of a positive study outcome. An interim analysis is planned to assess safety and whether early discontinuation of the trial is required for futility. Clinical trial information: UMIN000006340.

**TPS8132 General Poster Session (Board #306A), Sat, 1:15 PM-5:00 PM**

**Metformin with a carbohydrate-restricted diet in combination with platinum-based chemotherapy in advanced-stage lung adenocarcinoma.** *Presenting Author: Benjamin Philip Levy, Mount Sinai Beth Israel Hospital, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** Metformin (MTF), an oral biguanide, has recently demonstrated preventative and therapeutic effects in both preclinical and observational clinical studies in non-small cell lung cancer (NSCLC), with minimal toxicity. MTF's antineoplastic effects are mediated by inhibition of the "energy sensing" AMP kinase pathway (AKP) and reversal of hyperinsulinemia. Preclinical data suggest that carbohydrate restriction (CR) also inhibits cancer growth by down-regulation of the AKP as this strategy is currently being investigated in multiple tumor types (NCT01716468). In vivo studies suggest alterations in LKB1, an upstream kinase of the AKP, may predict sensitivity to MTF and is altered in up to 30% of lung adenocarcinoma. We seek to exploit the potential synergy of MTF and a CR diet on this novel pathway as a unique approach to the treatment of NSCLC. **Methods:** Two out of a planned 60 patients have been enrolled in this open label, single arm phase II trial. Advanced stage adenocarcinoma patients with measurable disease, ECOG $<$ 2, and preserved organ function are included. Exclusion criteria included weight less than 80% of ideal body weight (IBW), previous use of metformin, or history of lactic acidosis. Patients are treated with carboplatin (Cb) AUC 5, pemetrexed (P) 500mg/m2 IV every three weeks followed by maintenance P until disease progression or unacceptable toxicity. MTF is initiated at 500mg bid on day 1 of chemotherapy and dose escalated in 500mg increments every 7 days to a final dose of 1,000 mg bid. Patients receive an early referral to a registered dietitian to assess daily caloric needs based on height and weight, and subsequent counseling on a CR diet ($<$30% of the patient's caloric needs from carbohydrates). Patients are removed from the diet portion of the study if they lose more than 10% of their IBW. The primary endpoint of the study is PFS, and the study will be considered positive if PFS is 6.6 months, based on comparison to 4.4 months in historic controls. Secondary objectives include correlation of archival tissue LKB1 mutations assessed by next generation sequencing (Ion Torrent, Integrative Oncology) and changes in serum insulin levels with clinical outcomes (ORR and PFS). Clinical trial information: NCT02019979.

**TPS8133 General Poster Session (Board #306B), Sat, 1:15 PM-5:00 PM**

**NLG-0301: An open-label, randomized phase 2B active control study of second-line tergenpumatucel-L immunotherapy versus docetaxel in patients with progressive or relapsed non-small cell lung cancer (NSCLC).** *Presenting Author: Ramaswamy Govindan, Division of Oncology, Washington University School of Medicine, St. Louis, MO*

**Background:** Tergenpumatucel-L immunotherapy consists of allogeneic lung cancer cells that have been genetically modified to express the carbohydrate $\alpha$(1,3)Gal, to which humans have an inherent pre-existing immunity. It is $\alpha$Gal that is primarily responsible for the hyperacute rejection of foreign tissue via this potent immune defense mechanism in humans. Tergenpumatucel-L leverages this mechanism to educate the immune system towards components of the patients' own tumor cells. In a Phase 2 study of tergenpumatucel-L, patients with evidence of immune activation after therapy (11/18 patients with elevated IFN gamma via ELISPOT) had a median survival of 21.9 months. 16 of 28 patients went on to salvage therapy after progression and 9 of these 16 had objective responses (5PR, 4SD) to the post immunotherapy chemotherapy. This study is designed to further evaluate this potential chemo-sensitization effect of tergenpumatucel-L. **Methods:** This Phase 2B study is an open label, multi center randomized trial of single agent tergenpumatucel-L versus docetaxel. Eligible patients have pathologically confirmed NSCLC and may have previously undergone surgery, radiotherapy, and $\leq$ 2 prior chemotherapy regimens for this diagnosis. 240 patients will be randomized in a 2:1:1 manner to docetaxel (75mg/m$^2$ q3 weeks x 4 doses) versus tergenpumatucel-L (300 million cell intradermally weekly for 11 weeks and then q2 months for 5 additional doses) versus tergenpumatucel-L (300 million cell q2 weeks for 6 doses and then monthly for 10 months). Patients will be monitored and at progression may stay on study and receive gemcitabine or premetrexed if randomized to the docetaxel arm or docetaxel or gemcitabine or premetrexed if randomized to one of the tergenpumatucel-L arms. Patients randomized to immunotherapy may continue to receive tergenpumatucel-L while on salvage chemo until all 16 planned doses are administered. This design with the patients staying on trial after progression is intended to capture and evaluate the possible chemo-sensitization seen in previous trials. Primary endpoint is overall survival. Clinical trial information: NCT01774578.

**8135 General Poster Session (Board #220), Sat, 1:15 PM-5:00 PM**

**The *KRAS*-variant and treatment response in BATTLE-1.** *Presenting Author: Joanne B. Weidhaas, Yale School of Medicine, New Haven, CT*

**Background:** The program, "BATTLE: Biomarker-integrated Approaches of Targeted Therapy of Lung Cancer Elimination" was initiated to establish individualized targeted therapy for NSCLC patients for whom standard therapy had failed. This trial prospectively examined patient tumor biomarker profiles, and assigned them to corresponding targeted therapies (erlotinib, vandetanib, bexarotene+erlotinib, and sorafenib). The primary end-point was 8-week disease control (DC) rate, with a secondary endpoint of overall survival (OS). The *KRAS*-variant is a germ-line mutation that predicts increased NSCLC risk, as well as tumor biology across numerous cancer types. **Methods:** 161 patients from the BATTLE-1 clinical study with sufficient DNA available were tested for the *KRAS*-variant. Overall survival (OS) and progression-free survival (PFS) were estimated by the Kaplan-Meier method. Log-rank test was used to test the difference in survival distributions among groups. **Results:** Overall, 16 BATTLE patients had the *KRAS*-variant, 10.2% (11/107) without tumor acquired EGFR or KRAS mutations (WT), 4.3% (1/23) with tumor acquired EGFR mutations, and 9.7% (3/31) with tumor acquired KRAS mutations. For the primary objective of the study of 8-week DC, *KRAS*-variant patients faired worse (48.5% non-variant vs 28.6% *KRAS*-variant patients). For WT patients, the *KRAS*-variant predicted borderline worse OS (p=0.072) and significantly worse PFS (p=0.01). The impact of the *KRAS*-variant on outcome depended significantly on treatment type. *KRAS*-variant patients treated with Erlotinib had significantly worse PFS (p=0.001). *KRAS*-variants patients treated with Vandetanib had significantly worse OS (p=0.029). However, *KRAS*-variant patients treated with Sorafenib had borderline improved OS (p=0.056). For Sorafenib treated patients with tumor acquired KRAS mutations, those with the *KRAS*-variant had significantly improved PFS (p=0.045) vs non-variant patients. **Conclusions:** The *KRAS*-variant appears to be a predictive biomarker in NSCLC, regardless of tumor acquired KRAS and EGFR mutations. These findings will be further investigated in the BATTLE2 trial as well as RTOG 0617 to confirm the potential of the *KRAS*-variant to be employed to direct treatment for NSCLC patients. Clinical trial information: NCT00409968.

**8500 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Randomized phase 3 study of rituximab, cyclophosphamide, doxorubicin, and prednisone plus vincristine (R-CHOP) or bortezomib (VR-CAP) in newly diagnosed mantle cell lymphoma (MCL) patients (pts) ineligible for bone marrow transplantation (BMT).** *Presenting Author: Franco Cavalli, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland*

**Background:** R-CHOP is standard therapy for newly diagnosed, BMT-ineligible MCL pts. Bortezomib (V) is approved in the US for relapsed MCL. This study evaluated whether replacing vincristine with V in R-CHOP improves outcomes in newly diagnosed, BMT-ineligible MCL pts (NCT00722137). **Methods:** Adults with treatment-naive, measurable stage II–IV MCL and ECOG PS 0–2 were randomized 1:1 (stratified by IPI score and disease stage) to 6–8 21-d cycles of rituximab 375 mg/m$^2$, cyclophosphamide 750 mg/m$^2$, doxorubicin 50 mg/m$^2$, all IV d 1, and prednisone 100 mg/m$^2$ PO d 1–5, plus V 1.3 mg/m$^2$ IV d 1, 4, 8, 11 (VR-CAP) or vincristine 1.4 mg/m$^2$(max 2 mg) IV d 1 (R-CHOP). Primary endpoint was PFS by independent radiology review (IRC); secondary endpoints included TTP, TTNT, OS, response by modified IWRC criteria, and safety. 486 pts were planned for 295 total PFS events, to provide 80% power ($\alpha$=.05, 2-sided) to detect 40% PFS improvement with VR-CAP. **Results:** 487 pts were randomized (244 R-CHOP, 243 VR-CAP; median age 66 yrs, 74% male, 74% stage IV MCL, 54% IPI ≥3). Pts received a median of 6 cycles. After 40 mos' median follow-up (298 PFS events), median PFS by IRC was 14.4 (R-CHOP) vs 24.7 mos (VR-CAP) (ITT analysis: HR=.63* [.50, .79], *P*<.001**). Secondary efficacy data are below. Rates of grade ≥3 AEs were 85% (R-CHOP) vs 93% (VR-CAP), serious AEs 30% vs 38%, discontinuations due to AEs 7% vs 9%, and on-treatment drug-related deaths 3% vs 2%. **Conclusions:** VR-CAP significantly prolonged PFS and consistently improved secondary efficacy endpoints vs R-CHOP in newly diagnosed, BMT-ineligible MCL pts, with additional but manageable toxicity. Clinical trial information: NCT00722137.

**8501 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Increased rituximab (R) doses and effect on risk of elderly male patients with aggressive CD20+ B-cell lymphomas: Results from the SEXIE-R-CHOP-14 trial of the DSHNHL.** *Presenting Author: Michael Pfreundschuh, Saarland University Medical School, Homburg, Germany*

**Background:** Elderly male patients have significantly lower R serum levels, shorter exposure times and a worse outcome in RICOVER-60, RICOVER-noRTh, and Pegfilgrastim trials (Blood 2012, 119:3276; Blood 2014, 123:640-646). **Methods:** To test increasing R doses, male patients received 500 instead of 375 mg/m$^2$ in the SEXIE-R-CHOP-14 trial which also compared six cycles of CHOP-14 in combination with eight 2-week applications with eight upfront dose-dense applications of R (days -1, 0, 3, 7, 14, 21, 28, 42) in a randomized phase-II trial. 271 patients (61-80 years) were randomized, 268 patients are evaluable. 148 patients males received 500 mg/m$^2$, 120 females 375 mg/m$^2$R. **Results:** Protocol adherence was excellent with median relative doses of R and myelosuppressive drugs >98%. During the treatment period, the increased R dose in males resulted in slightly higher trough serum levels than in females; however, R levels dropped faster in males resulting in nearly identical serum levels thereafter and a very similar overall R exposure time. The increased R dose in males was not associated with increased toxicities. 3-year PFS was 74% in males and 68% in females (p=0.396), 3-year OS was 80% in males and 72% in females (p=0.111). In a multivariable analysis adjusting for IPI factors, male hazard was 0.9 (p=0.817) for PFS, and 0.8 for OS (p=0.317). In a historical comparison by multivariable analysis adjusting IPI risk factors and age >70 years, of 148 elderly males who received 500 mg/m$^2$ in SEXIE-R-CHOP-14 and 250 males who received 375 mg/m$^2$ in RICOVER-60, the increased dose of R was associated with a reduced risk for an event in PFS (HR=0.7; p=0.128) and 0.7 in OS (p=0.223). **Conclusions:** Increasing R dose by one third from 375 mg/m$^2$ to 500 mg/m$^2$ eliminated the increased risk of elderly males. That the increased R dose significantly improves outcome not only of elderly male patients, but also in young male and female patients who have a R pharmacokinetics similar to elderly males should be confirmed in a larger randomized study of these subpopulations with aggressive CD20$^+$ B-cell lymphomas. Supported by Roche and Deutsche Krebshilfe. Clinical trial information: NCT00290667.

**8502 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Prognostic value of PET-CT after frontline therapy in follicular lymphoma: A pooled analysis of central review in three multicenter studies.** *Presenting Author: Judith Trotman, Concord Hospital, University of Sydney, Sydney, Australia*

**Background:** The value of $^{18}$F-FDG PET-CT (PET) in response assessment after induction rituximab-chemotherapy for advanced stage symptomatic follicular lymphoma (FL) has recently been documented. To provide more precise survival estimates from a larger patient cohort with longer follow-up we conducted a pooled analysis of centrally reviewed scans in three studies. **Methods:** Patient data and conventional CT-based response assessment (IWC 1999) were recorded for all patients undergoing central PET review in the prospective multicenter GELA (PRIMA and PET Folliculaire), and FIL (FOLL05) studies. Scans were assessed independently by three reviewers applying the standardized Five-Point Scale (5PS). Postinduction PET status was compared with patient characteristics, CT-based assessment and survival endpoints of PFS and OS. **Results:** Of 246 scans performed at the end of the induction immunochemotherapy, 178 (27.6%) were positive with a cut-off ≥3 (FDG uptake >mediastinum), and 41 (16.7%) with a cut-off ≥4 (moderately >liver). Patient and baseline disease characteristics did not differ significantly between PET+ and PET- patients. With a median follow-up of 55 months, both PET cut-offs were highly predictive of PFS and OS, with a cut-off ≥4 being most reproducible and discriminatory. With this cut-off the HR for PFS and OS of PET+ vs. PET- patients was 3.9 (95% CI 2.5-5.9, P<.0001), and 6.7 (95% CI 2.4-18.5, P=0.0002) respectively. For PET+ patients 4 year PFS was 23.2% (95% CI 11.1-37.9%) vs. 63.4% (95% CI 55.9-70.0%) in those who became PET- (P<.0001). Four year OS was 87.2% (95% CI 71.9-94.5%) vs. 97.1% (95% CI 93.2-98.8%), (P<.0001). Conventional CT-based response (CR/CRu vs.PR) was weakly predictive of PFS (HR 1.7, p=0.02) but not OS. **Conclusions:** This large pooled analysis with longer patient follow-up and standardized central review of scans confirms PET status after first-line therapy is strongly predictive of survival in FL. PET-CT rather than contrast enhanced CT scanning should be considered the new gold standard for response assessment in clinical practice, and a platform for study of response-adapted therapy.

**8503 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Final results of a randomized phase II GELA/LYSA study of rituximab plus ACVBP or CHOP, using a PET-driven consolidation strategy, in patients with high-risk diffuse large B-cell lymphoma (DLBCL).** *Presenting Author: Rene-Olivier Casasnovas, Hôpital Le Bocage, Dijon, France*

**Background:** GELA standard for young patients (pts) with high-risk DLBCL (aaIPI 2-3) is R-ACVBP induction plus consolidative BEAM and autologous stem cell transplantation (ASCT). R-CHOP induction might be as efficient and possibly less toxic than R-ACVBP. Also, early PET-negative patients may not need first-line ASCT. A phase II randomized trial was designed in 2007 to test both induction regimen and a PET-driven consolidation strategy (NCT00498043). **Methods:** Eligible pts were 18-59 years with a previously untreated CD20+ DLBCL, an aaIPI 2-3. Pts were randomly assigned to 4 cycles of either R-ACVBP14 or R-CHOP14 induction. Consolidation treatment was driven by centrally reviewed PET assessment (IHP visual criteria) after 2 (PET2) and 4 (PET4) induction cycles. Pts classified as PET2-/PET4- received a sequential immuno-chemotherapy consolidation; PET2+/PET4- pts underwent ASCT; PET4+ pts were considered as induction treatment failure and eligible for a salvage therapy. Primary endpoint was to evaluate the complete response (CR) rate after 4 induction cycles according to IWG 07 criteria. **Results:** 222 pts (R-ACVBP: 114; R-CHOP: 108) with a median age of 46 yrs were included: 97% had stage III/IV, 95% elevated LDH, 24% ECOG≥2. After induction treatment, 47% of the R-ACVBP arm and 39% of the R-CHOP arm pts achieved a CR. PET2 and PET4 were negative in 30% and 53% of pts in the R-ACVBP arm, and 25% and 40% in the R-CHOP arm, respectively. PET2-/PET4- pts were 27% and 24% in the R-ACVBP and R-CHOP arms respectively. Due to more frequent PET4+, pts in the R-CHOP arm more often received salvage therapy as post-induction treatment (39%) than pts in the R-ACVBP arm (27%) (p = 0.048). With a median follow-up of 45 months, PFS and OS were similar in both arms (4y-PFS=75%; 4y-OS=83%). **Conclusions:** A PET driven treatment of high risk DLBCL pts is feasible in a multicenter trial setting. Based on PET visual criteria at 4 cycles, CR rate was higher in the R-ACVBP arm and salvage was more frequently used after R-CHOP, possibly explaining similar PFS and OS in the two induction arms. 25% of pts found to be PET2-/PET4- do not require ASCT. Clinical trial information: NCT00498043.

**8504 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Noninvasive monitoring of cellular versus acellular tumor DNA from immunoglobulin genes for DLBCL.** *Presenting Author: David Matthew Kurtz, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

**Background:** In patients with diffuse large B cell lymphoma (DLBCL), tumor specific immunoglobulin genes can be detected in both the cellular and acellular compartments of blood (Green et al ASH 2013; Armand et al BJH 2013; Roschewski et al ASH 2013). Detection of these genes by high-throughput sequencing (Ig-HTS) has promise for monitoring minimal residual disease (MRD). We compared the performance of Ig-HTS in the cellular and acellular compartments of blood and related them to other measures of disease. **Methods:** We profiled 50 patients with DLBCL at time of diagnosis, therapy, remission, and relapse. Forty-two patients were treated at Stanford University with curative intent. Eight patients were from an Australian Phase 2 study (ALLG NHL21) for patients with poor risk treated with R-CHOP. Involved tissue was used to define clonotypic tumor heavy and light chains by Ig-HTS. Identified sequences were tracked in the cellular and acellular compartments of blood (Faham M et al Blood 2012). **Results:** We identified clonotypic sequences in 100% of fresh tissue but only 59% of FFPE (72% overall). Heavy chains were more frequent than light chains (86% vs 47%). For 36 cases with clonotypic sequences, we followed MRD with 216 tests on 98 blood samples. Within the cellular compartment of blood, we identified disease in 70% of patients at diagnosis, but only 20% at relapse. In the acellular compartment, we identified disease in 78% at diagnosis and 83% at relapse. In those achieving complete response, MRD became undetectable by cycle 2 and remained so while in CR. Only 1 of 46 assays revealed MRD in the cellular compartment while in CR; this in a patient with double-hit DLBCL and high relapse risk. Using radiographic assessment as gold standard, cellular Ig-HTS had 52% sensitivity and 97% specificity and acellular Ig-HTS had 67% Sn and 100% Sp. MRD level correlated with LDH ($R=0.76$, $p<0.0001$) and metabolic tumor volume (MTV) ($R=0.58$, $p<0.01$). **Conclusions:** Ig-HTS can detect tumor specific DNA in the blood of patients with DLBCL. Performance is superior in cell-free DNA from the acellular compartment of blood compared to the cellular compartment. Given its high specificity, Ig-HTS has potential clinical utility during surveillance after achieving CR.

**8505 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Interim analysis of a phase 1, open-label, dose-escalation study of SGN-CD19A in patients with relapsed or refractory B-lineage non-Hodgkin lymphoma (NHL).** *Presenting Author: Andres Forero-Torres, The University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

**Background:** CD19, a member of the immunoglobulin superfamily, is expressed in most patients with B-cell NHL. SGN-CD19A is a novel antibody-drug conjugate composed of a humanized anti-CD19 monoclonal antibody conjugated to the microtubule-disrupting agent monomethyl auristatin F (MMAF) via a maleimidocaproyl linker. **Methods:** This phase 1, open-label, dose-escalation study investigates the safety, tolerability, pharmacokinetics (PK), and antitumor activity of SGN-CD19A in patients with relapsed or refractory B-cell NHL with at least 1 prior systemic regimen (NCT01786135). Patients with DLBCL or follicular lymphoma grade 3 (FL3) must have received intensive salvage therapy. A modified continual reassessment method is used for dose allocation and maximum tolerated dose (MTD) estimation. SGN-CD19A is given by IV on Day 1 of 21-day cycles. **Results:** To date, 22 patients with a median age of 63 years (range, 33 to 81) with DLBCL (18), MCL (3), and FL3 (1) have been treated with SGN-CD19A. 50% of patients were refractory to their last treatment; 6 patients received prior autologous SCT. Patients have received a median of 2 cycles (range, 1 to 9) at dose levels from 0.5 mg/kg to 6 mg/kg. 11 patients remain on treatment and 11 have discontinued due to progressive disease (10) and patient decision (1). No dose-limiting toxicity (DLT) has been reported in 21 DLT-evaluable patients; the MTD has not yet been identified. Adverse events occurring in $\geq$10% of patients are fatigue (27%), blurred vision (27%), dry eye (23%), constipation (23%), dyspnea (14%), and keratitis (14%). Of the 20 patients evaluated, objective responses were observed in 8 patients (40%), 6 CRs (30%) and 2 PRs (10%); 3 patients had SD (15%) and 9 had PD (45%). SGN-CD19A ADC plasma exposures were approximately dose-proportional in preliminary PK analysis with mean terminal half-lives between 9-30 days. **Conclusions:** To date, SGN-CD19A has shown evidence of clinical activity with an objective response rate of 40% (8 of 20 patients) and an observed CR rate of 30% (6 of 20 patients). No DLTs have been reported in tested dose levels; enrollment is ongoing to identify the optimal dose of SGN-CD19A for future studies. Clinical trial information: NCT01786135.

**8506 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Starlyte phase II study of coltuximab ravtansine (CoR, SAR3419) single agent: Clinical activity and safety in patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL; NCT01472887).** *Presenting Author: Marek Trneny, Charles University Hospital, Department of Hematology, Prague, Czech Republic*

**Background:** CoR is an anti-CD19 antibody maytansinoid conjugate. CD19 is expressed in the majority of B cell lymphomas. Phase I program showed clinical activity in pts with both indolent and aggressive lymphomas. **Methods:** Pts withCD19+ R/R DLBCL after at least one standard treatment including rituximab and not candidate for transplantation were eligible. Primary refractory pts were excluded. Biopsy was required at baseline. CoR 55 mg/m$^2$ was administered weekly for 4 weeks then bi-weekly until disease progression or other study discontinuation criteria. The primary objective was to demonstrate an overall response rate (ORR) of at least 20% following Cheson 2007 criteria. Tumor assessments were done every 12 weeks. Secondary objectives were: safety, pharmacokinetics (PK), duration of response (DOR), progression free and overall survival (PFS, OS). Assessment of correlation between biomarkers (BM) status and disease outcome was an exploratory objective. **Results:** 41 pts were evaluable. Median age was 71 (39:85), 53.7% were male; 92.7% had ECOG performance status 0-1. 31.7% had received $\geq$ 3 prior regimens for DLBCL. The ORR was 43.9% (90% CI: 30.6% to 57.9%, p-value$<$0.0001) including 5 complete responses (12.2%). DOR, OS and PFS data are not mature (11 pts ongoing). The most common (>10%) all grades (gr) non-hematologic treatment-emergent adverse events (TEAEs) were nausea (23.0%), diarrhea (19.7%), fatigue and cough (18.0%), vomiting and decrease appetite (13.1%), asthenia, abdominal and back pain (11.5%). TEAEs led to treatment discontinuation in 4 pts. Only gr 1-2 eye disorders were reported, including 1 pt with unrelated gr 2 keratitis. Peripheral neuropathies were observed in 5 pts, all were gr 1-2. Hematological toxicity was moderate, with gr 3-4 neutropenia, thrombocytopenia and anemia in 26.4%, 9.9% and 6.6% pts respectively. PK assessment and investigations on BM expression are ongoing. **Conclusions:** CoR as single agent demonstrated significant activity in R/R DLBCL pts and reached its primary endpoint for ORR, with acceptable safety profile. Trial funded by Sanofi. Clinical trial information: NCT01472887.

**8507 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**A pilot phase II study with brentuximab vedotin followed by ABVD in patients with previously untreated Hodgkin lymphoma: A preliminary report.** *Presenting Author: Massimo Federico, Department of Diagnostic, Clinical and Public Health Medicine, University of Modena and Reggio Emilia, Modena, Italy*

**Background:** In the majority of patients with relapsed or refractory Hodgkin Lymphoma (HL) Brentuximab vedotin (BV) has shown significant activity, with a manageable safety profile. We aimed to assess the role of 2 cycles of BV before starting the standard treatment with ABVD +/- RT in patients with previously untreated HL. **Methods:** Patients with previously untreated CD30-positive HL, stage IA or IIA or IIIA, absence of bulky disease, defined as a mediastinal mass greater than one-third of the maximum chest diameter, or any other mass greater than or equal to 10 cm, received 2 cycles of BV 1.8 mg/Kg intravenously every 3 weeks over 30 minutes, as an outpatient infusion, followed by 3-6 cycles of ABVD depending on stage. Decision on radiotherapy was at physician's discretion. The primary endpoint of the study was the response to BV assessed by FDG/PET, defined as reduction of Deauville score or, in case of no change in Deauville score, as any reduction in SUV intensity compared to basal SUV. PET results (baseline and after 2 cycles of BV) were assessed by a panel of three external independent reviewers. The sample size was fixed at 12 patients. The treatment was considered promising if 10 or more responses were observed (response rate 83%, 95%CI 52-98%). **Results:** Between April and October 2013, 12 patients with a median age of 36 years (age range: 19-70 years), eleven in stage II (Early favorable 7, early unfavorable 4, according to EORTC criteria) and one in stage III, were enrolled. BV was administered as scheduled and at the full dose in all patients. After the 2 cycles of BV, all patients but one (91%) responded, ten with complete (83%) and one (8%) with partial metabolic response. Of note, all seven patients with early favorable disease achieved a complete metabolic response. The only non responding patient had stage III and showed a new lesion at PET2. The only grade 3 adverse events were transient and asymptomatic increase in liver transaminases (n=3, 25%) and gamma glutamyl transpeptidase (n=2, 17%). **Conclusions:** Two cycles of BV induced a complete metabolic response in the majority of patients with previously untreated, limited stage HL, and warrant further studies in first line therapy.

**8508 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Activity of the mTOR inhibitor sirolimus and HDAC inhibitor vorinostat in heavily pretreated refractory Hodgkin lymphoma patients.** *Presenting Author: Filip Janku, Department of Investigational Cancer Therapeutics (Phase I Program), The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Preclinical models suggested synergistic antineoplastic activity of HDAC and mTOR inhibitors in Hodgkin lymphoma by reducing the activity of AKT, mTOR and HDAC. **Methods:** We designed a phase I study to determine the safety of the mTOR inhibitor sirolimus (1mg-5mg PO daily q 28 days) and HDAC inhibitor vorinostat (100mg-400mg PO daily q 28 days) in advanced cancers with an expansion cohort at the recommended phase 2 dose (RP2D) of sirolimus 4mg and vorinostat 300mg for patients with refractory classical Hodgkin lymphoma. The expansion cohort included optional pre- and post-treatment tumor biopsies, peripheral blood mononuclear cells (PBMCs), plasma/serum collections for pharmacodynamic (PD) and pharmacokinetic (PK) endpoints. Upon identification of R2PD patients were allowed to be treated and registered off label if protocol spots were not available. **Results:** A total of 28 patients (men, n=15; women, n=13), median age 34 years, median of 6 prior therapies (including autologous SCT [n=23], autologous and allogeneic SCT [n=6]) were enrolled in dose escalation (n=1), RP2D (n=19) or registered off label (n=8). Per Cheson 2007 criteria the overall response rate was 57% with 9 CRs (32%) and 7 PRs (25%). At the median follow-up of 5.4 months, the median progression-free survival has not been reached. Also given successful induction of remissions 5 (18%) patients were referred for allogeneic SCT. Major grade 3-4 treatment-related toxicities included grade 3 thrombocytopenia (9 patients, 32%), grade 4 thrombocytopenia (8, 29%), grade 3 anemia (4, 14%), and grade 3 transaminitis (3, 11%). Treatment interruptions and/or dose modifications were needed in 19 (68%) patients. Ten (36%) patients had archival tissue available for targeted next-generation sequencing and one patient had a loss of *TSC2*, an abnormality that putatively activates mTOR (PR -56% for 8.4+ months). PD studies in pre- and post-treatment tumor biopsies, PBMCs and plasma as well as PK analysis are pending. **Conclusions:** The combination of sirolimus and vorinostat is well tolerated with encouraging activity in very heavily pretreated patients with Hodgkin lymphoma refractory to standard therapies. Clinical trial information: NCT01087554.

**8510^ Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Panorama 1: A randomized, double-blind, phase 3 study of panobinostat or placebo plus bortezomib and dexamethasone in relapsed or relapsed and refractory multiple myeloma.** *Presenting Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Panobinostat (PAN) is a potent pan-deacetylase inhibitor that demonstrates synergistic antimyeloma activity when combined with bortezomib (BTZ) + dexamethasone (Dex). Early studies demonstrated durable responses in patients (pts) with relapsed (Rel) and relapsed/refractory (RR) multiple myeloma (MM) treated with PAN + BTZ + Dex. This initiated the PANORAMA 1 study, presented herein. **Methods:** Eligible pts had Rel or RR (excluding BTZ- and primary-ref MM) following 1-3 prior regimens. Pts received oral PAN (20 mg) or placebo (pbo) 3 ×/wk + IV BTZ (1.3 mg/m$^2$; D 1, 4, 8, 11) during wks 1-2 with oral Dex (20 mg) on the days of and after BTZ in treatment phase (TP) 1, eight 3 wk cycles. Pts demonstrating benefit could proceed to TP2, with PAN dosing maintained and BTZ/Dex less frequent. The primary endpoint was progression free survival (PFS) with response assessed by modified EBMT criteria. Other endpoints included overall survival (OS), overall response rate (ORR), near complete/complete response (nCR/CR) rate, duration of response (DOR), and safety. PFS/ORR was confirmed by an independent review committee. **Results:** A total of 768 pts (PAN + BTZ + Dex [n = 387]; pbo + BTZ + Dex [n = 381]) were randomized. Median age was 63 y (42% ≥ 65 y) and 48% received ≥ 2 prior regimens. Prior therapies included BTZ (43%), thalidomide (51%), lenalidomide (20%), and 25% received both prior BTZ + IMiDs. The primary endpoint was met with median PFS of 12 mo vs 8.1 mo ($P < .0001$; HR 0.63, 95% CI [0.52, 0.76]) for pts treated on the PAN vs pbo arm. In the PAN and pbo arms, ORR was 61% vs 55% and nCR/CR rate was 28% vs 16%, with DOR of 13.1 mo vs 10.9 mo, respectively. OS data is not mature. Adverse events (AEs) led to discontinuation in 36% in the PAN arm and 20% in the pbo arm. Common grade 3/4 lab abnormalities and AEs (regardless of study drug relationship) in the PAN vs pbo arms included thrombocytopenia (67% vs 31%), neutropenia (35% vs 11%), and diarrhea (26% vs 8%); these were generally manageable with dose reduction/supportive care. On-treatment deaths occurred in 8% and 5%, respectively. **Conclusions:** PAN + BTZ/Dex significantly improves PFS in pts with Rel or RR MM, with manageable toxicity. Clinical trial information: NCT01023308.

**8511 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**E1A06: A phase III trial comparing melphalan, prednisone, and thalidomide (MPT) versus melphalan, prednisone, and lenalidomide (MPR) in newly diagnosed multiple myeloma (MM).** *Presenting Author: A. Keith Stewart, Mayo Clinic, Scottsdale, AZ*

**Background:** Melphalan, prednisone and thalidomide (MPT) is an accepted regimen in newly diagnosed MM. Early studies suggested that lenalidomide (R) might be substituted for thalidomide (T) with equal efficacy and less toxicity. We present E1A06, a randomized, multicenter phase 3 trial comparing MPT vs. MPR in pts with untreated, symptomatic, transplant ineligible MM. **Methods:** The primary objective was PFS differences between pts receiving MPT: M 9 mg/m$^2$ and P 100 mg p.o. each on days 1-4 with T 100 mg daily vs. MPR: M 5 mg/m$^2$and P 100 mg p.o. each on days 1-4 with R 10 mg p.o. on days 1-21. MPT or MPR therapy was continued for twelve 28 day cycles followed by T 100mg or R 10mg daily until relapse. Aspirin prophylaxis was required. Pts were stratified by ISS stage (I-II vs. III) and age (<65 vs. ≥65). Inferiority of MPR was defined as a PFS treatment hazard ratio (HR) of MPT/MPR ≤ 0.82. Secondary objectives included OS between the arms, toxicities, response rates, depth of response and quality of life (QoL) change. **Results:** 306 pts were enrolled. Treatment arms were balanced for age, ISS stage and other major prognostic factors. Median age was 75.7y. The median follow-up was 40.7 months (m). Median time on therapy was 12m, and 23m for the 46% of pts on maintenance therapy, with no differences by arm. Per protocol partial response rate was 62% (MPT) vs. 61% (MPR) with no difference in VGPR/CR rates (18.8% vs. 23%). Grade ≥3 toxicity was 71.6% (MPT) vs. 56.7% (MPR); p=0.008. By ITT, the median PFS was 21m on MPT and 18.7m on MPR; HR 0.84 [95%CI: 0.64, 1.09]. The null hypothesis of inferiority of MPR was not rejected. Three year OS was identical by arm at 63% and median OS was not significantly different; p=0.476. Second primary malignancies were observed in 17 (MPT) vs. 14 (MPR) pts with incidence rates of 3.47 and 2.01 (/100 person years). DVT/PE occurred in 8.8% vs. 6.7% of pts. QoL analysis favored MPR by induction end; p=0.007. **Conclusions:** This phase III trial compares the efficacy of MPT and MPR in elderly patients with newly diagnosed MM. Response rates, PFS and OS were similar between the two arms; however, there was significantly better QOL at 12m and lower toxicity with MPR. Clinical trial information: NCT00602641.

**8512 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**A phase Ib dose escalation trial of SAR650984 (Anti-CD-38 mAb) in combination with lenalidomide and dexamethasone in relapsed/refractory multiple myeloma.** *Presenting Author: Thomas G. Martin, University of San Francisco, San Francisco, CA*

**Background:** SAR650984 (SAR) is a humanized IgG1 monoclonal antibody that binds selectively to a unique epitope on human CD38 receptor. SAR kills tumor cells via antibody-dependent cellular-mediated cytotoxicity, complement-dependent cytotoxicity, direct apoptosis induction without secondary crosslinking and allosteric inhibition on CD38 enzymatic activity. We present data on the dose escalation phase of the study (NCT01749969). **Methods:** Three dose levels (DL) of SAR 3, 5 and 10 mg/kg were evaluated in combination with lenalidomide (LEN) and dexamethasone (Dex). LEN 25 mg was given on days (d) 1 – 21 and D 40 mg on d 1, 8, 15 and 22 every 28 d's. SAR was given IV on d 1 and 15 and escalated using the classic 3+3 design. **Results:** 13 patients (pts) with RRMM were treated; median age 61 yrs (48 - 73); median prior treatment regimens 6 (2 - 12), 100% had received prior LEN (23% prior pomalidomide) and 92.3% previously received bortezomib (38.5% prior carfilzomib). The median time from diagnosis to first SAR dosing was 4.5 yrs (3 - 11). The maximum tolerated dose was not reached. The most frequent adverse events included nausea, cough (n = 6 each); fatigue, muscle spasm, infection (n = 5 each); vomiting, diarrhea, dehydration and insomnia (n = 4 each). Grade (G) ≥ 3 hematologic abnormalities were neutropenia (n = 4) and thrombocytopenia (n = 3). One pt discontinued therapy (cycle 1, d 1) due to an infusion reaction (bronchospasm G 3). The ORR (≥ PR), according to IMWG criteria, among 12 evaluable pts was 58 %. Responses occurred at each DL of 3mg/kg (1PR), 5mg/kg (1PR, 1 VGPR) and 10 mg/kg (1PR, 3 VGPR). Clinical benefit response (≥ MR) was 67 % with 1 MR at 3 mg/kg. Median time on treatment was 20.6 weeks (0 - 35) and 7 pts remain on therapy. PK showed non linearity at select dose levels, SAR plasma trough levels were above target for tumor eradication from preclinical data. **Conclusions:** The combination of SAR with LEN/Dex was tolerated and no DLT's were reported at any DL. SAR + LEN/Dex demonstrated encouraging efficacy in pts with heavily pretreated RRMM. An expansion cohort of 18 pts recently enrolled on the trial and the results will be reported at the meeting. Clinical trial information: NCT01749969.

**8513 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Dose-dependent efficacy of daratumumab (DARA) as monotherapy in patients with relapsed or refractory multiple myeloma (RR MM).** *Presenting Author: Henk M. Lokhorst, UMC Utrecht, Utrecht, Netherlands*

**Background:** Pts with RR MM received DARA for 9 wks in doses of 0.005-24mg/kg in the GEN501 dose-escalation part (Lokhorst: EHA 2013 abstract S576). The purpose of the GEN501 expansion part, which has completed enrollment, was to evaluate safety and efficacy of 2 doses of DARA for up to 24 mths using alternate dose schedules. **Methods:** Pts ≥18 yrs, RR to at least 2 prior lines of therapy, incl. IMiDs and proteasome inhibitors, and ineligible for ASCT were enrolled at 2 dose levels: A: 8mg/kg +/- pre-dose (10mg) wkly for the first 8 infusions.B: 16mg/kg without pre-dose with a 3-wk washout period between the first 2 doses followed by 7 wkly doses. Then all pts were dosed every 2nd wk for 16 wks followed by dosing every 4th wk until disease progression, toxicity or for max 24 mths. **Results:** Data from 30 pts in the 8mg/kg cohort and 15 pts in the 16mg/kg cohort recruited into the GEN501 expansion part are presented. Median age was 58.2 (35.1-76.9) and 64.1 (50.5-75.0) years, prior treatment lines were 5 (3-11), and 4 (2-8) and time since diagnosis was 5.5 (2.1-15.2) and 7.1 (0.4-13.3) years, respectively. Median number of DARA infusions was 10.5 vs 7.0, reflecting the more recent initiation of the 16mg/kg cohort. Infusion times were 3.5 vs 3.4 hours in the 8 and 16mg/kg groups, respectively. Safety: No dose-related increase in adverse events (AEs) was observed. Most common AEs reported (in ≥20% of all pts) were pyrexia, allergic rhinitis, fatigue, upper respiratory tract infection, diarrhea, dyspnea and cough. Only mild (Gr 1 and 2) infusion-related reactions (IRRs) were reported with 27% in the 16mg/kg group vs 20% in the 8mg/kg group. 2 SAEs, 1 in each group, were assessed as related to DARA (1 thrombocytopenia, 1 lymphocytopenia). One pt was withdrawn after 1st full dose due to thrombocytopenia Gr 3. Omission of the pre-dose increased neither the incidence nor the severity of IRRs. **Conclusions:** DARA monotherapy in RR MM pts resulted in high single agent activity when administered at 16 mg/kg (46% ORR). The safety profile was manageable. Full response data will be presented at the meeting incl. bone marrow assessments. Clinical trial information: NCT00574288.

**8514 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Efficacy of siltuximab in patients with previously treated multicentric Castleman's disease (MCD).** *Presenting Author: Frits Van Rhee, Myeloma Institute for Research and Therapy, Little Rock, AR*

**Background:** Siltuximab is a chimeric anti−IL-6 monoclonal antibody under investigation for treatment of MCD.A randomized, double-blind, placebo-controlled study in MCD showed significant improvement in durable tumor and symptomatic response (34.0% vs 0.0% with placebo; $P = 0.001$), superior response in the secondary endpoints of tumor response rate, time to treatment failure, MCD symptom improvement, and no increased frequency of adverse events compared with placebo. A prespecified subanalysis evaluated the efficacy of siltuximab among patients who had received prior systemic therapy. **Methods:** Adults with confirmed symptomatic MCD were randomized 2:1 to siltuximab 11 mg/kg (n = 53) or placebo (n = 26) IV every 3 weeks and were stratified by corticosteroid use at randomization. All patients received best supportive care, and treatment was continued until treatment failure. **Results:** The majority (siltuximab, n = 29 [54.7%]; placebo, n = 17 [65.4%]) of patients had received prior systemic treatment for MCD. The most frequently used agents included corticosteroids 93.5%, cyclophosphamide 50%, vincristine 26.1% and rituximab 17.4%. Durable tumor and symptomatic responses were similar for pretreated and treatment naïve subgroups (34.5 % vs 0% and 33.3 % vs 0% respectively). Secondary endpoints consistently favored siltuximab in both subgroups as presented in the Table. Frequencies of adverse events (AE) and serious (S) AEs were similar across pretreated and treatment naive subjects. **Conclusions:** Siltuximab is an active agent in both newly diagnosed MCD and patients who have insufficient response to or failed other therapies. Clinical trial information: NCT01024036.

**Continuous treatment (CT) versus fixed duration of therapy (FDT) in newly diagnosed myeloma patients: PFS1, PFS2, OS endpoints.** *Presenting Author: Antonio Palumbo, Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy*

**Background:** Continuous therapy significantly prolongs remission duration, resistant relapse may reduce the duration of subsequent remission which can negatively impact on OS. PFS1 defines the time from start of therapy to the occurrence of 1st relapse. PFS2 is defined as per EMA as the time from start of therapy to the occurrence of 2nd relapse, incorporating the duration of both 1st and 2nd remission. We evaluated PFS1, PFS2 and OS in newly diagnosed multiple myeloma (NDMM) patients who received CT or FDT. **Methods:** Patients were enrolled in 2 phase III randomized trials, comparing CT vs FDT (RVMM209: lenalidomide-based induction, consolidation, followed by maintenance [CT] vs lenalidomide-based induction, consolidation, no maintenance [FDT]; GIMEMA0305: bortezomib-based induction followed by maintenance (CT) vs bortezomib-based induction, no maintenance [FDT]). At diagnosis, in all randomized patients, we evaluated PFS1 (time: diagnosis followed by 1st relapse), PFS2 (time: diagnosis followed by 2nd relapse), and OS (time: diagnosis followed by death). In patients who experienced 1st relapse we tested 2nd PFS (time: 1st relapse followed by 2nd relapse) and survival from relapse (time: 1st relapse followed by death). **Results:** In the pooled analysis, 452 patients received CT and 461 patients received FDT. Median follow-up was 52 months [mo]. CT significantly prolonged PFS1 (median 35 vs 24 mo, HR 0.58; P<0.0001), PFS2 (median 63 vs 47 mo, HR 0.69, p=0.0001) and OS (median not reached [NR] vs 70 mo, HR 0.70, P=0.0019) in comparison with FDT. 2nd PFS and OS from relapse were similar among patients who received CT or FDT upfront. Results were similar in the single studies (Table). **Conclusions:** In NDMM patients, CT significantly improved PFS1, PFS2, and OS. Prolongation of PFS2 suggests that the clinical benefit observed during 1st remission is not cancelled by a shorter 2nd remission. PFS2 should be included in all CT vs FDT studies to evaluate the risk of tumor-resistance induced by CT. Clinical trial information: NCT01063179 and NCT00551928.

**8516^ Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Health-related quality of life (HRQOL) in transplant-ineligible patients (pts) with newly diagnosed multiple myeloma (NDMM): Results from the first trial.** *Presenting Author: Michel Delforge, University Hospital Leuven, Leuven, Belgium*

**Background:** In the pivotal FIRST trial, continuous lenalidomide plus low-dose dexamethasone (Rd; [N = 535]) improved progression-free survival (PFS) and overall survival (OS) compared with 18 cycles of Rd (Rd 18; [N = 541] for and 12 cycles of melphalan-prednisone-thalidomide (MPT; [N = 547] for 72 weeks) (Facon, Blood 2013). This analysis evaluates HRQOL changes in these NDMM pts. **Methods:** HRQOL was assessed using the EORTC-QLQ-C30, QLQ-MY20, and EQ-5D validated questionnaires at baseline, end of cycle 1, then 3, 6, 12, 18 months (mos), and at study discontinuation. Cross sectional and longitudinal analyses were performed. Changes from baseline at each time-point were estimated with a focus on seven pre-selected and clinically-relevant domains (Global QOL, Physical Functioning, Pain, Fatigue, Disease Symptoms, Side Effects of Treatment, and Health Utility). **Results:** Questionnaire compliance was high (≥ 84%) at Cycle 1, 3 and 6 mos across treatment arms. At 12 and 18 mos, the compliance rates were lower in the MPT arm than the Rd arms, 81% vs. 91% and 67% vs. 89% respectively ($P \leq 0.002$). Statistically significant ($P \leq 0.05$) improvement from baseline in HRQOL scores was observed in all treatment arms, in 6 out of the 7 domains at most time-points. For the Side Effects domain, treatment with MPT showed a consistent and significant worsening from baseline at all the assessments. In addition Side Effects for MPT had a significantly worse score than continuous Rd at Cycle 1, 3 and 12 mos ($P \leq 0.05$). Progressive disease (PD) was associated with worsening in HRQOL scores for all domains across all 3 treatment groups ($P < 0.001$). **Conclusions:** In NDMM transplant ineligible pts, continuous Rd treatment resulted in improved PFS and OS thus improving clinically relevant HRQOL measurements over the course of treatment and better QOL related to treatment side effects than MPT. HRQOL improved with treatment and was generally maintained while subjects were progression-free. PD was associated with worsening HRQOL across evaluated domains. MPT therapy was perceived as having worse Treatment Side Effects as compared to Rd. Clinical trial information: 00689936.

**8517 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Survival benefit and cost of autologous hematopoietic stem cell transplantation (Auto HSCT) in elderly patients with multiple myeloma (MM) using the SEER-Medicare database.** *Presenting Author: Gunjan L. Shah, Division of Hematology/Oncology Tufts Medical Center, Boston, MA*

**Background:** Medicare coverage for Auto HSCT for MM began in 10/2000. By 2009, MM was the leading indication for this treatment (CIBMTR, 2011). The survival benefit and cost implications of the rise in Auto HSCT are not well described in this population. Using SEER-Medicare data, we explored these implications for MM patients (pts) age 66+ by comparing them with pts not undergoing Auto HSCT. **Methods:** We used auto HSCT-specific ICD-9 or HCPCS codes to identify pts as having an Auto HSCT. We restricted the sample to pts age 66+ at time of MM diagnosis and used propensity score matching to create a cohort not receiving Auto HSCT. We calculated costs and survival for the first 100 days (d), year (yr), 3 yrs, and 5 yrs post-diagnosis using Kaplan-Meier curves stratified by patients receiving a transplant. We inflation-adjusted cost data to 2009 US dollars, using the medical care component of the Consumer Price Index. Patients were followed for up to 9 years. **Results:** We identified 10,832 pts diagnosed with MM from 1/2000 to 1/2008. Of these, 267 received Auto HSCT. We created a matched "control" sample of 267 pts not having Auto HSCT (c-statistic 0.83). The samples had a median age at diagnosis of 69.8 yrs, with 60% males and 90% Caucasians. The Charleson comorbidity index (CCI) was 0 for 62% of the Auto HSCT and 67% of the control pts (p=0.52), with the rest having a CCI of 1+. Median time to transplant was 250d. Median survival increased from 822 to 1,705 days with Auto HSCT (p=<0.001). Overall survival (OS) with Auto HSCT was higher at all time points: 99 vs 87% at 100d (p=<0.001); 95 vs 71% at 1 yr (p=<0.001); 73 vs 45% at 3 yr (p=<0.001); and 48 vs 30% at 5 yr (p=<0.001). Mean cost post diagnosis was $301,000 vs 124,000 with a life year gain of 2 years with Auto HSCT. The incremental cost-effectiveness ratio was $88,500/life year. **Conclusions:** Auto HSCT significantly increases OS in elderly patients with MM. While the cost of treating the transplanted patients was higher, the incremental cost effectiveness ratio is below the commonly accepted threshold for cancer treatment. Components of cost will be presented to describe the impact of novel agents.

**8518 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM**

**A phase 1 dose-escalation study of the oral selective inhibitor of nuclear export (SINE) KPT-330 (selinexor) in patients (pts) with heavily pretreated non-Hodgkin lymphoma (NHL).** *Presenting Author: Martin Gutierrez, John Theurer Cancer Center, Hackensack, NJ*

**Background:** KPT-330 (Selinexor) is a SINE XPO1 antagonist that forces nuclear retention and activation of >10 tumor suppressor proteins (TSP) and associated with reduction in c-myc and Bcl-$X_L$. Anti-NHL activity was observed in murine models and in spontaneous canine aggressive lymphomas. **Methods:** Oral KPT-330 was given at 8-10 doses / 28-day cycle. XPO1 inhibition leads to rapid elevations in XPO1 mRNA, representing a pharmacodynamic (PDn) marker for KPT-330. Tumor biopsies were performed. Response evaluation was done in cycles 1, 2, and every 2 cycles. All pts had heavily pretreated NHL with progressive disease (PD) on study entry. **Results:** Thirty-two pts (18 M, 14 F; median age 68 yrs; ECOG PS 0/1: 9/23; median prior regimens: 3 range 1-11) received KPT-330 across 8 dose levels (3 to 60 mg/m$^2$). Dosing at 60 mg/m$^2$ twice weekly (BIW) is ongoing and MTD has not been reached. Cycle 1 (DLT period) Grade 3/4 events in >1 pt included thrombocytopenia (20%) and neutropenia (20%). The most common grade 1/2 AEs in cycle 1: anorexia (53%), nausea (50%), fatigue (50%), and vomiting (43%). Supportive care with appetite stimulants and anti-emetics diminished constitutional symptoms. Increases in XPO1 mRNA levels were observed at 4-48 hours, supporting BIW dosing. Tumor biopsies confirmed TSP nuclear localization, c-myc reduction, and apoptosis. Objective responses were observed in all histologies of NHL (Table). 5/16 pts have remained on therapy for an average of 9 months (>5-17) months without clinically significant toxicities. **Conclusions:** KPT-330 is generally well tolerated and can be administered over prolonged periods. The recommended phase 2 dose is ≥45 mg/m$^2$BIW. Durable single agent activity was observed in heavily pretreated NHL pts, and phase 2 studies in DLBCL and Richter's Syndrome are planned. Clinical trial information: NCT01607892.

**Response in 28 evaluable pts.**

| NHL | N | PR+SD (%) | PR (%) | SD (%) [%Change in LN Size] | PD |

**8519 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM**

**Preliminary results of a phase II randomized study (ROMULUS) of polatuzumab vedotin (PoV) or pinatuzumab vedotin (PiV) plus rituximab (RTX) in patients (Pts) with relapsed/refractory (R/R) non-Hodgkin lymphoma (NHL).** *Presenting Author: Franck Morschhauser, CHU Lille, Lille, France*

**Background:** PoV and PiV, antibody drug conjugates (ADC) containing the anti-mitotic MMAE targeting CD79b (PoV) and CD22 (PiV), showed clinical activity in Phase I. The current study aims to compare PoV and PiV + RTX in R/R DLBCL and R/R follicular lymphoma (FL). **Methods:** Pts were randomized to receive PoV or PiV + RTX (ADC 2.4 mg/kg + RTX 375 mg/m$^2$) every 21 days. Tumor assessments were performed every 3 months. **Results:** As of 8 November 2013, 58 received PoV + RTX (38 DLBCL; 20 FL), 63 PiV + RTX (42 DLBCL; 21 FL). Median prior therapies [DLBCL, 3 (1-10); FL, 2 (1-8)] were balanced between treatment arms; 46% were RTX refractory. Median treatment (tx) cycles in DLBCL: 5 for both ADC (1-15); FL: 8.5 PoV (3-15) and 6 PiV (1-13). Overall safety profiles of both regimens were similar. Tx-emergent adverse events (AE) >25%: fatigue (52%), diarrhea (42%), nausea (37%), peripheral neuropathy (PN) (32%), constipation (26%). Grade ≥ 3 AE >3%: neutropenia (21%), diarrhea (6%), dyspnea (4%), febrile neutropenia (4%), hyperglycemia (4%) and PN (4%). Serious AE reported in 36%. Thirty-eight discontinued tx for AE after median 5 doses (range 1-14), including 16 for PN. Tx delays and ADC dose reductions reported in 27% and 22%. Two of 7 deaths (sepsis, urosepsis) unrelated to NHL were attributed to PiV. Complete (CR) and partial (PR) responses, n (%) [% 95% CI] (see Table). **Conclusions:** PoV and PiV + RTX were generally well-tolerated with similar toxicity. Neutropenia, PN and diarrhea were principal toxicities. Similar efficacy was observed with both ADCs in heavily pretreated pts with DLBCL. The higher CR rate with PoV + RTX suggests greater clinical activity in R/R FL. Combination studies of R + PoV with chemotherapy and with ADC schedules to reduce PN are ongoing or in planning. Clinical trial information: NCT01691898.

| | PoV (CD79b) + RTX | PiV (CD22) + RTX |

| R/R DLBCL | N = 37 | N = 37 |
| ORR | 19 (51%) [34, 68] | 20 (54%) [37, 71] |
| CR | 5 (14%) [5, 29] | 7 (19%) [8, 35] |
| PR | 14 (38%) [23, 55] | 13 (35%) [20, 53] |
| R/R FL | N = 20 | N = 21 |
| ORR | 12 (60%) [36, 81] | 14 (67%) [43, 85] |
| CR | 6 (30%) [12, 54] | 1 (5%) [0.1, 24] |
| PR | 6 (30%) [12, 54] | 13 (62%) [38, 82] |

Pharmacokinetic profiles were similar for both ADCs across DLBCL and FL with no free MMAE accumulation.

**8520 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM**

**Effect of lenalidomide combined with R-CHOP (R2CHOP) on negative prognostic impact of nongerminal center (non-GCB) phenotype in newly diagnosed diffuse large B-cell lymphoma: A phase 2 study.** *Presenting Author: Grzegorz S. Nowakowski, Mayo Clinic, Rochester, MN*

**Background:** The non-germinal center B-cell like (non-GCB) subtype of diffuse large cell lymphoma (DLBCL) is associated with a worse outcome when treated with RCHOP chemotherapy. Lenalidomide has significant single-agent activity in relapsed DLBCL and might be particularly active in non-GCB DLBCL. We have previously reported that lenalidomide can safely be combined with RCHOP (R2CHOP). This phase 2 study evaluated the efficacy of this combination in newly diagnosed DLBCL and analyzed the outcomes based on DLBCL subtype. **Methods:** Eligible patients were adults with newly diagnosed, untreated, stages II-IV CD20 positive DLBCL. Patients received oral lenalidomide 25 mg days 1-10 with standard dose R-CHOP every 21 days for 6 cycles. All patients received pegfilgrastim on day 2 of each cycle and aspirin prophylaxis throughout. DLBCL molecular subtype was determined by tumor immunohistochemistry (Hans algorithm) and classified as germinal center B-cell (GCB) vs non-GCB in the R2CHOP patients and 87 control DLBCL patients from the Mayo Clinic Lymphoma Database meeting the same inclusion criteria and treated with conventional RCHOP. **Results:** 64 DLBCL patients were enrolled. Median age was 65 years (22-87) and 34 patients (53%) had IPI intermediate-high or high. 60 were evaluable for response. The overall response rate was 98% (59/60) with 80% (48/60) complete response (CR). 24 month EFS and OS rates (95% CI) were 59% (48%-74%) and 78% (68-90%), respectively. In RCHOP patients, 24 months PFS and OS were 28% vs 64%, p<0.001 and 46% vs 78% p<0.001 in non-GCB patients vs GCB patients respectively. In contrast, there was no difference in 24 months PFS or OS for R2CHOP treated patients based on non-GCB and GCB subtype, 60% vs. 0.59%, p= 0.83 and 83% vs. 75%, p=0.61 at 2 years respectively. **Conclusions:** R2CHOP shows promising efficacy in DLBCL. The addition of lenalidomide to RCHOP appears to mitigate the negative impact of non-GCB phenotype on the outcome. A randomized phase 2 study of RCHOP vs. R2CHOP utilizing gene expression profiling classification of DLBCL subtype and led by the Eastern Cooperative Oncology Group (E1412) is currently ongoing. Clinical trial information: NCT00670358.

**8521 Poster Highlights Session (Board #1), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**CALGB 50803 (Alliance): A phase II trial of lenalidomide plus rituximab in patients with previously untreated follicular lymphoma.** *Presenting Author: Peter Martin, Weill Cornell Medical College, New York, NY*

**Background:** The CALGB 50401 randomized phase II trial demonstrated the safety and efficacy of lenalidomide plus rituximab in (pts) with previously treated follicular lymphoma (FL). CALGB 50803 was a multicenter phase II trial of lenalidomide plus rituximab in pts with previously untreated FL. **Methods:** Pts with grade 1-3a FL, stage 3-4 or bulky stage 2 (> 7 cm), FLIPI 0-2, and no prior systemic therapy were eligible to receive rituximab 375 mg/m$^2$ weekly x 4 during cycle 1 and day 1 of cycles 4, 6, 8, and 10, plus lenalidomide 20 mg on days 1-21 for a total of twelve 28-day cycles. Restaging was performed on weeks 10, 24, and 52, then q4 months for 2 years, and q6 months until progression for up to 10 years. The primary objective was to evaluate complete response (CR) rate based on 2007 IWG criteria. **Results:** From October 2010 to September 2011, 65 subjects were enrolled. Median age was 53 years; 34 were female; 14 had bulky disease; 20 were FLIPI 0-1, 41 FLIPI 2, 2 FLIPI 3; and 2 had insufficient data. Fifty pts completed 12 cycles of lenalidomide. Reasons for discontinuation included refusal/withdrawal (N=6), adverse events (N=4), progression (N=2), and extended treatment delay (N=1). Grade 3-4 hematologic toxicity included neutropenia (19%), lymphopenia (8%), and thrombocytopenia (2%). Febrile neutropenia occurred in 1 pt. Grade 3-4 non-hematologic toxicity occurring in at least 2 pts included rash (8%), infection (8%), pain (8%), fatigue (6%), tumor lysis (3%). The overall RR in evaluable subjects was 93% (53/57); the CR rate was 72%. There was no significant association between CR rate and FLIPI risk, histological grade, or bulky disease. The median time to CR was 10 weeks and 92% of PET-negative CRs occurred by 24 weeks. With a median follow-up of 2.3 years, the 2-year PFS is 89%. **Conclusions:** Lenalidomide plus rituximab was well tolerated and effective in pts with untreated FL. These data are similar to those reported with chemotherapy-based therapy and support evaluation of this regimen in randomized trials. Clinical trial information: NCT01145495.

**8522 Poster Highlights Session (Board #2), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase I study of ABT-199 (GDC-0199) in patients with relapsed/refractory (R/R) non-Hodgkin lymphoma (NHL): Responses observed in diffuse large B-cell (DLBCL) and follicular lymphoma (FL) at higher cohort doses.** *Presenting Author: Matthew Steven Davids, Dana-Farber Cancer Institute, Boston, MA*

**Background**: The anti-apoptotic protein Bcl-2 is a highly expressed in NHL and contributes to chemotherapy resistance. ABT-199 is a selective, orally bioavailable, small molecule Bcl-2 inhibitor that is a promising agent for the treatment of patients (pts) with NHL. **Methods:** Objectives of this Phase I, dose-escalation study include evaluations of safety, pharmacokinetics (PK), and preliminary efficacy in pts with R/R NHL. ABT-199 was given on Week 1 Day -7 (W1D-7), followed by continuous, once-daily dosing from W1D1 until progressive disease or unacceptable toxicity. A 2 to 3 week lead-in period with stepwise dose titration was implemented. Final cohort doses of 200 - 900 mg have been evaluated. **Results:** As of December 4, 2013, 44 pts have been enrolled, 15 (35%) with mantle cell lymphoma (MCL), 11 (26%) with FL, 10 (23%) with DLBCL, 4 (9%) with Waldenström macroglobulinemia (WM), 2 (5%) with marginal zone (MZL), 1 (2%) with primary mediastinal B-cell lymphoma (PMBCL), and 1 (2%) with multiple myeloma (MM). The most common AEs (≥20% of pts) were nausea (34%), upper respiratory tract infection (27%), diarrhea (25%), and fatigue (21%). Grade (G) 3/4 AEs occurring in >3 pts were anemia (14%), neutropenia (11%), and thrombocytopenia (9%). G 3/4 thrombocytopenia was not dose-dependent or dose-limiting. Two of 10 pts in cohort 5 experienced a DLT (G3 febrile neutropenia and G4 neutropenia) at the target dose of 600 mg. G3 laboratory tumor lysis syndrome was seen after the initial dose in 1 pt with bulky MCL (elevations in phosphate and potassium only) and 1 pt with DLBCL (elevations in phosphate and uric acid only). For the 40 pts evaluable for efficacy, the overall response rate was 48%, 9/12 MCL (1 CR); 3/11 FL; 3/9 DLBCL (1 CR); 3/4 WM (1 CR); 1/2 MZL; 0/1 PMBCL; 0/1 MM. All responses in DLBCL and FL pts were observed at doses ≥600 mg; 3/8 DLBCL (38%) and 3/6 FL (50%). **Conclusions:** ABT-199 monotherapy showed anti-tumor activity across the range of ABT-199 cohort doses for several NHL subtypes, most notably in MCL and WM. In DLBCL and FL, responses were observed at higher doses. Dose escalation is continuing to determine the MTD and RP2D. Clinical trial information: NCT01328626.

**8523 Poster Highlights Session (Board #3), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**U.S. Intergroup phase II trial (SWOG 1108) of alisertib, an investigational aurora A kinase (AAK) inhibitor, in patients with peripheral T-cell lymphoma (PTCL; NCT01466881).** *Presenting Author: Paul M. Barr, James P. Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY*

**Background:** AAK is a serine/threonine kinase that regulates the G2-M transition and centrosome separation during mitosis. Alisertib (MLN8237) is an oral AAK inhibitor active in aggressive lymphoma, with 4 of 8 T cell lymphoma pts responding in a phase II trial (Friedberg JCO 2013). This phase II study was conducted to further investigate the efficacy of alisertib in PTCL. **Methods:** Eligible pts with histologically confirmed relapsed/refractory PTCL had normal organ function, ANC ≥1500/mm$^3$ and platelets ≥75,000/mm$^3$. Pts received alisertib 50mg BID for 7d on 21d cycles. Tumors were evaluated for expression levels of AAK, ABK, Myc, Bcl2, PI3Kδ, and Notch1 and quantified by image analysis. **Results:** Of 42 pts accrued, 37 eligible pts had a median age of 62 (range 22-86). Histologies included PTCL not otherwise specified (NOS)(13), angioimmunoblastic (AITL)(9), transformed mycosis fungoides (MF) (7), adult T-cell lymphoma (ATLL) (4), anaplastic large cell (ALCL) (2) and extranodal NK/T-cell (NK/T) (2). With a median number of 3 (range 1-18) prior therapies, 3 pts had undergone a prior stem cell transplant and 20 were refractory to prior therapy. Grade 3 and 4 AEs in ≥ 5% of pts included neutropenia (30%), anemia (27%), thrombocytopenia (24%), febrile neutropenia (14%), mucositis (11%) and rash (5%). 6 pts discontinued therapy and 9 were dose reduced due to AEs. Treatment was discontinued most commonly for PTCL progression. 2 complete responses and 7 partial responses were observed for a response rate (ORR) of 24% (95%CI: 12-41%). Among the most common subtypes, (PTCL NOS, AITL and ALCL), the ORR was 33% (95%CI: 16-55%). Of 27 pts with available biopsies, 0 and 6 expressed AAK and ABK respectively. **Conclusions:** Alisertib has antitumor activity in PTCL, including heavily pretreated pts. Toxicities to date were manageable and reversible. An international randomized phase III trial is comparing alisertib to investigator's choice in PTCL. Support: NIH/NCI Cooperative Group Grants CA32102 and CA38926; CA21115; CA21946; and Takeda Pharmaceuticals. Clinical trial information: NCT01466881.

**A phase I trial of ublituximab (TG-1101), a novel glycoengineered anti-CD20 monoclonal antibody (mAb) in B-cell non-Hodgkin lymphoma patients with prior exposure to rituximab.** *Presenting Author: Owen A. O'Connor, Columbia University Medical Center/New York Presbyterian Hospital, New York, NY*

**Background:** Ublituximab (UTX) is a novel mAb targeting a unique epitope on the CD20 antigen, glycoengineered for greater ADCC than rituximab (RTX). A prior Phase I/Ib trial with UTX monotherapy in patients (pts) with relapsed/refractory (R/R) CLL reported an ORR of 45%. Herein we report the results of a Phase I/Ib trial of UTX in pts with RTX R/R B-cell lymphoma (BCL). **Methods:** Eligible pts have R/R BCL that was previously treated with RTX containing regimens, with ECOG PS < 3. 3+3 dose-escalation evaluated cohorts of 450, 600, 900, and 1200 mg. Select expansion cohorts have included R/R NHL and CLL pts. UTX is administered weekly x 4 doses in Cycle 1 for NHL pts and on days 1, 8, 15 in Cycles 1 & 2 for CLL pts (cycle = 28 days), with maintenance for all pts. Primary endpoints: Maximum Tolerated Dose (MTD) and Dose Limiting Toxicities (DLT). Secondary endpoints: PK/PD and Efficacy. **Results:** 32 pts were enrolled. 17 M/15 F with: Median age 68 yr (range 45-88); ECOG 0/1/2: 12/18/2; Median prior Tx = 3 (range 1-9); 72% with > 2 prior RTX therapies; and 41% were RTX refractory. No DLTs have been observed. Gr 3/4 AE's at least possibly related to UTX have been reported in 6/32 pts (19%) and include: neutropenia, anemia, weakness, and fatigue. Infusion related reactions requiring interruption occurred in 8/32 pts (25%); however, all pts received all planned infusions with an ave infusion time of ~90 min for dose 4 and later. PK/PD analysis is ongoing. As of Jan 2014, 29/32 pts are evaluable for response (Table). Median ALC depletion in CLL pts was 93% after 2 UTX infusions. Median PFS for all pts is 34 weeks (95% CI: 19, NA) with no observed progression in 16/29 pts (range 4 - 18 mo). **Conclusions:** Single agent UTX is well tolerated and active in RTX exposed patients. Responses were observed in 67% of CLL and 67% MZL pts with median PFS not reached for each group. 86% of pts achieved at least SD, including 100% of CLL, MZL and DLBCL pts. Studies are ongoing with UTX in combination with novel targeted agents (PI3K-δ and BTK inhibitors). Clinical trial information: NCT01647971.

**A phase 1b study in cutaneous T-cell lymphoma (CTCL) with the novel topically applied skin-restricted histone deacteylase inhibitor (HDAC-i) SHP-141.** *Presenting Author: Youn H. Kim, Stanford Cancer Institute, Stanford, CA*

**Background:** The efficacy of HDAC-i as systemic therapy in CTCL is well-established although adverse effects limit use. The topical hydroxamic acid HDAC-i SHP-141 is intentionally designed to maximize activity in skin but limit systemic exposure by rendering the drug inactive via endogenous serum esterases. **Methods:** A phase 1b multi-center, double-blind, placebo (PBO)-controlled, randomized trial in stage IA-IIA CTCL was conducted in the USA to assess safety, pharmacokinetic (PK), pharmacodynamic, and preliminary efficacy with SHP-141 applied twice daily to index lesions (maximum 5% BSA) for 28 days; last assessment was 42 days after start of drug. Eighteen patients were enrolled: 6 patients (5 SHP-141:1 PBO) at each escalating dose level (0.1%, 0.5%, 1.0%). In SHP-141 arms there were 3 patients with stage IA, 11 IB, and 1 IIA; PBO arm with 2 stage IA and 1 IB. **Results:** No DLTs, early discontinuations, serious adverse events (AEs) or systemic AEs were recorded; SHP-141 related events were predominantly CTCAE Grade 1 and limited to skin (Skin, SHP-141: 4/15, PBO: 1/3; 1 CTCAE Grade 2 dermatitis in SHP-141). Only SHP-141 patients had clinical objective response (OR; >50% improvement by CAILS) and incremental weekly CAILS improvement through dosing period (see Table). Time to OR occured as early as Day 7; 2 others at Day 21 with the last at Day 42. Based on CAILS subscore a significant reduction in lesion thickness for SHP-141 groups was measured. Skin biopsy histology confirmed increased dermal actetylation by staining with a specific acetyl–lysine antibody. PK results confirmed lack of SHP-141 peripheral blood exposure. **Conclusions:** This is the first skin-optimized topical HDAC-i with evidence of early clinical activity and without systemic HDAC-i related toxicity. Patients responded after few weeks of treatment; rapidity is not a typical feature of approved topical drugs for CTCL. SHP-141 may address an important unmet medical need in early stage CTCL by feasibly offering clinical benefits of a HDAC-i without safety concerns. Clinical trial information: NCT01433731.

| | SHP-141 | Placebo |
|---|---|---|
| Objective response at day 42 | 4(28%) | 0 |
| Reduction in thickened lesions at day 42 | 89% | 0% |
| Incremental improvement to day 28 | 6(40%) | 0 |

**8526 Poster Highlights Session (Board #6), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Preliminary findings from a phase I, multicenter, open-label study of the anti-CD37 antibody-drug conjugate (ADC), IMGN529, in adult patients with relapsed or refractory non-Hodgkin lymphoma (NHL).** *Presenting Author: Anastasios Stathis, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland*

**Background:** IMGN529 is a CD37-targeting ADC comprising a CD37-binding antibody conjugated to the maytansinoid anti-mitotic, DM1. CD37 is present on the surface of normal and malignant B lymphocytes. In preclinical studies, IMGN529 exhibits potent antitumor activity against NHL cells via direct inhibition, effector function and delivery of the maytansinoid payload. **Methods:** Study objectives are: determine the maximum tolerated dose/recommended phase 2 dose of IMGN529 in adult patients (pts) with relapsed or refractory NHL, and evaluate safety, pharmacokinetics, pharmacodynamics, and evidence of preliminary efficacy. IMGN529 is given intravenously on Day (d) 1 of each 21d cycle (C). **Results:** To date, 22 pts have been enrolled across four dose levels ranging from 0.1 to 0.8 mg/kg. NHL subtypes enrolled: 10 Follicular lymphoma (FL), 7 Diffuse large B-cell (DLBCL), 5 other. A reduction in lymphocyte count seen early after dosing (d 2) in the majority of pts suggests a CD37-mediated reduction in lymphocytes. One pt with DLBCL treated at 0.4 mg/kg, and 1 pt with FL treated at 0.2 mg/kg achieved partial remission in C 3 and C 5 respectively. Dose limiting toxicities (DLTs) consisted of grade (G) 4 neutropenia > 7 days (1pt) and G2 peripheral neuropathy (1pt) at 0.8 mg/kg and G3 febrile neutropenia (2 pts) at 0.4 mg/kg. Adverse events (AEs) of G3 or higher occurred in 8 pts; those reported in more than 1 pt were: neutropenia (5 pts) and febrile neutropenia (2pts). Four of these pts experienced transient, early onset (C1d2-4) G3 neutropenia which may be a manifestation of cytokine release. The protocol was amended to provide peri-infusional steroids as a prophylactic regimen and dose re-escalation is ongoing; 3 patients treated at 0.4 mg/kg have completed C 1 with no DLTs. Clinical trial enrollment is ongoing with additional data expected. Preclinical studies to investigate the mechanism of the transient neutropenia are underway. **Conclusions:** IMGN529, a CD37-targeting ADC, has demonstrated early evidence of clinical activity and has the potential to be a novel therapeutic for B-cell lymphoproliferative malignancies. Clinical trial information: 01534715.

**8527 Poster Highlights Session (Board #7), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**G-PCNSL-SG-1 randomized phase III trial of high-dose methotrexate with or without whole brain radiotherapy for primary central nervous system lymphoma: Long-term follow-up.** *Presenting Author: Agnieszka Korfel, Department of Hematology and Oncology, Charité Campus Benjamin Franklin and Mitte, Berlin, Germany*

**Background:** The role of whole brain radiotherapy (WBRT) in first-line therapy of primary CNS lymphoma (PCNSL) has been increasingly questioned. This is the final report of the G-PCNSL-SG-1 trial evaluating WBRT in primary therapy of PCNSL after a median follow-up (MFU) of 81.2 months. **Methods:** G-PCNSL-SG-1 (www.clinicaltrials.gov NCT00153530) had randomised immunocompetent patients with newly diagnosed PCNSL to high-dose methotrexate (HDMTX) - based chemotherapy (CHT) followed by WBRT or CHT alone. We hypothesized that the omission of WBRT from first-line treatment would not compromise overall survival (OS; primary endpoint), using a non-inferiority design with a margin of 0.9. **Results:** Of 551 patients who entered the study 524 fulfilled the eligibility criteria (primary eligibility population), 410 entered the post-HDMTX phase (intention-to-treat, ITT population), and 320 were treated per protocol (PP). OS with *versus* without WBRT was different neither in the ITT (HR 0.997, 95%CI 0.79-1.26, p=0.98) nor in the PP population (HR 1.03, 95%CI 0.79-1.35, p=0.82). In the ITT population CR patients experienced neither a progression-free survival (PFS) benefit from the last HDMTX-based CHT (PFS-2) (HR 0.84, 95% CI 0.60-1.19, p=0.33) nor an OS benefit (HR 1.13, 95% CI 0.77-1.66, p=0.53) with WBRT. In CR patients of the PP population, WBRT conferred a benefit for PFS-2 (HR 0.68, 95%CI 0.46-1.01, p=0.059), but no OS benefit (HR 1.06, 95%CI 0.69-1.63, p=0.78). In non-CR patients of the ITT population, a benefit of PFS-2 (HR 0.58, 95%CI 0.44-0.77, p<0.001), but not of OS (HR 0.86, 95%CI 0.64-1.16 p=0.32) was found with WBRT; in non-CR patients of the PP population, WBRT conferred a benefit of PFS-2 over CHT alone (HR 0.41, 95%CI 0.29-0.57, p<0.001) and a trend for OS, too (HR 0.76, 95%CI 0.54-1.08, p=0.12). **Conclusions:** Despite improvement in PFS, particularly in patients without CR to HDMTX-based CHT, no significant difference in OS was found when WBRT was omitted from primary therapy in this long-term follow-up. The PFS afforded by WBRT has to be balanced against its long-term toxicity. Clinical trial information: NCT00153530.

**8528 Poster Highlights Session (Board #8), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**10-year remission rates following rituximab (R) and FND chemotherapy (fludarabine, mitoxantrone, dexamethasone) with interferon (IFN) maintenance in indolent lymphoma: Results of a randomized study.** *Presenting Author: Loretta J. Nastoupil, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Between 1997-2002, we conducted a randomized trial for patients (pts) with previously untreated stage IV small lymphocytic (SLL), marginal zone (MZL), or follicular lymphoma (FL), with the primary aim to compare concurrent FND+R versus sequential FND followed by R. This is the final analysis with mature data. **Methods:** Patients were randomized to 6 doses of R given during the first 5 of 8 courses of FND, or monthly during IFN maintenance following FND. We now report response rates, progression free survival (PFS), overall survival (OS), and adverse events (AE) including secondary malignancy with nearly 12 years of follow up. **Results:** Of the 157 pts, 18% had SLL, 11% MZL, and the remaining 71% had FL. 80 pts received concurrent FND+R, 77 sequential. Pts on the 2 arms were comparable in terms of prognostic features (FLIPI components). Median age for all pts was 54 years, 54% were female, 90% had bone marrow involvement, 80% had intermediate or high FLIPI score, 68% had high tumor burden. With a median follow up of 11.8 years, response rates, PFS, and OS were similar between the two groups and are included in the table below. Most AEs were hematologic, grade ≥3 neutropenia in 76%, thrombocytopenia 24%, and anemia in 13%. There was slightly more neutropenia with FND+R, but no excess infection or neutropenic fever. Non-hematologic AEs were mostly grade 1/2: 46% fatigue, 33% nausea, 31% alopecia, 18% neuropathy, and 18% infection (8% grade ≥3 infection). Six pts (4%) developed MDS/AML. **Conclusions:** With mature data, this large frontline study of FND with either concurrent or sequential R, and IFN maintenance in advanced stage indolent lymphoma demonstrated high complete response rates, robust PFS and OS. Determining the curative potential for this highly effective therapy will require further follow up. Concerns about tolerability and the incidence of secondary malignancy may impact treatment decisions. Clinical trial information: NCT00577993.

**Randomized, phase 3 trial of inotuzumab ozogamicin plus rituximab (R-InO) versus chemotherapy for relapsed/refractory aggressive B-cell non-Hodgkin lymphoma (B-NHL).** *Presenting Author: Nam H. Dang, University of Florida, Gainesville, FL*

**Background:** InO is an anti-CD22 antibody conjugated to calicheamicin; R-InO has shown activity in pts with relapsed/refractory aggressive B-NHL in a phase 1/2 study (Fayad, *J Clin Oncol* 2013; 31, 573-583: ORR, 74% and 20% for relapsed and refractory pts, respectively). **Methods:** This randomized, phase 3 trial (NCT01232556) compared efficacy and safety of R-InO (R 375 mg/m$^2$ IV–day [d] 1; InO 1.8 mg/m$^2$ IV–d 2 [each cycle]; 28 d cycles) vs investigator's choice (IC: R-bendamustine [R-B: R 375 mg/m$^2$ IV–d 1, B 120 mg/m$^2$–d 1 and d 2 each cycle] or R-gemcitabine [R-G: R 375 mg/m$^2$ IV–d 1, 8, 15, 22 cycle 1, d 1 all other cycles; G 1000 mg/m$^2$–d 1, 8, 15 each cycle]) in adults with relapsed/refractory CD22+ aggressive B-NHL; not candidates for high-dose chemotherapy. Endpoints were OS (primary), PFS, ORR (CR + PR); safety. A planned interim analysis based on 108 events (~40% of planned OS events) was conducted in May, 2013 when enrollment was stopped for futility. We present preliminary results for all enrolled pts. **Results:** 338 pts were enrolled (age ≥65 y, 68%; DLBCL, 91%; sIPI [≥4], 24%; best prior response of progressive disease [PD], 28%; previous time-to-progression ≥12 mo, 32%). See Table for efficacy results. Most common AEs (R-InO vs IC): thrombocytopenia (59% vs 37%), neutropenia (32% vs 47%), nausea (29% vs 33%), fatigue (33% vs 25%), and leukopenia (21% vs 31%). 2 R-InO pts had venoocclusive disease (VOD) on study treatment (1 additional pt had VOD after an allotransplant and ~13 mo after 1 R-InO dose). Treatment-related death occurred in 6 pts (4 R-InO, 2 IC). Among R-InO vs IC pts, 28% vs 15% discontinued due to AEs; 53% vs 57% due to PD. **Conclusions:** Although R-InO activity was observed, there was no statistical difference in ORR, PFS, or OS between R-InO vs IC treated pts. R-InO was not superior to IC among subgroups analyzed to date (to be presented). Poorer outcomes in this phase 3 study vs the phase 1/2 study may reflect more refractory pts in this study. Clinical trial information: NCT01232556.

**Updated results of the FOLL05 phase III trial from the Fondazione Italiana Linfomi comparing R-CVP, R-CHOP, and R-FM in patients with advanced follicular lymphoma.** *Presenting Author: Stefano Luminari, Department of Diagnostic, Clinical and Public Health Medicine, University of Modena and Reggio Emilia, Modena, Italy*

**Background:** The final results of FOLL05 for the initial therapy of advanced stage follicular lymphoma (FL) were recently reported with a median follow–up of 34 months. This trial showed that R–CHOP and R–FM were superior to R–CVP in terms of 3–year time to treatment failure (TTF), the primary study endpoint, and that R–CHOP had a better risk/benefit ratio compared with R–FM. Here, we present the 5–year follow–up analysis of progression free survival (PFS) of the 504 patients included in the study. **Methods:** Patients were 18–75 year old, with untreated stage II–IV FL, ECOG performance status of 0–2, and active disease according to the Italian Society of Hematology guidelines. They were randomly assigned to receive 8 doses of rituximab associated to 8 cycles of CVP, or 6 cycles of CHOP or FM. Maintenance was not admitted. **Results:** The median follow–up was 56 months (range 1–90). The overall 5–year TTF was 52% (95%CI, 47–56%). R–CHOP and R–FM had a better TTF compared to R–CVP (56% and 56% vs 43% at 5–years; p= 0.007 and p=0.017, respectively). Regarding PFS a total of 215 events were recorded, thus determining a 5–year PFS of 56% (95%CI, 52-61%). Compared to initial report 31 additional events for PFS were observed and were mainly represented by lymphoma relapses (80%). Better PFS rates were observed for R–CHOP and R–FM compared to R–CVP (62% and 60% vs 47% at 5–years). After adjustment by FLIPI, and using R–CVP as reference, HRs for PFS were 0.66 for R–CHOP (95%CI, 0.47–0.92; p=0.013), and 0.71 for R–FM (95%CI, 0.52–0.98; p=0.035); the HR between R–FM and R–CHOP was 1.08 (95%CI, 0.76–1.52; p=0.677). Considering additional events reported during the follow–up, 27 second malignancies were recorded in all treatment arms: four in R–CVP, 9 in R–CHOP and 14 in R–FM (p=0.062; R–CVP vs R–CHOP, p=0.169; R–CVP vs R–FM, p=0.018). Finally with 47 recorded deaths the 5–year overall survival rate was 91% (95%CI, 87–93%). **Conclusions:** The 5–year update of the FOLL05 study, with mature data on PFS, confirms that R–CHOP has the best efficacy profile compared to R–CVP and R–FM for the initial treatment of patients with advanced FL. Clinical trial information: NCT00774826.

**8531 Poster Highlights Session (Board #11), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Long-term results of the phase III GITMO/FIL trial of CHOP-R versus R-HDS plus autograft in high-risk follicular lymphoma (FL) at diagnosis.** *Presenting Author: Corrado Tarella, Hematology Univ. Div. and Cellular Therapy, A.O. Ordine Mauriziano-Umberto I, Torino, Italy*

**Background:** Early results of a randomized phase III GITMO/FIL study (www.clinicaltrials.gov NCT00435955) comparing CHOP-R vs. R-HDS + ASCT as primary treatment in134 FL pts, aged ≤60 yrs with aaIPI>1/IIL score>2, showed superior disease control with R-HDS but no OS advantage (Ladetto et al, Blood 2008). We here present an updated analysis from July 2013 at a median follow-up (MFU) of 9.5 yr including 125 pts of 134 originally randomized pts (61 CHOP-R/64 of R-HDS). **Methods:** Clinical features (CF) and treatment schedules have been already reported. Briefly, median age was 51 yrs. (22-60), M/F ratio 74/51, aaIPI 2-3 90%, retrospective FLIPI >2 60%, high LDH 49%, bulky disease 62%, B-symptoms 45%, BM+ 86%. CF were balanced among the two arms. Analysis was intention to treat and EFS the primary endpoint. Minimal residual disease was done by nested and RQ-PCR. **Results:** CR rate was 70.4% (57% with CHOP-R and 83% with R-HDS, p < .001); 64% patients achieved a Molecular Remission (MR). At MFU, 88 patients (70.4%) are alive. 19 pts died of lymphoma (CHOP-R:11; R-HDS: 8), 9 of second cancer (CHOP-R: 3; R-HDS: 6) and 9 for other causes, including 4 early toxic deaths. OS is 78% and 70% at 5 and 10 yrs, respectively. There was no difference in OS, with 5 and 10 yrs projections respectively of 75% and 70% for CHOP-R and 81% and 70% for R-HDS (p=0.96). Response to primary treatment had a major impact on OS, with 5 and 10 yr survival projections respectively of 90% and 80% for patients achieving CR, and of 49 and 43 for those with less than CR (p < .001). Similarly, MR achievement was associated with prolonged OS, with 5 and 10 yr survival projections respectively of 89% and 83% for patients achieving MR vs 76% and 57% for those remaining PCR-positive(p = .03). **Conclusions:** our results indicate that: i) 70% of high-risk FL now experiences a prolonged survival, being alive at 10 yrs; ii) the superior disease control of R-HDS does not translate in any OS advantage, iii) achieving CR and MR is crucial for long-term OS; iv) progression remains the major cause of death, though a major toll is paid to secondary neoplasms, particularly AML. Clinical trial information: NCT00435955.

**8532 Poster Highlights Session (Board #12), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase I trial of SAR650984, a CD38 monoclonal antibody, in relapsed or refractory multiple myeloma.** *Presenting Author: Thomas G. Martin, University of San Francisco, San Francisco, CA*

**Background:** SAR650984 (SAR) is a naked humanized IgG1 monoclonal antibody that binds to the CD38 receptor. SAR kills tumor cells via ADCC, CDC, direct apoptosis without secondary crosslinking and allosteric inhibition on CD38 enzymatic activity. Data on relapsed /refractory multiple myeloma (RRMM) patients (pts) in the dose escalation phase of the study are reported. (NCT01084252). **Methods:** SAR was given IV weekly (QW) or every 2 weeks (Q2W). Dose levels (DL) 0.3, 1, 3, 5, 10 and 20 mg/kg Q2W and 10 mg/kg QW using the classic 3+3 design were evaluated. **Results:** 35 pts with RRMM were treated; median age 64 yrs (40-76); median lines of therapy were 6 (2-14), 34/35 received an IMiD and a proteasome inhibitor (57% had carfilzomib (C) and/or pomalidomide (P). MTD was not reached at any DL. Adverse events in ≥ 10% of pts at all DL, regardless of causality, were fatigue (48.6%), nausea (34.3%), pyrexia (28.6%), anemia (28.6%), cough (25.7%), headache (25.7%), upper respiratory infection and chills (22.9%), dyspnea (20%), constipation (17.1%), diarrhea and vomiting (14.3%) and bone pain, chest discomfort, muscle spasms, thrombocytopenia and hypokalemia in 11.4% of pts. SAR related ≥ G 3 adverse events included pneumonia (n = 3), with hyperglycemia, hypophosphatemia, pyrexia, apnea, fatigue, thrombocytopenia and lymphopenia in 1 pt each. Investigator assessment by EBMT response criteria (ORR ≥ PR) among 34 evaluable pts was 24% (CR n = 2, PR n = 6). Responses occurred at all DL ≥ 1 mg/kg. Clinical benefit response (≥ MR) was 29% with 41% SD. In the ≥10 mg/kg cohort ORR was 33% (n =6/18) and CBR was 39% (n =7/18). The time to response was 4.6 weeks and time on treatment was 9.9 weeks (2-81). 10 pts remain on treatment. The expansion cohort dose was selected based on efficacy, safety, and receptor occupancy data. **Conclusions:** The MTD of SAR was not reached. SAR demonstrates encouraging and durable single agent efficacy in heavily pretreated RRMM pts, including those with prior (C) and (P) and warrants further evaluation. Clinical trial information: NCT01084252.

**Safety and efficacy of daratumumab with lenalidomide and dexamethasone in relapsed or relapsed, refractory multiple myeloma.** *Presenting Author: Torben Plesner, Vejle Hospital, Vejle, Denmark*

**Background:** Daratumumab (DARA) (HuMax-CD38), a human IgG1κ monoclonal antibody effectively mediates destruction of CD38-expressing malignant plasma cells. In the first-in-human dose-escalation study, 42% of heavily pretreated patients with relapsed or relapsed, refractory (RR) multiple myeloma (MM) treated with DARA alone (≥4mg/kg) achieved partial response (PR) and 25% had minimal response (MR) (modified IMWG guidelines). In preclinical studies, DARA + lenalidomide (LEN) enhanced killing of MM cells in vitro.We evaluated safety, pharmacokinetics (PK) and efficacy of DARA + LEN + dexamethasone (DEX) in patients with relapsed or RR MM. **Methods:** In this ongoing phase I/II open-label multicenter dose-escalation (part 1) study, patients (≥ 18 years old) with life expectancy ≥3 months and ECOG status 0, 1 or 2 received DARA+LEN+DEX: (DARA [2-16 mg/kg] per week [8 wks], twice a month [16 wks], then, once monthly until disease progression, unmanageable toxicity or ≤24 months; LEN [25 mg]; DEX [40 mg] once weekly). Cohort expansion (part 2) study explores testing of maximum DARA dose determined in part 1. **Results:** Data from 12 patients (10 men, 2 women), median age 62 years (48-76) are evaluable to date. Median prior therapies: 4 (2-4); median ECOG status: 0.5 (0-1); median DARA infusions: 14.5 (1-23); median infusion time: 6.6 (5.9-7.3) hours. One patient (2 mg/kg dose) withdrew from study due to recurrent grade 1 QT prolongation and hypokalemia. Most frequent (>40% patients) adverse events were neutropenia and diarrhea; 17 were ≥ grade 3 with 70% hematological (neutropenia, thrombocytopenia, anemia). MTD was not reached. DARA+LEN+DEX PK-profile was similar to DARA alone suggesting LEN and DEX do not affect the DARA PK-profile. Available efficacy data from 11 patients demonstrated marked decrease in M-protein in all patients; 8/11 patients achieved PR or better, 5/11 with VGPR, 2/11 with MR. Median time to response was 4.1 weeks (2.1-4.3). **Conclusions:** DARA+LEN+DEX has favorable safety profile with manageable toxicities in relapsed and RR MM. Encouraging early activity is seen with marked reduction in M-protein and 8/11 patients (72%) achieving PR or better. Part 2 data will be presented. Clinical trial information: 2011-005709-62.

**8534 Poster Highlights Session (Board #14), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Preliminary safety and efficacy of TH-302, an investigational hypoxia-targeted drug, and dexamethasone (dex) in patients (pts) with relapsed/refractory multiple myeloma (RR MM).** *Presenting Author: Jacob Laubach, Dana-Farber Cancer Institute, Boston, MA*

**Background:** While alkylators, IMiDs and proteasome inhibitors are current standard treatment for pts with MM, the presence of hypoxia in the diseased bone marrow (Colla, *Leukemia* 2010) presents a new therapeutic target for MM. TH-302 is a novel 2-nitroimidazole prodrug of the DNA alkylator bromo-isophosphoramide mustard that is selectively activated under hypoxia. Synergistic induction of apoptosis in MM cells by TH-302 and bortezomib was shown in MM models *in vivo* and *in vitro* (Hu et al, *Mol Cancer Ther* 2013). An ongoing Phase 1/2 study investigates TH-302 with dex in RR MM. In the dose-escalation stage of the study, the maximum tolerated dose (MTD) of biweekly TH-302 was established at 340 mg/m$^2$ and preliminary activity was reported based on the modified IMWG guidelines (Ghobrial et al., ASH 2013). The 340 mg/m$^2$ plus dex expansion arm is ongoing. **Methods:** The Phase 1/2 open-label multicenter study investigates IV TH-302 (240-480 mg/m$^2$) plus PO dex (40 mg) on Days 1, 4, 8 and 11 of a 21-day cycle. At the MTD, a Simon two-stage minimax design was implemented to pursue a regimen with ≥25% response rate or discontinue if ≤5% (90% power, 10% alpha). **Results:** 16 pts (11 male, 5 female) were enrolled through completion of the initial stage of the Simon design, including 9 at the MTD. Median prior therapies was 6 (3 – 11) and median age 60 years (53 – 86). All had previously received both bortezomib and lenalidomide/thalidomide containing regimens and an alkylating agent. The most common ≥Gr 3 AEs were thrombocytopenia (44%) and leukopenia (38%). Dose limiting Gr 3 stomatitis was only reported in the 480 mg/m$^2$ cohort. 7 pts had SAEs, 6 of which were related to TH-302, including 3 pts with pneumonia. The pre-specified target for response for the initial 9-pt Simon stage at the MTD was achieved with 1 PR, 2 MRs, 4 SDs, 1 PD and 1 NA. To date, 15 of 24 pts have been enrolled to evaluate safety and efficacy at the MTD. **Conclusions:** TH-302 can be administered at 340 mg/m$^2$ biweekly with dex. Preliminary clinical activity has been noted in pts with heavily pre-treated RR MM. Data from pts in the Simon two-stage treated at the MTD will be updated and presented at the meeting. Clinical trial information: NCT01522872.

**8535^ Poster Highlights Session (Board #15), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase I study of carfilzomib, lenalidomide, vorinostat, and dexamethasone (QUAD) in relapsed and/or refractory multiple myeloma (MM).** *Presenting Author: David H. Vesole, John Theurer Cancer Center, Hackensack, NJ*

**Background:** Carfilzomib in combination with an immunomodulatory agent has proven efficacy in NDMM and RRMM. There is also synergistic activity of the combination of a proteasome inhibitor and a histone-deacetylase inhibitor **Methods:** To determine the toxicity and activity of the quadruplet using carfilzomib with lenalidomide, vorinostat and dexamethasone. The primary objectives were to determine the maximum tolerated dose (MTD) and the safety/tolerability of QUAD. Secondary objectives included ORR, DOR, TTP and TTNT. All patients had relapsed or RRMM after at least one line of Tx. Tx consisted of 28-d cycles of lenalidomide d 1-21, vorinostat d 1-7 and 15-21, IV carfilzomib d 1, 2, 8, 9, 15 and 16 and IV/po dexamethasone 40 mg q wk. A standard 3+3 dose escalation schema to determine DLTs occurring in Cycle 1. AEs were graded using the NCI-CTCAE v3. Response was assessed by the modified IMWG criteria. **Results:** As of January 20, 2014, 21 pts have been enrolled: 1 patient was replaced due to inability to complete Cycle 1 due to AE. Pt characteristics included: median age 61 yrs (range 48-71), 57% male, median # of prior regimens: 3 (range 1-9), median time from Dx: 4 years. All pts had prior autotransplant, 20 bortezomib, 20 lenalidomide and 4 vorinostat. AEs were experienced by 100% of pts including: anemia (16), fatigue (11), thrombocytopenia (14), neutropenia (12), muscle cramping (10) and diarrhea (9). 15 pts experienced ≥ grade 3 AEs: neutropenia (9), anemia (7), thrombocytopenia (9), infection (2), electrolyte imbalances (2), hyperglycemia (3), fatigue (1) constipation (1) and 1 death from progressive disease (PD). No DLTs were observed. The ORR was 53% and the CBR was 82%. 2 patients had PD as best response. 9 pts discontinued due to PD, 1 pt choice and 1 pt due to toxicity. 3 pts have completed 18 cycles. **Conclusions:** QUAD is well tolerated in both relapsed and RRMM pts with no DLTs identified. The safety profile is manageable. The ORR of 53% and CBR of 82% are encouraging; the PFS is 12 months and OS not reached. Clinical trial information: NCT01297764.

**8536 Poster Highlights Session (Board #16), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase I trial of pomalidomide (P) in patients (pts) with relapsed and/or refractory (R/R) Waldenström's macroglobulinemia (WM).** *Presenting Author: Sheeba K. Thomas, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Thalidomide, and its analog, lenalidomide have shown activity in WM, when combined with rituximab. However, neuropathy and anemia respectively, have limited their use. P is a newer generation IMID® which has demonstrated efficacy and tolerability in R/R multiple myeloma. These results provided the rationale for a phase I study of P in pts with R/R WM. **Methods:** Eligible pts had WM that was R/R to ≥ 1 prior therapy. All pts received daily oral P (28d cycles), starting at a 1mg dose level. Following a 3+3 statistical design, the dose was increased by 1 mg increments until the MTD was reached. Overall response was assessed as per International WM Working Group Response Criteria. **Results:** Between 10/2010-01/2014, 9 pts (7 males, 2 females) were treated. Median age at enrollment was 64 yrs (range 51-85), median time from 1$^{st}$ therapy was 6.1 yrs (range 2.0-16.3), and median prior therapies was 2 (range 1-5). With a median f/u of 30 mos. (range: 6-36), 8 pts remain alive, and 1 continues to receive therapy. At 1 mg, no DLTs were seen, and pts received a median of 6 cycles (range: 4-12+). At 2 mg, 2 pts experienced DLTs, including dizziness (Gr 4) and syncope (Gr 3) in 1 pt and grade 4 neutropenia in 1 pt. A 3$^{rd}$pt withdrew after experiencing mild fever, headaches and blurred vision starting on day 4 of cycle 1. Fever and headache resolved with stopping P; blurred vision resolved after plasma exchange. Other grade 3-4 adverse events (AEs) included neutropenia (3 pts) and infection (knee joint, 1 pt). Gr 1-2 AEs include fatigue (6), rash (5), diarrhea (4), nausea/emesis (4), edema (3), myalgias (3), blurred vision (2), peripheral neuropathy (2), dyspnea (2), constipation (2), headache (2), dizziness (2), mucositis (1), infection [otitis media (1);URI –(3)], rash(1), pruritus (1), and night sweats (1). Among 8 evaluable pts, 2 had minor responses, 3 had stable disease (SD), and 3 had progressive disease as best response. **Conclusions:** The MTD of single agent P is 1 mg/day in pts with R/R WM. P provided ≥ SD in 63% of pts, suggesting that combinations with other effective agents should be studied. Abbreviated dosing schedules, such as d1-21 q28d may permit recovery of cytopenias between cycles, facilitating such combinations. Clinical trial information: NCT01198067.

**8537 Poster Highlights Session (Board #17), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Optimizing induction and pretransplant consolidation for myeloma: Results of Myeloma XI, a phase III trial comparing different IMiDs.** *Presenting Author: Charlotte Pawlyn, Centre for Myeloma Research, Institute of Cancer Research, London, United Kingdom*

**Background:** Treatment with immunomodulatory agents (IMiDs) and proteasome inhibitors (PIs) has dramatically increased response rates and survival for myeloma patients over the last decade. Triplet drug combinations are more effective than doublets or single agents. The more recently developed IMiD lenalidomide, with a different spectrum of effects to thalidomide, is an excellent option for induction therapy due to its oral administration and lack of significant peripheral neuropathy (PN) when compared with bortezomib and thalidomide. **Methods:** Myeloma XI, a phase III randomised trial for newly diagnosed patients of all ages, compared induction treatment with cyclophosphamide/lenalidomide/dexamethasone (CRD) to cyclophosphamide/thalidomide/dexamethasone (CTD) given to max. response or intolerance. To evaluate the role of pre-transplant consolidation with a PI we randomised patients achieving <VGPR to additional cyclophosphamide/bortezomib/dexamethasone (CVD) vs nothing. Fit patients went on to receive melphalan+ASCT. Recruitment is now complete. **Results:** Results are available for a total of 1939 patients, 1104 intensive pathway (540 CRD vs 564 CTD, median age 61 yrs, range 28-75) + 835 non-intensive (411 CRDa vs 424 CTDa, median 74 yrs, range 51-89). 274 patients received additional bortezomib. The pre-planned ITT analysis of combined CR+VGPR rates shows a significant difference between CRD and CTD treatment on multivariate analysis in favour of CRD with odds ratio 1.27 (95% CI 1.06-1.52, p = 0.009). This is due to different CR rates (CRD: CR 25%, VGPR 30%, PR 26% vs CTD: CR 15%, VGPR 33%, PR 31%). Additional bortezomib therapy for those with a suboptimal response upgraded response in 51% demonstrating that PI therapy can be effective in patients intrinsically resistant to IMiDs. Treatment with both IMiDs was well tolerated. Patients on lenalidomide had lower rates of PN (≥ grade II CRD 1.9% vs CTD 6.3%, p<0.001) but higher rates of grade III/IV cytopenias. **Conclusions:** We have demonstrated an important difference in response between the IMiDs thalidomide and lenalidomide however further follow up is required to see whether this translates into prolonged PFS and OS. Clinical trial information: NCT01554852.

**8538 Poster Highlights Session (Board #18), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Randomized phase III trial of busulfan plus melphalan versus melphalan alone for multiple myeloma.** *Presenting Author: Muzaffar H. Qazilbash, Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** High-dose melphalan at 200 mg/m$^2$ (Mel) is the standard for autologous hematopoietic stem cell transplantation (auto-HCT) for multiple myeloma. Two recent retrospective analyses suggested that a combination of busulfan and melphalan (Bu-Mel) may be associated with a longer progression-free survival (PFS). In this randomized phase III trial we compared the safety and efficacy of Bu-Mel vs. Mel. **Methods:** Patients were randomized to either Bu-Mel or Mel. In the Bu-Mel arm, Bu 130 mg/m$^2$ was infused daily for 4 days, either as a fixed dose, or to target an average daily area under the curve of 5000 $\mu$mol-min, followed by 2 daily doses of Mel at 70 mg/m$^2$. The primary endpoint was day +90 CR (IMWG criteria) rate. Secondary endpoints were 100-day treatment-related mortality (TRM) and grade 3-4 non-hematologic toxicity. Log-rank test was used to compare PFS and OS by treatment arm. **Results:** Ninety-two patients (Bu-Mel: 49, Mel: 43) were enrolled between October 2011 and August 2013. Median ages at auto-HCT were 58.4 and 58.5 years in Bu-Mel and Mel arms, respectively (p=0.75). Ten (20%) and 11 (26%) patients had high-risk chromosomal abnormalities in Bu-Mel vs. Mel, respectively (p=0.62). Forty-four (90%) and 40 (93%) patients received bortezomib-based induction therapy in the Bu-Mel and Mel, respectively (p=0.71). At the time of auto-HCT, 8/0 (18%) and 7/3 (23%) patients were in CR/near (n)CR in Bu-Mel and Mel arms, respectively (p=0.44), Grade 3-4 non-hematologic toxicity was seen in 41 (84%) and 20 (47%) patients in Bu-Mel and Mel, respectively (p=0.0003). There was no 100-day TRM in either arm. At day 90, 8 (18%) and 15 (35%) patients had achieved a CR (p=0.05), and 13 (27%) and 20 (47%) patients had achieved a CR + nCR (p=0.05) in Bu-Mel and Mel, respectively. All 49 patients in Bu-Mel and 43 in Mel had started maintenance therapy after day 90. Median follow up was 11.7 months (range 0.7-24.6), One-year PFS was 93% and 82% (p=0.26), and 1-year OS was 100% and 100% in Bu-Mel and Mel arms, respectively. **Conclusions:** Bu-Mel was associated with a significantly lower day 90 CR rate and a significantly higher rate of grade 3-4 non-hematologic toxicity, compared to Mel. A longer follow up is needed to evaluate the impact of Bu-Mel on PFS. Clinical trial information: NCT01413178.

**8539 Poster Highlights Session (Board #19), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Individualized therapy of relapsed or refractory myeloma with targeted agents.** *Presenting Author: Christoph Johann Heuck, Myeloma Institute for Research and Therapy, Little Rock, AR*

**Background:** Diagnostic and therapeutic advances have improved the outcomes for multiple myeloma (MM) patients (pts). However, pts who are refractory to or relapse after therapy with immune modulatory drugs and proteasome inhibitors remain a therapeutic challenge. Next generation sequencing (NGS) studies of MM cells have revealed multiple targetable mutations that were previously unexploited in MM. We now report on the use of NGS to individualize MM therapy. **Methods:** Between 4/2013 and 12/2013 we performed genomic profiling of 115 pts who had failed at least 3 lines of therapy. Cancer associated genes were sequenced to an average depth >500x using a clinical NGS-based assay (FoundationOne). Pts with activating mutations of KRAS, NRAS or BRAF were considered for therapy with the targeted agents trametinib (TMTB), dabrafenib (DBFB) or vemurafenib (VMFB). **Results:** Among the 115 pts we identified 44, 24 and 12 with activating mutations of KRAS, NRAS and BRAF, respectively. 32 pts were treated with TMTB, 2 with DBFB and one with VMFB. The median age was 63 and pts had a median of 4 lines of prior therapy (range 1-11). 23 of 35 pts had prior treatment with Total Therapy. Prior to starting targeted therapy 23 pts had GEP defined high-risk disease (mean GEP70 0.94) and 10 had PET defined extra medullary disease (EMD). 20 pts were administered drugs as single agent and 15 received the in combination with other drugs. Treatment was interrupted due to drug related adverse events (AE) in 4 pts and resumed with dose reduction in 3/4. Seven discontinued therapy because of progressive disease and 2 due to AE unrelated to targeted therapy. Treatment resulted in SD in 10, PR in 5 and CR/nCR in 3 of the 35 pts. For pts with available GEP data, treatment resulted in an average reduction of the GEP70 score by 0.33. For patients with evaluable PET data treatment resulted in complete resolution of bone or EMD lesions in 8/20 and 3/10 cases, respectively. **Conclusions:** Targeted therapy guided by NGS genomic analysis of cancer associated genes in this heavily pretreated population of MM patients resulted in an unexpectedly high objective response rate. Observation of CR with single agent therapy alone support further investigation of this individualized approach to MM therapy.

**8540 Poster Highlights Session (Board #20), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Ikaros expression levels to predict response and survival following pomalidomide and dexamethasone in multiple myeloma (MM).** *Presenting Author: Yuan Xiao Zhu, Mayo Clinic, Scottsdale, AZ*

**Background:** Cereblon (CRBN) binding mediates immunomodulatory drug (IMiD) action in MM. **Methods:** We identified CRBN binding proteins in the presence or absence of IMiD and examined the clinical significance of binding proteins. **Results:** The abundance of 46 CRBN binding proteins deceased after IMiDs and the most downregulated proteins include Ikaros transcription factors IKZF1 and IZKF3 (recently identified as rapidly downregulated subsequent to cereblon-IMiD interaction). We then explored the clinical significance of IKZF1/IKZF3 in MM. IZKF gene expression was similar across all MM stages or subtypes however on western blot in a subset of IMiD resistant cell lines IKZF1 is substantially lower. Genetic mutation in *IZKF1/3* is observed in < 1% of MM patients however 6/69 MM cell lines (8.7%) have nonsynonymous SNVs including a L208R substitution and codon deletion in the FR4 cell line which has very low levels of IZKF1 and is highly IMiD resistant. Recurrent SNV at Q156K (XG1 and H1112) and at G158R in OCI-MY7 all occur within the critical binding domain of IZKF1/ IZKF3 to CRBN. The significance of the Q156K SNV is unknown as XG1 cells are sensitive to IMiDs. Next, we analyzed *IKZF1* and *IKZF3* expression levels in 55 refractory MM patients in whom gene expression was measured prior to pomalidomide and dexamethasone therapy on phase II clinical trials. Responders were defined as ≥ PR after 2 cycles of treatment. We determined the quartile cut-off points for *IKZF1* expression (for all MM patients) to be 7.6, 8.1 and 8.48, respectively. Response rate was 6% in the lower quartile of *IKZF1* expression vs. 39% in the highest 3 quartiles ($P$ = 0.02). *IKZF3*, *IKZF4* and *IKZF5*, had no difference in expression in responding patients. We demonstrate that *IZKF1* levels also correlate with significant differences in progression free survival (3.0 vs. 13 months (m), p < 0.005) with the longest PFS in the highest expression cohort. The median OS for patients with highest 2 quartile *IZKF1* expression was 46.6 m and 31.7 m respectively, whereas patients in the lowest quartile had only 7.2 months median OS (p=0.002). **Conclusions:** IKZF1 binds CRBN and measured prior to pomalidomide therapy is a biomarker for response, PFS and OS.

**8541 Poster Highlights Session (Board #21), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Utility of restaging bone marrow biopsy (BMB) in PET-negative patients with diffuse large B-cell lymphoma (DLBCL) with bone marrow involvement.** *Presenting Author: Amie Elissa Jackson, Mayo Clinic, Rochester, MN*

**Background:** Less than 10% of DLBCL patients have stage IV disease with BM involvement at diagnosis. For these patients, restaging BMB is required to document complete remission (CR). In addition to cost, BMB is a potential source of anxiety and pain for patients. PET-CT is the standard for response assessment in DLBCL and may accurately detect BM involvement at diagnosis (Khan 2013). This raises the question of whether BM assessment on restaging PET-CT could obviate the need for repeat BMB. **Methods:** This was a single institution, retrospective cohort study. After IRB approval, patients with DLBCL and a positive BMB at diagnosis were identified from the Mayo Clinic Lymphoma Data Base. The concordance of BM status on restaging histopathology and PET-CT reports and the positive (PPV) and negative predictive value (NPV) of PET-CT were determined. Findings were validated in a prospective cohort of 68 DLBCL patients treated on an ongoing phase II clinical trial of frontline lenalidomide and RCHOP (R2CHOP). **Results:** Between 2004 and 2013, 1080 patients with DLBCL were evaluated. Of those, 69 (6%) had DLBCL involving the BM at diagnosis. Forty-six patients completed frontline chemoimmunotherapy; 8 were lost to follow-up; and 15 did not complete therapy because of death or progression. Of 46 patients completing therapy, 31 had restaging PET-CT and BMB and were included in the analysis. The concordance between BMB and PET-CT was 100%. Thirty patients had a negative BM by PET-CT and BMB (29 CR; 3PR; 1PD). One patient had persistent BM involvement by biopsy and PET-CT. Thus, restaging PET-CT had 100% PPV and 100% NPV for assessing residual BM disease. In the validation cohort, four patients (6%) had DLBCL involving the BM at diagnosis. All had a negative BM by both restaging BMB and PET-CT. **Conclusions:** Compared with the gold standard of BMB, PET-CT had a 100% NPV to exclude residual BM disease in DLBCL patients after frontline therapy. These findings are being further studied in ECOG1412 testing RCHOP vs R2CHOP in untreated DLBCL. If further validated, DLBCL practice guidelines and response criteria could be modified so BMB is no longer required to document CR if the restaging PET-CT is negative.

**8542 Poster Highlights Session (Board #22), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Net antitumoral immunity and the predictive power of conventional prognosticators in diffuse large B-cell lymphoma.** *Presenting Author: Colm Keane, Princess Alexandra Hospital, Brisbane, Australia*

**Background:** Immunity represents a balance between immune-effectors and immune-checkpoints. In DLBCL, circulating lymphocyte:monocyte ratios are prognostic, implicating them as surrogate immune-effectors and immune-checkpoints within the tumor microenvironment (TME). Detailed assessment of blood would enable identification of the optimal TME immune-effector and monocyte/macrophage-checkpoints to assist sub-stratification of conventional prognosticators. **Methods:** Blood from 140 R-CHOP treated DLBCL patients in the NHL21 Australasian Leukaemia and Lymphoma Group trial were analysed. A circulating immune-effector: monocyte-checkpoint signature segregating interim-PET/CT positivity was identified. Intratumoral applicability was tested in two independent R-CHOP treated DLBCL cohorts, with cell-of-origin (COO) and international prognostic index (IPI) as co-variates. **Results:** Patient monocytes suppressed T-cell proliferation and NK-cell rituximab-ADCC. Both $CD14^{+}$ $HLA\text{-}DR^{lo}$ monocytoid-myeloid derived suppressor cells (moMDSC) and arginase activity were elevated ($P<0.0001$ and $P=0.0005$ respectively) and correlated with CD163 ($r=0.4$, $P<0.0001$ and $r=0.45$, $P=0.002$ respectively). $CD8^{+}$:$CD163^{+}$moMDSC ratios were highest in interim-PET/$CT^{-ve}$ patients ($P\leq0.0001$). Digital bar-coding in 191 DLBCL tissues demonstrated co-clustering of CD8 with immune-checkpoints (CD163/PD1/PDL1/PDL2/TIM3/LAG3, all $P<0.0001$), indicating an adaptive immune-checkpoint response to immune-effector activation. In 128 R-CHOP treated patients (median FU 3.9yrs), CD8:CD163 ratios (net anti-tumoral immunity) were prognostic, independent of IPI and COO. Combining CD8:CD163 ratio with the germinal centre B cell marker LMO2 (LMO2/CD8:CD163) strengthened the predictive ability. Results were externally validated in 233 R-CHOP patients, separating good-risk (0-2) IPI into two categories of 85% and 48% ($P=0.0003$), and poor-risk (3-5) IPI into 66% and 36% 4 year survival ($P=0.0007$). **Conclusions:** Net anti-tumoral immunity within the TME is a powerful new prognosticator, independent of IPI and COO in DLBCL. LMO2/CD8:CD163 adds to the predictive ability of IPI.

**8543 Poster Highlights Session (Board #23), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Role of surveillance imaging in the management of peripheral T-cell lymphomas.** *Presenting Author: Tiffany Pool Ling Tang, Weill Cornell Medical College, New York, NY*

**Background:** The role of routine surveillance imaging (RSI) in patients with peripheral T-cell lymphoma (PTCL) in first complete remission (CR1) is unclear. RSI offers the theoretical advantage of detecting asymptomatic relapses so that second line therapy may be initiated earlier. We investigated the proportion of PTCL relapses detected by RSI and those by clinical findings (C) such as abnormal symptoms, signs or raised LDH, and compared outcomes of these two groups. **Methods:** PTCL patients were identified through prospectively maintained T-cell lymphoma databases from the National Cancer Centre Singapore/Singapore General Hospital and Weill-Cornell Medical College. PTCL subtypes included were PTCL-NOS, AITL, ALCL (ALK positive and negative), EATL, GDT, HSTL and ATLL. Patients with leukemias, indolent, composite and cutaneous lymphomas were excluded. Patients who achieved CR1 and then relapsed were retrospectively reviewed and stratified according to whether the relapse was detected by RSI or by C. Fisher exact and Mann Whitney U test was used to compare the baseline characteristics such as age, stage, PTCL subtype, IPI and treatments between the 2 groups. Progression-free survival (PFS) and overall survival (OS) were compared using the log-rank test. **Results:** There were 427 patients in the combined database and 341 were included in the study. Of these, 145 patients achieved CR1 and 64 relapsed. Relapses were detected by C in 51, RSI in 9 and unknown in 4 patients. Regardless of method of detection, 93% had symptoms, 87% had signs and 76% had raised LDH at relapse. Three patients had no clinical evidence of relapse: 2 had AITL and 1 had NKTL. A median of 2 scans were performed in the first 12 months of CR1. Baseline characteristics and median RSI numbers were similar in both groups. After a median follow-up of 37 months (range 5-402), the median PFS was 19.6 months (range 5-381) in the C group and 14.5 months (range 8-38) in the RSI group ($p=0.740$). The median OS was 65 months (95% CI 36-88) in the C group and NR (95% CI 16-NR) in the RSI group ($p=0.652$). **Conclusions:** Our data suggests that most patients with PTCL in CR1 have abnormal symptoms, signs or raised LDH at relapse and RSI does not impact the detection. RSI does not appear to affect survival outcomes.

**8544 Poster Highlights Session (Board #24), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Value of surveillance studies for patients (pts) with stage I-II diffuse large B-cell lymphoma (DLBCL) in the rituximab (R) era.** *Presenting Author: Susan M. Hiniker, Stanford University Medical Center, Stanford, CA*

**Background:** The role of surveillance studies in early-stage DLBCL in the R era has not been well defined. The goal of this study is to evaluate the use of imaging (CT and PET-CT) scans and LDH in surveillance of patients with stage I-II DLBCL. **Methods:** A retrospective analysis was performed of pts who received definitive treatment (Rx) at Stanford from 2000-2013, using Kaplan-Meier analysis to compute estimates of overall survival (OS) and freedom from progression (FFP). **Results:** 162 pts with stage I-II DLBCL were treated with R-chemotherapy, radiation (RT), or combined modality therapy (CMT). 5-year OS and FFP were 80.7% and 81.5% respectively. 94/162 pts (58%) achieved a complete metabolic response on PET scan after completion of chemotherapy, and this was associated with superior FFP (HR 3.06, $p=0.003$). 128/162 pts (79%) were followed with at least one surveillance PET scan beyond end-of-treatment scans. 18/162 pts relapsed after initial response to Rx. Of these, 9 relapses were detected initially by surveillance imaging studies (8 PET, 1 CT), and 9 were detected clinically (5 by pt-reported symptoms, and 4 by both symptoms and physical exam). No relapses were detected by surveillance LDH. At the time of relapse, LDH was found to be elevated in 3/13 pts, all of whom had relapse detected clinically. Median duration from initiation of Rx to relapse was 14.3 mos (range 7.8 – 121.1 mos) among pts with relapses detected by imaging, and 59.8 mos (9.3 – 123.3 mos) among pts with relapses detected clinically ($p=0.077$). There was no significant difference in OS from date of first Rx or OS following relapse between pts whose relapse was diagnosed by imaging vs clinically. 13/18 pts were successfully salvaged; salvage Rx included chemotherapy alone (10 pts), hematopoietic cell transplant (4 pts), CMT (3 pts) and RT alone (1 pt). **Conclusions:** A complete response on PET scan immediately after initial chemotherapy is associated with superior FFP in stage I-II DLBCL. Use of PET scans as post-treatment surveillance imaging is associated with earlier diagnosis of relapse, but no OS advantage. LDH is not a sensitive marker for relapse. Our results argue for limiting the use of post-Rx surveillance studies in asymptomatic pts.

**8545 Poster Highlights Session (Board #25), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Frontline bortezomib and rituximab for the treatment of newly diagnosed high tumor burden (HTB) indolent non-Hodgkin lymphoma (iNHL): A multicenter phase II study.** *Presenting Author: Andrew M. Evens, Tufts Medical Center, Boston, MA*

**Background:** There is a deficiency of published data examining non-cytotoxic options for the frontline treatment of HTB iNHL. In addition, few HTB iNHL series have reported outcomes with long-term follow-up (ie, >3-4 years). **Methods:** All patients (pts) were required to have HTB by GELF criteria. Treatment in this multicenter phase II study consisted of 3 induction cycles of bortezomib (1.6 mg/m$^2$ weekly x 4) and rituximab (4 weeks cycle 1; 1 dose cycles 2 + 3) administered q35 days. This was followed by an abbreviated consolidation (ie, each drug once q 2 months x 4). All outcomes were analyzed by intent-to-treat. **Results:** 42 pts were enrolled and all were evaluable. Histologies were follicular lymphoma (FL) (n=33, 79%), marginal zone lymphoma (n=6, 12%), small lymphocytic lymphoma (n=2, 7%), and Waldenstroms (n=1, 2%). Pt characteristics included median age 62 years (40-86); 38% bulky disease (>7cm); 19% malignant effusions; 91% advanced-stage; and the median FLIPI was 3. Therapy was well tolerated with few grade 3/4 toxicities and minimal neurotoxicity. Grade 3 adverse events (AE) were fever (5%), infusion reaction (5%), infection (5%), cardiac (5%), fatigue (5%), diarrhea, hypokalemia and bowel obstruction (2% each); the only grade 4 AEs were neutropenia (5%) and thrombocytopenia (2%). There was no motor neuropathy noted, no grade 3 or 4 sensory neuropathy, and the rates of grade 1 and 2 sensory neuropathy were 14% and 2%, respectively. Overall response rate (ORR) at end of therapy was 70% with a 40% complete remission (CR) rate (FL: ORR 76%, CR 44%). With 50 month median follow-up, 4-year progression-free survival (PFS) was 44% with 4-year overall survival (OS) of 87% (FL: 44% and 97%, respectively). Four-year PFS for FLIPI 0-2 vs 3-5 were 60% vs 26%, respectively ($P$=0.02), with corresponding OS rates of 92% and 81%, respectively ($P$=0.16). Interestingly, 4-year OS was superior for FL compared with non-FL histologies (97% vs 43%, respectively, $P$=0.003). **Conclusions:** Altogether, bortezomib/rituximab is a targeted therapeutic regimen that was very well tolerated and resulted in long-term survival rates approximating prior HTB FL rituximab/chemotherapy series. Clinical trial information: NCT00369707.

**8546 General Poster Session (Board #233), Mon, 1:15 PM-5:00 PM**

**Chemotherapy or combined modality therapy for early-stage Hodgkin lymphoma: A comparative, population-based study.** *Presenting Author: Rajesh Shrestha, Memorial Hospital of Rhode Island, Pawtucket, RI*

**Background**: The choice between chemotherapy alone (Ct) and combined modality therapy (Ct with radiation, CMT) in early-stage Hodgkin lymphoma (HL) remains controversial. Identifying patients (pts) who could omit radiotherapy is an important research goal. We compared the two strategies using the National Cancer Data Base, which captures >70% of incident cancer cases in the United States. **Methods**: We extracted data on 20,600 pts with stage I-II classical HL treated between 2003 and 2011. We studied factors predicting the use of Ct or CMT using logistic regression. Treatment selection bias was addressed by balancing groups with a propensity score, immortal time bias by landmark analysis, missing data bias by multiple imputation, with a sensitivity analysis for unobserved confounding. Overall (OS) and relative survival (RS, a surrogate for disease-related mortality) were then compared using proportional hazard models. **Results**: Administration of CMT (50.5%) rather than Ct (49.5%) was significantly influenced by clinical factors (B symptoms, histology and comorbidities, all $P$<.0001), but also by demographic ones: age/sex (odds ratio, OR .85, $P$=.0007 for women vs. men <30 years old), race (OR .83, $P$=.0007 for black vs. white pts), lack of insurance (OR .71, $P$<.0001), treatment in an academic center (OR .81, $P$=.0001) or after 2006 (OR .63, $P$<.0001). After bias adjustment, CMT was associated with a better OS (hazard ratio, HR 0.56, 95% CI 0.49-0.64) and RS (HR 0.37, 95% CI 0.29-0.47) than Ct. The 5-year OS was 94.0% for CMT and 88.7% for Ct. There was no evident heterogeneity of the CMT benefit in subgroups defined by age, sex, histology, B-symptoms, stage, anatomical origin or hospital type (all $P$>.20). **Conclusions**: Treatment selection in early-stage HL is influenced by sociodemographic factors, which may lead to outcome disparities. In this comprehensive dataset, CMT was associated with the same survival advantage as in the prior meta-analysis (Herbst et al., *Haematologica* 2010, HR .41). No clinical factors (including some defining "early unfavorable" stratum) could identify subsets without advantage from CMT, so CMT should remain a standard of care pending further prospective studies.

**8547 General Poster Session (Board #234), Mon, 1:15 PM-5:00 PM**

**Pharmacokinetics and tolerability of doxorubicin in newly diagnosed lymphoma patients with hepatic impairment.** *Presenting Author: Catherine Lai, NIH/NCI, Bethesda, MD*

**Background:** Doxorubicin (dox) is critical for the curative treatment of DLBCL. Principally metabolized in the liver, early studies showed significantly decreased clearance (cl) in patients (pts) with hepatic impairment, leading to empiric dox reduction in pts with elevated bilirubin. No studies have analyzed dox pharmacokinetics (pk) and clinical toxicity in lymphoma pts with hepatic impairment. **Methods:** Pts with newly diagnosed aggressive lymphoma received 6 to 8 cycles of DA-EPOCH +/-R at the NCI. Of 70 pts studied, 61 had normal and 9 had elevated bilirubin (> 1.2mg/dL). All pts received full dose dox (40 mg/m$^2$) over 96-hours on cycle 1. Blood samples were collected for dox and doxorubicinol (doxor) pk at 0, 22 and 96 hours after infusion began. **Results:** The median (range) dox cl in pts with elevated versus normal bilirubin was 393ml/min/m$^2$ (294-610) vs. 630 ml/min/m$^2$(262-1596) (p= 0.0036). Median (range) plasma dox steady state concentrations (Css) at 96 hours were 0.031 (0.020-0.042) vs. 0.021 (<LLQ-0.045) $\mu$M (p=0.0036) and doxor Css were 0.025 (0.008–0.052) vs. 0.010 (<LLQ–0.021)$\mu$M (p=0.0028) in elevated versus normal bilirubin. Neutropenia was lower and thrombocytopenia (tcp) was higher in pts with elevated bilirubin (see table below). Response rates (RR) were similar: Complete response (CR) was achieved in 78% (7/9) versus 82% (50/61) and PR in 0% (0/9) vs 7% (4/61) of pts with elevated vs normal bilirubin. **Conclusions:** Pts with elevated bilirubin had reduced cl of dox, but was within the range of normal. Importantly, there were no differences in febrile neutropenia - tcp was higher in pts with elevated bilirubin but was not clinically meaningful. RR were similar between the 2 groups. Our results do not support the empiric dose reduction of dox in pts with aggressive lymphomas receiving potentially curative treatment.

| Characteristics | Elevated bilirubin | Normal bilirubin |
|---|---|---|
| Median age (yrs) | 44 (24-62) | 46 (21-75) |
| IPI (int hi/hi risk) | 67% (6/9) | 28% (17/61) |
| ANC nadir < 500/mm$^3$ (% pts C1) | 33% (3/9) | 52% (32/61) |
| TCP nadir < 25x103/mm$^3$ (% pts C1) | 89% (8/9) | 0% (0/61) |
| Febrile neutropenia (% pts C1) | 22% (2/9) | 16% (10/61) |
| G3/4 GI and neuro tox (% pts C1) | 33% (3/9) | 11% (7/61) |

**8548 General Poster Session (Board #235), Mon, 1:15 PM-5:00 PM**

**Survival of patients with different AIDS-related lymphoma subtypes.** *Presenting Author: Marcus Hentrich, Harlaching Hospital, Department of Hematology, Oncology and Palliative Care, Munich, Germany*

**Background:** Previous data indicated that the overall survival (OS) of patients (pts) with AIDS-related Burkitt lymphoma (BL) is inferior to that of diffuse large B-cell lymphoma (DLBCL), and that the OS of pts with plasmablastic lymphoma (PBL) is inferior to that of BL and DLCBL. We aimed to analyse the OS of pts with these lymphoma subtypes enrolled in the German AIDS-related Lymphoma (ARL) Cohort Study. **Methods:** The prospective observational cohort study includes all adult HIV-infected pts with biopsy proven ARL diagnosed in 31 participating German centers since January 2005. Data on HIV-infection and lymphoma characteristics, treatment and outcomes were recorded until December 2012. OS was calculated from the date of ARL diagnosis until death of any cause or last follow-up. **Results:** Of 291 pts included in the analysis 154 (53%) had DLBCL, 103 (35%) BL, and 34 (12%) PBL. The mean CD4-count at ARL diagnosis was significantly higher in pts with BL (349/$\mu$l) compared to DLBCL (209/$\mu$l) or PBL (205/$\mu$l) ($P$ < 0.001 and $P$ = 0.008, respectively). After a median follow-up of 1.3 years there was no significant difference in the 2-year OS rates (2yOS) between pts with BL (69% [95%CI 59-79]) and DLBCL (63% [55-71]) ($P$ = 0.65). By contrast, the 2yOS of PBL was significantly lower (43% [23-63]) compared to that of DLBCL and BL ($P$ = 0.024). The OS rates for pts with low risk vs. intermediate/high risk international prognostic index (IPI) were 82% (70-95) vs. 52% (40-63) for DLBCL ($P$ = 0.001), 87% (74-101) vs. 60% (47-73) for BL ($P$ = 0.011) and 83% (60-105) vs. 20% (-2.8-42.6) for PBL ($P$ = 0.003), respectively. Pts with DLBCL and CD4 cells >100/$\mu$l had significantly better OS than those with CD4 cells ≤100/$\mu$l (66% [55-77] vs. 51% [36-66], $P$ = 0.022). However, this was not true for pts with BL (OS 74% [63-85] vs. 51% [24-77], $P$ = 0.069) and PBL (36% [12-59] vs. 63% [32-93], $P$= 0.459). Prior AIDS defining illnesses did not adversely impact OS of each lymphoma subtype. **Conclusions:** In contrast to previous data the present study showed no significant difference in the 2yOS rates between DLBCL and BL while the OS of pts with PBL remains poor. The improvement in survival of BL may be explained by the widespread use of antiretroviral therapy and the more frequent use of intensive chemo-immunotherapy regimens.

**8549 General Poster Session (Board #236), Mon, 1:15 PM-5:00 PM**

**Utility assessment of interim FDG-PET/CT in frontline therapy of patients with diffuse large B-cell lymphoma (DLBCL).** *Presenting Author: Scott F. Huntington, Division of Hematology/Oncology, University of Pennsylvania, Philadelphia, PA*

**Background:** FDG-PET/CT (PET/CT) is part of standard pre-treatment staging and post-treatment response assessment in patients undergoing first line therapy for DLBCL. While many providers obtain interim PET/CT (I-PET) during the course of therapy, the role of these scans remains unclear. We investigated the clinical utility of interim and end of treatment PET/CT (E-PET) in patients with DLBCL. **Methods:** All patients with biopsy confirmed DLBCL undergoing first line therapy at our institution between January 1, 2008 and June 1, 2012 were screened for this retrospective study. Patients who received immunochemotherapy and underwent at least one I-PET were included for analysis. Scan results were interpreted as positive or negative based on consensus criteria from the International Harmonization Project. Results from I-PET and E-PET were analyzed and clinical outcomes were recorded. **Results:** Of 101 patients with DLBCL undergoing first line treatment at our institution, 94 patients underwent at least one I-PET. The median age was 58.5 years (range 20-91), 55% were male, and median follow-up time was 32.2 months. The majority (61%) of patients had at least one negative I-PET and a total of 133 I-PETs and 84 E-PETs were obtained. The positive predictive value (PPV) and negative predictive value (NPV) of I-PET for predicting primary refractory disease were 40.5% (95% CI:25-58%) and 100% (95% CI: 92-100%) respectively. The PPV and NPV of I-PET for predicting primary refractory or relapsed disease were 51.4% (95% CI: 35-68%) and 86.8% (95% CI: 74-94%). Obtaining at least one negative I-PET was strongly associated with improved progression-free survival (PFS) and remained an independent prognostic factor in a bivariate Cox model with revised-IPI (negative I-PET: HR 0.31, p=0.002; R-IPI: HR 2.4, p=0.02). **Conclusions:** Negative I-PET predicted superior clinical outcomes in our DLBCL patient cohort. All patients with negative I-PET were in remission at end of treatment and E-PET offered little clinical utility in this patient subset. Therefore, I-PET may offer an approach of early prediction of treatment outcome and obviate the need for end of therapy imaging in a majority of patients with DLBCL.

**8550 General Poster Session (Board #237), Mon, 1:15 PM-5:00 PM**

**Differences in disease characteristics, treatment patterns, and outcomes between men (M) and women (W) with follicular lymphoma (FL): Prospective evaluation of 2,650 U.S. patients (pts).** *Presenting Author: Chadi Nabhan, The University of Chicago, Chicago, IL*

**Background:** Differences in disease presentation, characteristics, treatment patterns, and outcomes between sexes among pts with FL have not been well-described. **Methods:** Using the National LymphoCare Study, a prospective registry sponsored by Genentech, that enrolled newly diagnosed FL pts (2004–2007), we analyzed differences in baseline characteristics and outcomes by gender. Associations of gender with disease characteristics, treatment, R dose intensity, and overall response (OR) were assessed using Pearson $\chi^2$tests. For pts receiving R-based induction, median progression-free survival (PFS), overall survival (OS), and lymphoma related mortality (LRM) by gender, age, and treatment regimen were estimated using Kaplan-Meier method. Adjusted Cox modeling for baseline factors and treatment regimens assessed gender differences in PFS, OS, and LRM. **Results:** 1,276 M and 1,374 W were prospectively enrolled (median F/U 6.9 yrs). More W had poor-risk FLIPI (36% vs 32%; P=0.05), which was likely due to anemia (27% vs 15%; P<0.0001) without other differences. Treatment varied by gender (P=0.002) with more W receiving R-monotherapy (15% vs 11%). R-containing regimens were given to 62% M and 61% W respectively with no differences in dose intensity (P=0.428). ORs were similar for M and W across regimens and age groups but in M and W, R-chemotherapy provided superior OR to R-monotherapy. After adjusting for baseline factors and treatment, W receiving R-based induction had superior PFS (HR 0.82, 95% CI 0.71–0.95; P=0.009) and OS (HR 0.73, 95% CI 0.58–0.90; P=0.003). Comparisons to pts who did not receive R-treatment were not performed due to low pt numbers. There were no significant difference in LRM overall (HR 0.86, P=0.35), but W had superior LRM in the pts ≤60. W had superior PFS and OS across all age categories (Table). **Conclusions:** This is the first prospective report to show that PFS and OS of W with FL are superior to M in the modern era. Clinical trial information: NCT00097565.

| | W vs M | | |
|---|---|---|---|
| | ≤60 yrs | 61–80 yrs | >80 yrs |
| PFS | 0.79 (0.62–1.00) | 0.91 (0.73–1.12) | 0.58 (0.37–0.91) |
| OS | 0.61 (0.38–0.99) | 0.87 (0.66–1.14) | 0.47 (0.29–0.78) |
| LRM | 0.41 (0.20–0.87) | 1.07 (0.71–1.61) | 0.90 (0.39–2.07) |

**8551 General Poster Session (Board #238), Mon, 1:15 PM-5:00 PM**

**A phase 1 multicenter clinical trial of alemtuzumab and CHOP chemotherapy for peripheral T-cell lymphomas.** *Presenting Author: Rena Buckstein, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

**Background:** Alemtuzumab is an anti CD52 monoclonal antibody with single agent activity in relapsed peripheral T cell lymphomas (PTCL), but the optimal dose/schedule to combine with chemotherapy is unknown. **Methods:** The primary objectives of this phase 1 study were to establish the maximally tolerated dose (MTD) and pharmacokinetics (PK) of alemtuzumab combined with cyclophosphamide, doxorubicin, vincristine, prednisone (CHOP) q21days. The MTD with highest trough levels would define the recommended phase II/III dose. Patient eligibility included: > age 18, untreated CD52+ PTCL, stage 2-4, measurable disease and adequate organ function. Alemtuzumab was given subcutaneously in 1 of 4 schedules using a 3+3 design with CHOP chemotherapy: 1) 10 mg day 1; 2) 10 mg weekly days 1, 8, 15; 3) 30 mg day 1; 4) 60 mg day 1. Trough PK were measured on day 1 of each 21d CHOP cycle. **Results:** 20 patients were enrolled; histology: AILD (n=7), PTCL NOS (n=6), ALK 1–ALCL (n=3), subpanniculitic (n=2), hepatosplenic (n=1) and enteropathy associated (n=1). DLT's necessitated dose expansion of dose level 2 (fatal TB reactivation) and 4 (grade 4 thrombocytopenia). The MTD was not reached. The most common hematologic toxicities were lymphopenia (65% grade 3-4), neutropenia (55% grade 3-4) and febrile neutropenia (25%). Ten (50%) patients developed asymptomatic CMV reactivations at a median of 39 days (range 4-99) treated with valganciclovir. Two patients developed fungal pneumonias. Of 18 evaluable for response, the overall response rate was 65% (CR/Cru (n=7), PR (n=6)). With a median f/u of 28 months (range 1.3-77.4), 10 patients (52%) have relapsed or progressed and 4 (21%) have died. Median OS has not been reached and median PFS is 23 months. Peripheral blood CD3+ T cells declined by 80-100% from baseline and recovered in 55% of patients at a median time of 15 mos. Mean trough alemtuzumab levels by dose level were 1) 57, 2) 464, 3) 124 and 4) 501 ng/ml. **Conclusions:** Weekly SC alemtuzumab 10 mg achieves trough levels comparable with 60 mg q21d when given with CHOP. With close monitoring, toxicity was manageable and CMV disease was not seen. These doses with CHOP should be tested in patients with peripheral T cell lymphoma. Funded by NCIC grant#16398. Clinical trial information: NCT00363090.

**8552 General Poster Session (Board #239), Mon, 1:15 PM-5:00 PM**

**Extranodal natural killer T-cell lymphoma, nasal-type—A new staging system from CSWOG—A multicenter study.** *Presenting Author: Tongyu Lin, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

**Background:** Extranodal NK/T-cell lymphoma, nasal type (ENKTL), is a rare and high aggressive disease with poor prognosis. The Ann Arbor staging system had been unable to define ENKTL staging in specific way. This study conduct a new staging system specified for ENKTL, which can identify poor prognostic patients who need more aggressive therapy. **Methods:** Based on the primary studied of one single center consecutive patients diagnosed as ENKTL treated with CHOP-like regimens on ASCO meeting 2008, the new staging system was established as stage I: lesions confined within nasal cavity or nasopharynx without local invasiveness (paranasal sinuses or bony or skin invasion); stage II: localized disease with local invasiveness; stage III: localized disease with regional lymph node involvement (cervical lymph nodes); stage IV: disseminated disease (lymph nodes on both sides of diaphragm, multiple extranodal site). We further undertaken two multicenter study, one retrospective analyzed the patients treated with CHOP-like to confirm the new system and the other prospective validate the new system in current treatment modality containing L-asp-based chemotherapy in ENKTL. **Results:** A total of 821 patients with final diagnosis of ENKTL (ranging 9-90 years old) were included. Among them 588 were retrospective studied between Jan 2000 and Jun 2008, and 233 were prospective studied from Jul 2008 to Dec 2012. The distribution of all patients using the new system compared with Ann Arbor system were stage I: 19.6% vs 56.9%; stage II: 38.1% vs 20.1%; stage III: 17.8% vs 7.2%; stage IV: 24.5% vs 15.8%, respectively. In the retrospective study, the 5-year OS rate of stage I to IV using the new system were 63%, 51%, 38% and 29% compared with 55%, 45%, 15% and 29% using the Ann Arbor system, respectively. For prospective study, the 5-year OS rate of stage I to IV of the new system were 82%, 73%, 67% and 54%, respectively, while stage IV was better than stage III (74% vs 47%) when the Ann Arbor system was adopted. **Conclusions:** The new staging system with a more balanced distribution and a superior prognostic discrimination as compared with the Ann Abor staging system is more suitable for ENKTL and should be recommended used in the future.

**8553 General Poster Session (Board #240), Mon, 1:15 PM-5:00 PM**

**The Bruton's tyrosine kinase (BTK) inhibitor ONO-4059: Single-agent activity in patients with relapsed and refractory non-GCB-DLBCL.** *Presenting Author: Martin Dyer, Leicester Royal Infirmary, Leicester, United Kingdom*

**Background:** Bruton's tyrosine kinase (BTK) is a critical kinase involved in B-cell receptor signal transduction. ONO-4059, a highly potent and selective oral BTK inhibitor has demonstrated anti-tumour activity in pre-clinical models (Yasuhiro et al, AACR 2013) and in the clinic in both NHL and CLL patients (Salles et al, ASH 2013; Rule et al, ASH 2013). Here, we present data from non-GCB DLBCL patients enrolled in the ongoing Phase I study ONO-4059POE001. **Methods:** Thirteen patients with relapsed (n=8) or refractory (n=5) non-GCB-DLBCL were administered ONO-4059 as monotherapy, given once daily (QD) at doses ranging from 160-480mg, to determine safety, pharmacokinetics and pharmacodynamics, as well as any preliminary efficacy. Patients had a median age of 65yrs [range 30-72], median of 4 prior therapies [2-8], and a median baseline tumour burden of 2,504mm$^2$ [619-15,750mm$^2$]. All 13 patients had prior exposure to a rituximab-containing regimen and 5/13 patients (38%) had prior ASCT. **Results:** Thirteen patients were evaluable for safety - ONO-4059 was found to be well tolerated with a total of twenty seven (27) ONO-4059 related adverse events reported in 5/13 patients (CTCAE-V4.0 G1 [n=20 in 4 patients] and G2 [n=5 in 3 patients]). Two ONO-4059-related G3 events reported in two patients were: drug reaction and lymphopenia, with drug reaction reported as an SAE. The pharmacokinetics of ONO-4059 reflects a half-life of ~5-7 hours with sustained inhibition of BTK observed in PBMCs up to 24 hours from first dose. Eight patients are currently evaluable for efficacy - Six patients experienced reductions in lymphadenopathy within the first treatment cycle. Responses occurred at doses of 160mg (n=6) and 320mg (n=2), including 2 refractory patients, with a best overall response rate of 75% (6/8) with 6 PR (median reduction of lymph nodes was 81.5% [52.4-86.6%]) and 2 PD. Of note, no CD79b mutations were identified (n=7 evaluable). **Conclusions:** ONO-4059 showed a favorable safety profile along with promising preliminary efficacy in this difficult-to-treat non-GCB-DLBCL patient population. The study is ongoing with additional dose escalation cohorts underway. Clinical trial information: NCT01659255.

**8554 General Poster Session (Board #241), Mon, 1:15 PM-5:00 PM**

**Retrospective analysis of treatment patterns and outcomes with subcutaneous (SQ) bortezomib (BTZ) in patients (pts) with relapsed mantle cell lymphoma (MCL).** *Presenting Author: Vijayveer Bonthapally, Millennium: The Takeda Oncology Company, Cambridge, MA*

**Background:** Intravenous (IV) BTZ was approved in the US for the treatment of relapsed MCL in 2006 based on the phase 2 PINNACLE study (Fisher, JCO 2006). In 2012, SQ BTZ was approved based on the phase 3 MMY-3021 study (Moreau, Lancet Oncol 2011), which showed non-inferior efficacy and an improved safety profile with SQ vs IV BTZ in relapsed multiple myeloma. There are limited data on SQ BTZ in relapsed MCL. **Methods:** In this retrospective observational study, data on relapsed MCL pts aged ≥18 years with ≥1 SQ BTZ dose during 2010–2013, either as a single agent or in combination therapy, were collected from an oncology electronic medical records (EMR) database and patient medical charts (Altos Solutions, Inc). Analyses of treatment patterns and outcomes, including best response, PFS, OS, and AEs, were conducted. **Results:** Of 37,996 lymphoma pts in the database, 806 had MCL; 42 had ≥1 SQ BTZ dose, of whom 30 had ≥1 prior therapy identified. Of these 30 pts median age was 68.7 years, 70% were male, and 53% had stage IV MCL. Pts had a median of 3 lines of prior therapy (range 1–6). Median time from diagnosis to SQ BTZ was 2.5 years. 97% of pts received SQ BTZ in 2012–2013. Median treatment duration was 2.3 months (range 0.03–19.4); 13 (43%) had single-agent SQ BTZ and 17 (57%) had combination therapy (8 with rituximab [R], 6 with R+bendamustine, 1 each with R+lenalidomide, methotrexate, and dexamethasone). Overall response rate was 37% (11/30 pts; 3% CR). After a median follow-up of 8.8 months, median PFS was 10.5 months (IQR 3.8–29.3), median OS was not reached (1-year OS 72%). Common AEs included 57% fatigue, 27% neutropenia, 27% anemia, 27% neuropathy, 20% thrombocytopenia, and 20% nausea. Local redness/tenderness were seen in 10%/7%. Common grade 3/4 AEs were 10% neuropathy and 7% infection. Outcomes with single-agent SQ BTZ (n=13) were similar to overall data but with only 2 grade 3/4 AEs: 8% neuropathy, 8% diarrhea. **Conclusions:** SQ BTZ was active and well tolerated in relapsed MCL. These data are consistent with the non-inferior efficacy and improved safety profile of SC BTZ in multiple myeloma. As data mature, additional analyses will further evaluate treatment outcomes and safety profile.

**8555 General Poster Session (Board #242), Mon, 1:15 PM-5:00 PM**

**The outcome of patients with "nodal" peripheral T-cell lymphomas in a complete response following standard chemotherapy.** *Presenting Author: Jean-Michel Lavoie, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** The outcome of peripheral T-cell lymphomas (PTCLs) treated with anthracycline-based chemotherapy (CHT) regimens is poor. Previous studies have suggested a benefit of high dose chemotherapy and autologous stem cell transplant (HDC/ASCT) in first complete remission (CR). However, in the absence of a randomized trial, the benefit is unclear. We evaluated the outcome of patients in CR following CHOP (like) CHT to provide a comparison to outcomes with HDC/ASCT. **Methods:** The BCCA Lymphoid Cancer database was searched to identify all cases of 'nodal' PTCLs between 16 and 67 y with stage 3/4, or stage 1/2 with B symptoms, bulky (>10cm) or extensive disease, that were in a CR by clinical assessment and imaging at the end of curative intent combination CHT and did not undergo consolidative transplant. Charts were reviewed to confirm response assessment. **Results:** Between October 1980 and January 2014, 103 cases were identified to be in a CR (6 by PET scan): PTCL-NOS = 39/94 (45%); ALK-positive (ALK-pos) ALCL = 29/34(85%); ALK-negative (ALK-neg) ALCL = 17/34 (50%); AITL= 17/37 (46%). All patients received CHOP (like) CHT. The median age at diagnosis for non-ALK-pos vs. ALK-pos patients was 57 y (23-67 y) and 29 y (17-65), respectively. Patients with ALK-pos ALCL more often had low risk disease (IPI 0, 1 48% vs. all others 23%) (P=0.036) and patients with AITL commonly had bone marrow (bm) involvement. (41%, P=0.01). With a median follow-up for living patients of 9.0 years (1.75-24.0 years), the 5 y OS for ALK-pos ALCL was 79% vs. 57% for all other subtypes (P=0.0048) and the 5 y PFS was 65% vs. 42% (P=0.010). The 5 y OS by subtype was 69%, 67% and 46% for ALK-neg, AITL and PTCL-NOS respectively (P=0.006) and the 5 y PFS was 62%, 50% and 30%, respectively (p=0.001). Interestingly, the IPI and bm involvement were not prognostic for either PFS or OS in any subtype. **Conclusions:** The majority of patients with PTCL-NOS ultimately relapse despite achieving a CR at the end of standard CHT. In contrast, patients with ALK-neg ALCL have an excellent outcome if a CR is achieved with comparable survival rates to patients treated with HDC/ASCT. These data support separation of these entities for the evaluation of novel treatment regimens.

**8556 General Poster Session (Board #243), Mon, 1:15 PM-5:00 PM**

**Results of a phase I study of bendamustine in combination with ofatumumab, carboplatin, and etoposide (BOCE) for refractory or relapsed aggressive B-cell non-Hodgkin lymphomas (NHL).** *Presenting Author: Sameh Gaballa, Department of Medical Oncology, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

**Background:** No salvage regimen has shown clear superiority in relapsed NHL. Bendamustine has single agent activity in relapsed aggressive NHL. We conducted a phase I trial using a novel RICE-like salvage regimen in which ofatumumab was substituted for rituximab and bendamustine replaced ifosfamide, combined with carboplatin and etoposide (BOCE) **Methods:** Patients (pts) with relapsed or refractory aggressive B NHL were eligible. The design was a standard 3+3 design using escalating doses of bendamustine [70, 90, and 120 mg/m$^2$ D1-2] with ofatumumab (cycle 1: 300 mg D1, 1000 mg D3, cycle 2 and 3: 1000 mg D1), carboplatin AUC 5 D2 and etoposide 100mg/m$^2$ D1-3. **Results:** Eleven pts were enrolled (7M/4F). Median age was 62 (range 53-75), 5 pts (45%) had diffuse large B NHL, 4 pts (36%) had grade 3 follicular NHL, 1 pt (9%) had mantle cell NHL, and 1 pt (9%) had transformed CLL. Five pts (46%) had refractory disease and 6 pts (56%) had relapsed disease. All pts with refractory disease were refractory to rituximab. All pts had stage III or IV disease. sAAIPI was: low-int 55%, high-int 36%, high risk 9%. ORR was 64% [CR: 5 pts (46%); PR: 2 pts (18%)]. Two pts (18%) had progressive disease and 1 pt (9%) had stable disease. Five pts (46%) subsequently underwent an allogeneic transplant. Four pts (36%) died, all of progressive disease. After a median follow-up of 6 months, the estimated 12-months OS is 63.5% DLT was not reached. Grade III-IV toxicity included neutropenia (82%), thrombocytopenia (64%), anemia (64%), lymphopenia (27%), febrile neutropenia (27%), hyponatremia (18%), and hypophosphatemia (18%). Six serious adverse events were reported in 4 pts including acute kidney injury, urinary tract infection, pleural effusion, GI bleeding, thromboembolic event and febrile Infusion related reactions occurred in 27% of pts (all grade I-II). **Conclusions:** The BOCE regimen is well tolerated in pts with relapsed or refractory aggressive NHL. A phase II trial with bendamustine at the dose of 120mg/m2 is ongoing. The advantage of this regimen over other commonly used salvage strategies is that it can be administered safely in the outpatient setting. Clinical trial information: NCT01458366.

**8557 General Poster Session (Board #244), Mon, 1:15 PM-5:00 PM**

**Post-treatment PET scan is highly predictive of outcome (PFS and OS) in MCL pts treated with R-Hyper-CVAD in the frontline setting regardless of MIPI score.** *Presenting Author: Anthony R. Mato, John Theurer Cancer Center, Hackensack, NJ*

**Background:** MIPI score (age, LDH, WBC, ECOG PS) defines 3 distinct risk groups in MCL pts. Though MIPI has been validated in series with dose intensive (DI) strategies and rituximab, a number of other prognostic factors have been reported that affect MCL survival. There remains a need to further stratify pts in each MIPI risk category despite optimal treatment approaches. We previously identified (Mato et al, Cancer 2012) FDG PET-CT as an important prognostic marker for survival in MCL pts following R-HyperCVAD completion. We examined here the additive prognostic utility of post-treatment PET-CT imaging to baseline MIPI scores. **Methods:** Primary endpoints were PFS and OS. PET-CT images were dichotomized using IHP response criteria (Juweid et al, JCO 2007). Reviewers were blinded to outcomes. MIPI scores were calculated as described by Hoster et al (Blood, 2008). Utilizing KM methods, we compared outcomes stratified by post-treatment PET-CT status and MIPI risk groups. Utilizing Cox regression, we tested the association between PET-CT + MIPI and survival. **Results:** 140 MCL pts (med age 60, 95% stage IV) treated with 1st line R-HyperCVAD were identified in our MCL outcome database. Of these, 58 pts had a post-treatment PET-CT available for review. MIPI scores were 44% low, 34% intermediate and 22% high risk. Post treatment PET-CTs were 18% (+) and 82% (-). Med PFS and OS estimates were 56 and 108 mo respectively (med follow up 35.2 mo). Both MIPI (HR 1.9 CI: 1.1-3.2 p=.012) and PET-CT (HR 7.1 CI:2.9-17.1 p=.001) independently correlated with PFS and OS MIPI (HR 3.3 CI: 1.5-7.3 p=.04) and PET-CT (HR 9.2 CI: 2.5-33.0 p=.001). The following defines a model, which includes baseline MIPI and PET-CT status: Low MIPI (HR=1), Int MIPI (HR=2.1), High MIPI (HR=3.5), PET-CT (-) (HR=1), PET-CT (+) (HR=7.1). **Conclusions:** Post treatment FDG-PET status and MIPI are validated independent predictors of survival in MCL pts treated with R-HyperCVAD. Outcomes are extremely poor in PET (+) patients regardless of MIPI risk group: Low risk / PET (+) had similar PFS as high risk / PET (-). Our results may identify MCL patient candidates for novel maintenance / consolidation approaches after 1st line therapy.

**8558 General Poster Session (Board #245), Mon, 1:15 PM-5:00 PM**

**Utility of surveillance imaging in patients with non-Hodgkin lymphoma.** *Presenting Author: Rangaswamy Chintapatla, Mount Sinai St. Luke's Hospital, Mount Sinai Roosevelt Hospital, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** The optimal surveillance imaging in the management of patients (pts) with non-Hodgkins lymphoma (NHL) remains undefined. Unnecessary scans increase health care costs and radiation related health hazards. A recent report (Thompson, C.A. et.al; ASCO 2013) suggests that routine surveillance scans did not add much value to follow up of pts treated for NHL. We reviewed our hospital's patient charts to further explore the effectiveness and cost of surveillance imaging. **Methods:** We retrospectively studied the records of 218 pts (118 male, 100 female) with NHL managed at our institution from 2008 to 2012. Pts with high-grade (HG) NHL treated to complete remission, and pts managed for low-grade (LG) NHL were included. Patients with HIV-related NHL were analyzed separately. Primary CNS lymphoma was excluded. Data were analyzed to determine if re-treatment decisions at relapse, as well as decisions to initiate therapy in pts with LG NHL, were based on clinical features (physical exam, laboratory abnormalities) or findings noted on scans. **Results:** Of 218 pts, 115 (53 %) pts had HG NHL, and 103 (47 %) had LG NHL. Patients were managed with observation, radiation therapy, rituximab, and/or immunochemotherapy as appropriate. Median age was 60 years (Range: 24 - 97) and median follow-up was 31 months. Median overall survival was not reached. Forty -six pts had disease relapse or progression warranting treatment initiation: 38 were detected by symptoms and 8 were diagnosed by imaging alone. A total of 834 surveillance scans were done including 373 PET/CT scans with an estimated total cost of over USD 750,000. (Medicare reimbursement prices 2014). Of the 218 pts, 32 (15 %) had HIV-related NHL. Eleven of these patients had disease relapse, all detected by symptoms. HIV patients averaged 2.9 scans/pt compared to 3.9 scans/pt in non-HIV pts (p: 0.156). HIV-NHL pts had a higher relapse rate compared to non-HIV pts, which did not reach statistical significance. (34% vs 19% (p: 0.059). **Conclusions**: Disease relapses were mostly diagnosed due to a change in patient's clinical status. Only 8 of the 46 cases of relapse were detected by surveillance imaging alone. We plan to further explore whether the outcomes were different for patients with relapse detected by imaging.

**8559 General Poster Session (Board #246), Mon, 1:15 PM-5:00 PM**

**First-in-human study of 4SC-202, a novel oral HDAC inhibitor in advanced hematologic malignancies (TOPAS study).** *Presenting Author: Bastian von Tresckow, Department I for Internal Medicine, University Hospital of Cologne, Cologne, Germany*

**Background:** 4SC-202 is a specific inhibitor of protein deacetylases HDAC1, 2 and 3 and lysine specific demethylase LSD1 (KDM1A). Enzymatic inhibition leads to transcriptional repression of Wnt and Hedgehog signaling. 4SC-202 provokes the inhibition of stemness-related properties of cancer cells and affects their viability. **Methods:** Patients with advanced hematological malignancies including AML, ALL, CLL, MM, MDS or lymphoma were orally dosed either once daily (QD) or twice daily (BID) from days 1 to 14, or BID continuously, in a 21-day cycle. Dose escalation followed a 3+3 design. Study objectives include safety, tolerability and pharmacokinetics (PK), determination of MTD and DLT as well as optimization of dosing. Biomarker program includes measuring of HDAC inhibition, total lysine acetylation and gene expression profiling. Additionally, the anti-tumor effect of 4SC-202 was evaluated. Dose escalation part is completed and data allow for reliable evaluation. Further patients will be enrolled to establish the MTD at prior dose levels. **Results:** 24 patients were treated at 7 dose levels of 25/50/100/200/400mg QD and 200mg BID (N=3, each), and 200mg BID continuous dosing (N=6). Treatment was very well tolerated by heavily pre-treated patients up to the highest dose group. Possibly drug-related AE were less frequent, e.g. low-grade GI complaints such as nausea. Higher-grade hematological toxicity e.g. leading to treatment changes was not observed. Elevation of liver enzymes was observed at 200mg BID during continuous dosing. Two objective responses (PR & CR, unconfirmed) were observed. 75% of patients went into follow-up treatment due to stable disease. Median time on treatment was 98 days with 3 patients treated > 400 days. Plasma exposure reached one digit $\mu$M concentrations over 24h. Modulation of Wnt pathway gene-signature was observed in blood samples, as well as HDAC inhibition and lysine acetylation. **Conclusions:** 4SC-202 could be safely administered up to 200mg BID. Anti-cancer activity could be demonstrated by two patients achieving PR and CR, respectively, and long term stabilization of several patients. The mode of action of 4SC-202 is demonstrated by biomarker response. Clinical trial information: NCT01344707.

**8560 General Poster Session (Board #247), Mon, 1:15 PM-5:00 PM**

**A multicenter study of 66 patients with spinal cord compression at diagnosis of B-cell non-Hodgkin lymphoma.** *Presenting Author: Isabelle Fleury, AP-HP at Saint-Louis Hospital, Paris Diderot- Sorbonne University, Paris, France*

**Background:** Spinal cord compression (SCC) in non-Hodgkin lymphoma (NHL) is rare but associated with an increased risk of central nervous system (CNS) relapse. Our objective was to retrospectively analyze the outcome of patients with SCC caused by B-cell NHL and their CNS relapse risk. **Methods:** Patients with SCC at diagnosis of B-cell NHL from six centers in France were eligible. Burkitt and HIV-related lymphoma were excluded. Intradural extension on spine imaging was centrally reviewed. The primary endpoints were progression-free survival (PFS) and relapse site. Survival functions were estimated by the Kaplan-Meier method and compared by the log-rank tests. **Results:** We identified sixty-six patients treated between 1987 and 2012. Median age was 61,5 years. Histology was: diffuse large B cell (DLBCL) (71%), follicular (19%), small lymphocytic (6%), marginal zone (3%) and B-cell unclassified (3%) lymphomas. An intradural extension of lymphoma was detected in 29% (10/35) of the patients and cytological analysis of cerebrospinal fluid (CSF) revealed an infiltration in 9% (5/58) of the patients. Twenty-eight (42%) patients were managed by a surgical decompressive procedure before chemotherapy. All but two patients received CHOP or CHOP-like regimen and 61% received rituximab. Forty-six patients received CNS prophylaxis based on intravenous methotrexate and/or intrathecal therapy. At a median follow-up of 53 months, 5-year OS was 64% and 5-year PFS was 53%. CNS relapses occurred in 4 (6%) patients with DLBCL, all involving the cerebellum. Non-CNS relapse occurred in twenty (30%) patients. Neither CSF involvement nor intradural extension influenced PFS ($p = 0.5544$ and $p = 0.3399$ respectively). Initial decompressive surgery did not influence PFS or OS ($p = 0.4231$, and $p = 0.1823$ respectively). The use of at least 3 g/m$^2$ of MTX or the lack of any CNS prophylaxis modality did not influence PFS ($p = 0.1414$ and $p = 0.8221$ respectively). **Conclusions:** SCC at diagnosis of B-cell NHL carries a low risk of CNS relapse. Outcomes were not improved by CNS prophylaxis. Benefit from CNS prophylaxis according to intradural extension needs prospective evaluation.

**8561 General Poster Session (Board #248), Mon, 1:15 PM-5:00 PM**

**Stage migration and survival in DLBCL patients before and after the approval of positron emission tomography (PET) scan: Population-based analysis using the U.S. National Cancer Data Base (NCDB).** *Presenting Author: Anusha Reddy Madadi, Gundersen Lutheran Medical Center, La Crosse, WI*

**Background:** PET scan was approved by the US Medicare for diagnosis and staging of NHL in July 2001. We studied the DLBCL stage distribution and overall survival (OS) before and after introduction of PET scan. **Methods:** We identified DLBCL patients diagnosed in 1998 to 2011 from the NCDB. We obtained data pertaining to stage and OS. We grouped patients into 2 cohorts: pre (1998-2001) and post (2002-2005) PET approval. To minimize bias in improvement of OS due to new treatments, year 2005 cut-off was chosen as rituximab was approved by the US Food and Drug Administration for treatment of B-cell NHL in 2006. **Results:** There were 202,294 patients with DLBCL. Of these, 30.5% had extra-nodal disease presentation. The stage distribution over time is shown in table 1. Overall, early stage disease (I/II) remained relatively stable over time (35.1% in 1998 to 38.3% in 2011). Advanced stage disease (III/IV) increased from 30.7% to 51.8%. In contrast, patients with unknown stage decreased from 34.2% to 9.4%. We observed similar stage migration in both nodal and extra-nodal DLBCL subgroups.The median OS was significantly better (all P values $< 0.001$) in the post-PET approval era for all stages: combined (64.5 vs. 38.4 months), I/II (not reached (NR)[mean 103.8 months]) vs. (NR [mean 75.3 months]), III/IV (28.2 vs. 13.0 months), and unknown (57.2 vs. 39.9 months). **Conclusions:** Since the approval of PET scan for NHL diagnosis and staging in 2001, there has been a substantial change in the stage distribution among DLBCL patients. This is predominantly due to a migration from unknown stage into advanced stage disease. The OS has improved across all stages but most marked among patients with advanced stage disease. The latter may be in part due to stage migration.

| Stage (%) | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 |

**Early negative circulating EBV DNA as prediction of survival in extranodal NK/T-cell lymphoma, nasal type (ENKL).** *Presenting Author: Chaoyong Liang, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

**Background:** Predictive tumor markers are essential for extranodal NK/T cell lymphoma, nasal type (ENKL), which pursues an aggressive clinical course with poorer prognosis. This prospective study was conducted to evaluate the dynamic monitoring value of circulating EBV DNA concentration for the prediction of ENKL. **Methods:** From Jan 2006 to Aug 2012, plasma samples from 113 ENKL pts were collected before and/or every 2 cycles of chemotherapies for circulating EBV DNA measurement by a real-time PCR assay. **Results:** The positive rate of circulating EBV DNA was 61.9% (70/113) with a median concentration of $1.21\times10^3$copies/ml. After two cycles of chemotherapies, 45 pts were tested circulating EBV-DNA and 53.33% (24/45) pts became negative EBV-DNA candidates. There were 87.5% (21/24) pts obtained complete remission at the end of the treatment, comparing as 42.86% (9/21) in the still positive EBV-DNA groups(P= 0.002). There was a tendency that the pts whose circulating EBV-DNA became negative after two cycles would have better prognosis (5-year OS: 75% vs 46%, P=0.074). The similar situation of CR rate and OS happened in the EBV-DNA detection of completion of total chemotherapies. The more advance of the stage, the higher concentration of EBV-DNA was found. When divided the positive group as low and high-dose ones by the cut-off value as $2\times10^4$copies/ml, the CR rate of the high-dose group was much lower and the 5-year OS was significantly better than the low-dose group and the negative group.7 of 13 relapsed pts of $>1\times10^3$copies/ml EBV-DNA at the time of recurrent, and the survival outcome was dismal for them compared to the other 6 pts of $\leq1\times10^3$copies/ml(5- year OS: 0% vs 80%, P=0.001). **Conclusions:** Circulating EBV-DNA level can predict the efficacy of treatment as a dynamic marker of ENKL. Pts with early positive detection of EBV-DNA after 2 cycles of chemotherapy maybe received more aggressive treatments.

**8563 General Poster Session (Board #250), Mon, 1:15 PM-5:00 PM**

**Responses to romidepsin by line of therapy in patients with relapsed/refractory (R/R) peripheral T-cell lymphoma (PTCL).** *Presenting Author: Francine M. Foss, Yale Cancer Center, New Haven, CT*

**Background:** Most patients with PTCL, an aggressive form of non-Hodgkin lymphoma, experience R/R disease with few effective salvage treatments. Romidepsin is a histone deacetylase inhibitor approved by the US FDA for treatment of patients with PTCL who have received $\geq$ 1 prior therapy. Durable clinical responses (objective response rate [ORR] of 25% and median duration of response [DOR] of 28 mo; median follow up 22.3 mo) and tolerability with extended dosing have been reported. As heavily pretreated patients are especially challenging, responses to romidepsin by line of therapy were examined herein. **Methods:** Patients with PTCL (N = 130) who were R/R to $\geq$ 1 prior therapy received romidepsin 14 mg/m$^2$on days 1, 8, and 15 every 28 days. The primary endpoint was confirmed/unconfirmed complete response (CR/CRu), and secondary endpoints included ORR (CR/CRu + partial responses) and DOR; progression-free and overall survival (PFS, OS) were also assessed. In this analysis, baseline characteristics, responses to therapy, and safety are examined for patients who received 1, 2, or $\geq$ 3 prior therapies. **Results:** Nearly all patients received chemotherapy in the first line, and patients with more lines of prior therapy were more likely to have prior radiation, monoclonal antibody or other immunotherapy or stem cell transplant. Response rates, DOR, and survival with romidepsin were not significantly different for patients with R/R PTCL who received 1, 2, or $\geq$ 3 prior therapies, though heavily pretreated patients discontinued due to adverse events (AEs) more frequently (Table). **Conclusions:** Romidepsin resulted in durable responses in patients with 1, 2, or $\geq$ 3 prior treatments for PTCL. These data support the use of romidepsin in the second line, particularly as patients with PTCL may receive a limited number of regimens due to age or comorbidities. Clinical trial information: NCT00426764.

**8564 General Poster Session (Board #251), Mon, 1:15 PM-5:00 PM**

**Treatment outcomes and prognostic factors for primary mediastinal B-cell lymphoma: The MD Anderson experience.** *Presenting Author: Mohamed Amin Ahmed, Department of Lymphoma and Myeloma, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Primary mediastinal B-cell lymphoma (PMBL) has been treated with different chemotherapy regimens. We reviewed medical records and histopathology to determine predictive factors and outcomes for patients (pts) with PMBL seen at the MD Anderson Cancer Center (MDACC) between 1995 and 2013. **Methods:** Baseline characteristics complete (CR) and partial (PR) response to initial therapy, and status of disease and survival over time were collected. Event-free survival (EFS) was based on dates of relapse, progression, or death. Radiotherapy data will be presented separately. **Results:** 274 pts with PMBL were identified, making this the largest single-center retrospective report of PMBL. Median age was 40 years (range, 17-86), and 149 pts (54%) were female. For patients treated with R, the CR rates were higher, and EFS and overall survival (OS) were improved for all pts at the median follow-up (MFU) of 38 months (mo), and for CHOP-treated pts at MFU of 37 mo (Table). As R is now standard with initial therapy, we analyzed results for the 3 main R-containing therapies (Table). By univariate log-rank analysis, therapy choice affected the CR rate, and EFS at MFU of 39 mo. R-HCVAD had superior EFS vs. R-CHOP (p=0.015), even though low-stage pts were more common for R-CHOP. For pts given the 3 main R-containing therapies, higher stage (III/IV vs. I/II) was an adverse univariate predictor for EFS (p=0.036) and OS (p=0.04), and B symptoms were adverse for OS (p = 0.026). Multivariate Cox analysis including stage, B symptoms, and therapy (CHOP vs. EPOCH/HCVAD) found only B symptoms to be predictive of shorter OS (p = 0.032), and only treatment to be predictive of shorter EFS (p=0.029). **Conclusions:** Response rates and survival outcomes are improved for pts with PMBL by R and its use with intensified therapy (R-HCVAD or R-EPOCH). Longer follow-up is needed to compare R-HCVAD and R-EPOCH.

**The utility of HTS TCR analyses in the management of patients with T-cell malignancies.** *Presenting Author: Ilan Lanny Kirsch, Adaptive Biotechnologies, Seattle, WA*

**Background:** We have pioneered a method to sequence the diversity of the TCR CDR3 rearrangements that exploits the capacity of high-throughput sequencing (HTS) to document the diverse repertoire of *TCR* CDR3 chains. **Methods:** These assays can describe both the breadth of T-cell repertoire diversity and quantify individual clones. This technology thus provides an opportunity to identify and then track the presence and frequency of clones in lymphoid malignancies. **Results:** HTS improves the detection and monitoring of minimal residual disease in precursor acute T lymphoblastic leukemias over other available methods. We have also sequenced the *TCRB* repertoire in a morphologic mix of T-cell lymphoma specimens. HTS of *TCRB* was concordant with flow cytometry or PCR-based evaluation of *TCRG* rearrangement in 46 of 59 samples with recognition of residual disease based on the previously identified diagnostic index clones. However, 5 samples were only positive for recurrent disease based on HTS. We have also demonstrated the ability of HTS to detect malignant cells beneath the level of detection of flow cytometry in a cohort of patients with Sezary Syndrome and have also demonstrated the utility of this assay for early detection of relapse and for providing potential useful information that distinguishes among drug toxicity, GVHD, or clinical relapse in skin lesions from this same patient population following allogeneic transplant. In an analysis of skin biopsies from patients with CTCL in which data from flow cytometry, qPCR, and HTS were performed comparatively, HTS was able to identify a significantly greater number of trackable diagnostic clones in the suspect lesions and distinguish malignant from non-malignant lesions. **Conclusions:** HTS TCR repertoire profiling is the most sensitive and accurate method for clonal detection and monitoring in T-cell malignancies. The assay is now being incorporated into clinical management in CTCL.

**8566 General Poster Session (Board #253), Mon, 1:15 PM-5:00 PM**

**A phase 1/2 study of lenalidomide and bendamustine (LEBEN) in chemorefractory Hodgkin lymphoma.** *Presenting Author: Gaetano Corazzelli, Hematology-Oncology and Stem Cell Transplantation Unit, Istituto Nazionale Tumori, Fondazione G. Pascale, Naples, Italy*

**Background:** Implementing strategies for Hodgkin lymphoma (HL) patients failing stem cell transplantation (SCT) remains a crucial need. We investigated for the first time safety and efficacy of a combination of lenalidomide and bendamustine (LEBEN), two agents synergistically framing different targets on both neoplastic and microenvironment tumor-supporting cells of HL. **Methods:** A weekly schedule of bendamustine (60 $mg/m^2$; d 1, 8, 15) plus continuous daily lenalidomide (10, 15, 20 or 25 mg), in a 28-day cycle, was tested in a Bayesian phase 1/2 study (Thall & Cook, Biometrics 2004) defining the optimal lenalidomide dosage through the best efficacy/toxicity trade-off. Response (CR or PR at PET/CT) and toxicity (CTCv3.0 grade >3 lasting >2 weeks) endpoints were assessed at 2 cycles (day +56). Non-progressing patients received additional 4 courses. **Results:** Seventeen chemorefractory patients [SCT failures n=12 (single auto SCT, n=4; tandem n=3; tandem auto/allo, n=5 ); unresponsive to pre-SCT salvage, n=5] were enrolled in 6 cohorts of 3. Patients [males, 80%; median age 29 years (r,19-56)] had a median of 4 prior therapies (r, 2-9), including brentuximab (n= 5). A median of 5 cycles was delivered to 15 evaluable patients. The primary endpoint analysis at 2 cycles showed response without toxicity in 9 patients (60%), response with toxicity in 2 (13%), neither efficacy and toxicity in 4 (27%), toxicity without response in none. The overall response rate (ORR; CR+PR) was 73% with 6 CRs (40%). After 4 cycles, ORR increased to 12/15 (80%) and CRs to 8/15 (53%). The median PFS was 8.7 months. Response was associated to change in circulating myeloid-derived suppressor and dendritic cells. Most common AEs (71 cycles) were (any grade%/≥G3%) diarrhea (27/3), rash (14/3), neutropenia (72/44), thrombocytopenia (65/24), lymphopenia (88/34). Due to the highly favorable efficacy/toxicity trade-off achieved, the Monitoring Committee proposed 10 mg as the optimal lenalidomide dose for subsequent patients. **Conclusions:** Continuous lenalidomide with low-dose protracted bendamustine was very active and well tolerated in highly refractory HL patients. Enrollment continues, and updated results with correlative data will be presented. Clinical trial information: NTC01412307.

**8567 General Poster Session (Board #254), Mon, 1:15 PM-5:00 PM**

**Temsirolimus (TEM) and lenalidomide (LEN) in relapsed/refractory Hodgkin lymphoma including in patients with prior exposure to brentuximab vedotin (BV).** *Presenting Author: Jagoda Jasielec, The University of Chicago, Chicago, IL*

**Background:** Hodgkin lymphoma (HL) patients (pts) ineligible for or relapsed after transplant pose a considerable treatment (tx) challenge. While BV is an active agent in this setting, HL remains incurable and new therapies are needed. The PI3K/Akt/mTOR axis and the microenvironment are rational targets in HL. We previously reported phase I results of a phase I/II study of TEM and LEN across lymphoma subtypes demonstrating good tolerability (J Clin Oncol 30, 2012 abstr 8075). Here we report the results of an interim analysis of HL patients. **Methods:** NCI8309 is a multi-institutional phase II trial with 3 cohorts. Cohort C includes R/R HL.Key inclusion criteria are: ANC > 1,000/uL, platelets > 75,000/uL, normal renal and hepatic function, ECOG performance status of ≤2. Pts receive TEM 25 mg IV weekly and LEN 20 mg orally on D1-D21, q28 days until progression/intolerability up to 1 year. Responses are evaluated using the Cheson 2007 criteria at 2 months (mos), then every 3 mos thereafter. **Results:** Thirteen pts (8 male, 5 female) with a median age of 32 years (range, 23-53) were enrolled and evaluable. Pts received a median of 4 prior therapies (range, 2-11); 5 had prior radiation, 8 had prior autologous stem cell transplant (ASCT), and two received both ASCT and an allogeneic transplant. Importantly, 11/13 pts relapsed after BV. With a median follow-up of 9 mos, pts received a median of 4 cycles (range, 2-11) of therapy. The best overall response rate was 85%: 5 (38%) complete responses, 6 (46%) partial responses, 1 (8%) stable disease; median time to best response was 2 cycles. One pt progressed prior to planned evaluation and subsequently died of disease. Of the remaining 12 pts, 5 eventually progressed and 4 went on to transplant including 1 pt with progressive disease. The most common grade 1/2 toxicities included hyperglycemia (77%), fatigue (70%), and LFT abnormalities (77%). The most common grade 3/4 toxicities were neutropenia (46%), thrombocytopenia (38%), and lymphopenia (38%). **Conclusions:** The combination of TEM plus LEN shows promising activity in R/R HL, including prior BV exposure or failure and warrants further evaluation. Clinical trial information: NCT01076543.

**8568 General Poster Session (Board #255), Mon, 1:15 PM-5:00 PM**

**Allogeneic hematopoietic stem cell transplantation in a cohort of 314 advanced lymphoma patients.** *Presenting Author: Sylvain Garciaz, Institut Paoli Calmettes, Marseille, France*

**Background:** Patients with refractory/relapsed Hodgkin Lymphoma and Non Hodgkin Lymphoma (R/R HL-NHL) have poor prognosis. Allogeneic stem cell transplantation (allo-HSCT) represents a potentially curative strategy. The increased use of Reduced Intensity conditioning (RIC) regimens has decreased the non-relapse mortality (NRM) previously reported with myeloablative conditioning. However, Chronic Graft versus Host disease (cGVHD) is still matter of concern. The aim of this study is to evaluate the long-term survival of a cohort of R/R HL-NHL. **Methods:** From 9/1999 to 10/2013, 314 patients from 2 associated institutions received allo-HSCT. Diagnoses were aggressive-NHL in 157 patients, indolent-NHL in 59 and HL in 98. 148 patients relapsed after autologous transplant (auto-HSCT). Out of the 166 remaining patients, 109 received a tandem auto-allo-HSCT and 57 benefit of allo-HSCT without prior auto-HSCT. At transplant, 172 were on complete remission, 86 were on partial remission and 56 were not in response. Donors were HLA identical sibling in 54%, unrelated in 21% and haploidentical in 21%. Conditioning regimen consisted in RIC in 68% of cases. **Results:** With a median follow-up of 29 months [2-160] the 5-year overall survival (OS), the 5-years progression free survival (PFS) and the five years incidence of relapse were 53.9% [47-61], 47.2% [41-54] and 26%[21-32]. The 1-years NRM was 18% [14-23]. Incidence of acute and chronic GVHD was 28% (9% grade 3-4) and 35% (severe NIH cGVHD: 14%). The median duration of immunosuppressive therapy was 7 months [2-117] and it was interrupted in 72% at 1 year for patients who did not relapse. In multivariate analysis, disease status at transplant only influences OS. Age, comorbidities, prior auto-ASCT, donor and conditioning regimen do not have any significant prognostic impact. **Conclusions:** Allo-ASCT is an option for patients with R/RHL-NHL with a 5-years OS of 54% and PFS of 47%. Taking into account population characteristics and period of treatment, toxicity is acceptable with only 14% of severe NIH cGVHD. Most of patient (72%) could stop immunosuppressive therapy demonstrating the absence of GVHD affecting their quality of life.

**8569 General Poster Session (Board #256), Mon, 1:15 PM-5:00 PM**

**PET/CT in lymphoma surveillance: A large single-center experience.** *Presenting Author: Lourdes M. Mendez, Beth Israel Deaconess Medical Center, Boston, MA*

**Background**: The role of FDG PET-CT in the modern management of lymphoma continues to evolve. Current guidelines are largely based on studies with limited numbers of patients. The aim of this study was to define the utility of PET-CTs in identifying asymptomatic relapsed disease during post-treatment follow-up. **Methods**: We performed a large, retrospective cohort study of all PET-CTs performed for patients with pathologically proven lymphoma at our institution from 2003-2005. 1,085 consecutive PET-CTs from 370 patients with lymphoma and accompanying clinical data were reviewed. 81 patients had Hodgkin lymphoma (HL), 154 aggressive Non-Hodgkin lymphoma (a-NHL) and 135 indolent Non-Hodgkin lymphoma (i-NHL). Most scans were obtained in the post-treatment setting (861: either at completion of therapy or during follow-up); 110 and 114 were performed as part of initial staging and during therapy respectively and were excluded from the following analysis. **Results**: 44% of all scans were positive of which 75.7% were associated with progressive disease and 24.3% with disease remission. PET-CT had a sensitivity of 97.5%, specificity of 90.3%, PPV of 75.7% and NPV of 99.2% for relapsed disease in our cohort (Table 1 shows sub-group statistics). The false positive rate for PET-CT was 24.3% most often leading to further imaging. In comparison, the presence of symptoms had a sensitivity of 43.6%, specificity of 88.5%, PPV of 53.8% and NPV of 83.7% without significant variation among HL, a-NHL and i-NHL. Notably, 52% of a-NHL patients with relapsed disease documented by PET-CTs were asymptomatic. **Conclusions**: Our results indicate that PET-CT is highly sensitive for detecting progressive lymphoma in the context of post-treatment follow-up offset by a high rate of false-positives. This highlights the need for algorithms incorporating additional parameters for risk stratification. In this series, a significant portion of a-NHL recurrences detected by PET-CTs were clinically silent. Analysis of how detection of asymptomatic relapse affects patient outcomes is underway.

**Measures of performance of PET-CT by lymphoma subgroup.**

| Lymphoma | Sensitivity (%) | Specificity (%) | PPV (%) | NPV (%) |
|---|---|---|---|---|
| **HL** | 100 | 94 | 80.5 | 100 |
| **a-NHL** | 97.8 | 76.1 | 50.9 | 99.3 |
| **i-NHL** | 96.3 | 90.2 | 82.3 | 98.1 |

**8570 General Poster Session (Board #257), Mon, 1:15 PM-5:00 PM**

**CNS involvement in patients with AIDS-related lymphomas.** *Presenting Author: Jitesh Joshi, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY*

**Background:** CNS involvement (CNSi) at baseline and CNS relapse (CNSr) appears increased in pts with AIDS-related lymphomas (ARL) although this has not been systematically examined. The aim of our study was to better describe factors and outcomes associated with CNSi at baseline and relapse in patients with ARL. **Methods:** We used an existing database of patients with newly diagnosed ARL (Barta et al, Blood 2013) and identified 886 pts with complete information on CNSi at baseline and relapse. We used descriptive statistics to define the prevalence of baseline CNSi and incidence of CNSr. We used Cox-proportional hazard models to assess associations of baseline characteristics (age, sex, time of enrollment, CD4 count, viral load, hx of prior AIDS, concurrent cART, lymphoma subtype, IPI, type of initial chemotherapy, rituximab use) with CNSr, and the Kaplan-Meier method to assess overall survival (OS) for patients with baseline CNSi or CNSr. **Results:** 69% of the pts (n=607) were treated in the post-cART era; 31% (n=276) received rituximab-containing induction chemoimmunotherapy. All included 880 pts received either intrathecal (IT) therapy for CNSi or IT prophylaxis (ppx) with 1- or 3-agent regimens. CNSi at diagnosis was found in 13 % (BL/BLL 27%; DLBCL 6%; $p < 0.001$). There was no difference in the prevalence of baseline CNSi between pre- and post-cART era (13% each). 5.3% of pts experienced CNSr at a median of 4.2 mo (0.3-19.3) after diagnosis (12% if CNSi at baseline; 4% if not). Median OS after CNSr was 1.6 mo (0-86.4). On multivariate analysis, only baseline CNSi was significantly associated with frequency of CNSr (HR 2.9, p=0.01), but no other baseline characteristic. When restricted to pts with no CNSi at diagnosis, IT CNS ppx with 3 vs. 1 agent did not significantly impact the frequency of CNSr (HR 0.33, p= 0.38). CNSi vs. no CNSi at diagnosis was not associated with reduced OS (HR 0.85, p= 0.32). **Conclusions:** 5% of patients with ARL treated with IT CNS-directed therapy experience CNS relapse; it occurs early and has a poor outcome. We did not find a reduced frequency of CNSr with the use of cART, rituximab, or 1- vs. 3-agent IT CNS ppx. Although CNSi at diagnosis confers a 2.9-fold higher risk for CNSr, it does not appear to impact OS, likely because of the low overall frequency of CNSr.

**8571 General Poster Session (Board #258), Mon, 1:15 PM-5:00 PM**

**Association of *helicobacter pylori* CagA translocation with the expression of CagA-signaling transduction molecules in gastric mucosa-associated lymphoid tissue lymphoma.** *Presenting Author: Sung Hsin Kuo, National Taiwan University Hospital, Taipei, Taiwan*

**Background:** We previously reported that a direct contact of *Helicobacter pylori* (HP) with B cells results in CagA translocation into the latter, and the translocated CagA regulates intracellular signaling pathways. Toward this end, we recently found that CagA do exist in the malignant B cells of gastric mucosa-associated lymphoid tissue (MALT) lymphoma, and its presence is closely associated with HP-dependence. In this study, we further evaluate whether CagA expression regulates signaling transduction molecules in tumor cells of HP-positive gastric MALT lymphoma. **Methods:** Forty-seven patients of stage IE HP-positive gastric MALT lymphoma, who received *HP* eradication as their frontline therapy, were included. The expression of CagA, and its signaling pathway-related proteins, such as phosphorylated-SHP-2 (p-SHP-2), p-ERK, p-p38MAPK, Bcl-2, and Bcl-xL in tumor cells were evaluated by immunohistochemistry. **Results:** There were 25 HP-dependent and 22 HP-independent cases. Expression of CagA was closely associated with p-SHP-2 ($P = .012$), p-ERK ($P = .002$), p-p38MAPK ($P = .006$), Bcl-2 ($P = .020$, and Bcl-xL ($P = .006$) expression. Spearman's correlation coefficient analysis showed the strong correlation between CagA-signaling transduction molecules. Combined CagA expression, p-SHP-2 expression and p-ERK expression showed an increased positive predictive value (93.3% [14/15] versus 81.8% [18/22]) and an increased specificity (95.5% [21/22] versus 81.8% [18/22]) for HP-dependence than CagA expression alone. **Conclusions:** Our results indicate that the expression of CagA protein is biologically active and is associated with activation of its downstream signals of HP-dependent gastric MALT lymphoma.

**8572 General Poster Session (Board #259), Mon, 1:15 PM-5:00 PM**

**Hodgkin lymphoma-like post-transplant lymphoproliferative disorder (HL-PTLD): Characteristics, survival, and prognostication in a large U.S. cohort.** *Presenting Author: Aaron Seth Rosenberg, Tufts Medical Center, Boston, MA*

**Background**: Post-transplant lymphoproliferative disorder is a well described complication of solid organ transplant (SOT), however relatively little is known about HL-PTLD. **Methods**: We examined a large cohort of HL-PTLD (1999-2011) in the Scientific Registry of Transplant Recipients (SRTR), focusing on detailed characteristics, overall survival (OS), and prognostic factors. Cox-proportional hazards models were utilized to estimate hazard ratios (HR) and 95% confidence intervals (CI); and we compared characteristics and OS with HL pts from SEER 18. **Results**: We identified 204 HL-PTLD pts. Median age at diagnosis was 52 years (0-80); 74% were male, 82% Caucasian and the most common SOT was renal (52%). Median time from SOT to HL-PTLD was 6.9 years (<0.1-20 years), while tumor was EBV+ in 73%. Older pts were more likely to have EBV- disease (OR 1.42/decade, (95% CI 1.14-1.81), $P<0.01$), however early vs late HL-PTLD was not associated with EBV status. Compared with SEER HL, HL-PTLD pts were older (median 52 vs 38 years, $P=0.006$), more often male (74% vs 55%, $P<0.001$) and with more extranodal (43% vs 3%, $P<0.001$). Median OS for HL-PTLD was 6.3 years with 3- and 5-year OS rates of 65% and 55%, respectively. These rates were significantly inferior compared with SEER HL pts (83% and 79%, respectively, $P<0.001$). For HL-PTLD pts, age (HR 1.29/decade (95% CI 1.15-1.44) $P<0.001$), EBV- (2.03 (95% CI 1.03-4.01) $P=0.04$), increased creatinine (Cr) (HR 1.87 (95% CI 1.43-2.44) $P<0.01$), and performance status <80 (HR 2.10 (95% CI 1.06-4.17) $P=0.03$) were associated with increased risk of death. When controlling for age, only Cr remained significant. Finally, on multivariable analysis controlling for diagnosis date, age, sex and extranodal status, HL-PTLD pts had twice the risk of death (HR 2.05 (95% CI 1.65-2.55) $P<0.001$) vs SEER HL pts. **Conclusions**: These data represent the largest report of HL-PTLD to date. HL-PTLD pts are commonly older, male, and have EBV+ disease, the latter despite typically having "late" PTLD. The dominant factors predicting OS were age and Cr. In addition, OS for HL-PTLD was modest and significantly inferior to a SEER HL population. Continued study of HL-PTLD is needed.

**8573 General Poster Session (Board #260), Mon, 1:15 PM-5:00 PM**

**Polymorphism *BCL2* c(-717)a and prognosis in diffuse large B-cell lymphoma patients.** *Presenting Author: Angelo Borsarelli Carvalho Brito, Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil*

**Background:** High expression of the anti-apoptotic BCL-2 protein was previously described as a predictor of poor prognosis in diffuse large B cell lymphoma (DLBCL). The *BCL2* gene is polymorphic in humans and the single *BCL2* C(-717)A nucleotide polymorphism (SNP) has its variant AA genotype associated with increased Bcl2 expression. The aim of this study was to evaluate whether the *BCL2* C(-717)A SNP influence the outcome of DLBCL patients. **Methods:** Our prospective analysis included 122 consecutive DLBCL patients at diagnosis seen at the Hematology and Hemotherapy Center, between December 2007 and October 2013. Median age of patients was 57 years old (range: 17-89), 63 patients (51.6%) were females, 89 patients (72.9%) had B symptoms, 21 patients (17.2%) had bone marrow involvement (BMI), and 73 (59.8%) patients had advanced tumors (Ann Arbor stage III or IV). Genomic DNA from peripheral blood of all individuals was analysed by polymerase chain reaction followed by enzymatic digestion for discrimination of distinct *BCL-2* C (-717)A genotypes. Patients received 6 cycles of R-CHOP as treatment. Overall survival (OS) time was calculated using the Kaplan-Meier estimate probabilities, and differences between survival curves were analysed by the log-rank test. OS was calculated from date of diagnosis until the date of death or last follow-up. **Results:** The median of observation of patients enrolled in the study was 23 months (range: 1-68). On univariate analysis, B symptoms (68% *versu*s 86%, P=0.04), BMI (52% versus 77%, P=0.01), stage IV (59% versus 82% P=0.01), and BCL2 -717 CA+AA genotype (68% versus 88%, P=0.04) were predictive of worse outcome of DLBCL patients at 24 months of follow up. **Conclusions:** The data present, for the first time, preliminary evidence that inherited abnormality in intrinsic pathway of apoptosis, related to the SNP *BCL2* C(-717)A, influence the outcome of DLBCL patients treated with conventional chemotherapy regimen.

**8574 General Poster Session (Board #261), Mon, 1:15 PM-5:00 PM**

**Reverse phase protein microarray for identification of IL6 receptor ligation-induced insulin receptor, PI3K/AKT, and JAK/STAT signaling pathways in the CARD11 mutated lymphoma cell line OCI-Ly3.** *Presenting Author: Greg Coffey, Portola Pharmaceuticals, Inc., South San Francisco, CA*

**Background:** A subset of diffuse large B cell lymphoma of the activated B cell subtype bear mutations that drive B cell antigen receptor (BCR) independent chronic activation of NFkB. The consequence appears to be loss of dependency for survival on BCR proximal kinases (BTK, SYK) and the initiation of a cytokine autocrine stimulation loop conferring an alternate survival mechanism. In the OCILy3 cell line, for example, IL6 is produced de novo as a consequence of NFkB gene transcription, and both neutralizing anti-IL6 antibody and small molecule JAK inhibition affects cell survival. The exact nature of this survival mechanism, however, is unclear. The goal of our studies was to more clearly define the molecular events induced by IL6 stimulation that promote survival inOCILy3 DLBCL. **Methods:** Reverse phase protein microarray is a high throughput methodology to evaluate multiple intracellular phosphoryaltion events in whole cell lysates. Using a panel of 180 phospho-specific antibodies, we assessed phosphorylation events in OCILy3 cells following IL6 receptor stimulation with and without treatment with the dual SYK/JAK inhibitor PRT062070 (Cerdulatinib). **Results:** 28 of the 180 phosphorylation events tested were induced by approximately 20% or greater upon IL6 receptor stimulation. The most heavily represented categories were within the PI3K/AKT/mTOR, insulin receptor, and JAK/STAT signaling pathways. This was evidenced most notably by robust IL6-mediated induction of Akt, Foxo3a, insulin growth factor receptor and insulin substrate, as well as STAT3 and STAT5 phosphorylation. Treatment with PRT062070 completely inhibited these phosphorylation events. Moreover, PRT062070 dramatically reduced basal phosphorylation of STAT3 Y705, Foxo3a S253, S6Rb S235/236, NFkB p65 S536, BIM S69, and BCL2 T56, and inhibited OCILy3 survival. **Conclusions:** We conclude from these data that in a subset of B cell lymphomas, IL6 receptor signaling likely contributes to survival via induction of multiple signaling arms, not limited to JAK/STAT pathway activation.

**8575 General Poster Session (Board #262), Mon, 1:15 PM-5:00 PM**

**Responses to romidepsin in patients with cutaneous T-cell lymphoma (CTCL) with tumors and/or folliculotropic involvement.** *Presenting Author: Francine M. Foss, Yale Cancer Center, New Haven, CT*

**Background:** CTCL is a heterogeneous group of non-Hodgkin lymphomas that arises in the skin (patches, plaques, tumors, and/or erythroderma) but can involve the lymph, blood, and/or viscera. Additionally, patients with cutaneous tumors or folliculotropic involvement typically have poor prognoses. Romidepsin is a histone deacetylase inhibitor approved by the US FDA for the treatment of patients with CTCL who have received ≥ 1 prior systemic therapy. Durable responses (objective response rate [ORR; complete [CR] + partial responses] of 34% and median duration of response of 15 mo) and tolerability with extended dosing have been reported. To examine responses to romidepsin in these less favorable prognostic subsets, patients with tumors or folliculotropic involvement in the pivotal study of romidepsin for the treatment of CTCL were analyzed. **Methods:** Patients with CTCL (N = 96) who had ≥ 1 prior systemic therapy received romidepsin 14 mg/m$^2$on days 1, 8, and 15 every 28 days. Responses were determined by a rigorous composite endpoint that included changes in the skin, blood, and lymph. Patients with cutaneous tumors or folliculotropic involvement were identified by reviewing diagnosis and histology reports. **Results:** Of 96 patients with CTCL, 20 had tumors, and 10 had folliculotropic involvement (2 had both). All but 2 patients with tumors and 1 with folliculotropic involvement achieved ≥ stable disease (SD) with romidepsin (Table). Time to response and DOR ranged from 0.9-4.7 mo and 1.4-18.7+ mo, respectively, for patients with tumors and 1.0-8.3 mo and 2.1-5.0+ mo for patients with folliculotropic involvement. Discontinuation due to an adverse event occurred in 1 patient with tumors (fatigue) and 0 with folliculotropic involvement. **Conclusions:** In the pivotal study of romidepsin for the treatment of CTCL, patients with cutaneous tumors or folliculotropic involvement commonly responded to therapy. Additionally, despite rapid onset of response, patients with tumors rarely discontinued romidepsin due to adverse events, with the longest duration of response ongoing at 18.7 mo. Clinical trial information: NCT00106431.

| Best response, n (%) | Tumors (n = 20) | Folliculotropic involvement (n = 10) |
|---|---|---|
| ORR | 9 (45) | 6 (60) |
| CR | 2 (10) | 1 (10) |
| SD | 9 (45) | 3 (30) |

**8576 General Poster Session (Board #263), Mon, 1:15 PM-5:00 PM**

**Effect of siltuximab on lean body mass (LBM) in multicentric Castleman's disease (MCD) patients (pts).** *Presenting Author: Michael B. Sawyer, Cross Cancer Institute, Edmonton, AB, Canada*

**Background**: MCD is a rare lymphoproliferative disease with wasting, fever, night sweats, and fatigue. Interleukin-6 (IL-6) plays a pivotal role in MCD and has a major role in cachexia. Siltuximab is a chimeric anti−IL-6 monoclonal antibody being studied for MCD treatment. A randomized, double-blind, placebo-controlled study in MCD showed significant improvement in durable tumor and symptomatic response (34 vs 0% placebo; $P$ = 0.0012), with consistent improvements in major secondary endpoints and no increase in AEs compared with placebo. **Methods**: Pts with confirmed symptomatic MCD were randomized 2:1 to siltuximab 11 mg/kg (n = 53) or placebo (n = 26) IV q3wk. Mean baseline wt was 77 kg for placebo and 69 kg for siltuximab. Pts received best supportive care, and were treated to treatment failure. Abdominal CT scans suitable for body composition analysis were available for 57 (37 on siltuximab, 20 on placebo)/79 subjects. CT scans for each pt time point were landmarked at the 3rd lumbar vertebra (L3). L3 images were analyzed using Slice-O-Matic with Hounsfield units (HU) set at different levels for each tissue: skeletal muscle range of -29 HU to 150 HU, visceral adipose tissue: within -150 HU to -50 HU, intramuscular adipose tissue: within -190 HU to -30 HU, and subcutaneous adipose tissue: within -190 HU to -30 HU. **Results**: The median age of 79 treated pts was 48 years and 53M/26F. 58% had previous therapy and 30% were on steroids. 30 % of pts reported weight loss and 38% of pts reported anorexia at baseline. Mean maximal gain in lean body mass (LBM) in siltuximab pts was 2.4 vs. 1.1 kg in placebo ($P$ = 0.04). Mean maximal gain in fat mass (FM) in siltuximab pts was 6.4 vs. 1.4 kg in placebo pts ($P$ = 0.003). At the first CT scan at 9 wks 50% of siltuximab pts had gained 1 kg of LBM, at no point did 50% of placebo pts gain 1 kg. Gain in fat mass preceded gain in LBM. **Conclusions**: This study has shown that siltuximab caused statistically and clinically meaningful LBM gains compared to placebo pts with MCD. Further study of siltuximab for treating decreases in LBM in IL-6 associated malignancies is warranted. Clinical trial information: NCT01024036.

| | Siltuximab | Placebo |
|---|---|---|
| LBM gain >1 kg | 73% | 35% |
| Stable LBM (gain/loss <1 kg) | 22% | 40% |
| LBM loss >1 kg | 5% | 25% |

**8577 General Poster Session (Board #264), Mon, 1:15 PM-5:00 PM**

**Feasibility and efficacy of high doses of antimetabolites followed by high-dose sequential chemoimmunotherapy (R-HDS) and autologous stem cell transplant (ASCT) in patients (pts) with systemic B-cell lymphoma (BCL) and central nervous system (CNS) involvement: A multicenter phase II trial.** *Presenting Author: Andres J.M. Ferreri, Università Vita e Salute; San Raffaele Scientific Institute, Milano, Italy*

**Background:** This is a phase II trial addressing a new treatment in pts with BCL and CNS disease (NCT00801216). Treatment is based on the encouraging experiences with high doses of antimetabolites in pts with primary CNS lymphoma (Ferreri et al. Lancet 2009) and with R-HDS/ASCT in pts with relapsed BCL (Tarella et al.JCO 2008). **Methods:** HIV- pts (18-70 ys; ECOG PS ≤3) with BCL and CNS disease at diagnosis or relapse were treated with 2 c. of methotrexate 3.5 g/m$^2$ d1 + cytarabine 2 g/m$^2$ x2/d d2-3, followed by R-HDS (cyclophosphamide 7 g/m$^2$ d1, cytarabine 2 g/m$^2$ x2/d d22-25, VP16 2 g/m$^2$ d43) and BCNU-thiotepa conditioning + ASCT. Treatment included 8 doses of rituximab and 4 of intrathecal liposomal cytarabine. Primary endpoint: 2-yr PFS; planned accrual: 38 pts. **Results:** 40 pts were registered (age 32-70 ys, median 59; M/F ratio 1.5): 34 had DLBCL, 3 MCL blastoid variant, 3 FL. CNS disease (brain 23, meninges 6, spinal cord 2, multiple 9) was detected at diagnosis in 17 pts (all with extra-CNS disease) and at relapse in 23 (8 with extra-CNS disease). Response: CR in 23 pts and PR in 1 (ORR= 60%; 95%CI=45-75%), 1 pt had SD, 11 PD (CNS in all pts; plus extra-CNS in 4), 4 died of toxicity (sepsis 2, stroke). G4 neutropenia, thrombocytopenia and anemia were recorded in 90%, 76% and 8% of courses, febrile neutropenia in 26%; opportunistic infections (CMV 6 pts, aspergillosis 1) were successfully managed. Transient transaminases increase (2) and intestinal perforation (1) were the only G4 non-hematol toxicities. ASCs were collected in 23/25 (92%) pts (median 9.5 x 10$^6$/kg; range 6-19); 20 pts underwent ASCT. At a median f-up of 3 ys, 16 pts remain relapse-free, with a 2-yr PFS of 40±8%; 17 pts are alive, with a 2-yr OS of 41±8%; 2-yr OS of transplanted pts was 64±11%. Extra-CNS and/or meningeal disease did not affect survival. **Conclusions:** This feasible and effective treatment is recommended in pts ≤70 ys with secondary CNS lymphoma. Toxicity is usually haematological and manageable. Survival benefit is attainable also in pts with extra-CNS and/or meningeal disease. Clinical trial information: NCT00801216.

**8578 General Poster Session (Board #265), Mon, 1:15 PM-5:00 PM**

**Hepatitis C co-infection in HIV-positive patients treated for lymphoma.** *Presenting Author: Ashwin Sridharan, Montefiore Medical Center, Bronx, NY*

**Background:** While reactivation of Hepatitis B virus (HBV) infection is well described in patients treated for hematological malignancies, less is known about outcomes in patients co-infected with the Hepatitis C virus (HCV). Co-infection with HCV is frequent in HIV+ patients. We aimed to describe characteristics and outcomes of HIV+ patients co-infected with HCV and treated for lymphoma. **Methods:** HIV+ patients diagnosed with lymphoma between 01/01/1997 - 12/31/2013 at the Albert Einstein Cancer Center were identified. HBV+ alone and PCNSL patients were excluded. Characteristics of HCV+ and HCV- patients were compared using Fisher's exact, Chi-Square, or Mann-Whitney U tests. HCV reactivation was defined as a 3-fold increase in ALT from baseline or 1-log increase in HCV viral load within 1 year of diagnosis. The association of HCV co-infection with OS was assessed by multivariate analysis adjusting for age, sex, race, CD4 count, presence of cirrhosis, type of lymphoma, stage, LDH, and Charlson comorbidity score (CCS). We compared overall survival (OS) of HCV+ and HCV- patients using the Kaplan-Meier method and log-rank test. **Results:** 190 HIV+ lymphoma patients were identified. 28% (n=53) were co-infected with HCV, and 8.4% were co-infected with HBV (n=16); 1 patient was co-infected with both HCV and HBV. 50 HCV+HBV-, 107 HCV-HBV- and 1 HCV+HBV+ patients were included in the final analysis. HCV+ patients were older (52 vs. 44, $p < 0.001$), had higher CCS (13 vs. 11, $p < 0.01$), and more often cirrhosis (24% vs. 0%, $p < 0.001$) than HCV- patients. In HCV+ patients, HCV reactivation occurred 33% (n=17) and persisted in 7.4% (n=4) until 1 year after lymphoma diagnosis; none died from liver failure. Median OS in HCV co-infected patients was 59.7 mo vs. 88.6 mo in HCV-HBV- patients (p=0.76). In multivariate analysis, HCV co-infection was not associated with worse survival (HR 0.98, 95% CI 0.54-1.8; p=0.96), while low CD4 count (<100 cell/mm3), NHL subtype, advanced stage, high LDH (>190 U/L), and cirrhosis were independently associated with worse OS. **Conclusions:** While HCV reactivation is common in co-infected HIV+ patients treated for lymphoma, HCV co-infection did not portend worse OS in our cohort. Our analysis is limited by the small size of the cohort.

**8579 General Poster Session (Board #266), Mon, 1:15 PM-5:00 PM**

**Longitudinal diffusion MRI in PCNSL treated with methotrexate, rituximab, and temozolomide (MRT).** *Presenting Author: Vyshak Chandra, Massachusetts General Hospital, Boston, MA*

**Background:** High-dose methotrexate (HD-MTX) is the backbone of therapy for PCNSL but induction chemotherapy can also include temozolomide and rituximab (MRT). We evaluated baseline tumor ADC values and change in ADC values as markers of response. **Methods:** After receiving IRB consent, we retrospectively evaluated PCNSL patients treated at our hospital with MRT. Patients were treated in 28-day induction cycles: HD-MTX (8g/m$^2$-dose adjusted based on creatinine clearance) on days 1 and 15; rituximab (375 mg/m$^2$) weekly for 6 doses; and temozolomide (150-200 mg/m$^2$) on days 7-11 of each cycle for a goal of 12 cycles. HD-MTX was continued every 2 weeks until complete response (CR). Brain MRI was done after every other MTX treatment to assess response. Volume of contrast enhancing tumor and median tumor ADC values at baseline, 1 month, and 2 months after treatment began was measured. **Results:** From August 2003 to September 2013, 42 patients received MRT as first-line therapy at the time of initial diagnosis and 10 received MRT as salvage therapy at first or second recurrence. The median age of all patients was 63 (range 49-84). With first-line MRT therapy, there were 34 CRs (median cycles to CR = 4), 5 PRs, 2 PD's, and 1 nonevaluable for response. With salvage MRT therapy, there were 6 CRs (median cycles to CR = 4), and 4 PR's. After a median follow-up of 23.5 months in the first-line group and 51.6 months in the relapse group, 14 patients have progressed and 6 died (1 from an unrelated heart attack). After analysis of 22 imaging datasets, 18/22 patients saw a reduction of >70% in enhancing volume from baseline to month 2 of treatment. Shorter time to CR was associated with lower baseline median tumor ADC (p=0.035). There was no statistically significant association in baseline or change in ADC and PFS or OS. **Conclusions:** MRT resulted in a promising early response rate. Lower baseline tumor ADC was associated with shorter time to CR so may be a helpful biomarker. Lower ADC may reflect hypercellular, rapidly proliferating tumor that is more sensitive to chemotherapy. The lack of association with tumor ADC and survival was likely because of the few progression/death events in our dataset and longer term follow-up is needed with more imaging time points.

**8580 General Poster Session (Board #267), Mon, 1:15 PM-5:00 PM**

**Antitumor activity of inhibiting SYK kinase with TAK-659, an investigational agent, in DLBCL models.** *Presenting Author: Jessica Huck, Takeda Pharmaceuticals International Co., Cambridge, MA*

**Background:** Spleen Tyrosine Kinase (SYK) is a non-receptor cytoplasmic tyrosine kinase that is a common member of various signal transduction cascades in cells of the hematopoietic lineage including those involved in B-cell receptor (BCR) activation, B cell migration, and B cell polarization. Abnormal SYK activation has been implicated in several hematopoietic malignancies including chronic lymphocytic leukemia (CLL), peripheral T-cell lymphoma (PTCL) and diffuse large B-cell lymphoma (DLBCL). **Methods:** TAK-659 is an investigational inhibitor of SYK that is currently being evaluated in a Phase I clinical trial (NCT02000934). **Results:** TAK-659 inhibits SYK with an IC50 of 3.2nM and has the ability to inhibit cellular proliferation in relevant models with an EC50 between 25 to 400nM. Daily oral administration of 60 mg/kg TAK-659 showed anti-tumor activity in DLBCL cell-line xenograft models representing ABC (OCI-LY-10 (TGI 50%), HBL-1 (TGI 40%) and a primary human tumor xenograft model, PHTX-95L (TGI 70%), GCB (OCI-LY-19 (TGI 37%) and non-ABC/GCB (WSU (TGI 50%)) subtypes. Interestingly, in the OCI-LY-19 GCB-type DLBCL model, 60 mg/kg TAK-659 (TGI 37%) showed increased activity over a BTK inhibitor (TGI 15%) suggesting the hypothesis that inhibition of BCR signaling upstream of BTK could be beneficial in treating a broader range of sub-types of B-cell malignancies. The time course of pSYK (pSYK$^{525}$) and pBLNK (pBLNK$^{65}$) expression were assessed following single doses of TAK-659. Time dependent inhibition of these phosphoproteins and also increase in expression of cleaved caspase 3, an apoptosis marker was observed in the DLBCL models studied here. Phenotypic assessment of 15 primary DLBCL samples for pSYK and other relevant pathway markers revealed that SYK activation occurs in a considerable number of molecularly heterogeneous DLBCL samples and is consistently associated with activation of the BCR pathway. **Conclusions:** These results together suggest that SYK activation occurs in various subsets of DLBCL samples and TAK-659 showed activity in pre-clinical models of the various subtypes of DLBCL supporting its clinical investigation in DLBCL patients.

**8581 General Poster Session (Board #268), Mon, 1:15 PM-5:00 PM**

**Efficacy, safety, and cost efficiency of rituximab, gemcitabine, dexamethasone, and oxaliplatin (RGDOx) in B-cell NHL: Report of the prospective multicentric trial NCT01019863.** *Presenting Author: Marco Lefebvre, CHUS, Sherbrooke, QC, Canada*

**Background:** Cisplatinum-based 2nd line therapy is poorly tolerated. We evaluated the activity and toxicity of an outpatient RGDOx regimen **Methods:** Patients (pts) with CD20+ NHL, without limitation of age, general condition or prior treatments, were eligible for up to 8 biweekly cycles of rituximab 375 mg/m², gemcitabine 1000 mg/m², oxaliplatin 100 mg/m² on day 1 and dexamethasone 40mg/day orally on day 1- 3. Toxicity was reported according to NCI criteria. Response was assessed at mid and end of treatment. Pts were followed up to 24 months. Costs were collected on per diem canadian interprovincial rates and hospital pharmacy medication costs as of Oct. 2011. **Results:** The planned 50 pts were included from 2009 to Jan. 2013. Two died before starting therapy and were not included in this analysis; 17 females, 31 males, median age 70 (47 - 86) yrs with relapsed (37) or refractory (11) B-NHL (DLBCL 25, FL 8, MCL 11, Richter 2 and CLL 2). 83% had stage III/IV disease, aaIPI / FLIPI ≥2 (85%), median Charlson co-morbidity score of 4, average 2 (1-8) previous treatment lines, 47 previously treated with rituximab and 9 with cisplatin. A total of 250 cycles were given. This was well tolerated. Common grade I-II AE: Sensory neuropathy 66%, diarrhea 36% asthenia 35%, and bone pain 18%. Grade III/IV: Lymphopenia 12%, neutropenia 3% and thrombocytopenia 4%. Two died after 1 and 3 cycles, before documenting response. The overall response was 57% (n=46, CR 40%, PR 17%, PD: 43%). DLCBL (40%, 8%, 52%), FL (38%, 25%, 38%), MCL (50%, 20%, 30%). The median survival was 18.4 months (n=48) and disease-free median survival among responders was 15.7 months (n=27). Refractoriness to previous treatment or response lasting less than 12 months was associated with poorer outcome. Previous cisplatin therapy tended to predict lower response. Average 6-cycle course was associated with 4.8 days of hospitalization, 0.7 medical visits for iatrogenic side effects and 7.3 visits for additional laboratory tests. Mean cost for 6 cycles of RGDOX was $Can 54,991 with a median cost per life year of $Can 35,863. **Conclusions:** RGDOx is safe, effective and cost-effective for relapsing/refractory B-Cell NHL. Clinical trial information: NCT01019863.

**8582 General Poster Session (Board #269), Mon, 1:15 PM-5:00 PM**

**A phase I/II trial of the combination of romidepsin and lenalidomide in patients with relapsed/refractory lymphoma and myeloma: Phase I results.** *Presenting Author: Matthew Alexander Lunning, University of Nebraska Medical Center, Omaha, NE*

**Background:** Epigenetic manipulation and immunomodulation are therapeutic strategies in hematologic malignancies. Romidepsin (Romi), a histone deacetylase inhibitor, and lenalidomide (Len), an immunomodulatory agent, both have efficacy and lack cumulative toxicity in relapsed/refractory (rel/ref) lymphoma and myeloma. We report the phase I results from an ongoing phase I/II study. **Methods:** The phase I portion evaluated toxicity (tox), maximum tolerated dose (MTD) and clinical activity of Romi-Len. Romi was given IV on days 1, 8, and 15 and Len was given orally on days 1-21 of a 28-day cycle. A standard 3+3 dose escalation schema was followed and 4 cohorts were planned: 1) Romi 8 mg/m²-Len 15 mg, 2) Romi 8 mg/m²-Len 25 mg, 3) Romi 10 mg/m²-Len 25 mg, 4) Romi 14 mg/m²-Len 25 mg. Dose-limiting tox (DLT) was defined as any of the following in cycle 1: ≥ grade 3 non-heme tox, ≥ grade 4 heme tox or grade 3 heme tox resulting in a significant delay of treatment. Tumor response was based on disease-specific criteria. Patients (pts) could be treated to progression or intolerance. **Results:** Nineteen pts with rel/ref lymphoma have been enrolled with 15 pts evaluable for DLT (13 pts for response). Three pts progressed prior to study drug and 1 pt progressed in cycle 1; all were replaced for DLT assessment. Two DLTs have occurred to date: cohort 2, 1/7 pts had grade 4 pneumonia; cohort 4, 1/3 pts had grade 3 thrombocytopenia delaying therapy. One grade 3 neutropenic fever has been seen post cycle 1. Of the 13 pts evaluable for response, the overall response rate is 54% (7/13) with complete response in 15% (2/13) and partial response in 39% (5/13). Four responses are ongoing at 4-13 cycles. Responses by subtype include B-cell 50% (2/4), T-cell 67% (4/6), and Hodgkin 33% (1/3). No cumulative tox has been seen. **Conclusions:** The combination of Romi-Len appears to be well tolerated without unexpected tox up to standard single agent doses of each drug. Responses have been seen across multiple lymphoma subtypes. Disease specific phase II cohorts will include B-cell lymphomas, T-cell lymphomas, and multiple myeloma. Final phase 1 safety and efficacy data will be presented. Clinical trial information: NCT#01755975.

**8583 General Poster Session (Board #270), Mon, 1:15 PM-5:00 PM**

**Treatment of HIV-associated plasmablastic lymphoma: A single-center experience with 25 patients.** *Presenting Author: Ibrahim Fuad Ibrahim, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Plasmablastic lymphoma (PBL) is a rare and aggressive subtype of B-cell lymphoma with a predominant occurrence in patients with HIV and other immune compromised states. It commonly affects the jaw and oral cavity but has also been described involving the gastrointestinal tract, bone, bone marrow, and lymph nodes. The historical treatment regimens have typically included CHOP, but more recently dose-adjusted EPOCH has become the standard for HIV-associated lymphomas. It is unclear if regimens other than CHOP can significantly improve the outcome in patients with PBL. **Methods:** We identified 25 patients with PBL at Parkland Hospital treated between 2000 to 2012. Data regarding patient age, gender, HIV status, initiation of antiretroviral therapy, immunophenotype, EBV status, administration of radiotherapy and primary site of presentation were recorded. Log-rank test was used to assess differences in survival by treatment regimen. **Results:** The median age at presentation was 44 years with a 4:1 male predominance. Most (92%) were infected with HIV and had a median CD4+ count of 87 cells/mm3. A minority of patients (32%) were on antiretroviral therapy at the time of diagnosis. The most common primary sites of disease were oral/maxillofacial sites and the gastrointestinal tract with most patients presenting with stage III or IV disease (64%). EBV was detected in the majority of cases (91%) and HHV-8 was detected in none of the cases. CD20 positivity was rare (12%). MYC rearrangements were described in 32% of the cases. Chemotherapy was used to treat most patients (76%) with EPOCH being the most common treatment choice (56%). Radiotherapy was administered in 28% of patients. Primary refractory disease was observed in 16% of the patients. The median overall survival observed in all patients who received chemotherapy was 11.6 months (range 2-63 months). Those who were treated with EPOCH demonstrated a better median overall survival (17 months) compared to those treated with CHOP and CHOP-like regimens (7 months, p=0.04). **Conclusions:** This retrospective single center study suggests that EPOCH may improve survival in PBL.

**8584 General Poster Session (Board #271), Mon, 1:15 PM-5:00 PM**

**Older patients and risk of developing and dying from bleomycin-induced lung toxicity.** *Presenting Author: Preethi Reddy Marri, Mayo Clinic, Pediatric Hematology-Oncology, Rochester, MN*

**Background:** Bleomycin-induced pneumonitis (BIP) has been well described in classical Hodgkin lymphoma (cHL) patients treated with bleomycin-containing chemotherapy regimens. The incidence of acute and subacute pulmonary toxicity varies widely and multiple factors contribute to mortality in patients with BIP. We therefore reviewed the outcome of cHL patients treated at a single institution to further define the incidence of BIP and to identify major contributors to BIP-associated morbidity and mortality. **Methods:** One hundred sixty-one pediatric and adult patients who were treated with bleomycin-containing chemotherapy for newly diagnosed cHL between January 2000 and December 2012 were eligible for this retrospective review. BIP was defined by fever, pulmonary symptoms, pulmonary infiltrates, or a decline in DLCO, with no evidence of an infectious etiology. **Results:** BIP was observed in 43.5 % (n=70) of patients. Age >/=45 years was associated with both an increased incidence (p= <0.0001) and increased severity (p=0.0005) of lung toxicity. ABVD regimen as initial therapy (p= <0.001), obesity (p=0.0331) and the presence of at least one cardiac or respiratory comorbidity (p=0.0088) was also associated with the development of BIP. Higher BMI was associated with earlier onset of lung toxicity. No significant increase in pulmonary toxicity was noted with co-administration of G-CSF (p=0.7249). Bleomycin related mortality rate was 4.97 % (n=8) when all patients were considered and 11.43 % (8/70) in patients who developed pulmonary symptoms. Seventy five percent (6/8) of those who died were older than 60 years. **Conclusions:** The risk of BIP is significant in cHL with the use of bleomycin-containing regimens. Age >/= 45 years appears to increase the risk of BIP and is associated with increased mortality. These findings highlight the need for testing novel treatment combinations in cHL patients that omit bleomycin.

**8585 General Poster Session (Board #272), Mon, 1:15 PM-5:00 PM**

**Mantle cell lymphoma: Toll-like receptors (TLRs) and B-cell receptor (BCR) gene expression analysis for identification of a distinct BCR-activated subset, with germinal center signature and indolent biology.** *Presenting Author: Ariz Akhter, University of Calgary, Calgary, AB, Canada*

**Background:** Mantle cell lymphoma (MCL) is an aggressive disease with complex biology. Enhanced understanding of pathogenesis can result in better utilization of novel therapies. MCL is believed to arise from naïve B-lymphocytes; however, there are indications that at least a subset of MCL arises from antigen-experienced B cells; where Toll-like Receptors (TLRs) and B-cell receptor (BCR) play an intricate role. **Methods:** Here, we report Gene Expression Profile (GEP) data on TLRs/BCR related genes and associated down stream pathways (154 gene-set) in a cohort (n=81) of MCL patients (pts.). GEP was assessed by Nano string technology utilizing mRNA from diagnostic biopsy tissue. **Results:** Hierarchical clustering based on TLR/BCR genes (n= 18), revealed four distinct clusters (A, n=12; B, n=30; C, n=19 and D, n=20) with differential expression of *CD79b, SYK, LYN; BTK* ($p<0.002$) and *TLRs* (2,3,6,7,8,9,) ($p<0.01$). On further analysis, Cluster C revealed higher expression of Germinal Centre (GC) associated genes (GCET, LMO2 and HGAL) ($p<0.001$). This cluster (C) showed lower expression of PI3K/Akt pathway ($p<0.005$) and MAP/ERK pathway associated genes ($p<0.009$) as compared to cluster B. Patients in cluster C, had a trend toward better overall survival (OS), in comparison with cluster B &D ($p=0.07$)(Log Rank (Mantel-Cox). **Conclusions:** Our data suggest that MCL pts. can be stratified based on BCR activity and these pts. can benefit from array of BCR inhibitors as second line therapy. A subset of MCL shows exposure to GC microenvironment, low PI3K/Akt and MAP/ERK pathway activity and a trend towards a better overall survival.

**8586 General Poster Session (Board #273), Mon, 1:15 PM-5:00 PM**

**Cyclophosphamide, bortezomib, and dexamethasone (CYBORD) treatment for relapsed/refractory multiple myeloma.** *Presenting Author: Jorge Monge, Mayo Clinic, Scottsdale, AZ*

**Background:** Patients with multiple myeloma have experienced an increase in survival due to rescue options provided by novel agents used alone and in combination. There is a paucity of data for combinatorial regimens in this population. CYBORD has been validated as an upfront strategy with excellent long-term outcomes, but its use in relapsed disease has not been fully reported. We report a series of 55 pts with relapsed/refractory MM and their response to CYBORD. **Methods:** 55 pts with relapsed/refractory MM were treated with CYBORD on a 28 day cycle. Dosing was cyclophosphamide 300 mg/m$^2$ PO q.wk; bortezomib 1 (2%), 1.3 (22%) or 1.5 mg/m$^2$ (76%), IV (89%) or SQ (11%), once (87%) or twice weekly (13%); and dexamethasone 40 mg PO q.wk. We report response using the IMWG criteria, and new onset neuropathy based on NCI CTCAE. **Results:** Mean age was 65.6 years and 56% were male. Of the 55 pts, 64% had progressed while on therapy and 56% had a previous ASCT. Mean number of previous treatment lines was 3.3, and 36% and 82% were proteasome inhibitor (PI) and CYBORD naïve. Median follow up time was 24.1 mos and mean number of cycles was 5 ($\pm$4.4). ORR was 71%, 26% had $\geq$VGPR, and 13% CR. PI naïve pts had an ORR of 95% while pts who had previously received a PI had an ORR of 57%. Median PFS and OS were 9.2 and 29 mos. After a mean of 6 cycles, 22% of pts underwent subsequent ASCT. New onset grade 1 neuropathy was present in 16% of pts, while only 2% had grade 2 and none had grade 3 neuropathy. We found an increase in PFS in PI naïve pts (14.8 v 5.2 mos, HR 0.4, 95%CI 0.2-0.7), pts that underwent subsequent ASCT (19.7 v 6.3 mos, HR 0.3, 95%CI 0.2-0.7) and pts that had $\leq$3 prior treatment lines (12.1 v 6.1 mos, HR 0.5, 95%CI 0.2-0.8); no difference was found by mSMART risk or prior ASCT. An increase in OS was found only in PI naïve pts (35.4 v 21.2 mos, HR 0.5, 95%CI: 0.3-0.98) and pts that underwent subsequent ASCT (53.1 v 26.7 mos, HR 0.3, 95%CI 0.2-0.8); no difference was found by number of previous treatment lines, mSMART risk or prior ASCT. **Conclusions:** CYBORD is an effective treatment regimen without significant increase in side effect profile for pts with relapsed/refractory MM, achieving better outcomes in PI naïve pts and those who undergo subsequent ASCT, regardless of mSMART risk.

**8587 General Poster Session (Board #274), Mon, 1:15 PM-5:00 PM**

**Focal bone marrow processes and early bone lesions in patients with multiple myeloma (MM) precursor diseases: A prospective study using molecular imaging.** *Presenting Author: Manisha Bhutani, Lymphoid Malignancies Branch, Center for Cancer Research, National Cancer Institute, NIH, Bethesda, MD*

**Background:** The incidence and impact ofbone marrow processes and/or early bone lesions in patients with MM precursor diseases is largely unknown. We prospectively compared the sensitivity of several imaging modalities among patients with monoclonal gammopathy of undetermined significance (MGUS), smoldering multiple myeloma (SMM) and MM. **Methods:** Ninety-one patients were evaluated: Thirty (10 each with MGUS, SMM and MM) had skeletal survey, [$^{18}$F]-FDG PET/CT, [$^{18}$F]-NaF PET/CT, and lumbosacral dynamic contrast enhanced (DCE)-MRI. Sixty-one newly diagnosed patients (16 high risk SMM and 45 MM) had skeletal surveys and FDG PET/CT. **Results:** Among ten patients with MGUS, MRI found only one unifocal marrow process; all other evaluations were negative. Among 26 SMM patients who by definition had negative skeletal surveys, 11(42%) had abnormalities on FDG PET/CT including four with lytic bone lesions on CT, one with a biopsy-confirmed intramedullary lesion that was negative on both CT and NaF PET/CT and six with unifocal or diffuse marrow process; DCE-MRI was negative in those assessed. Among 55 MM patients, 35 (70%) and 47 (85%) had lytic lesions on skeletal survey and CT, respectively, with 15 and five having >7 sites on CT and skeletal survey, respectively. Marrow involvement was observed on FDG PET/CT in seven (31%), and on DCE-MRI in 6/9 (67%). NaF uptake was observed only in patients with lytic lesions on CT, and provided no additional information. The normal vertebral FDG or NaF $SUV_{mean}$ was not correlated with marrow plasmacytosis and did not increase from MGUS>SMM>MM. **Conclusions:** Using sensitive molecular imaging tools we detected bone and marrow changes not present on skeletal surveys in SMM patients, consistent with the concept of a disease continuum leading to MM. These results provide a framework to include molecular imaging in trials with SMM and MM patients with the hope of improving risk/prognosis categorization. Molecular image-guided biopsies will also allow longitudinal evaluation of bone marrow processes. By integrating modern imaging and molecular profiling, we may be able to develop more precise treatment strategies for precursors to myeloma. Clinical trial information: NCT01237054; NCT01402284; NCT01572480.

**8588 General Poster Session (Board #275), Mon, 1:15 PM-5:00 PM**

**Effect of combination of proteasome inhibitor marizomib and immunomodulatory agent pomalidomide on synergistic cytotoxicity in multiple myeloma.** *Presenting Author: Dharminder Chauhan, Dana-Farber Cancer Institute, Boston, MA*

**Background**: Our prior studies showed that the proteasome inhibitor marizomib, distinct from bortezomib, triggers apoptosis in multiple myeloma (MM) cells resistant to bortezomib, and induces synergistic anti-MM activity in combination with immunomodulatory agent lenalidomide. Like lenalidomide, pomalidomide is an analogue of thalidomide, has immunomodulatory properties, and has been approved by FDA for treatment of MM. The approved indication for pomalidomide is for MM patients who have received at least two prior therapies including lenalidomide and bortezomib and have demonstrated disease progression on or within 60 days of completion of the last therapy. Approval is based on response rate. Clinical benefit, such as improvement in survival or symptoms, has not been verified. Here, we examined the combined anti-MM activity of marizomib and pomalidomide using in vitro models of MM. **Methods**: MM cell lines, patient MM cells, and PBMCs from normal healthy donors were utilized to assess the synergistic anti-MM activity of marizomib and pomalidomide. **Results**: MM cells were pretreated with DMSO control or with pomalidomide for 24h; marizomib was then added for an additional 24h, followed by analysis of cell viability. A significant decrease in viability of all cell lines was observed in response to treatment with combined low doses of marizomib and pomalidomide, compared with either agent alone. Isobologram analysis confirmed the synergistic anti-MM activity of these agents. The cytotoxicity of combination therapy was observed in MM cells resistant to bortezomib therapies. Marizomib plus pomalidomide-induced apoptosis was associated with: 1) activation of caspase-8, caspase-9, caspase-3, and PARP; 2) downregulation of IRF4, c-myc, and Mcl-1; 3) inhibition of migration of MM cells and angiogenesis; and 4) suppression of proteasome activity. Finally, low doses of marizomib and pomalidomide overcomes the cytoprotective effects of MM-host bone marrow microenvironment. **Conclusions**: Our study provides the preclinical rationale for a clinical protocol evaluating pomalidomide together with marizomib to potentially improve patient outcome in MM.

**MM-005: Phase 1 trial of pomalidomide (POM), bortezomib (BORT), and low-dose dexamethasone (LoDEX [PVD]) in lenalidomide (LEN)-refractory and proteasome inhibitor (PI)-exposed myeloma.** *Presenting Author: Paul G. Richardson, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Combination treatment (Tx) with IMiDs immunomodulatory agents and PIs demonstrated substantial efficacy in myeloma patients (pts) (Richardson, *Blood,* 2010). MM-005 was designed to identify the optimal PVD dose for a phase 3 trial (MM-007) comparing PVD vs. BORT + LoDEX in RRMM pts. A secondary objective examined subcutaneous (SC) BORT as part of PVD Tx. **Methods:** Eligible pts had 1-4 prior Tx lines, including ≥2 consecutive cycles (C) of LEN and a PI. Pts must have been LEN-refractory and PI-exposed but not BORT refractory. MTD was determined using a 3+3 design; an SC BORT cohort was added at the MTD. Tx continued until PD or unacceptable AE. MTD was the primary endpoint; additional endpoints included safety, overall response rate (ORR; ≥ partial response [PR]), time to response (TTR), duration of response (DoR), and pharmacokinetics. **Results:** The trial is fully enrolled (N=28): 22 pts in intravenous (IV) BORT and 6 pts in SC BORT cohorts. Median prior Tx was 2 (1-4). No dose-limiting toxicities (DLTs) were observed. Recommended PVD dose (21-day C) is POM 4 mg D1-14, BORT 1.3 mg/m$^2$ on D1, 4, 8, 11 for C1-8; D1, 8 for C9+, and LoDEX 20 mg (10 mg for pts > 75 y) on D1-2, 4-5, 8-9, 11-12 for C1-8; D1-2, 8-9 for C9+. Most common grade (Gr) 3-4 AEs included (IV cohorts): neutropenia (36%) and thrombocytopenia (27%); (SC cohort): 7 Gr 3 AEs occurred in one pt each; no Gr 4 AEs were observed. Peripheral neuropathy (PN) in IV cohorts was 0% (Gr 3-4), 14% (Gr 2), and 32% (Gr 1); 1 pt reported Gr 2 PN (SC cohort). No pt discontinued due to Tx-related AEs. ORR (IV cohorts) was 71% (38% ≥ very good PR [VGPR]), median TTR was 1 C, and median DoR was 11 C. Preliminary (median 5 C) ORR for SC pts was 67% (1 PR, 2 VGPRs, 1 complete response). 4 of 6 pts receiving BORT SC still remain on Tx; 1 of 4 pts has not yet responded. BORT administration route (IV/SC) did not impact POM exposure, which was within the range previously observed. Long-term follow-up will be presented. **Conclusions:** PVD was effective and well tolerated across all cohorts in LEN-refractory/BORT-exposed pts with no DLTs or discontinuations due to Tx-related AEs to date. PVD is now under evaluation in the MM-007 phase 3 trial. Clinical trial information: NCT01497093.

**8591 General Poster Session (Board #278), Mon, 1:15 PM-5:00 PM**

**A randomized phase 3 trial of thalidomide and prednisone (TP) as maintenance therapy following autologous stem cell transplantation (ASCT) in patients with multiple myeloma (MM): An updated analysis of the NCIC Clinical Trials Group MY10 trial.** *Presenting Author: Annette E. Hay, NCIC Clinical Trials Group, Kingston, ON, Canada*

**Background:** Primary analysis of the MY.10 trial (Stewart, Blood 2013) demonstrated, with a median f/u of 4.1 yrs, MM patients completing ASCT and randomized to receive 4 yrs of TP experienced superior progression free survival (PFS) and poorer quality of life scores as compared with those randomized to observation. No differences in overall survival (OS) were detected (HR=0.77). We now report long term survival. **Methods:** From 2002-09, 332 patients were enrolled. Primary endpoint was OS; secondary endpoints were myeloma-specific PFS (MS-PFS) defined as time from randomization to progressive myeloma, and PFS which also includes death without myeloma progression as an event. Trial arms were compared with a stratified (by age and response to transplant) log-rank test; all analyses were by intent-to-treat. This report is based on the final 2013 December 20 locked database. **Results:** Median age at study entry was 58 years. Among 166 TP patients, 8 (5%) completed 4 years of at least one drug. With a median follow-up of 6.1 years (range 0 – 10.4), TP continued to be associated with superior MS-PFS and PFS. No differences in OS were detected. There were 17 second cancers in 13 TP patients (6 skin, 2 acute myeloid leukemia (AML), 9 solid tumors) compared with 9 in 8 observation patients (3 skin, 2 AML / myelodysplasia, 4 solid tumors). A higher incidence of thromboembolic events was observed in the TP arm (12 vs. 1, p = 0.003). **Conclusions:** A PFS advantage of TP maintenance therapy continues to be seen at 6 years without improvement in OS. As the HR for OS has increased from 0.77 with median f/u of 4.1 yrs to 0.88 with median f/u of 6.1 yrs, we expect that longer f/u will not permit detection of a difference in OS. Our data are consistent with other data showing that PFS is an unreliable surrogate for OS when evaluating maintenance therapies for MM patients. Clinical trial information: NCT00049673.

**Age-related trends in utilization and outcome of autologous haematopoietic cell transplantation for multiple myeloma.** *Presenting Author: Holger W Auner, Imperial College London, London, United Kingdom*

**Background:** Autologous haematopoietic cell transplantation (AHCT) is considered a standard of care in eligible patients with multiple myeloma (MM) aged <65 years but is not generally recommended in patients ≥65 years of age. We analysed all first AHCTs that were reported to the EBMT 1991-2010 to study trends in utilisation and outcome of AHCT for the treatment of MM in relation to age. **Methods:** A total of 53675 patients from 31 European countries and 497 centres were included in the analysis. Patients were grouped into six age groups (<40, 40-49, 50-59, 60-64, 65-69, ≥70 years) and four calendar periods (1991-1995, 1996-2000, 2001-2005, and 2006-2010) by age at, and year of, first AHCT. **Results:** Median age at AHCT increased from 52.8 years in 1991-1995 to 59 years in 2006-2010 (p<.001). The number of patients undergoing AHCT increased throughout all four calendar periods for all age groups. The highest proportional increase was observed for patients aged 65-69 and ≥70 years. While the number of tandem AHCTs decreased in 2006-2010 in all age groups, patients aged ≥70 years showed the smallest decrease and had the highest rate of tandem transplants in this calendar period (19%). Two-year survival rates increased for all age groups since 1991-1995. The greatest improvement was observed in patients aged 65-69 years (from 55.3% in 1991-1995 to 82.9% in 2006-2010). The smallest improvement in 2-year survival was seen in patients aged <40 years (from 82.2% in 1991-1995 to 85.9% in 2006-2010). Consequently, the maximum difference in 2-year survival between age groups decreased from 27.9% in 1991-1995 to 5.7% in 2006-2010. Five-year survival was higher in 2006-2010 compared to 1991-1995 in all age groups. However, we observed an emerging trend of decreasing 5-year survival for patients aged <40 and 40-49 years in the most recent calendar period. **Conclusions:** The data demonstrate that utilisation of AHCT for MM continued to increase in recent calendar periods, particularly in patients aged ≥65 years. The data also show that post-transplant survival improved considerably more in older than in younger patients. Thus, AHCT is a commonly used treatment strategy with good outcome in MM patients aged ≥ 65 years.

**8593 General Poster Session (Board #280), Mon, 1:15 PM-5:00 PM**

**Pomalidomide plus low-dose dexamethasone (POM plus LoDEX) versus high-dose dexamethasone (HiDEX) for relapsed or refractory multiple myeloma (RRMM): Overall survival (OS) results of MM-003 after adjustment for crossover.** *Presenting Author: Gareth J Morgan, Centre for Myeloma Research, Institute of Cancer Research, London, United Kingdom*

**Background:** The pivotal, randomized phase 3 MM-003 trial in patients (pts) with RRMM demonstrated significantly longer median progression-free survival (PFS) with POM + LoDEX (n = 302, 4 months) than with HiDEX (n = 153; 1.9 months; $P < 0.0001$). Unadjusted median OS was also significantly longer with POM + LoDEX than with HiDEX (HR 0.74; $P = 0.0285$) despite the crossover of approximately 50% of pts from the HiDEX arm to POM + LoDEX or POM monotherapy. In the presence of extensive crossover, conventional survival analysis methods are biased. Here, we used the 2-stage Weibull method for crossover adjustment to estimate the OS difference between POM + LoDEX and HiDEX. **Methods:** A 2-stage model was used to estimate counterfactual, adjusted survival data for the HiDEX arm, using a secondary baseline defined by the time of disease progression. To extrapolate the counterfactual data as required by health technology assessment bodies, standard model selection methods were used to identify the best fitting parametric model. **Results:** Unadjusted median OS in MM-003 was 12.7 and 8.1 months in the POM + LoDEX and HiDEX groups, respectively. After adjusting for crossover, the difference in median OS in the 2 groups was 7.0 months (12.7 vs 5.7 months). Median OS in the POM + LoDEX arm was therefore more than double that in the HiDEX arm. Extrapolation using a log-normal model fitted to the adjusted OS data produced an estimated difference in mean survival times of 14.6 months (28.0 vs. 13.4 months). Predicted survival at 3 years was 21% for pts on POM + LoDEX compared with 8% for pts on HiDEX. **Conclusions:** The MM-003 intent-to-treat analysis showed a significant increase in median PFS and OS for POM + LoDEX vs HiDEX. The present analysis suggests that OS with POM + LoDEX is double that with HiDEX after accounting for crossover. Extrapolation over a lifetime horizon predicts a mean survival difference between POM + LoDEX and HiDEX of more than 14 months. These data provide important evidence for understanding the clinical efficacy and evaluating the overall economic value of POM in the treatment of RRMM. Clinical trial information: NCT01311687.

**8594^ General Poster Session (Board #281), Mon, 1:15 PM-5:00 PM**

**Results of the dose-escalation portion of a phase 1/2 study (CHAMPION-1) investigating weekly carfilzomib in combination with dexamethasone for patients with relapsed or refractory multiple myeloma.** *Presenting Author: James R. Berenson, Institute for Myeloma and Bone Cancer Research, West Hollywood, CA*

**Background:** Carfilzomib (CFZ) is a selective proteasome inhibitor approved in the US for the treatment of relapsed and refractory multiple myeloma (MM). This multicenter, single-arm phase 1/2 study (NCT01677858) is evaluating the safety and efficacy of once-weekly CFZ with dexamethasone (DEX). **Methods:** Patients (pts) with relapsed or refractory MM who received 1−3 prior regimens were eligible. Pts received CFZ as a 30-minute IV infusion on days (D) 1, 8, and 15 of a 28-day cycle in a standard 3+3 dose-escalation scheme. All pts received CFZ at 20 mg/m$^2$ on D1 of cycle 1; subsequent doses started at 45 mg/m$^2$ and were escalated to 56, 70, or 88 mg/m$^2$in successive cohorts until the maximum tolerated dose (MTD) was reached. Pts received 40 mg DEX (IV or oral) on D1, 8, 15, and 22 of cycles 1–8; DEX was omitted on D22 in cycles ≥9. Response was assessed by IMWG criteria; minimal response (MR) was assessed by EBMT criteria. The primary objective of the phase 1 portion of the study was to determine the MTD. **Results:** As of 11/5/2013, 27 pts were enrolled (median age, 64 years [range, 43–84]; median prior regimens, 1 [range, 1–3]). At 88 mg/m$^2$, 2 dose-limiting toxicities (DLTs) were observed: grade [Gr] 3 dyspnea and Gr 3 vomiting. At the MTD (70 mg/m$^2$), 1 patient of 15 experienced a DLT (Gr 3 dyspnea). Gr ≥3 AEs reported in >1 pt were thrombocytopenia, increased blood creatinine, dyspnea, and hyperglycemia (n=2 each; all Gr 3). No Gr ≥3 peripheral neuropathy was reported. All 27 pts were included in the preliminary efficacy evaluation. The overall response rate (ORR; ≥partial response) was 63% and the clinical benefit rate (CBR; ≥MR) was 74%. At the MTD, the ORR was 60% and the CBR was 67%. Pharmacokinetic analysis (n=21) showed a dose-dependent increase in mean $C_{max}$ and AUC for 20−88 mg/m$^2$CFZ. The mean terminal half-life was ~0.8 hours. **Conclusions:** At the MTD, weekly CFZ with DEX had an acceptable safety and tolerability profile with promising efficacy after a short follow-up period in pts with relapsed or refractory MM. The phase 2 portion of the study is currently enrolling pts at 70 mg/m$^2$ CFZ. Updated results from the phase 1/2 study will be presented. Clinical trial information: NCT01677858.

**8595 General Poster Session (Board #282), Mon, 1:15 PM-5:00 PM**

**Free light chain assay and cytogenetic abnormalities for identification of high-risk smoldering myeloma.** *Presenting Author: Jeremy Todd Larsen, Mayo Clinic, Rochester, MN*

**Background:** Translocation (4;14) and deletion 17p in smoldering multiple myeloma (SMM) have been identified as high risk cytogenetic abnormalities (CAs). Risk stratification incorporating CAs and biomarkers are needed to identify high risk SMM patients. The aim of this study was to determine the predictive value of the free light chain (FLC) assay in combination with high-risk CAs. **Methods:** The study included SMM patients seen at Mayo Clinic from 1991-2010 screened for available FISH and serum FLCs at diagnosis. Receiver operating characteristics analysis determined the optimal involved FLC (iFLC) cut-point to predict progression to MM within 24 months. Univariate analysis and multivariate analysis were performed. Time to progression (TTP) was calculated using Kaplan-Meier analysis. **Results:** The FLC was measured in 249 patients; t(4;14) was found in 33 (13.3%) and deletion 17p in 6 (2.4%). Median age at SMM diagnosis was 62 years (range, 30-90). The optimal iFLC cut-point was 41 mg/dL. The iFLC was >40 in 23% of the 39 high-risk CA (n=9) and 22% of non-high risk CA patients (n=46). In the high-risk CAs group, median TTP if iFLC >40 was 20 months (95% CI 5-24) versus 30 months (19-60) in the iFLC <40 group. In the low-risk CAs, median TTP if iFLC >40 was 34 months (26-51) versus 62 months (48-86) in the iFLC <40 group (p <0.0001). One and two-year progression rates for iFLC >40 in high-risk CAs were 23% and 89%. In comparison, progression rates were 7% and 14% at one and two years in low-risk CAs with iFLC <40. Table 1 shows the univariate and multivariate analysis. **Conclusions:** Integration of the FLC assay and CAs may facilitate recognition of SMM patients at highest risk for rapid progression as increasing hazard with each risk factor was demonstrated . Elevation of the iFLC >40 in the presence of adverse CAs identified a high-risk subset with 90% progression at 24 months for whom early intervention strategies may be considered.

**Treatment of dendritic cell sarcoma: 18-year experience at the MD Anderson Cancer Center.** *Presenting Author: Preetesh Jain, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Dendritic cell sarcomas (DCS) are rare tumors including follicular dendritic cell sarcoma (FDCS) and interdigitating cell sarcoma (IDCS). Typically DCS are difficult to diagnose and are associated with poor outcomes with standard therapy. **Methods:** This is a comprehensive retrospective analysis of 35 pts with confirmed diagnosis of DCS (FDCS n=31; IDCS n=4) treated at MDACC between 1995 and 2013. Pts were identified from an institution database and data was collected on the diagnosis, management and clinical outcomes of pts. **Results:** Median age at diagnosis was 50 yrs (range 17-74 yrs) and 58% were female. 60% pts presented with localized disease and 40% with systemic involvement. Abdomen was involved in 17/35 pts and the spleen (7/35) was the most common extranodal site. Bulky disease (> 5 cm) was noted in 21 pts. Nine pts had pre-existing or subsequent autoimmune disease. Common markers for FDCS were clusterin; EGFR, CD21, CD35 and CD23 in 94%, 87%, 89%, 77% and 63% samples. For IDCS, common markers included S-100 and CD68 in 100% and 75% pts. Molecular studies were performed in 2 pts who were negative for *BRAF* mutations. One pt had *TP53* exon 8 and another *PTEN* mutation. Surgery followed by adjuvant chemotherapy was initial treatment in (23/35) and chemotherapy alone in (12/35) pts. Gemcitabine with taxanes and CHOP based regimens were most commonly used, and were associated with response rates of 86% and 60% respectively. Complete responses were rare. Median progression free and overall survival following systemic therapy was 41 and 59 months respectively. Pts with systemic presentation had inferior outcomes compared to those with localized disease. **Conclusions:** We present the largest single center report of pts with DCS. While detailed histopathological studies are necessary to define DCS, we identified several makers common to both FDC and IDCS. We observed higher responses with gemcitabine/docetaxel combinations compared to CHOP based therapy, but limited numbers make comparisons difficult and prospective studies are needed to define optimal treatment in this rare disease. Studies are currently underway at our institution to define the genomic profile in DCS and identify potential targets for therapy.

**8597 General Poster Session (Board #284), Mon, 1:15 PM-5:00 PM**

**Large granular lymphocyte (LGL) subsets in smoldering multiple myeloma (SMM): Immunophenotypic profiles that predict progression to multiple myeloma (MM).** *Presenting Author: Talib Dosani, Lymphoid Malignancies Branch, Center for Cancer Research, National Cancer Institute, NIH, Bethesda, MD*

**Background:** SMM is an asymptomatic precursor condition to MM. The immune system is known to play an important role in progression of SMM to MM. However, current risk-stratification schemes are often discordant, and there are presently no reliable biomarkers to predict progression to MM. In this study, we quantified various LGL subsets of SMM patients and identified potential LGL markers that may predict progression. **Methods:** Flow cytometric analysis was used to quantify LGL subsets in the peripheral blood (PB) of SMM patients (N=80) enrolled in the NCI Natural History of SMM/MGUS prospective clinical trial. PB samples were collected at enrollment and at every 12 months, in addition to regular 3-6 month clinical follow-ups. We conducted an analysis of LGL subsets using samples collected at diagnosis or follow-up on patients who progressed to MM at a subsequent 6-month or 12-month follow-up (N=8, median age 64) versus patients who had not progressed at 12 months of follow-up (N=72, median age 60). Two-tailed Mann-Whitney U test was used for all statistical analyses. **Results:** SMM patients who progressed to MM demonstrated a distinct LGL profile 6-12 months before progression. These patients had decreased levels of both relative and absolute numbers of CD3(-) CD16(+) CD57(-) NK cells (p=.03 and .09, respectively) and decreased levels of both relative and absolute numbers of CD56(+) CD57(-) lymphocytes (p=.003 and .02, respectively). Furthermore, there was an increase in relative numbers of total CD57(+) lymphocytes and CD57(+) CD8(-) NK cells (p=.23 and .13, respectively). There were no statistically significant differences in total WBCs, absolute lymphocyte counts, CD3(-) CD16(+) CD56(+) NK cells or CD3(+) CD16(+) CD56(+) NKT-like cells between the cohorts. **Conclusions:** SMM patients who progressed to MM possessed a distinct LGL immunophenotypic profile that was characterized by a decrease in CD57(-) lymphocyte subsets and a mild increase in CD57(+) lymphocyte subsets. These results suggest an LGL immunophenotypic profile that may be used as a marker of progressive disease in SMM patients.

**8598 General Poster Session (Board #285), Mon, 1:15 PM-5:00 PM**

**Outcomes after relapse from first autologous stem cell transplantation in multiple myeloma.** *Presenting Author: Wilson I. Gonsalves, Mayo Clinic, Rochester, MN*

**Background:** Autologous stem cell transplant (ASCT) is an integral treatment for eligible patients (pts) with multiple myeloma (MM). However, disease relapse post-ASCT remains inevitable for many pts. We describe the natural course of the disease and its outcomes in MM pts relapsing post-ASCT. **Methods:** Pts were included if they met the following criteria: 1) ASCT at the Mayo Clinic within 12 months of diagnosis; AND relapse post-ASCT between 2000 to 2012. Pts were excluded if they received a tandem or an allogeneic transplant post first ASCT. Multivariate analysis was performed using a Cox proportional hazards model. **Results:** Median (range) age at ASCT was 59 yrs (29-74). The median time to ASCT was 6 mos (2-12). Pts were transplanted in the years of 1994-2012. The median time to relapse was 16 mos (2-184). The median follow-up (95% CI) from relapse was 79 mos (72-89). The median (range) number of regimens prior to ASCT and post relapse were 1 (0-3) and 2 (1-11), respectively. Of the 254 pts who had FISH testing, 28% were categorized as high risk. Seventy-nine pts (17%) had a prior diagnosis of MGUS or SMM. All pts received novel agent therapy during their disease course with 57% receiving them during induction. At Day 100 post-ASCT, a PR or better was seen in 416 (92%) pts, including a stringent CR in 10%, CR in 12% and VGPR in 36%. Only 9% of pts received maintenance therapy with immunomodulators or proteasome inhibitors. The median (95% CI) post-ASCT relapse survival (PRS) and overall survival from diagnosis was 40 (34-45) and 67 (62-75) mos, respectively. In a multivariate analysis, only shorter time to relapse, presence of CRAB symptoms or extramedullary disease at relapse, shorter time to initiating salvage therapy, higher pre-ASCT plasma cell labeling index and beta-2 microglobulin predicted for a shorter PRS. Prior history of MGUS/SMM, high-risk FISH, choice of salvage therapy and use of maintenance therapy did not affect PRS. **Conclusions:** In a population of mostly unmaintained pts who relapse post-ASCT, PRS is longer than PFS. Predictors for increased PRS include a longer duration of response to ASCT, biochemical progression (rather than CRAB symptoms or extramedullary disease at relapse) and a longer time to salvage therapy initiation.

**8599 General Poster Session (Board #286), Mon, 1:15 PM-5:00 PM**

**Effect of a novel agent, SL-401, targeting interleukin-3 receptor (IL-3R) on plasmacytoid dendritic cell (pDC)-induced myeloma cell growth and osteolytic bone disease.** *Presenting Author: Dharminder Chauhan, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Multiple myeloma (MM) remains incurable despite novel therapies, highlighting the need for further identification of factors mediating disease progression and resistance. We showed that plasmacytoid dendritic cells (pDCs) in the MM bone marrow promote MM cell growth *(Chauhan et al., Cancer Cell 2009, 16:309-323)*. pDC-MM interactions trigger secretion of interleukin-3 (IL-3), which in turn, induces MM cell growth, and pDCs survival. Additionally, IL-3 contributes to the progression of osteolytic bone disease in MM. Here, we examined the effect of SL-401, a novel targeted therapy directed to IL-3R, on pDC-induced MM cell growth and osteoclast (OCL) formation. **Methods:** Patient MM cells, pDCs, and MNCs were obtained from normal donors or MM patients. Cell growth/viability was analyzed using MTT assays. OCL function and bone resorption was measured using the OsteoAssays and TRAP staining. **Results:** SL-401 decreased the viability of pDCs even at low concentrations ($IC_{50}$: 0.83 ng/ml; 14.6 pM). SL-401 decreased the viability of MM cells at clinically achievable doses without significantly affecting the viability of normal PBMCs. Co-culture of MM patient-derived pDCs triggered proliferation of MM cell lines and primary MM cells; and importantly, SL-401 inhibited pDC-triggered MM cell growth ($P < 0.005$). Moreover, 3 of 5 samples were obtained from patients whose disease was progressing while on bortezomib, dexamethasone, and lenalidomide therapies. SL-401 blocked pDC-induced growth of dexamethasone-, doxorubicin- or melphalan-resistant MM cells.Combination of SL-401 with bortezomib, melphalan, lenalidomide, or pomalidomide showed synergistic anti-MM activity. Finally, SL-401 inhibited monocyte-derived osteoclast formation in a dose-dependent manner as well as stabilized MM patient BM-derived osteoblast formation. **Conclusions:** Our study provides the basis for directly targeting pDCs and inhibiting the pDC-MM interaction, as well as targeting osteolytic bone disease, in novel therapeutic strategies with SL-401 to enhance MM cytotoxicity, overcome drug-resistance, and improve patient outcome.

**8600 General Poster Session (Board #287), Mon, 1:15 PM-5:00 PM**

**ECOG multiple myeloma (MM) clinical trial (CT) accrual performance evaluation utilizing the NCI–Trial Complexity and Elements Scoring (NCI-TCES) and the NCI Myeloma Steering Committee Accrual Working Group (NCI MYSC AWG) scoring models.** *Presenting Author: Matthias Weiss, Marshfield Clinic, Marshfield, WI*

**Background:** Accrual to NCI CTs is often slower than planned and at times mandating premature closure resulting in loss of valuable resources and delay of scientific progress. The NCI MYSC AWG identified 10 barriers to accrual (BtA) to MM CTs (reimbursement, competing treatment options, treatment at NCI designated sites only, etc.). The NCI-TCES was created to objectively assess CT complexity (study arms, registration/randomization steps, treatment and follow-up complexity and duration, etc.). We evaluated the accrual performance of all previously conducted and currently ongoing (as of 12-31-2013) therapeutic ECOG MM CTs (excluding transplant) utilizing these tools. **Methods:** The planned and actual accrual, duration of open enrollment and accrual per month of each selected CT was determined. The NCI-TCES model was applied to each CT and a total score calculated (range 0-18). The 10 NCI MYSC AWG BtA were reviewed as it concerns their relevance for each selected CT and described as unlikely (0), possibly (1) or definitely (2) impacting accrual adversely. A total score was calculated (range 0-20). **Results:** 11 ECOG MM CTs were evaluated. 6 of 11 achieved planned accrual goals and 5 of 11 did not due to premature closure due to lack of accrual, less than half of planned accrual per month or more than twice the planned enrollment period. CTs achieving planned accrual performance had a NCI MYSC AWG score average of 4.83 versus 8.0 for those CTs failing accrual goals. The NCI-TCES score was 4.83 versus 4.2, respectively. None of the 6 CTs, which successfully enrolled were identified to have BtA, which definitely impacted accrual adversely versus 3 out of 5 of the CTs which failed planned accrual performance. **Conclusions:** In this retrospective analysis of ECOG MM CT accrual performance, the NCI MYSC AWG scoring model correlated well with actual accrual performance. Given its general applicability to therapeutic CTs evaluating any malignant disease, this tool may be useful for prospective accrual performance assessment of planned therapeutic clinical trials.

**8601 General Poster Session (Board #288), Mon, 1:15 PM-5:00 PM**

**Autologous stem cell transplantation in dialysis-dependent myeloma patients.** *Presenting Author: Riad Omar El Fakih, Baylor College of Medicine, Houston, TX*

**Background:** The incidence of renal insufficiency at presentation is approximately 30% in patients with multiple myeloma (MM). 5% of these patients are dialysis dependent. Presence of renal dysfunction is associated with increased treatment related toxicity and poor survival. **Methods:** We retrospectively analyzed our transplant database from July 2000 to June 2012 to identify myeloma patients who received autologous hematopoietic stem cell transplantation (autoHCT) while they were dialysis dependent. Univariate Cox proportional hazards regression was performed to assess the association between survival and covariates of interest. Kaplan Meier curve was used to estimate progression free survival (PFS) and overall survival (OS). **Results:** 2,091 patients underwent autoHCT during this interval. 24 (1.1%) were dialysis dependent (21 on hemodialysis and 3 on peritoneal dialysis). Median age was 53 (29-70) years. 63% were male. ISS stage at diagnosis was I & II in 4%, III in 54%, and unknown in 38%. Median duration of dialysis prior to auto-HCT was 235 (1-1481) days. Four patients had high risk cytogenetics. Melphalan dose was 200 $mg/m^2$ in 58% and $<$ 200 $mg/m^2$ in 42%. The median collected CD34+ cells count was 4.35 x $10^6$/Kg. All patients engrafted. 100 day and 6 month treatment related mortality (TRM) was 0%. The incidence of grade II-IV non hematological toxicity was similar across different melphalan doses. Overall response rate was 92% (CR = 25%, VGPR = 29.2%, PR = 37.5%). Two patients had SD. The median follow up is 6.7 years. At the time of last follow up, 13 patients had died and 11 (45.8%) were still alive. The median PFS and OS were 1.9 years and 3.8 years, respectively. In univariate analysis, high-risk cytogenetics was a significant predictor of poor PFS (p0.04) and OS ($p<0.009$). A multivariate analysis was not performed due to the small sample size. Only 3 patients (12.5%) became dialysis independent after transplant. No variable was predictive of becoming dialysis independent. **Conclusions:** AutoHCT can be safely performed in dialysis dependent myeloma patients. While majority of patients continue to require dialysis after transplant, long term disease control can be expected. Dialysis dependent renal failure should not be an exclusion for autoHCT.

**8603 General Poster Session (Board #290), Mon, 1:15 PM-5:00 PM**

**Further exploring the mutational landscape of multiple myeloma via a targeted gene panel assay.** *Presenting Author: Donald Joseph Johann, Myeloma Institute for Research and Therapy, Little Rock, AR*

**Background:** Multiple myeloma (MM) is a cancer of the bone marrow characterized by a malignant transformation of plasma cells. The pathogenesis of MM is only partially understood. Identifying the acquired somatic mutations in MM is a practical approach to reveal and clarify the mechanisms of a particular patient's cancer. By identifying the mutational status of key and relevant genes, pathways and targets in these pathways may be examined, and a rationally-based therapy plan devised for each individual patient. Since patients eventually become refractory to available therapies, the identification of additional therapeutic targets has important clinical utility. **Methods:** DNA sequencing was performed utilizing a targeted approach of ~300 genes relevant to heme malignancies on 115 heavily pretreated patients as of 4/2013 - 12/2013. gDNA was obtained from CD-138 selected cells from bone marrow aspirates. All libraries were sequenced on an Illumina HiSeq at a depth of ≥ 500X. **Results:** Clinically actionable mutations (n = 197) were found in 105 of the 115 patients, ranging from 1-14 mutations per patient with an avg of 2. Mutations important in hematologic malignancies but still classified as variants of unknown significance (VUS, n=861) were found in 97 of the 115 patients, ranging from 3 to 39 VUS per patient with an average of 9. The top 10 genes showing actionable mutations were: KRAS (41%), TP53 (37%), NRAS (23%), BRAF (11%), RB1(10%), TRAF3(7%), CDKN2C(7%), ATM, LRP1B and MYC (all 6%). The MAPK pathway displayed a high frequency of mutations including concomitant mutations of KRAS and NRAS in five patients, and BRAF V600E mutation in six patients. RAS hotspot analysis showed KRAS Q61H and G13D combining to a frequency of 45%, and for NRAS, Q61-mutations occurring at a 67% frequency. Top genes in the VUS category showing mutations included the methyltransferase MLL2 (24%), PCLO (20%), LRP1B (16%), the MEK kinase MAP3K1 (12%), and NOTCH1 (11%). **Conclusions:** Next generation sequencing of CD-138 selected bone marrow aspirate cells allows for the identification of actionable mutations and targets, and helps facilitate consideration of individualized clinical strategies for MM patients refractory to standard of care therapies.

**8604 General Poster Session (Board #291), Mon, 1:15 PM-5:00 PM**

**Differentiating asymptomatic monoclonal gammopathy (AMG including MGUS and AMM) from clinical multiple myeloma (CMM) by gene expression profiling of purified plasma cells (PC-GEP).** *Presenting Author: Rashid Khan, MIRT/UAMS, Little Rock, AR*

**Background:** Previous research indicated that PC from AMG and CMM could not be distinguished at the GEP level. We reported that a GEP70 risk score could identify a subset of AMG patients at high risk for progression to CMM requiring therapy. We now re-address this issue in a larger population of patients (pts) in order to contribute to a better understanding of the genetics of this progression event from clinically benign to malignant disease. **Methods:** We identified baseline GEPs of 89 pts with AMG and 38 pts with MGUS in our observational study and compared them to 785 GEPs of previously untreated pts with MM who were enrolled in Total Therapy 2 and 3. GEPs were separated into training and test sets of 60 and 29 pts for AMM, 26 and 12 pts for MGUS and 524 and 261 pts for CMM respectively. We performed t-tests to identify differentially expressed probesets between AMM and CMM, MGUS and CMM and AMM and MGUS. Results adjusted for multiple testing and probesets were ranked by q-value for each comparison. **Results:** In the comparison between AMM and CMM we identified 74 probesets significantly differentially expressed with a q-value $<1 \times 10^{-6}$. Using a class predictor approach the log2 transformed expression values for each gene were summed. An optimal cutpoint was identified in the training set and validated in the test set, performance was satisfactory with a sensitivity of 79.3%, a specificity of 92.0% and a positive predictive (PPV) value of 90.7%. AMM samples classified as CMM had a significantly shorter time to progression to CMM than those classified as AMM. Conversely pts with CMM who were classified as AMM had a better PFS and OS than those classified as CMM. 206 genes were differentially expressed between MGUS and CMM and a predictive model based on these genes showed a sensitivity of 83%, specificity of 92.3% and PPV of 91.9%. 11 probesets were common between the AMM/CMM and MGUS CMM gene lists. **Conclusions:** Gene expression profiling can readily differentiate between MGUS or AMM and CMM. More importantly pts with AMM who have a CMM-like GEP signature have a significantly shorter time to progression to CMM while AMM-like signature in CMM predicts better outcome.

**8605 General Poster Session (Board #292), Mon, 1:15 PM-5:00 PM**

**Clarifying immunoglobulin gene usage in immunoglobulin light chain amyloidosis by mass spectrometry of amyloid in clinical tissue specimens.** *Presenting Author: Taxiarchis Kourelis, Department of Medical Oncology, Mayo Clinic, Rochester, MN*

**Background:** The goal of this study was to investigate the relative use of light chain variable region genes (LCVG) among patients with systemic (SAL) and localized (LAL) amyloidosis and assess for associations between LCVG and organ tropism. **Methods:** We evaluated charts from 361 AL patients seen at Mayo who had tissue samples typed using laser dissection mass spectrometry (MS). **Results:** We identified 240 patients with SAL and 105 with LAL. When compared to LAL, lambda light chain (LC) overall and LV6 in particular were more common in SAL. KV3 and LV2 were overrepresented in LAL. KV1 accounted for 71% of kappa genes in SAL and for 37% in LAL. LV4, KV2 and KV4 were distinctly uncommon, each identified in ≤ 5% of patients in both SAL and LAL. Among patients SAL who had clinical cardiac involvement, only KV3 was underrepresented as compared to patients without clinical cardiac involvement (1% vs 9%, p=0.008). In patients with clinical renal involvement, LV6 was more common (26% vs 9%, p=0.002) and KV3 less common (1% vs 7%, p=0.03).LV6 was also more commonly identified in SAL patients with clinically isolated renal involvement (35% vs.13%, p=0.02). **Conclusions:** LCVG usage in SAL is different from that of LAL. It is also restricted, with KV1, LV1, LV3 and LV6 accounting for 70% of cases.

**8606 General Poster Session (Board #293), Mon, 1:15 PM-5:00 PM**

**Plerixafor plus G-CSF (P+G) compared with G-CSF alone (G) for hematopoietic progenitor cell (HPC) mobilization in AL amyloidosis (AL).** *Presenting Author: Binod Dhakal, Medical College of Wisconsin, Milwaukee, WI*

**Background:** Cytokine-based HPC mobilization in AL is frequently complicated by fluid overload, weight (wt.) gain, arrhythmia, collection failure and peri-mobilization mortality. **Methods:** We analyzed HPC mobilization outcomes of 49 consecutive AL pts. at our institution between 2004-2013 with G alone (10$\mu$g/kg/d) (n=25) vs. an institutional protocol to limit G exposure using plerixafor (P+G) (P at 0.24mg/kg SC starting 3 day of G 10$\mu$g/kg) (n=24). CD34+ HPC yield on day 1 of collection, total CD34+ yield, apheresis days and perimobilization morbidity were analyzed. Mobilization failure was defined as failure to collect $\geq 2\times10^6$cells/kg body weight. **Results:** Baseline characteristics of two groups are shown in Table. P+G strategy yielded higher total CD34+ cells/kg ($12.8 \times10^6$ vs. $6.3 \times10^6$; p<0.001), CD34+ cells/kg collected on day 1($10.8 \times10^6$ vs. $4.9 \times10^6$, p=0.004) compared with G alone cohort. More P+G pts. collected $\geq 5 \times10^6$ CD34+HPCs/kg (22 vs.16, p=0.02) and $\geq 10 \times10^6$ CD34+ HPCs/kg (13 vs. 5,p=0.01). Four pts. (16%) had mobilization failure with G alone, none with P+G. G exposure was less and peri-mobilization weight gain lower with P+G strategy (median weight gain 1 lbs. vs. 7 lbs., p=0.009). Numbers of apheresis sessions (median 1 vs. 1,p=0.52), the hospital days during mobilization (1.1 vs. 1.6,p=0.52), transfusion, antibiotic needs and arrythmia were similar between groups. **Conclusions:** This first report of upfront P+G mobilization in AL provides key feasibility data. Robust HPC mobilization in AL pts. with no unexpected adverse events was achieved with P+G.Superior HPC numbers, no mobilization failure and less weight gain are advantages compared to G alone.

**Modeling the risk of progression in smoldering multiple myeloma.** *Presenting Author: Adam J Waxman, Department of Medicine, University of Pennsylvania, Philadelphia, PA*

**Background:** Smoldering multiple myeloma (SMM) is a precursor state to multiple myeloma (MM) with a highly variable risk of progression to active MM. Identifying patients at risk of imminent progression to MM is critical for redefining MM requiring therapy and for designing clinical trials of early intervention. Existing biomarkers and risk models have not been validated. We sought to validate the Mayo Clinic risk models and biomarkers and to derive a novel risk model for an ethnically diverse SMM population seen at an urban academic medical center. **Methods:** We performed a retrospective study of all SMM patients seen within the University of Pennsylvania Health System (2008-2012). Patients were identified by ICD9 codes for MGUS and MM and classified as SMM per IMWG criteria after review of electronic medical records. Using classification and regression tree and Cox regression analyses, we developed a model for risk of progression to active MM. **Results:** We identified 126 SMM patients, median age 62 years, 55% male, 78% Caucasian, 19% African-American, and 3% other races. Median follow-up was 4 years. We validated the Mayo models and biomarkers (table). The Penn model included 3 factors: bone marrow plasma cells (BMPC) ≥40% (HR 2.72, CI 1.28-5.77, p<0.009), serum free light chain ratio (sFLCR) ≥50 (HR 4.57, CI 1.99-10.5, p <0.001) and albumin ≤ 3.5 gm/dL (HR 3.38, CI 1.57-7.27, p<0.001) [Low-risk = 0 factors, Intermediate risk = 1 factor, high risk ≥ 2 factors]. Adjusting for race did not impact risk of progression in any of the models. All patients with BMPC ≥60% progressed to MM within 2 years. **Conclusions:** We validated the Mayo risk models and biomarkers. In our population, albumin was a useful biomarker for risk of progression in SMM.

**Trends in survival of patients with primary plasma cell leukemia: A population-based analysis from 1973 to 2010.** *Presenting Author: Wilson I. Gonsalves, Mayo Clinic, Rochester, MN*

**Background:** Primary plasma cell leukemia (pPCL) is a rare plasma cell malignancy with a very aggressive course and poor outcome compared to multiple myeloma (MM). There has been significant improvement in the survival of MM patients over the past decade as a result of the incorporation of novel agents that are now also used in pPCL. The time period after 1995 represented adoption of autologous stem cell transplantation as a standard treatment modality and 2003 marked the wide availability of the novel agents in the relapsed and refractory setting due to accelerated FDA approval. However, it was not until 2006 that these novel agents were approved to be utilized in the first-line treatment of MM. The question remains whether the survival of pPCL has improved since the advent of these novel agents. **Methods:** We analysed the Surveillance, Epidemiology, and End Results (SEER) database for trends in survival of patients with pPCL (ICD-O: 9733) over the time period of 1973-2010 using the *SEER Stat 8.1.2*software. Kaplan-Meier analysis was used to analyze the overall survival (OS) and the Cox proportional hazards model was used to assess the influence of various prognostic factors on OS. **Results:** A total of 318 pPCL patients were identified in the SEER database. The median age at diagnosis was 62 years (range, 19-91) and 52% were females. The median follow up was 56 months (range, 39-102) and 83% of patients had died at the time of this analysis. The median 1, 2 and 5-year OS rates were 57%, 32% and 6% respectively. The median OS based on time periods of diagnosis of 1973-1995, 1996-2002, 2003-2005 and 2006-2010 were 9, 9, 8, and 19 months, respectively (P = 0.002). OS was similar regardless of subgroups based on age, gender, and marital status at diagnosis. Among patients <70 years age, the median OS was 11 months compared to 10 months in patients >70 years age (P = 0.378). Only diagnosis in the 2006-2010 era predicted for a better OS (HR: 0.65; 95% CI: 0.45-0.94; P = 0.0018, with reference to 1973-1995 era). **Conclusions:** Our study identifies a recent major improvement in survival amongst patients diagnosed with pPCL within a large US population. This suggests a positive impact of incorporating novel agents in the treatment of pPCL since 2006.

**8609 General Poster Session (Board #296), Mon, 1:15 PM-5:00 PM**

**Outcomes of young patients with Waldenstrom macroglobulinemia (WM).** *Presenting Author: Nishanth Vallumsetla, Mayo Clinic, Rochester, MN*

**Background:** WMis infrequentin young population, and data in patients (pts) ≤50 years of age are sparse. We present outcomes of a large cohort of young WM pts seen at Mayo Clinic, Rochester between 01/2000-12/2013. **Methods:** Sixty-nine (10.7%) of 640 consecutive pts were ≤50 years at diagnosis. Overall survival (OS) was calculated with Kaplan-Meier method and years of life lost were computed based on expected mortality for the age group. **Results:** Males constituted 65% of pts. Nine (14%) pts had familial WM. Patient characteristics and therapy related information are tabulated. Median follow up (FU) was 8years from diagnosis and 7.8 years from initial therapy. Eight-year OS was 84%from frontline therapy (median 14.8 years). Of all deaths (n=18), only 1 was non WM related. Over 30 years of FU, the average years of life lost were 10.8 years. Stem cells were successfully harvested from 10 of the 12 attempted. Only 5 (8%) pts underwent autologous stem cell transplantation (ASCT), one of whom had ASCT post transformation. In the non-transformed pts, ASCT was used as salvage therapy after a median of 6.5 regimens. Among these pts, median FU was 4.6 years from ASCT and median OS was not reached. Of 67 pts treated, 65 (97%) received rituximab (R) during their disease course. Overall, 6/25 (24%) who received nucleoside analogs (NA) developed therapy related myelodysplastic syndrome (t-MDS) or transformed lymphoma compared to 1/42 (2%) who received non NA based therapy (p=0.009). These events occurred at a median of 7.6 years from NA therapy. Median number of regimens utilized was 3.75. **Conclusions:** Despite its indolent course, WM remains a major cause of morbidity and mortality in young pts with this cancer. NA-based therapy is best avoided in this population due to high risk of developing t-MDS or transformation. Although effective, ASCT appears to be an underutilized approach.

**Clinical and cost benefit of aprepitant in patients receiving high-dose chemotherapy prior to autologous peripheral blood stem cell transplantation.** *Presenting Author: Ayumi Nakamura, Department of Pharmacy, National Hospital Organization Nagoya Medical Center, Aichi, Japan*

**Background:** The clinical benefit of aprepitant has not been elucidated in the patients (pts) receiving high-dose chemotherapy (HD-CT) prior to autologous peripheral blood stem cell transplantation (APBSCT). We retrospectively surveyed the efficacy of aprepitant and the total cost during hospitalization of APBSCT. **Methods:** All pts received HD-CT at our institute between 2009 and 2013 were registered. We identified a total 38 pts (27 non-Hodgkin lymphomas and 11 multiple myelomas). Thirteen pts received aprepitant and granisetron (aprepitant group) for the prophylaxis of the emesis, whereas, 25 pts received granisetron only (non-aprepitant group). Nausea, vomiting, and appetite loss during were evaluated according to NCI-CTCAE version 4.0. Total costs including hospitalization, and supportive care were calculated from medical records. **Results:** The incidence of severe nausea (>=grade 3) was 15.4% in aprepitant group and 52.0% in non-aprepitant group (p=0.028). Percentages of pts with appetite loss (>=grade 3) in the aprepitant group were 23.1% in aprepitant group and 72.0% non-aprepitant group (p=0.028). In addition, the median length of total hospitalization from day of HD-CT in aprepitant group and non-aprepitant group were 22 and 29 days (p=0.005), respectively. The time of engraftment of the hematopoietic stem cells from auto-PBSCT and the incidences of infectious events were not significantly different between these groups. Furthermore, in aprepitant group, the mean total costs decreased from $20,204 to $17,256 per patient, respectively. The common causes for reduction of total costs in the aprepitant group were reduction in costs of hospitalization, transfusion, and treatment for infections. **Conclusions:** Our data indicated that the addition of aprepitant for the prophylaxisis of the emesis decreased the incidence of severe nausea and appetite loss, and might introduce some economic benefits in the total management of HD-CT followed by APBSCT.

**TPS8611^ General Poster Session (Board #298A), Mon, 1:15 PM-5:00 PM**

**A phase 3 study of ibrutinib in combination with either bendamustine and rituximab (BR) or rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) in patients with previously treated follicular lymphoma or marginal zone lymphoma.** *Presenting Author: Nathan Hale Fowler, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Follicular lymphoma (FL) and marginal zone lymphoma (MZL) are indolent non-Hodgkin lymphomas (iNHL) and account for approximately 22% and 10%, respectively, of all NHLs. Although patients often respond to initial therapy, most will relapse and suffer substantial morbidity and mortality related to persistence/recurrence of disease. For patients with relapsed iNHL, the most common chemoimmunotherapy regimens are BR and R-CHOP; however, outcomes in the relapsed setting remain suboptimal. Ibrutinib is an oral Bruton's tyrosine kinase (BTK) inhibitor that has demonstrated activity in a phase 1 study in patients with various B-cell malignancies, including iNHL. A phase 2 monotherapy study in chemoimmunotherapy-resistant FL is ongoing. Other completed and ongoing studies have demonstrated that ibrutinib can be safely combined with BR or R-CHOP. Based on these observations, this phase 3 trial has been designed to investigate the combination of ibrutinib with BR or R-CHOP in patients with iNHL. **Methods:** The SELENE study, PCI32765FLR3001, is a randomized, double-blind, placebo-controlled, multicenter, phase 3 study of ibrutinib combined with either BR or R-CHOP for previously treated FL or MZL. The study aims to enroll approximately 400 patients with disease that has relapsed after, or was refractory to, prior chemoimmunotherapy. All patients will receive 6 cycles of BR or R-CHOP (based on prior treatment) and either a daily oral dose of 560 mg ibrutinib or placebo continued up to progression. The primary objective is to evaluate whether the addition of ibrutinib to BR or R-CHOP will prolong progression-free survival, with secondary objectives of evaluation of overall survival, CR rate, ORR, patient-reported lymphoma symptoms, and safety. Exploratory objectives include the minimal residual disease negative rate in FL patients, patient-reported outcomes related to general health status, and the pharmacokinetics of ibrutinib. Approximately 145 sites in Europe, Asia, Australia, USA and South America will participate. Enrollment began in Q1 2014. Clinical trial information: NCT01974440.

**TPS8612 General Poster Session (Board #298B), Mon, 1:15 PM-5:00 PM**

**Phase 3 trial of brentuximab vedotin and CHP versus CHOP in the frontline treatment of patients (pts) with CD30+ mature T-cell lymphomas (MTCL).** *Presenting Author: Owen A. O'Connor, Columbia University Medical Center/ New York Presbyterian Hospital, New York, NY*

**Background:** MTCL including systemic anaplastic large cell lymphoma (sALCL) are aggressive neoplasms. Anthracycline-based multiagent chemotherapy regimens have demonstrated response rates ranging from 76 to 88%. Five-year overall survival rates range from 12 to 49% depending on the histologic subtype. Brentuximab vedotin is an antibody drug conjugate that has shown efficacy in a pivotal phase 2 study as a single agent in relapsed sALCL (Pro et al., J Clin Oncol, 2012) and evidence of clinical activity in combination with CHP in the frontline treatment of MTCL including sALCL in a phase 1 study (Fanale et al., ASH 2012). **Methods:** This randomized, double-blind, placebo-controlled, multicenter, phase 3 study (NCT01777152) is evaluating the safety and efficacy of 1.8 mg/kg brentuximab vedotin with CHP (A+CHP) vs CHOP for frontline treatment of CD30+ MTCL. Pts must have FDG-avid disease by PET and measureable disease of at least 1.5 cm by CT. Approximately 300 pts will be randomized 1:1 to receive A+CHP or CHOP for 6–8 cycles (q3wk). Randomization will be stratified by ALK+ sALCL vs other histologic subtypes and IPI score (0–1, 2–3, or 4–5). The target proportion of pts with a diagnosis of sALCL will be 75%. The primary objective is to compare progression-free survival (PFS) between the 2 treatment arms as determined by an independent review facility (IRF). Secondary objectives include comparisons of PFS per IRF in sALCL patients, safety, overall survival, and complete remission rate between the 2 arms. After completion of treatment, pts will be followed for disease progression, medical resource utilization, quality of life, and survival. Post-treatment stem cell transplant is permitted. Efficacy assessments will use the Revised Response Criteria for Malignant Lymphoma (Cheson 2007). CT and PET scans will be performed at baseline, after Cycle 4, and after the completion of treatment. CT scans will also be performed at regular intervals during follow-up until disease progression, death, or analysis of the primary endpoint. Safety assessments will occur throughout the study until 30 days after last dose of study treatment. Enrollment for this global trial began in early 2013. Clinical trial information: NCT01777152.

**TPS8613 General Poster Session (Board #299A), Mon, 1:15 PM-5:00 PM**

**Phase 3 study of brentuximab vedotin plus doxorubicin, vinblastine, and dacarbazine (A+AVD) versus doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD) as front-line treatment for advanced classical Hodgkin lymphoma (HL): Echelon-1 study.** *Presenting Author: Stephen Maxted Ansell, Mayo Clinic, Rochester, MN*

**Background:** Brentuximab vedotin (ADCETRIS), a CD30-targeted antibody-drug conjugate, has been approved for adults with relapsed or refractory CD30+ HL in 39 countries including the US and Europe. Front-line ABVD achieves complete response (CR) rates of 70–80% in patients (pts) with advanced HL. However, 10–20% of pts are refractory to front-line treatment and an additional ≤25% relapse. Further, bleomycin-induced pulmonary toxicity occurs in 10–25% of pts (Horning, J Clin Oncol 1994). In pts with relapsed HL post-autologous stem cell transplantation, objective response rate to single-agent brentuximab vedotin is 75% (CR, 33%; Chen, ASH 2012). In a ph 1 dose-escalation study (NCT01060904), 51 pts with treatment-naïve HL stage IIA bulky or stage IIB–IV disease were enrolled to evaluate safety, maximum tolerated dose and antitumor activity of brentuximab vedotin combined with ABVD (A+ABVD) or AVD (A+AVD) (Younes, Lancet Oncol 2013). 80% pts had stage III–IV, 25% had International Prognostic Score ≥4. Brentuximab vedotin was given on days 1 and 15 of 28-day cycles (≤6 cycles), 25 pts received ABVD plus brentuximab vedotin at 0.6, 0.9, or 1.2 mg/kg; 26 received AVD plus brentuximab vedotin 1.2 mg/kg. A+AVD was associated with a PET2 negative rate of 92%, CR rate of 96% and manageable toxicity. Although A+ABVD induced an unacceptably high rate of pulmonary toxicity compared to known rates with ABVD alone, pulmonary toxicity was not observed in the A+AVD cohort. We hypothesized that substituting bleomycin with brentuximab vedotin may improve progression-free survival (PFS) compared to ABVD and, eliminate bleomycin-related pulmonary toxicity. **Methods:** ECHELON-1 (NCT01712490), an ongoing, open-label, randomized, ph 3 study, will compare A+AVD vs ABVD in 1,040 pts with untreated stage III/IV classical HL. Pts will receive A+AVD (brentuximab vedotin 1.2 mg/kg with each dose of AVD) or ABVD on Days 1 and 15 of 28-day cycles (≤6 cycles). Primary endpoint: modified PFS (death, progression, receipt of chemotherapy or radiotherapy by pts not in CR after completing front-line therapy). Clinical trial information: NCT01712490.

**TPS8614 General Poster Session (Board #299B), Mon, 1:15 PM-5:00 PM**

**AUGMENT: A phase 3, randomized trial to compare efficacy and safety of lenalidomide plus rituximab versus placebo plus rituximab in patients with relapsed/refractory indolent non-Hodgkin lymphoma (NHL).** *Presenting Author: John Leonard, Weill Cornell Medical College, New York, NY*

**Background:** Lenalidomide (L) is an immunomodulatory drug with both anti-inflammatory and antiangiogenic properties. Preclinical studies demonstrate that the immunological function of tumor-infiltrating lymphocytes is impaired in patients with follicular lymphoma (FL) and that treatment with L can repair this dysfunction (Ramsay, *Blood*, 2009). In phase 2 investigations of frontline L + rituximab (R), in patients with indolent NHL, overall response rate (ORR) reached 90% and complete response/complete response unconfirmed (CR/CRu) was 64% (Fowler, ASH, 2012); a second study in patients with FL achieved 93% ORR and 72% CR (Martin, ICML, 2013). In patients with recurrent FL, treatment with L+R yielded higher response rates (73% ORR, 36% CR) compared with L alone (51% ORR, 13% CR; Leonard, ASCO 2012 oral presentation). Together, these preclinical and phase 2 data provide a rationale for further investigation of L+R in indolent NHL. **Methods:** This phase 3, multicenter, double-blind, randomized study (AUGMENT) is designed to evaluate the efficacy and safety of L+R versus placebo (P)+R in patients with relapsed/refractory indolent lymphoma. Eligible patients must have grade 1, 2, or 3a FL or marginal zone lymphoma; have received previous systemic therapy; be refractory to or have relapsed after their last treatment; be R-sensitive if prior R therapy was administered; have ≥1 measurable lesion; and have adequate bone marrow, liver, and renal function (moderate renal impairment acceptable). Approximately 350 patients will be randomized 1:1 to one of two study arms (experimental or control). During each 28-day cycle, patients enrolled in the experimental group will receive L (20 mg/day; days 1 to 21 up to 12 cycles) + R (375 mg/m$^2$; days 1, 8, 15, 22 of cycle 1 and day 1 of cycles 2 to 5). Patients in the control group will receive P+R (375 mg/m$^2$) in the same schedule. The primary endpoint is progression-free survival. Key secondary endpoints include rate of durable CR, overall survival, ORR, safety, and time to next anti-lymphoma treatment. This trial is currently enrolling patients. Clinical trial information: NCT01938001.

**TPS8615^ General Poster Session (Board #300A), Mon, 1:15 PM-5:00 PM**

**A randomized, double-blind, placebo-controlled phase 3 study of ibrutinib in combination with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) in subjects with newly diagnosed nongerminal center B-cell subtype of diffuse large B-cell lymphoma (DLBCL).** *Presenting Author: Anas Younes, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** The standard regimen for frontline treatment of DLBCL is R-CHOP, which results in a complete response (CR) in 76% of patients and a 10-year overall survival (OS) rate of 44%. DLBCL can be classified by immunohistochemistry (IHC) into 2 subgroups: germinal center B-cell-like (GCB) or non-GCB (including the activated B-cell-like and some intermediate molecular subtypes). Prognosis is suggested to be least favorable for non-GCB DLBCL, the subgroup associated with NF-κB pathway activation and chronic active B-cell receptor (BCR) signaling. Ibrutinib inhibits BCR signaling by covalently binding to Bruton's tyrosine kinase. A phase 2 monotherapy study in relapsed/refractory DLBCL showed a 41% overall response rate (ORR) in the non-GCB subgroup (ASH 2012). A phase 1 study combining ibrutinib with R-CHOP showed an ORR of 100% in DLBCL and a favorable safety profile (ASH 2013), suggesting that ibrutinib can be safely combined with R-CHOP. **Methods:** The PHOENIX study, PCI32765DBL3001, is a phase 3 randomized, placebo-controlled, double-blind study of ibrutinib in combination with R-CHOP versus R-CHOP for the treatment of newly diagnosed non-GCB DLBCL. The study aims to enroll 800 patients (≈400 per arm). All patients will receive standard doses of R-CHOP therapy for 6 or 8 cycles (according to local practice), with ibrutinib 560 mg daily or placebo. The primary objective is to evaluate if the addition of ibrutinib to R-CHOP will result in prolongation of event-free survival. Secondary objectives include progression-free survival, OS, ORR (CR + PR), CR rate, and safety. The study will enroll previously untreated adult patients with the non-GCB subgroup of DLBCL determined by central IHC (Hans algorithm). Key exclusion criteria include central nervous system involvement or primary mediastinal lymphoma, diagnosis or treatment for malignancy other than DLBCL, or history of indolent lymphoma. Approximately 280 sites globally will enroll patients. Enrollment began in Q4 of 2013. Clinical trial information: NCT01855750.

**TPS8616 General Poster Session (Board #300B), Mon, 1:15 PM-5:00 PM**

**Phase 1-2 open-label, multiple-dose, dose-escalation study to evaluate the safety and tolerability of intravenous infusion of SNS01-T, a first-in-class modulator of eukaryotic translation initiation factor 5A (eIF5A) in patients (pts) with relapsed or refractory B-cell malignancies.** *Presenting Author: Michael Craig, West Virginia University, Morgantown, WV*

**Background:** eIF5A has been implicated in the regulation of cell proliferation, apoptosis, and inflammation. It is the only known protein to be modified by hypusination, and is highly conserved across species and is active in plants and animals. Hypusinated eIF5A, the predominant form in normal and cancer cells, is involved in cell survival and inflammatory pathway activation. siRNAs targeting eIF5A inhibit NF-kB activation and reduce pro-inflammatory cytokine production. Accumulation of the unhypusinated lysine form of eIF5A is associated with apoptosis. Mutants of eIF5A that cannot be hypusinated (e.g. $eIF5A_{K50R}$) are pro-apoptotic in vitro and have anti-tumoral activity in vivo in multiple cancer types including melanoma and lung cancer. SNS01-T is a novel therapeutic with a dual mechanism of eIF5A modulation: inducing cell death via siRNA-mediated inhibition of hypusinated eIF5A while simultaneously causing over-expression of pro-apoptotic $eIF5A_{K50R}$ via a DNA plasmid with a B-cell promoter to induce tumor cell death. SNS01-T significantly inhibited tumor growth and increased survival in mouse models of myeloma (MM), mantle cell and diffuse large B-cell lymphoma. **Methods:** This is an open label, phase 1-2 dose escalation study in pts with refractory B-cell cancers. The study has 4 dose cohorts: 0.0125, 0.05, 0.2 and 0.375 mg/kg twice weekly IV for 6 weeks. Main inclusion criteria are: MM per IMWG criteria or lymphomas or plasma cell leukemia with histologic confirmation; measurable disease; relapsed or refractory disease after ≥2 prior regimens; life expectancy ≥3 months; not eligible for any other standard therapy known to extend life expectancy. Primary endpoints are safety and tolerability of SNS01-T. Secondary endpoints include pharmacokinetics, tumor response (M protein, % plasma cells, radiologic response) and time to relapse or progression. To date, 15 patients have been included in the study. Enrolment (n=6) at the highest dose cohort has commenced (1 pt enrolled). Cohort 4 is expected to be completed in 1H2014. Clinical trial information: NCT01435720.

**TPS8617 General Poster Session (Board #301A), Mon, 1:15 PM-5:00 PM**

**MAGNIFY: A phase 3B, randomized trial of lenalidomide plus rituximab induction and maintenance therapy followed by lenalidomide single-agent versus rituximab maintenance in patients with relapsed/refractory indolent non-Hodgkin lymphoma (NHL).** *Presenting Author: David J Andorsky, Rocky Mountain Cancer Centers, Boulder, CO*

**Background:** Immunomodulation with lenalidomide (L) + rituximab (R) is a promising treatment approach for patients (pts) with indolent NHL. In indolent NHL, frontline L+R provided a 90% overall response rate (ORR) and 64% complete response/complete response unconfirmed (CR/CRu) (Fowler, ASH, 2012). In phase 2 trials of L+R in relapsed/refractory (R/R) disease, pts with mantle-cell lymphoma (MCL) achieved 57% ORR and 36% CR (Wang, *Lancet Oncol*, 2012); pts with follicular lymphoma (FL) treated with L+R had a higher response rate (73% ORR, 36% CR) compared with those receiving L alone (51% ORR, 13% CR; Leonard, ASCO, oral presentation, 2012). **Methods:** The phase 3b MAGNIFY study will compare the efficacy and safety of 12 cycles of combination L+R for induction with randomization to L+R (Arm A) vs R (Arm B) maintenance in pts with R/R FL, MCL, or marginal zone lymphoma (MZL). Target enrollment is ~500. Pts will be randomized 1:1 to 28-day (d) treatment cycles. In both arms, pts will receive induction L (20 mg/d on d 1-21; 12 cycles) + R (375 mg/m$^2$ on d 1, 8, 15, 22 in cycle 1; d1 of cycles 3, 5, 7, 9, 11). In Arm A, pts will receive maintenance L (10 mg/d on d 1-21; cycles 13-30) + R (375 mg/m$^2$ on d1 of every other cycle from 13-29), followed by L (10 mg/d on d 1-21) until progression. Following 12 cycles of induction with L+R, pts in Arm B will receive maintenance R (375 mg/m$^2$ on d1 of every other cycle from 13- 29). Eligible pts must have R/R grade 1, 2, or 3a FL, MZL, or MCL; have completed previous systemic therapy; have ≥1 measurable lesion; and have adequate bone marrow, liver, and renal function (moderate renal impairment acceptable). The primary endpoint is progression-free survival. Key secondary endpoints include rate of CR/CRu, overall survival, ORR, duration of response, duration of CR/CRu, and safety. Health-related quality of life, as measured by the FACT-Lym questionnaire, will be assessed as an exploratory endpoint. This trial is currently enrolling pts. Clinical trial information: NCT01996865.

**TPS8618 General Poster Session (Board #301B), Mon, 1:15 PM-5:00 PM**

**LEGEND: A randomised phase II study comparing lenalidomide plus rituximab, gemcitabine, and methylprednisolone (R-GEM-L) to rituximab, gemcitabine, methylprednisolone, and cisplatin (R-GEM-P) in second-line treatment of diffuse large B-cell lymphoma (DLBCL).** *Presenting Author: Mary Gleeson, The Royal Marsden NHS Foundation Trust, London and Surrey, United Kingdom*

**Background:** Diffuse Large B-cell lymphoma (DLBCL) exhibits high sensitivity to first-line chemo-immunotherapy, however approximately one-third of patients (pts) will relapse. A number of salvage regimens including R-GEM-P (rituximab, gemcitabine, cisplatin and methylprednisolone), are used in the relapsed/refractory (RR) setting, with overall (OR) and complete (CR) response rates of 50-70% and 20-50% respectively. Pts eligible for post-salvage consolidation with autologous stem cell transplantation (ASCT) have an overall survival (OS) of 40% at 3 years, while ASCT-ineligible pts have a very poor prognosis. More efficacious salvage regimens are urgently needed for this patient group. Lenalidomide has shown activity in RR DLBCL (both as monotherapy and in combination with rituximab), and has been safely combined with gemcitabine in pancreatic cancer. In the LEGEND trial R-GEM-L (rituximab 375mg/m$^2$ D1 and 15, gemcitabine 1000mg/m$^2$ D1, 8 and 15, methylprednisolone 1000mg D1-5 and lenalidomide 25mg od D1-21) and R-GEM-P are compared as second-line regimens in RR DLBCL. **Methods:** This is a randomised phase II open-label multicenter study. 92 eligible pts with RR DLBCL after 1 previous line of therapy, PS 0-2 and FDG-avid disease will be randomised on a 1:1 basis to 3 cycles of R-GEM-P (Arm A) or R-GEM-L (Arm B), following which pts in CR may undergo ASCT if eligible. Response will be assessed according to the Modified IWG 2007 Revised Response Criteria incorporating PET/CT. Following R-GEM-L (+/-ASCT) pts on Arm B and in CR will receive an additional 12 months of single-agent lenalidomide maintenance (25mg od D1-21 every 28 days). The primary endpoint is CR rate following induction chemotherapy. Secondary endpoints include ORR, event free survival (EFS), OS, rates of successful stem cell harvest and toxicity. Sample size was estimated using an optimal Simon 2-stage design (based on a true response probability of ≥60% and closing either arm if <40%, one-sided $\alpha$: 0.05, 80% power). A total of 46 patients will be recruited to each arm. Clinical trial information: 2012-002620-32.

**TPS8619 General Poster Session (Board #302A), Mon, 1:15 PM-5:00 PM**

**DYNAMO: A phase 2 trial of the PI3K-δ,γ inhibitor IPI-145 in patients with refractory indolent non-Hodgkin lymphoma.** *Presenting Author: Nina Wagner-Johnston, Washington University in St. Louis, St. Louis, MO*

**Background:** Phosphoinositide 3-kinase (PI3K)-δ,γ isoforms are preferentially expressed in leukocytes, have significant roles in normal B and T cell function, and are central to the growth and survival of certain B and T cell malignancies. Inhibition of these isoforms by IPI-145, an oral PI3K-δ,γ inhibitor, has unique therapeutic potential in hematologic malignancies. IPI-145 has shown clinical activity and a favorable safety profile across a broad range of hematologic malignancies in an ongoing phase 1 trial (IPI-145-02). Based on these results, the DYNAMO phase 2 trial (IPI-145-06) was initiated in May 2013 to evaluate the efficacy and safety of IPI-145 in patients with indolent non-Hodgkin lymphoma (iNHL) refractory to rituximab and chemotherapy or radioimmunotherapy (RIT). **Methods:** This open-label, single-arm trial includes adult patients diagnosed with iNHL (defined as follicular lymphoma [FL], marginal zone lymphoma, or small lymphocytic lymphoma) whose disease has progressed within 6 months of their last dose of a chemotherapy regimen or RIT. Eligible patients must have been previously treated with rituximab, and had either no objective response or documented progression within 6 months of completing therapy. Approximately 120 patients will be enrolled, including at least 100 patients with FL, at sites in and outside the US. All patients will receive 25 mg IPI-145 orally, twice daily during 28-day treatment cycles, for up to 12 cycles. After 12 cycles, patients may receive additional cycles of IPI-145 if they have documented evidence of response according to the International Working Group (IWG) criteria. The primary efficacy endpoint is the objective response rate and secondary endpoints include safety and tolerability of IPI-145, duration of response, progression-free survival, overall survival, and pharmacokinetic parameters. Assessment of response, best overall response, and progression status will be evaluated according to the IWG response criteria for NHL. This trial is currently enrolling patients. Clinical trial information: NCT01882803.

**TPS8620 General Poster Session (Board #302B), Mon, 1:15 PM-5:00 PM**

**A phase 3, randomized, double-blind, placebo-controlled study evaluating the efficacy and safety of idelalisib in combination with rituximab for previously treated indolent non-Hodgkin lymphomas (iNHL).** *Presenting Author: Gilles A. Salles, Lyon Sud University Hospital, Pierre-Bénite, France*

**Background:** PI3Kδ is critical for activation, proliferation and survival of B cells and plays a role in homing and retention in lymphoid tissues. PI3Kδ signaling is hyperactive in many B-cell malignancies. Idelalisib (GS-1101) is a first-in-class, targeted, highly selective, oral inhibitor of PI3Kδ that reduces proliferation, enhances apoptosis, and inhibits homing and retention of malignant B cells in lymphoid tissues (Lannutti et al, 2011). A phase 2 trial demonstrated that idelalisib is highly active in pts with heavily pretreated iNHL: response rate was 57% (6% CR) and median PFS was 11 mos with an acceptable safety profile (Gopal et al, 2014). **Methods:** A planned 375 pts with previously treated recurrent iNHL, who have measurable lymphadenopathy, have received prior anti-CD20-antibody-containing therapy, and who have iNHL that is not refractory to rituximab (R) will be randomized in a 2:1 ratio into Arm A or Arm B of the study. In Arm A, subjects will receive idelalisib at 150 mg BID continuously + R at 375 mg/m$^2$ (weekly x 4 then every 8 weeks x 4). In Arm B, subjects will receive placebo BID instead of idelalisib. Stratification factors include tumor type (follicular lymphoma vs others), tumor burden (high vs low), and time since completion of last prior therapy for iNHL ($<$18 months vs $\geq$18 months). The primary endpoint is PFS and secondary endpoints include ORR, lymph node response rate, CR rate, and OS. This is an event-driven trial and primary endpoint evaluation will be based on independent central review. For the primary efficacy analysis, the difference in PFS between the treatment arms will be assessed in the ITT analysis set using Kaplan-Meier methods and the stratified log-rank test. The study opened for enrollment in Dec 2012. Clinical trial information: NCT01732913.

**TPS8621 General Poster Session (Board #303A), Mon, 1:15 PM-5:00 PM**

**A phase 3, randomized, double-blind, placebo-controlled study evaluating the efficacy and safety of idelalisib (GS-1101) in combination with bendamustine and rituximab for previously treated indolent non-Hodgkin lymphomas (iNHL).** *Presenting Author: Myron Stefan Czuczman, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** PI3Kδ is critical for activation, proliferation and survival of B cells and plays a role in homing and retention in lymphoid tissues. PI3Kδ signaling is hyperactive in many B-cell malignancies. Idelalisib is a first-in-class, targeted, highly selective, oral inhibitor of PI3Kδ that reduces proliferation, enhances apoptosis, and inhibits homing and retention of malignant B cells in lymphoid tissues (Lannutti et al, 2011). A phase 2 trial demonstrated that idelalisib is highly active in pts with heavily pretreated iNHL: response rate was 57% (6% CR) and median PFS was 11 mos with an acceptable safety profile (Gopal et al, 2014). **Methods:** A planned 450 pts with recurrent iNHL, who require therapy for iNHL, have received prior anti-CD20-antibody-containing therapy and chemotherapy, and who have iNHL that is not refractory to bendamustine (B) with measurable lymphadenopathy, will be randomized in a 2:1 ratio into Arm A or Arm B of the study. In Arm A, subjects will receive rituximab (R) at 375 mg/m$^2$ every 28 days + B at 90 mg/m$^2$ on days 1 and 2 of each 28-d cycle up to 6 cycles with idelalisib at 150 mg BID continuously until progression. In Arm B, subjects will receive placebo BID instead of idelalisib. Stratification factors include tumor type (follicular lymphoma vs others), tumor burden (high vs low), and time since completion of last prior therapy for iNHL ($<$18 months vs $\geq$18 months). The primary endpoint is PFS, and secondary endpoints include CR rate, ORR, lymph node response rate, and OS. This is an event-driven trial and primary endpoint evaluation will be based on independent central review. For the primary efficacy analysis, the difference in PFS between the treatment arms will be assessed in the ITT analysis set using Kaplan-Meier methods and the stratified log-rank test. The study opened for enrollment in Dec 2012. Clinical trial information: NCT01732926.

**TPS8622 General Poster Session (Board #303B), Mon, 1:15 PM-5:00 PM**

**Anti-CCR4 monoclonal antibody KW-0761 (mogamulizumab) or investigator's choice of chemotherapy in subjects with relapsed or refractory adult T-cell leukemia-lymphoma (ATL).** *Presenting Author: Adrienne Alise Phillips, Columbia University, New York, NY*

**Background:** The receptor for macrophage derived chemokine (MDC) and thymus- and activation-regulated chemokine (TARC) CC chemokine receptor 4 (CCR4) is over expressed in several T-cell malignancies including HTLV-1 related ATL where approximately 90% of malignant cells have been shown to overexpress this chemokine receptor. The HTLV-1 transactivator gene (Tax) does not directly induce CCR4 expression. Rather, expression of CCR4 is controlled by the constitutive activation of several transcription factors in HTLV-1 infected cells. Inhibiting the expression of these transcription factors with small-interfering RNAs has been shown to block CCR4 expression and also reduce proliferation of the affected cells.[2] Patients with CCR4 positive ATL are more likely to have skin involvement and shorter overall survival (OS; median 9.5 months) compared with CCR4-negative (20.6 months). Mogamulizumab is a defucosylated, humanized, monoclonal antibody with enhanced antibody-dependent cellular cytotoxicity (Potelligent) against primary ATL cells that bind to CCR4. **Methods:** This study includes patients with previously treated ATL, excluding smoldering type, who have relapsed or are refractory after at least 1 prior systemic therapy. CCR4 expression is not required for eligibility. Patients are randomized (2:1 ratio) to either mogamulizumab or Investigator's choice (pralatrexate; gemcitabine plus oxaliplatin; or dexamethasone, cisplatin and cytarabine) and stratified by disease type (ie, acute, chronic, and lymphomatous). Patients who progress on the Investigator's choice regimen may cross over to treatment with mogamulizumab. The primary endpoint is the overall response rate. Efficacy evaluation is based on the Tsukasaki criteria and includes assessment of lymph nodes, extranodal masses, the spleen, liver, skin, peripheral blood, and bone marrow. Safety analyses and an exploratory evaluation of mogamulizumab exposure-response relationship will be performed. The study is being conducted in the US, Europe, and Central/South America. As of 24 January 2014, 44% of 70 planned patients have been randomized. Clinical trial information: NCT01626664.

**TPS8623 General Poster Session (Board #304A), Mon, 1:15 PM-5:00 PM**

**Phase 3 study of anti-CCR4 monoclonal antibody mogamulizumab versus vorinostat in relapsed or refractory cutaneous T-cell lymphoma (CTCL).** *Presenting Author: Youn H. Kim, Stanford Cancer Institute, Stanford, CA*

**Background:** CC chemokine receptor 4 (CCR4) is selectively expressed on type 2 helper T cells and certain functional regulatory T cells. Its expression allows T-cell trafficking to skin and lymph nodes. CCR4 is also expressed on CTCL cells. Expression increases with advancing disease stage and is closely associated with an unfavorable disease outcome. Advanced CTCL is a clinically unmet need due to short survivals and absence of curative treatments. Mogamulizumab (KW-0761) is a humanized anti-CCR4 monoclonal antibody with a defucosylated Fc region that enhances antibody-dependent cell-mediated cytotoxicity (ADCC). In an in vitro ADCC assay and a humanized mouse in vivo model, mogamulizumab exhibited potent antitumor activity against T-cell lymphoma cell lines as well as against primary CTCL cells from patients. Preliminary clinical data suggest mogamulizumab may lead to responses in CTCL, even in CCR4 negative disease by immunohistochemistry. **Methods:** This is a first-in-kind Phase 3 trial that compares mogamulizumab to a standard of care in patients with relapsed/refractory CTCL afterat least 1 prior systemic therapy, regardless of CCR4 expression. Inclusion criteria include: ECOG performance score $<$ 1; adequate hematological, hepatic, and renal function. Patients are stratified by disease type (Sézary syndrome vs mycosis fungoides) and stage, and are randomized (1:1) to receive mogamulizumab or vorinostat. Patients who are unable to tolerate or progress on vorinostat may cross over to mogamulizumab. Response assessments are done by the modified skin weighted assessment tool and global composite response including skin, blood, lymph node and viscera assessments. The study's primary endpoint is progression free survival (PFS). The PFS of the experimental and comparator arms will be compared using a stratified log-rank test at the one-sided 2.5% significance level. The median PFS for mogamulizumab therapy is targeted for 254 days, a 50% improvement over the reference median PFS for vorinostat of 169 days. A total of 255 PFS events will give 90% power. Clinical trial information: NCT01728805.

**TPS8624 General Poster Session (Board #304B), Mon, 1:15 PM-5:00 PM**

**SWOG 1211: A randomized phase I/II study of optimal induction therapy for newly diagnosed high-risk multiple myeloma (HRMM).** *Presenting Author: Saad Zafar Usmani, Carolinas Healthcare System, Charlotte, NC*

**Background:** The introduction of immunomodulatory agents and proteasome inhibitors, and advances in high dose therapy administration have made an impact on progression free survival (PFS) and overall survival (OS) for multiple myeloma (MM) patients in general, but patients with HRMM still have a poor long-term prognosis. Therefore, it is imperative to develop novel therapeutic regimens that will extend PFS and OS in this group. The SWOG 1211 is the first national and inter-group study targeting the HRMM population. **Methods:** Eligibility and Trial Design: A randomized phase I/II trial was designed to evaluate the efficacy of incorporating novel agents into first line therapy for HRMM patients comparing lenalidomide, bortezomib and dexamethasone (RVD) with or without addition of elotuzumab (Elo). Eligible patients must have a documented history of HRMM defined by one or more of the following: Poor risk genomics defined by 70-gene model. Translocation (14;16), translocation (14;20) and/or deletion (17p) by florescent in-situ hybridization (FISH). Primary plasma cell leukemia. Serum LDH $>$ 2 times normal levels. Objectives: Phase I: To determine the maximum tolerated dose (MTD) of RVD-Elo. Phase II: To assess whether incorporation of the novel agent Elo into treatment algorithm of HRMM will improve PFS. Statistical Considerations: The phase I study enrolled 6 DLT evaluable patients; no DLTs were observed. The phase II study is now open and will accrue 100 eligible patients (50 per arm). An additional 10 patients (5 per arm) will be accrued to account for ineligibility/patients withdrawing consent. The median expected PFS in the control arm (RVD) is 2.2 years, based on the experience in Total Therapy 3a and 3b studies (high risk genomics defined by 70-gene model). Assuming uniform accrual of 25 patients per year, four years of accrual and an additional 2 years of follow-up yields a study with 82% power and a one-sided significance level alpha of 0.1 to detect a hazard ratio of 1.75 between two treatment arms, or an increase in median PFS from 2 years to 3.5 years in the RVD-Elo arm versus the RVD arm. Clinical trial information: NCT01668719.

**TPS8625 General Poster Session (Board #305A), Mon, 1:15 PM-5:00 PM**

**The STRATUS trial (MM-010): A single-arm phase 3b study of pomalidomide plus low-dose dexamethasone (POM + LoDEX) in refractory or relapsed and refractory multiple myeloma.** *Presenting Author: Meletios A. Dimopoulos, Alexandra Hospital, University of Athens School of Medicine, Athens, Greece*

**Background:** POM is a distinct oral IMiD immunomodulatory agent with direct anti-myeloma, stromal cell support-inhibitory, and immune-modulating activities. In the phase 3 MM-003 trial, POM + LoDEX significantly extended progression-free survival (PFS) and overall survival (OS) vs. high-dose dexamethasone in patients (pts) who failed bortezomib (BORT) and lenalidomide (LEN) treatment (Tx; Dimopoulos, ASH 2013). STRATUS is a multicenter, single-arm, open-label phase 3b trial with $>$ 85 sites across Europe to further evaluate safety and efficacy and explore cytogenetics, pharmacokinetics (PK), and biomarkers in a large pt population (target enrollment: 720 pts; NCT01712789). **Methods:** Eligible pts have refractory or relapsed and refractory disease, having failed BORT and LEN and received adequate prior alkylator therapy. Key exclusion criteria include absolute neutrophil count $<$ 800/$\mu$L, platelet count $<$ 75,000 or 30,000/$\mu$L (for pts with $<$ 50% or $>$ 50% of bone marrow nucleated cells as plasma cells, respectively), creatinine clearance $<$ 45 mL/min, hemoglobin $<$ 8 g/dL, and peripheral neuropathy $>$ grade 2. POM is administered 4 mg D1-21/28-day cycle and LoDEX 40 mg/day (20 mg for pts aged $>$ 75 yrs) on D1, 8, 15, and 22 until progressive disease or unacceptable toxicity. All pts receive low-dose ASA or equivalent thromboprophylaxis. Upon Tx discontinuation, follow-up will continue up to 5 yrs from enrollment of last pt for survival, second primary malignancies, and subsequent anti-MM Tx. The primary endpoint is safety. Secondary endpoints include POM exposure, PK, efficacy (overall response rate, time to response, duration of response, PFS, time to progression, OS, and cytogenetics). Cytogenetics are collected at initial diagnosis, study entry, and upon discontinuation to better understand the evolution of cytogenetics throughout the disease course and elucidate the role of POM in pts with different cytogenetic profiles. As exploratory endpoints, bone marrow and blood samples are collected for biomarker analysis to predict response or resistance to POM Tx. As of Jan 22, 2014, 400 pts have been enrolled and enrollment continues. Clinical trial information: NCT01712789.

**TPS8626 General Poster Session (Board #305B), Mon, 1:15 PM-5:00 PM**

**MM-013: An ongoing phase 2 trial of pomalidomide and low-dose dexamethasone (POM + LoDEX) in relapsed/refractory multiple myeloma (RRMM) with moderate or severe renal impairment (RI) including patients (pts) undergoing hemodialysis.** *Presenting Author: Pieter Sonneveld, Erasmus MC, Rotterdam, Netherlands*

**Background:** RI occurs in $>$ 40% of MM pts and can be associated with poor prognosis (Knudsen, *EJH* 2000). Data from 2 pivotal trials (MM-002, MM-003) suggested comparable efficacy and tolerability for POM + LoDEX in pts with or without moderate RI (Siegel, ASH 2012; Weisel, ASCO 2013). However, pts with severe RI were excluded from these trials. Because POM is extensively metabolized, with $<$ 5% of active substance eliminated in the urine, RI may not affect POM exposure in a clinically relevant manner. However, this has not been definitively tested in a clinical trial, and is under investigation in the US in MM-008. MM-013is a European, multicenter, open-label phase 2 study designed to assess the efficacy, safety, and pharmacokinetics (PK) of POM + LoDEX in RRMM pts with moderate or severe RI, including those undergoing dialysis (NCT02045017). **Methods:** The trial is enrolling RRMM pts (N = 80) across 3 cohorts: Cohort A (n = 33 with moderate RI, estimated glomerular filtration rate [eGFR] $\geq$ 30 and $<$ 45 mL/min/1.73 m$^2$), Cohort B (n = 33 with severe RI [eGFR $<$ 30 mL/min/1.73 m$^2$] and no dialysis), and Cohort C (n = 14 with severe RI requiring dialysis). Pts must have biopsy-confirmed MM-related RI and RRMM with $\geq$ 1 prior therapy (Tx; including lenalidomide). POM 4 mg is administered D1-21/28-day cycle and LoDEX 40 mg/day (20 mg for pts $>$ 75 y) on D1, 8, 15, and 22 until progressive disease or unacceptable toxicity. Thromboprophylaxis is required for all pts not on dialysis; pts on dialysis should receive anticoagulants as appropriate. After Tx discontinuation, pts will be followed for survival, subsequent anti-MM Tx, and second primary malignancies for 5 y after enrollment of last pt. The primary endpoint is overall response rate; secondary endpoints include assessment of renal response ($\geq$ 2 mos improvement in eGFR from $<$ 15 to 30-59 mL/min/1.73 m$^2$ [partial] + improvement from $<$ 50 to $\geq$ 60 mL/min/1.73m$^2$ [complete]), time to renal response, PFS, TTP, OS, safety, and PK. Additional analyses will examine biomarkers predictive of response or resistance to POM. MM-013 is open for enrollment across Europe. Clinical trial information: NCT02045017.

**TPS8627 General Poster Session (Board #306A), Mon, 1:15 PM-5:00 PM**

**MM-014: A phase 2 trial evaluating efficacy, safety, and biomarkers of pomalidomide plus low-dose dexamethasone (POM + LoDEX) in relapsed/refractory multiple myeloma (RRMM) following second-line lenalidomide plus dexamethasone (LEN + DEX).** *Presenting Author: David Samuel DiCapua Siegel, John Theurer Cancer Center, Hackensack, NJ*

**Background:** Challenging relapsed disease with drugs of the same class remains an area of investigation. Subanalyses of MM-002 and MM-003 in advanced RRMM demonstrated comparable efficacy for POM + LoDEX in patients (pts) refractory to LEN as last prior treatment (Tx) vs. all pts (Richardson, 2014; San Miguel, 2013). To confirm this, MM-014, a multicenter, single-arm, open-label phase 2 trial in the US and Canada evaluating POM + LoDEX immediately following second-line LEN + DEX, was designed (NCT01946477). **Methods:** Pts (N = 85 planned) must have received 2 prior lines of myeloma Tx, with LEN + DEX as second line. Pts must have relapsed from or become refractory to LEN + DEX as last prior Tx ($\geq$ 2 cycles). Prior Tx may include all predetermined components of induction followed by ASCT and maintenance. Key exclusion criteria are creatinine clearance $<$ 30 mL/min requiring dialysis, ECOG PS $>$ 2, neutrophils $<$ 1000/$\mu$L, platelets $<$ 75,000 or $<$ 30,000/$\mu$L (for pts with $<$ 50% or $\geq$ 50% of bone marrow [BM] nucleated cells as plasma cells, respectively), Hb $<$ 8 g/dL, and prior ($<$ 5 y) non-MM malignancies. Pts must provide a BM sample at screening to establish presence or absence of myelodysplastic changes. Tx is POM 4 mg D1-21 of a 28-day cycle and LoDEX 40 mg/day (20 mg for pts aged $>$ 75 y) on D1, 8, 15, and 22 until progression or unacceptable toxicity. Thromboprophylaxis with low-dose aspirin or equivalent is mandated. Upon discontinuation, follow-up will continue for OS, second primary malignancies, and subsequent anti-MM Tx for up to 5 y from enrollment. The primary endpoint is ORR by modified IMWG criteria (with minimal response). Secondary endpoints include PFS, OS, duration of response, TTP, and safety. To elucidate POM mechanism of action in LEN-exposed disease, MM-014 includes exploratory endpoints to identify molecular, immune, and cellular biomarkers and evaluate clonality. Specifically, markers that may predict POM response or resistance, underlie POM + LoDEX synergy, indicate dysregulated pathways or key MM targets, and chromosomal aberrations will be evaluated. Sites are open for enrollment. Clinical trial information: NCT01946477.

**TPS8628 General Poster Session (Board #306B), Mon, 1:15 PM-5:00 PM**

**A randomized, double-blind, multinational trial comparing denosumab with zoledronic acid for treatment of bone disease in adults with newly diagnosed multiple myeloma.** *Presenting Author: Noopur S. Raje, Center for Multiple Myeloma, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background:** A characteristic feature of multiple myeloma (MM) is bone destruction mediated by osteoclasts. This breakdown of bone releases factors that mediate myeloma cell growth, creating a cycle of skeletal damage and tumor cell growth. Patients with MM and bone lesions can experience debilitating pain and skeletal complications including pathologic fractures, need for radiotherapy or surgery to bone, and spinal cord compression, collectively termed skeletal-related events (SREs). RANKL is the key mediator of osteoclast activity. Denosumab, a fully human monoclonal antibody specific to RANKL, inhibits the formation, function, and survival of osteoclasts, thus decreasing cancer-mediated bone destruction. The primary endpoint of this trial is to determine whether denosumab is noninferior to zoledronic acid (ZA) in delaying the time to 1$^{st}$ on-study SRE in patients with MM. Secondary endpoints include superiority of denosumab vs ZA in delaying the time to 1$^{st}$ on-study SRE and time to 1$^{st}$-and-subsequent SRE and overall survival. Safety endpoints will be assessed. This trial is registered (ClinicalTrials.gov NCT01345019) and sponsored by Amgen Inc. **Methods:** We are targeting enrollment of ~1520 adults with newly diagnosed MM and $\geq$1 bone lesion. Patients with $\leq$30 days of anti-myeloma therapy, $\leq$1 prior dose of IV bisphosphonate, an ECOG status $\leq$2, and adequate organ function are eligible. Use of any approved treatment regimen is permitted as anti-myeloma treatment in this trial. Enrolled patients are stratified by whether they intend to undergo autologous stem cell transplant; use of novel vs non-novel anti-myeloma agents as 1$^{st}$-line therapy; stage at diagnosis per the International Staging System; SRE at time of presentation; and geographic region. Randomized (1:1) patients receive either SC denosumab 120 mg + IV placebo *or* IV ZA 4 mg (adjusted for CrCl) + SC placebo once every 4 weeks. Daily calcium ($\geq$500 mg) and vitamin D ($\geq$400 IU) supplements are strongly recommended. The primary analysis is planned when ~800 patients experience an on-study SRE. Enrollment is currently ongoing and enrollment rates are as planned. Clinical trial information: NCT01345019.

**TPS8629 General Poster Session (Board #307A), Mon, 1:15 PM-5:00 PM**

**Efficacy of lenalidomide maintenance (LEN) therapy versus placebo, after melphalan, prednisone, bortezomib (MPV) induction therapy in patients (pts) with newly diagnosed multiple myeloma (NDMM): The ARUMM (MM-026) trial.** *Presenting Author: Cyrille Hulin, Hematology Department, University Hospital, Nantes, France*

**Background:** Improved progression-free survival (PFS) benefits have been reported in several large phase 3 trials with LEN therapy (Attal NEJM 2012, Facon ASH 2013, McCathy NEJM 2012, Palumbo NEJM 2012, Palumbo ASCO 2013), overall survival (OS) advantage has also been observed in some of them. Treatment with LEN therapy has also been well tolerated. Effective continuous maintenance therapy is of great importance to prolong response duration and consequently improved disease outcomes (PFS, OS). **Methods:** ARUMM is a phase 3b, double-blind, 2-arm study which will compare efficacy and safety of continuous maintenance therapy with LEN vs. placebo until progressive disease (PD) in NDMM pts. Inclusion criteria are: pts $\geq$ 65 yrs or $<$ 65 yrs not candidates for stem cell transplantation, and who achieved $\geq$ partial response (PR) as best overall response after 6 to 9 cycles of MPV induction therapy. Exclusion criteria include: prior treatment (Tx) with other anti-myeloma therapies than MPV, and pts who did not reach $\geq$ PR after MPV induction Tx. Eligible pts will be randomized either to LEN (10 mg/day days 1–21/28-day cycle) or placebo (days 1–21/28-day cycle) until PD. Pts will be stratified according to disease stage (ISS) and prognostic factors at initial diagnosis, and response to MPV induction therapy. PFS is the primary study endpoint and defined as the time from randomization to PD based on IMWG criteria and reviewed by an independent physician or death from any cause, whichever occurs first; secondary endpoints will include overall response rate, OS, quality of life, cytogenetics and tolerability. Safety will include adverse events (AEs), laboratory abnormalities, serious AEs, and second primary malignancies. Exploratory endpoints will include the assessment of minimal residual disease. Approximately 351 pts will be enrolled. The trial has been powered at 80% with a hazard ratio of 0.66 (LEN vs. placebo) for PFS between the 2 arms (29 vs. 19 months) at the 2-sided significance level of 0.05. EudraCT Number: 2013-001729-26 Clinical trial information: 2013-001729-26.

**TPS8630 General Poster Session (Board #307B), Mon, 1:15 PM-5:00 PM**

**Continuous lenalidomide (LEN) therapy versus observation following nonimmunomodulatory compound-based induction therapy in newly diagnosed multiple myeloma (NDMM): MM-027 trial.** *Presenting Author: Saad Zafar Usmani, Levine Cancer Institute/Carolinas Healthcare System, Charlotte, NC*

**Background:** Several recent trials have shown improvements in progression-free survival (PFS) with continuous LEN treatment (Tx) in NDMM patients (pts). PFS was 45%-59% higher using LEN therapy vs. control arm and rates of overall survival (OS) were consistently improved (Attal, NEJM 2012; Facon, ASH 2013, McCarthy, NEJM 2012; Palumbo, NEJM 2012, Palumbo ASCO 2013). Therefore an effective strategy of continuous Tx is of great importance to outcomes. **Methods:** This phase 3b, multicenter, randomized, open-label study will compare PFS of LEN single-agent vs. observation after non-immunomodulatory compound based induction therapy in NDMM pts ($\geq$ 65 yrs) or $<$ 65 yrs non eligible for/decline SCT. Main inclusion criteria are: induction Tx with 6–12 cycles of non-immunomodulatory compound, achievement of $\geq$ stable disease (SD) according to the International Myeloma Working Group (IMWG) criteria. Exclusion criteria include: previous antimyeloma Tx and pts who did not achieve $\geq$ SD after $>$ 6 cycles of non-immunomodulatory Tx. Eligible pts will be screened and randomized 1:1 in either the LEN arm (10 mg/day on day 1–21/28-day cycle) or observation arm until progressive disease (PD). Dose adjustments will be made in case of adverse events (AEs). All pts who progress will enter long-term follow-up and will be monitored for OS and second primary malignancy every 3 months (mos) for at least 5 yrs. Primary endpoint is PFS from time of randomization to PD or death from any cause; secondary endpoints will include overall response rate and safety. AEs will be evaluated and graded according to the NCI CTCAE Version 4.0. Group sizes were calculated for a median PFS of 20 mos in the LEN arm and 10 mos in the observation arm, 90% power and a two-sided 0.05 level test. Counting for a non-evaluable rate of 15%, a total of 172 pts will be needed (86 per arm). Exploratory objectives will include assessment of minimal residue disease (MRD), clonal heterogeneity measurements and their correlation to clinical outcomes, molecular, immunological and mechanistic biomarkers will be assessed.

**LBA9000^** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Efficacy and safety of the anti-PD-1 monoclonal antibody MK-3475 in 411 patients (pts) with melanoma (MEL).** *Presenting Author: Antoni Ribas, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA*

**The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Monday, June 2, 2014, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2014, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.**

**9001** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Phase 2, multicenter, safety and efficacy study of pidilizumab in patients with metastatic melanoma.** *Presenting Author: Michael B. Atkins, Georgetown University Lombardi Comprehensive Cancer Center, Washington, DC*

**Background:** Pidilizumab (CT-011), a humanized anti PD-1 IgG1k, was studied in two Phase 2 studies in aggressive and indolent lymphomas showing clinical activity correlated with PD-1/PD-L1+ lymphocytes. Thus, we initiated a Phase 2 multicenter, randomized, open-label, study to evaluate the safety and efficacy of pidilizumab in patients (pts) with metastatic melanoma (MM). **Methods:** Eligibility criteria: measurable disease; Stage IV clearly progressive; ECOG 0-1; ≤ 3 prior systemic therapies for MM; stabilized brain mets allowed; 6 weeks from prior ipilimumab (Ipi), no prior PD-1/PD-L1/PD-L2 blockade. Pts were randomized to 2 dose levels (1.5 or 6 mg/kg IV q2 wk X 27), each with 50 pts and each balance stratified by prior Ipi (yes/no). **Results:** 103 pts were randomized; 75% M1c, 15.5% brain mets, 30% elevated LDH, 33% disease spread to ≥ 3 organs. 77% received prior systemic therapy for MM; 51% prior Ipi, 7.8% prior Braf inhibitor, 44% prior biologics (cytokines). 45% did not respond to most recent therapy. 45% received pidilizumab less than 4 months after prior therapy. ORR using irRC for all pts was 5.9% [90% CI: 2.3, 12.0] and 10.0% [90% CI: 1.8, 28.3] for 1.5mg/kg & prior Ipi. Pts with prior Ipi had higher irSD (53.7% vs 20.5%) and slightly longer median PFS (2.8 vs 1.9 months). Overall Survival at 12 months (12mo survival) was 64.5% (90% CI: 55.6, 72.0), with insignificant differences between strata or doses and irrespective of therapies given before study entry or after study withdrawal; 12mo survival for pts without prior or post-study Ipi (n=26) was 55.7% [90% CI: 35.6, 71.8], 12mo survival for pts with B-RAF V600 WT tumors (n=63) was 69.3% [90% CI: 58.2, 78.1]. 12mo survival for M1c pts (n=77) was 67.2%; [90% CI: 57.0, 75.5]. The most frequent AEs were fatigue (43%), diarrhea (22.5%), arthralgia (21%) and SAEs of pneumonia (5%) and dyspnea (3%). **Conclusions:** Despite low response rates, pidilizumab therapy results in substantial 12mo survival in heavily pretreated pts. The 12mo survival appears comparable to that of other anti- PD-1 MAbs. Treatment is very well tolerated. Further studies of pidilizumab in pts with MM are warranted, preferably in combination with other therapeutics. Clinical trial information: NCT01435369.

**9002** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Long-term survival of ipilimumab-naive patients (pts) with advanced melanoma (MEL) treated with nivolumab (anti-PD-1, BMS-936558, ONO-4538) in a phase I trial.** *Presenting Author: F. Stephen Hodi, Dana-Farber Cancer Institute, Boston, MA*

**Background:** We have shown that nivolumab, a fully human IgG4 PD-1 immune-checkpoint inhibitor antibody, is tolerable and active in pts with advanced solid tumors in a large phase I trial (Topalian et al. N Eng J Med 366:2443-54, 2012). For the MEL pts in this trial, we report long-term clinical activity, pts' response off therapy, tumor PD-1 ligand (PD-L1) expression associated with survival endpoints, and for the first time, 3-y overall survival (OS). **Methods:** Previously treated advanced MEL pts with no prior ipilimumab therapy received nivolumab (0.1, 0.3, 1, 3, or 10 mg/kg IV) Q2Wk for ≤96 wk and were evaluated for OS and progression-free survival (PFS). PD-L1 tumor cell membrane expression was retrospectively assessed in archival specimens by a Dako immunohistochemistry assay with ≥5% tumor cells designated as PD-L1(+). **Results:** From 2008-2012, 107 MEL pts initiated treatment with nivolumab; 25% had ≥3 prior therapies. Across doses, the 2- and 3-y OS rates were 48 and 41%, respectively (Table). For the 34/107 (32%) pts with objective responses (OR; RECIST), median response duration was 22.9 mo. Twenty-four OR pts stopped nivolumab for reasons other than disease progression; 11 (46%) maintained responses for ≥24 wk off drug (range: 24, 56+ wk). Four (4%) pts had unconventional "immune-related" responses. In a subset of pts with evaluable tumor samples (41/107), pts with PD-L1(+) and (–) tumors (n=18 and 23, respectively) had median OS of not reached and 12.5 mo; median PFS was 9.1 mo and 1.9 mo. Safety has been previously reported (Sznol et al. J Clin Oncol 31:abs CRA9006, 2013). **Conclusions:** In advanced MEL pts, nivolumab demonstrated favorable 2- and 3-y OS rates, durable responses with a number persisting off therapy, and an acceptable safety profile. Additional analyses will be presented by pts' characteristics across the full population, the long-term survival subgroup, and the PD-L1(+/–) tumor subgroups. Ongoing phase III trials are further evaluating nivolumab for MEL pts and PD-L1 as a potential predictive biomarker for response to nivolumab. Clinical trial information: NCT00730639.

| OS rate* n=107 | % (95% CI) | Pts at risk |
|---|---|---|
| 1 y | 63 (53, 71) | 63 |
| 2 y | 48 (38, 57) | 44 |
| 3 y | 41 (31, 51) | 22 |

*September 2013 analysis.

**9004** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Correlation between pre-existing MEK1$^{P124}$ mutations and clinical and in vitro response to BRAF inhibitors in metastatic melanoma.** *Presenting Author: Matteo S. Carlino, Melanoma Institute Australia; Westmead Institute for Cancer Research & Westmead Millennium Institute, University of Sydney, Sydney, Australia*

**Background:** MEK1 mutations can confer resistance to BRAF inhibitors although pre-existing MEK1$^{P124}$ mutations do not preclude clinical responses to BRAF inhibitor therapy. We sought to determine if pre-existing MEK1$^{P124}$ mutations affected clinical outcome in BRAF inhibitor treated melanoma. **Methods:** Data from three published data sets, and from patients treated at our institutions, were analyzed to determine if pre-existing MEK$^{P124}$ mutations affect radiological response or progression-free survival (PFS) in BRAF$^{V600}$ mutant metastatic melanoma patients treated with vemurafenib or dabrafenib. The effects of MEK1$^{P124}$ mutations on MAPK pathway activity and response to dabrafenib were also investigated in a series of cell models. **Results:** 123 patients with pre-treatment tumors tested for MEK1 mutations were included. Those with a pretreatment MEK$^{P124}$ mutation (n=12) had a poorer RECIST response (33% vs 71% CR or PR in MEK1$^{P124}$ vs MEK1 wild-type, p=0.008), this was associated with a shorter median PFS in those with a MEK1$^{P124}$ mutation (Median 3.1 vs 4.8 months, p=0.004). Introduction of MEK1 P124Q or P124S variants into BRAF-mutant SKMel28 melanoma cells resulted in diminished inhibition of ERK phosphorylation by dabrafenib and enhanced clonogenic survival compared to cells ectopically expressing wild-type MEK1. The impact of MEK1$^{P124}$-variants was significantly less than the effect of MEK1$^{K57E}$, a known mechanism of acquired BRAF inhibitor resistance. Consistent with these data, two BRAF mutant cell lines with endogenous MEK1$^{P124}$ mutations, including a short term culture generated pre-treatment from a patient who responded poorly to combined dabrafenib and trametinib, showed weak sensitivity to dabrafenib (IC50s 21 and 26nM) compared to a panel of MEK1 wild type/BRAF mutant cell lines (median IC50 7nM; range 4-14nM). In contrast, melanoma cell lines showed equivalent sensitivity to ERK inhibition, irrespective of the MEK1 genotype. **Conclusions:** Pre-existing MEK$^{P124}$ mutations are associated with a reduced response to BRAF inhibitor therapy but are unlikely to affect response to ERK inhibitors.

***BRAF*$^{V600}$ mutation levels and response to vemurafenib in metastatic melanoma.** *Presenting Author: Celeste Lebbe, Hôpital Saint-Louis, Paris, France*

**Background:** Resistance mechanisms acquired during BRAF inhibitor (BRAFi) treatment were shown to involve multiple signalling pathways including MAPK, PI3K pathways and tumor microenvironment. They may also be complicated by intra-tumor heterogeneity of *BRAF* mutational status which paradoxically enhances wild-type *BRAF* cells proliferation. We therefore wanted to evaluate using a quantitative pyrosequencing assay whether the level of *BRAF*$^{V600}$ mutation in tumor tissue could predict clinical response and outcome of *BRAF*$^{V600}$melanoma patients treated with the BRAFi, vemurafenib. **Methods:** melanoma specimen from 44 patients with advanced melanoma treated with vemurafenib were available at abseline. The *BRAF*$^{V600}$ mutation level was defined as the ratio of the *BRAF*$^{V600}$ allele quantification to the percentage of tumor cells in the sample. The main end point were response according to RECIST, progression free survival, overall survival and ratio of the mutated allele to percentage of tumor cells. **Results:** The *BRAF*$^{V600}$ mutation level was significantly associated with the best response rate to vemurafenib (*BRAF*$^{V600E}$ and *BRAF*$^{V600K}$ *P*=0.003; *BRAF*$^{V600E}$ only *P*=0.003). The median PFS and OS for all patients were respectively 4 (95%CI 3 to 6) and 13 (95%CI 6 to 15) months. Interestingly, until 10 months of treatment the PFS of patients with high ratio (≥ 0.5; median) was significantly better than those of patients with a low ratio) but the benefit did not last. Indeed the progression free survival (PFS) benefit in those patients with a high mutation levels (≥ 0.5) gradually decreased during the first 6 months of treatment as the risk of progression increased and, beyond 10 months of treatment, became even lower than in patients with low mutation level. **Conclusions:** We show that quantification of BRAF mutant allele (V600E and V600K) is a predictive marker of BRAFi response in metastatic melanoma patients. This preliminary study constitutes a first step in the identification of surrogate biomarkers of melanoma response to BRAFi and provides a promising tool that might help in the management of metastatic melanoma.

**9006^** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Metabolic tumor burden for prediction of overall survival following combined BRAF/MEK inhibition in patients with advanced BRAF mutant melanoma.** *Presenting Author: Grant A. McArthur, Skin and Melanoma Service, Peter MacCallum Cancer Centre, East Melbourne, Australia*

**Background:** BRAF mutation is a common and potent oncogenic driver of ERK signalling in melanoma. Abrogation of pERK reduces 18-F-fluorodeoxyglucose (FDG) uptake on PET with recovery in glycolytic metabolism being a hallmark of resistance. FDG-PET also allows accurate quantification of melanoma burden. In a Ph1b trial (BRIM7), combining vemurafenib (vem) with a MEK inhibitor, cobimetinib (cobi), BRAFi-naïve patients (pts) with advanced *BRAF*$^{V600}$-mutated melanoma attained 87% confirmed response rate, by RECIST and median progression-free survival of 13.7 months. We evaluated FDG-PET response as predictor of clinical outcome in BRAFi/MEKi naïve patients (pts) treated with this combination. **Methods:** FDG-PET scanning was performed in cycle 1 (C1) (day 10-15) and in C2 (day 35-49) of BRIM7. The percentage of the injected dose (%ID) of FDG and metabolic tumor volume (MTV), as measures of tumor burden, and maximum standardized uptake value (SUVmax) in up to 5 target lesions, as an indicator of metabolism, were assessed at baseline, C1 and C2. PFS and OS were analysed by the log rank method. **Results:** 35 evaluable BRAFi-naïve pts (mean %ID 1.6±2.9% and mean 'MTV 166±251 ml) demonstrated a mean reduction in %ID, MTV and SUVmax of 86±14%, 72±23% and 76±18% at C1, respectively, and 95±10%, 92±12% and 89±14% at C2, respectively. All pts achieved a partial metabolic response (PMR) (> 30% decrease in SUVmax) by C1 with 5 complete metabolic responses (CMR) (14%) in C1 and 17 CMR (51%) in C2. Pts achieving a CMR in C1 had longer PFS when compared to Pts achieving PMR. Although tumor burden at baseline was not correlated with metabolic response, both %ID and MTV were predictors of OS. Pts with a baseline %ID <median (0.36%) or MTV <median (47.5 ml) had better OS (HR 0.19, p<0.02 and 0.14, p=0.03) compared to pts with >median values. **Conclusion:** Independent of tumor burden, BRAFi/MEKi naïve pts treated with vem/cobi achieved a marked, early and progressive metabolic response on FDG-PET consistent with successful inhibition of ERK-signaling. Tumor burden was a predictor of clinical outcome in this small patient cohort with low baseline %ID or MTV associated with longer overall survival; further validation is warranted. Clinical trial information: NCT01271803.

**9007** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Comparative health care (HC) costs in patients (pts) with metastatic melanoma (mM).** *Presenting Author: Chun-Lan Chang, IMS Health, Plymouth Meeting, PA*

**Background:** Advances in mM have increased treatment (tx) options, where previously, few therapies were available. This study compares HC and adverse event (AE) costs in a U.S. managed care population of mM pts. **Methods:** This retrospective study used a large claims database comprised of 55 U.S health plans. mM pts who initiated treatment with vemurafenib (VEM), ipilumimab (IPI), dacarbazine (DTIC), paclitaxel (PAC) or temozolomide (TMZ) from 7/2009-9/2012 were identified. A treatment episode (TE) was defined as time from index date to addition or switch to different study drug, or a gap >45 days (>112 days for IPI). Adverse events (AEs) were selected if reported in package inserts (Grade 3/4 occurring ≥5%) and identified by ICD-9 codes occurring within TEs and 30 days after end of TEs. All-cause costs for TEs and AEs were normalized as monthly costs. Multivariate regression models with repeated measures were used to estimate adjusted monthly HC and AE costs. **Results:** The study identified 541 mM pts with mean (SD) age of 57.5 (11.5) years; 62.1% were male; 49.0% had >3 sites of metastases. A total of 809 TEs (VEM:143; IPI:147; DTIC:89; PAC:139; TMZ:291) were identified. Total mean (SD) all-cause costs for VEM were $77,687 (60,329); IPI $153,062 (134,048); DTIC $35,243 (33,641); TMZ $42,870 (41,384); PAC $58,991 ($81,306). Adjusted mean monthly TE costs for VEM was significantly lower than IPI and comparable to other mM drugs. VEM had significantly lower monthly AE costs than all other study drugs (Table). **Conclusions:** HC costs were highest for IPI, followed by TMZ, VEM, PAC and DTIC. This study is amongst the 1st economic analyses to include recently approved therapies in mM. In combination with safety and efficacy findings, these results may assist clinicians, policy makers and managed care organizations with treatment strategies in mM.

**9008a** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Primary overall survival (OS) from OPTiM, a randomized phase III trial of talimogene laherparepvec (T-VEC) versus subcutaneous (SC) granulocyte-macrophage colony-stimulating factor (GM-CSF) for the treatment (tx) of unresected stage IIIB/C and IV melanoma.** *Presenting Author: Howard L Kaufman, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

**Background:** T-VEC is an oncolytic immunotherapy derived from herpes simplex virus type-1 designed to selectively replicate in tumors and produce GM-CSF to enhance systemic antitumor immune responses. OPTiM is a randomized, phase 3 trial of T-VEC or GM-CSF in patients (pts) with unresected melanoma with regional or distant metastases (NCT00769704). OPTiM met the primary endpoint of a statistically significant improvement in durable response rate (DRR) with T-VEC vs GM-CSF (Andtbacka et al. ASCO 2013). The primary analysis of OS is reported here. **Methods:** Key entry criteria were age ≥ 18 yrs, ECOG ≤1, unresectable melanoma stage IIIB/C or IV, injectable cutaneous, SC, or nodal lesions, LDH ≤1.5X ULN, ≤ 3 visceral lesions (excluding lung), none > 3 cm. Pts were randomized 2:1 to intralesional T-VEC (initially ≤ 4 mL x$10^6$ pfu/mL then after 3 wks, ≤ 4 mL x$10^8$ pfu/mL Q2W) or SC GM-CSF (125 $\mu$g/m$^2$qd x 14 days q28d). The primary endpoint was DRR: partial or complete response continuously for ≥ 6 mos starting within 12 mos. Responses were per modified WHO by blinded central review. The primary analysis of OS (290 planned events) had 90% power to detect a HR of 0.67 with two sided $\alpha$=0.05. **Results:** 436 pts are in the ITT set: 295 (68%) T-VEC, 141 (32%) GM-CSF. 57% were men; median age was 63 yrs. An increase of 4.4 mos in OS with T-VEC vs GM-CSF was observed (p =0.051): HR 0.787 (95% CI: 0.62, 1.00); median (95% CI) OS was 23.3 (19.5, 29.6) mos with T-VEC vs 18.9 (16.0, 23.7) mos with GM-CSF. Objective response rate with T-VEC was 26% (95% CI: 21%, 32%) with 11% CR, and with GM-CSF was 6% (95% CI: 2%, 10%) with 1% CR. DRR for T-VEC was 16% (95% CI: 12%, 21%) and 2% for GM-CSF (95% CI: 0%, 5%), p<0.0001. Most common adverse events (AEs) with T-VEC were fatigue, chills, and pyrexia. No ≥ grade 3 AE occurred in ≥ 3% of pts in either arm. **Conclusions:** In pts with unresectable Stage IIIB-IV melanoma, T-VEC demonstrated a significant improvement in the DRR vs GM-CSF with a tolerable safety profile. An improvement in OS approaching statistical significance was seen in the ITT population. Clinical trial information: NCT00769704.

**9009** **Clinical Science Symposium, Sun, 8:00 AM-9:30 AM**

**A phase 1b/2 study of LEE011 in combination with binimetinib (MEK162) in patients with *NRAS*-mutant melanoma: Early encouraging clinical activity.** *Presenting Author: Jeffrey Alan Sosman, Vanderbilt University Medical Center, Nashville, TN*

**Background:** *NRAS*-mutant melanoma has poor prognosis with no approved targeted therapies. Enhanced MAPK pathway signaling and cell cycle checkpoint dysregulation are frequent in *NRAS*-mutant melanoma. Thus, simultaneous inhibition of MEK and CDK4/6 could further suppress pathway activation. The MEK inhibitor binimetinib (MEK162) showed clinical activity in patients (pts) with *NRAS*-mutant melanoma. In preclinical studies, the selective CDK4/6 inhibitor LEE011 demonstrated tumor growth inhibition, and in combination with binimetinib led to regressions in *NRAS*-mutant melanoma models, warranting clinical study. **Methods:** This is a phase 1b/2, open-label study of LEE011 + binimetinib in pts with *NRAS*-mutant melanoma. The primary objective of the phase 1b part is to estimate the MTD/RP2D of the combination, using a Bayesian logistic regression model (BLRM) with overdose control. Secondary objectives include safety, pharmacokinetics (PK), and preliminary efficacy. LEE011 is administered once daily for 21 days of each 28-day cycle and binimetinib is administered twice daily continuously. **Results:** As of Dec 20, 2013, 14 pts were enrolled (93% stage M1c; ECOG PS 0/1/2 [43%/50%/7%]; median 2 prior lines) and were treated with LEE011 at 200 mg (dose level [DL] 1, n = 8) or 300 mg (DL 2, n = 6) and with binimetinib 45 mg. DLTs occurred at DL 1 (grade 3 acute renal injury, n = 1) and DL 2 (grade 4 asymptomatic creatine phosphokinase [CPK] elevation and grade 3 edema plus grade 4 atrial fibrillation, 1 pt each). Common treatment-related toxicities included CPK elevation, rash, edema, anemia, nausea, diarrhea, and fatigue. Preliminary PK was consistent with single-agent data for either drug, with no evidence of drug-drug interaction. Six pts achieved partial response (43%; 1 confirmed, 5 unconfirmed) and 6 had stable disease (4 with tumor shrinkage > 20%). Several pts experienced early tumor shrinkage with major symptomatic improvement; 8 pts remain on treatment (duration 2-8 mo). **Conclusions:** Combined LEE011 + binimetinib shows promising preliminary antitumor activity in pts with *NRAS*-mutant melanoma. Determination of a phase 2 dose and schedule and PD effects are ongoing. Clinical trial information: NCT01719380.

**9009a^** **Clinical Science Symposium, Sun, 8:00 AM-9:30 AM**

**Randomized, double-blind study of sonidegib (LDE225) in patients (pts) with locally advanced (La) or metastatic (m) basal-cell carcinoma (BCC)** *Presenting Author: Michael Robert Migden, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Pts with advanced BCC have limited treatment options. Sonidegib blocks the hedgehog pathway (overexpressed in ≥ 95% of BCCs) by selective inhibition of smoothened. **Methods:** In this ph 2 study (BOLT; NCT01327053), pts with LaBCC, not amenable to curative surgery or radiation, or mBCC were randomized 1:2 to receive sonidegib 200 or 800 mg daily. The primary endpoint, objective response rate (ORR—histopathologically confirmed complete response [CR] + partial response [PR]—achieved if point estimate ≥ 30% and 95% CI lower bound > 20% [either arm]), and secondary endpoints duration of response (DoR), CR rate, time to tumor response (TTR), and PFS were assessed according to modified RECIST (mRECIST; LaBCC) or RECIST 1.1 (mBCC) by central review. Statistical comparison of arms was not planned. Safety was assessed up to ≈30 days post-last dose. **Results:** Pts (194 LaBCC; 36 mBCC) were enrolled from Jul 2011-Jan 2013. The primary endpoint was met for both arms (Table; median follow-up 13.9 mo). Median exposure was 8.9 (200 mg) and 6.5 mo (800 mg). AEs were less frequent at 200 mg. AEs leading to discontinuation (200/800 mg) included muscle spasms (3.8%/8.7%), dysgeusia (2.5%/4.7%), weight decreased (2.5%/4.7%), and nausea (2.5%/4.0%). **Conclusions:** Meaningfuldisease control with sustained DoR and prolonged PFS were achieved with both doses of sonidegib, with a more favorable benefit-risk profile for 200 mg. Clinical trial information: NCT01327053.

**Updated overall survival (OS) for BRF113220, a phase 1-2 study of dabrafenib (D) alone versus combined dabrafenib and trametinib (D+T) in pts with *BRAF* V600 mutation-positive (+) metastatic melanoma (MM).** *Presenting Author: Keith Flaherty, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

**Background:** D, a selective BRAF inhibitor, and T, a reversible, highly selective allosteric inhibitor of MEK1/2, are approved monotherapies, and an FDA approved combination therapy for $BRAF^{V600}$mutation + MM. **Methods:** Safety and efficacy of D+T were evaluated in this Phase 1-2 study. $BRAF^{V600E/K}$mutation + MM pts naive to BRAFi and MEKi were enrolled. Part B (Ph 1, n=77 BRAF naive) pts enrolled into escalating cohorts of D mg BID + T mg QD – 75/1, 150/1, 150/1.5 and 150/2 respectively. Part C (Ph 2, n=162) pts were randomized 1:1:1 to D 150 mono, 150/1 and 150/2. Cross-over from D mono to 150/2 was allowed post progression of disease (PD). Primary endpoints were progression free survival (PFS), response rate (RR), duration of response (DoR), and safety; secondary endpoints were OS and PK. **Results:** Updated OS for pts in Parts B and C with median follow-up of 28 and 24 months (mo) presented in Table 1.In Part C, median OS for 150/2 pts is 23.8 mo (HR=0.73 vs. D mono, p-value=0.24); 18-mo OS rate is 63%, reflective of paradigm shifting improvements in OS in this population. OS for D mono is confounded by cross-over to 150/2; 45 (83%) pts crossed over at time of analysis. In 150/1 and 150/2, 43 (80%) and 24 (44%) continued to receive D+T beyond RECIST PD. Subsequent systemic therapies were similar across arms; 38 (23%) pts received immune checkpoint inhibitors (19% ipilimumab and 8% PD-1/PD-L1 13), and 19 (12%) received vemurafenib. **Conclusions:** Updated median OS is 23.8 mo for 150/2. Contribution of treatment beyond PD or post-treatment therapy is unknown. Follow-up continues; updated OS and safety data analysis will be performed in the final analysis after 30 mo follow-up or 75% events. Clinical trial information: NCT01072175.

**9011^ Clinical Science Symposium, Sun, 8:00 AM-9:30 AM**

**COMBI-d: A randomized, double-blinded, Phase III study comparing the combination of dabrafenib and trametinib to dabrafenib and trametinib placebo as first-line therapy in patients (pts) with unresectable or metastatic $BRAF^{V600E/K}$ mutation-positive cutaneous melanoma** *Presenting Author: Georgina V. Long, Melanoma Institute Australia, Sydney, Australia*

**Background**: As monotherapies, the BRAF inhibitor dabrafenib (D) and the MEK inhibitor trametinib (T) demonstrated superior progression-free survival (PFS) v chemotherapy in pts with $BRAF^{V600}$ mutant, metastatic melanoma (MM). Resistance develops in most pts, and oncogenic toxicities (e.g., cutaneous squamous carcinoma (cuSCC)) are associated with BRAF inhibition. Simultaneous inhibition of BRAF and MEK mitigated these effects in the Phase I/II study of D+T v D (NCT01072175), with an improvement in overall response rate (ORR), PFS and reduced frequency of cuSCC. This Phase III study (NCT01584648) was conducted to confirm the superiority of D+T over D in pts with $BRAF^{V600E/K}$ mutant MM. **Methods:** Pts were randomized 1:1 to receive D (150 mg twice daily) + T (2 mg once daily) or D+ placebo (P) as first-line therapy. Eligible pts were ≥18 years and ECOG performance status ≤1, with histologically confirmed unresectable stage IIIC or IV, $BRAF^{V600E/K}$ mutant cutaneous melanoma. The primary endpoint was investigator-assessed PFS; secondary endpoints were overall survival (OS), ORR, duration of response, and safety. Cross over was prohibited. The study has 95% power and a one-sided $\alpha$=0.025 to detect a PFS hazard ratio (HR) of 0.59. **Results:** From May 2012 to Jan 2013, 423 pts were randomized (211 to D+T, 212 to D+P). Median follow up was 9 mo (0-16 mo). HR for investigator-assessed PFS was 0.75 (95% CI: 0.57, 0.99; p=0.035), in favor of D+T with a median PFS of 9.3 v 8.8 mo with D+P. The confirmed ORR was 67% (complete response [CR] 10%) for D+T and 51% (CR 9%) for D+P (p=0.0015). HR for interim OS was 0.63 (95% CI 0.42, 0.94; p=0.023), in favor of D+T (40 v 55 deaths). Rates of AEs were similar for both arms. More pts had AEs leading to dose modifications with D+T v D+P. Increased incidence (51% v 28%) and severity (grade 3, 6% v 2%) of pyrexia occurred with D+T v D+P. Fewer cutaneous hyperproliferative events occurred with D+T v D+P (cuSCC 2% v 9%; hyperkeratosis 3% v 32%). **Conclusions:** D+T demonstrated a significant improvement in PFS compared to D+P in pts with $BRAF^{V600E/K}$ mutant MM. Clinical trial information: NCT01072175.

**9012 Poster Highlights Session (Board #27), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Vismodegib in the treatment of patients with metastatic basal cell carcinoma (mBCC) and distant metastases: Survival in the pivotal phase II and phase I studies.** *Presenting Author: Karl D. Lewis, University of Colorado Cancer Center, Aurora, CO*

**Background:** mBCC is rare and poorly characterized. Recent data (McCusker, in press, *Eur J Cancer*) indicated that between 1981-2011, the median overall survival (OS) of patients (pts) with mBCC and distant metastases was 2.0 years (95% CI 1–2.9) from time of diagnosis, with a 1-year survival probability of 58.6% (95% CI 44.6–72.6). Vismodegib (VISMO) is a first in-class Hedgehog pathway inhibitor approved for adults with mBCC or locally advanced BCC that is inoperable. Here we report OS in a pooled aBCC population of pts with distant metastases from the pivotal phase II and phase I studies in the context of survival estimates from the literature. **Methods:** 45 mBCC pts with radiographically measurable distant metastases, present at any site, including soft tissue, other than or in addition to regional lymph nodes, were enrolled in the phase I (NCT00607724; Von Hoff, 2009; n=16) and pivotal phase II (NCT00833417; Sekulic, 2012; n=29) trials. Pts received VISMO 150/270/540 mg/d in the phase I and 150 mg/d in the pivotal phase II trials until disease progression/intolerable toxicity. Analysis of OS in mBCC pts with distant metastases was performed 26 Nov 2013 after primary analysis for the phase I (28 Feb 2009) and the pivotal phase II (26 Nov 2010) trials. OS probability and median OS were estimated with 95% CIs by the Kaplan-Meier method. **Results:** The clinical characteristics of these 45 pts treated with VISMO were similar to those in the McCusker review, including mean age at mBCC diagnosis (58 yrs vs 58.5 yrs), male predominance (72% vs 80%), and mean time from initial BCC diagnosis to detection of metastases (6.3 yrs vs 7.4 yrs). 22 of 45 pts (49%) with mBCC and distant metastases who were treated with VISMO were alive at the last assessment. VISMO therapy resulted in a median OS of 2.8 yrs (95% CI 2.0–not estimable) from first dose of VISMO (vs 2.0 yrs [95% CI 1.0–2.9] in the McCusker review), and 1- and 2-year survival estimates of 84.4 % (95% CI 73.9%–95.0%) and 68.0 (95% CI 54.2%–81.9%), respectively. **Conclusions:** Survival of these 45 pts with mBCC and distant metastases compares favorably to historical reports. VISMO may improve OS of mBCC pts with distant metastases. Clinical trial information: NCT00833417.

**9013 Poster Highlights Session (Board #28), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Long-term safety and efficacy of vismodegib in patients with advanced basal cell carcinoma: Final update (30-month) of the pivotal ERIVANCE BCC study.** *Presenting Author: Aleksandar Sekulic, Mayo Clinic, Scottsdale, AZ*

**Background:** BCC pathogenesis involves abnormal Hedgehog pathway (HP) signaling. In the ERIVANCE BCC trial, vismodegib (VISMO), the first FDA-approved HP inhibitor (HPI), showed objective response rates (ORRs) by independent review of 30% in metastatic (m) BCC and 43% in locally advanced (la) BCC, with median duration of response (DOR) of 7.6 mo for both. ORRs by investigator (INV) review were 45% (mBCC) and 60% (laBCC), with median DOR of 12.9 and 7.6 mo, respectively. Some patients (pts) continued VISMO treatment >3 yrs after start of therapy. We present safety and INV-assessed efficacy results 30 mo (30 May 2013) after primary analysis (26 Nov 2010). **Methods:** ERIVANCE BCC was a multicenter, international, nonrandomized study in pts (N=104) with radiographically measurable mBCC or laBCC (surgery inappropriate due to multiple recurrence, or substantial morbidity or deformity anticipated) receiving oral VISMO 150 mg daily until disease progression or intolerable toxicity. Key secondary endpoints included INV-ORR, progression-free survival (PFS), DOR, overall survival (OS), and safety. **Results:** At data cutoff, 9 pts (9%) continued to undergo protocol-specified assessments and 69 pts (66%) were in survival follow-up. ORR (INV) was 48.5% (mBCC) and 60.3% (laBCC), comparable with primary analysis. Median DOR (INV) improved from 12.9 and 7.6 mo for mBCC and laBCC (primary analysis) to 14.8 and 26.2 mo, respectively. Median (95% CI) PFS was 9.3 (7.4-16.6) and 12.9 (10.2-28.0) mo in mBCC and laBCC, respectively; median OS for mBCC was 33.4 (18.1-not estimable) mo and not reached in laBCC. Adverse events (AEs) remained consistent with the primary analysis; >30% of pts reported muscle spasm, alopecia, dysgeusia, weight decrease, fatigue, and nausea. 23 (22.1%) pts reported AEs leading to treatment discontinuation. 17 deaths (mBCC=10; laBCC=7) have been reported since the primary analysis and were not considered drug related. 16 deaths occurred in survival follow-up; 1 pt died due to general deterioration of health. **Conclusions:** The 30-month ERIVANCE BCC update confirmed the efficacy of the primary analyses and showed long-term consistent safety of VISMO in pts with aBCC. Clinical trial information: NCT00833417.

**9014 Poster Highlights Session (Board #29), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Adjuvant radiation therapy and chemotherapy in Merkel cell carcinoma: Survival analysis of 6,908 cases from the National Cancer Data Base.** *Presenting Author: Shailender Bhatia, University of Washington/Fred Hutchinson Cancer Research Center/Seattle Cancer Care Alliance, Seattle, WA*

**Background:** Merkel cell carcinoma (MCC) is an aggressive skin cancer with high risk of recurrence after surgery. Adjuvant radiation therapy (RT) and/or chemotherapy are commonly used, but with limited data regarding their effectiveness. To assess the impact of adjuvant RT and chemotherapy on MCC survival, we performed a retrospective analysis of the National Cancer Data Base (NCDB) that has the largest known cohort of MCC patients (pts). NCDB also collects data on adjuvant chemotherapy and comorbidity status (Charlson/Deyo score) that were missing in a prior study of outcomes with adjuvant RT in 1,487 pts in the Surveillance, Epidemiology, and End Results (SEER) database. **Methods:** 6,908 MCC pts with stage, treatment and survival data available were included in this analysis. Multiple covariate analyses were conducted for overall survival outcomes with various treatment modalities while adjusting for age, sex, comorbidity score, and other therapies. **Results:** In pts with localized MCC (AJCC stage I N=3,369; stage II N=1,474), surgery plus RT was associated with significantly better survival than seen with surgery alone (Stage I HR 0.75 [95% CI 0.67–0.83], p<0.0001; Stage II HR 0.77 [95% CI 0.67–0.90], p=0.0006). In pts with nodal involvement (stage III N=2,065), adjuvant chemotherapy was not associated with improved or worsened survival versus no chemotherapy (HR 1.07 [95% CI 0.93–1.22], p=0.37). Even among a subgroup of stage III pts aged < 65 and with comorbidity score=0, adjuvant chemotherapy was not associated with improved survival. **Conclusions:** This retrospective study analyzed the largest MCC dataset to date for outcomes with adjuvant therapy. These results suggest improved survival with the use of adjuvant RT in stage I-II MCC pts. Adjuvant RT or chemotherapy were not associated with improved survival in stage III MCC pts. Despite the ability to assess comorbidity scores, treatment biases that could have accounted for some of the observed effects cannot be directly addressed, and prospective multicenter evaluations of adjuvant RT and chemotherapy remain warranted. Until then, multidisciplinary evaluation and individualized care is appropriate for all pts with MCC.

**9015 Poster Highlights Session (Board #30), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Sentinel node biopsy in the initial evaluation of 87 patients with Merkel cell carcinoma.** *Presenting Author: Eve Maubec, Assistance Publique–Hôpitaux de Paris, Hôpital Bichat, Paris, France*

**Background:** Merkel cell carcinoma (MCC) is a rare cutaneous neuroendocrine tumor. The objective was to determine the role of sentinel lymph node biopsy (SNB) in the management of patients with MCC. **Methods:** A SNB procedure was proposed to all patients, from 5 hospitals, referred for a MCC without palpable regional lymph node from 1999 to 2013. Features between positive (SNB+) and negative (SNB-) SNB patients (pts) were compared using a Fisher's exact test. **Results:** Eighty-seven pts with a F/M ratio=0.85, a median age =74 yrs (31-90 yrs; 63% aged at least 70 yrs), a stage T1 (N=54), T2 (N=30) or T3 (N=3), a location on extremities (56%), head and neck (32%) or trunk (12%) were included. Among pts, 8% were immunosuppressed. The frequency of SNB metastasis (20/83=24% of successful SNB) did not differ significantly in T1 and T2 stages (p= 0.4). 19/20 SNB+ pts had a radical lymph node dissection and additional positive lymph nodes were found in 6/19 (31%) pts. Adjuvant radiotherapy was delivered to the primary tumour site in 71/87 pts and to the involved lymph node basin in 18/20 SNB+ pts. During a median follow-up period of 25 mths (4-158 mths) (25 mths in SNB+ and 23 mths in SNB- pts) recurrence developed in 23% of all pts within a median period of 13 mths (3-115 mths). Fifteen per cent of pts died of MCC. Although higher in SNB+ pts (20% vs 9.5%) the frequency of specific death did not differ significantly in the 2 groups (p=0.19). SNB- pts who did not received radiotherapy to the primary tumour site had a worse course of the disease with more recurrences (42% vs 14%; p= 0.04) and a trend to a higher death rate (25% vs 6%; p= 0.08). **Conclusions:** SNB positivity is not associated with T stage and is high in T1 stage. All pts without palpable lymph node should be considered for SNB. Negative SNB might predict for better outcome.

**9016 Poster Highlights Session (Board #31), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Plasma vemurafenib concentrations in advanced *BRAFV600*$^{mut}$ melanoma patients: Impact on tumor response and tolerance.** *Presenting Author: Elisa Funck-Brentano, APHP, University of Versailles, Boulogne-Billancourt, France*

**Background:** Vemurafenib (V), a *BRAFV600*$^{mut}$ targeted therapy, improves survival in advanced melanoma pts, but tolerance is often poor and resistance frequently occurs. No predictive factor of intolerance or escape is well known. We searched for a relation between plasma V concentration (PVC) and V intolerance or melanoma resistance. **Methods:** After obtaining informed consent, blood was prospectively collected in 23 successive previously BRAF$^{inh}$ naive pts with AJCC stage IIIc (n=3) or IV (n=20) inoperable *BRAFV600*$^{mut}$melanoma receiving V monotherapy. Blood was harvested when tumor response was evaluated or when toxicity occurred. Tumor response to V was assessed every 2 months blinded to PVC results using RECIST 1.1 and adverse effects were graded using CTCAE 4.0. PVC was measured with liquid chromatography-tandem mass spectrometry (precision: 13%). Herein, we report on PVC at steady state (≥14d after V introduction or dose modification). As V could be continued in slowly progressing pts, samples collected after first melanoma progression were excluded from the response-concentration analysis. All samples were included in the tolerance-concentration analysis, where each adverse event occurrence was linked to the closest sample collected. Wilcoxon rank sum test was used. **Results:** V was first line systemic treatment for 17 pts. Initial V dose was 960 mgx2/d, reduced by 25% (n=6) or 50% (n=1) for intolerance. 12 pts experienced first progression during study after a mean 35 weeks on V. PVC showed high inter-individual variability (13 to 104 $\mu$g/mL, mean 56). Mean PVC was lower at time of first progression (37.8±19.3 $\mu$g/mL) compared to PVC found when tumor was considered stable or in complete or partial response (56.9±20.8 $\mu$g/mL, *p=0,003*). 105 samples were included in the tolerance-concentration analysis: PVC tended to be higher when toxicity occurred, without reaching statistical significance. All pts declared high compliance to treatment. **Conclusions:** PVC at steady state is highly variable, and low PVC was associated with tumour progression, suggesting a new (and simple) path to melanoma resistance to V. This preliminary finding should be confirmed in larger series.

**9017 Poster Highlights Session (Board #32), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**BRAF mutation in circulating DNA of melanoma patients at baseline and intertumor heterogeneity.** *Presenting Author: Marc G. Denis, Department of Biochemistry, Nantes University Hospital, Nantes, France*

**Background:** Determination of the BRAF mutation status is a requirement for treatment selection of metastatic melanoma patients. However, the inter and intra-tumor genetic heterogeneity for BRAF status has been described supporting the need for testing multiple sites for the same patient. Circulating DNA is considered a promising non-invasive tool for cancer monitoring. The objective of our work was to determine the potential of plasma DNA to detect BRAF mutations, particularly in patients presenting discordant BRAF status from different tumor sites. **Methods:** Plasma DNA was extracted using the iPrep PureLink Virus Kit on an iPrep purification system (Invitrogen). BRAF mutations were detected using the Therascreen BRAF RGQ kit (Qiagen). **Results:** Ninety-nine patients were included, and plasma was collected at baseline. Nine stage III melanoma patients presenting a mutant BRAF (6 V600E, 2 V600K and 1 V600D) were tested and for 4 of them we detected the corresponding mutation (including the V600D and both V600K) in circulating DNA (sensitivity 44.4 %). Similarly, 20 stage IV patients were tested (17 V600E, 2 V600K and 1 V600R). The corresponding mutation (including the V600R and both V600K) was detected in 15 of these patients (sensitivity 75.0%). Interestingly, 4 stage IV patients included in our series presented discordant BRAF mutation status on different sites (1 patient with a WT primary tumor (PT) and a V600E lymph node (LN) metastasis; 1 patient with a V600E PT and WT LN metastasis; 2 patients with a V600E PT, V600E LN and WT liver metastasis). We were able to detect the expected BRAF mutation in circulating DNA for all these patients. **Conclusions:** The sensitivity of our procedure, based on approved kits, suggests a high interest for use in clinical practice, even for non-V600E mutations. Plasma DNA might be less sensitive to heterogeneity between tumor samples, and therefore might represent an interesting alternative source of DNA to detect BRAF mutations in clinical setting.

**9018 Poster Highlights Session (Board #33), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Identification of multiple informative genomic mutations by deep sequencing of circulating cell-free tumor DNA in plasma of metastatic melanoma patients.** *Presenting Author: Dave S. B. Hoon, Department of Molecular Oncology, John Wayne Cancer Institute, Santa Monica, CA*

**Background:** We have been assesseing the prognostic utility of genomic changes in circulating cell-free DNA(cfDNA) in melanoma patients. The limitation has been assessing a few selected genomic targets and sensitivity. The approach of cfDNA analysis in melanoma patients offers detection of potential targeted tumor-related genes mutation(mt) without tumor biopsy. **Methods:** AJCC stage IV melanoma patients (n=18; different metastasis sites) plasma and paired metastatic tumor tissues resected after blood draw were assessed. The assay was performed on 2 ml filtered plasma. We employed Guardant360, a single-molecule digital sequencing assay that enables detection of rare genomic abnormalities with ultra high-specificity and sensitivity. Using bioinformatics and single molecule sensitivity, rare variants could be detected in cfDNA. **Results:** In an initial 8 patients, BRAF and TP53 in tumor genomic DNA were sequenced. We found ctDNA with somatic mt in 6/8 matched tumor and plasma specimens(mt allele frequency of 0.2-23.1%) with an overall concordance of 86% for the status of BRAF and TP53 mt in a single bleed. To note known BRAFmt at multiple exons were detectable. Subsequently, matched tumor and plasma from 10 patients were analyzed. We found ctDNA mt in 8/10 cases (mt allele frequency of 0.1-19.1%). Well known frequent melanoma-related mt were detected in patients cfDNA(BRAF, TP53). Other known tumor mt were also detected(CDKN2A, NRAS, PTEN, NOTCH1, EGFR, JAK2) that have not been reported. We established the overall concordance of cfDNA mt with metastatic melanomas across all 54 genes and 80kbps to be 49% whereby, individual single gene concordance were significantly much higher. **Conclusions:** This ongoing study demonstrates that using Guardant360, cfDNA mt can be detected that match with paired melanomas. The approach offers a more comprehensive approach of monitoring metastatic melanoma patients' blood for multiple mt during tumor progression. This unique approach will allow for much more comprehensive blood tumor genetic profiling to provide better treatment decision and monitoring for multiple drugable targeted genes without tissue biopsies.

**9019 Poster Highlights Session (Board #34), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Droplet digital PCR monitoring of BRAF and NRAS plasma DNA as biomarkers of treatment response in stage IV melanoma.** *Presenting Author: David Polsky, The Ronald O. Perelman Department of Dermatology, NYU Langone Medical Center, New York, NY*

**Background:** Management of melanoma suffers from a lack of robust biomarkers of disease activity. In this study, we tested the ability of droplet digital PCR (ddPCR) to quantitatively measure levels of circulating BRAF and NRAS mutant DNA in the plasma of metastatic melanoma patients undergoing treatment with BRAF-targeted therapy or immunotherapy. **Methods:** We analyzed plasma samples from 45 patients with stage IV melanoma prospectively enrolled in the NYU Melanoma Biorepository program. All patients were commercially genotyped for BRAF V600E. SNaPshot assays were used to identify NRAS Q61 mutations in BRAF-WT tumors. Each patient had at least 3 serially collected plasma samples including one drawn prior to treatment, one or more after treatment began and one upon signs of disease progression. ddPCR was used to measure mutant copies/ml of BRAF V600E and NRAS Q61K/L/R DNA in plasma samples. **Results:** Among 45 patients, 28 patients had BRAF and 8 patients had NRAS tumor mutations. We extracted DNA from 151 plasma samples. Our preliminary results include analysis of 50 plasma samples from 10 BRAF-mutant and 5 NRAS-mutant patients. All BRAF V600E patients received BRAF inhibitor therapy and had partial responses followed by disease progression. Levels of circulating V600E DNA decreased with clinical response and/or increased with disease progression in 8/10 patients. In 3 patients with progressing disease, plasma samples drawn in-between imaging visits showed increasing BRAF mutant copies/ml up to 2 months prior to clinical scans. Among NRAS mutant patients, all were treated with Ipilimumab: 3 patients progressed, 1 had a near complete response, and 1 progressed and was then treated with Nivolumab. Levels of circulating Q61 DNA rose with disease progression and/or fell with clinical response in 5/5 immunotherapy treated patients. **Conclusions:** Our results indicate that ddPCR is able to measure clinically meaningful changes in the levels of BRAF and NRAS mutant copies/ml in the plasma of stage IV melanoma patients. This analytical platform has the potential for monitoring disease progression and patient response to both targeted and immune-based therapies, and may be a useful adjunct to imaging studies.

**9020 Poster Highlights Session (Board #35), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Ultrasensitive detection and identification of BRAF V600 mutations in fresh frozen, FFPE, and plasma samples of melanoma patients by enhanced-ice-cold-PCR.** *Presenting Author: Alexandre How-kit, Laboratory for Functional Genomics, Fondation Jean Dausset - CEPH, Paris, F-75010, France, Paris, RI, France*

**Background:** Two BRAF inhibitors have been approved for patients with BRAF V600 activating mutation. However, to date the different tools developed for the detection of BRAF V600 mutations lack sensitivity and/or specificity or do not allow sequencing-based identification of the mutation. Enhanced-ice-COLD PCR is a very sensitive assay, which enables a strong enrichment of the mutation during the PCR where mutant and WT alleles undergo exponential and linear amplification, respectively. **Methods:** Methods: Two melanoma-derived cancer cell lines harboring different heterozygous BRAF codon 600 mutations were used in this study for assay optimization. Molecular analyses were performed on 18 fresh frozen, 17 FFPE melanoma and 17 plasma samples from patients suffering from advanced melanoma were used. E-ice-COLD-PCR was performed using a 96-well real-time thermocycler followed by pyrosequencing and automatic mutation identification and quantification. **Results:** This assay has a large dynamic range as 25 pg to 25 ng can be used as DNA input without any reduction in mutation enrichment efficiency and is ultra-sensitive as it can detect up to 0.01% of mutated alleles in a wild-type background. The assay has been validated on fresh frozen, FFPE and plasma samples of melanoma patients and has allowed the detection and identification of BRAF mutations present in the samples which appear as wild-type using standard pyrosequencing, endpoint genotyping or Sanger sequencing. **Conclusions:** This BRAF V600 E-ice-COLD PCR assay is currently the most powerful molecular diagnostic tool for ultra-sensitive detection and identification of BRAF codon 600 mutations.

**9021 Poster Highlights Session (Board #36), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Development and validation of a gene expression signature to distinguish malignant melanoma from benign nevi.** *Presenting Author: Colleen Rock, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

**Background:** Histopathologic distinction between benign and malignant melanocytic tumors can be unreliable and may lead to misdiagnosis. Measurement of biomarker gene expression has been proposed as an adjunctive diagnostic method in the evaluation of ambiguous melanocytic lesions with uncertain malignant potential. This study aimed to develop and validate a gene signature capable of accurately differentiating malignant melanoma and benign nevi. **Methods:** Seventy-nine candidate genes were identified based on expression changes previously observed in melanoma or other cancer types. RNA expression in five 5-$\mu$m recut sections from FFPE skin biopsy specimens was measured by qRT-PCR. The panel was refined to 40 genes based on the ability of each gene to differentiate benign from malignant lesions (AUC >70%). Expression of this refined panel was measured in 464 melanocytic lesions and forward selection in a logistic regression model was used to finalize the signature. By applying a weighting algorithm and threshold value to the expression data, the signature was translated into a numeric score capable of classifying melanocytic lesions as benign or malignant. Performance of the assay was clinically validated in a second cohort of 437 melanocytic lesions representing a spectrum of histopathologic types. **Results:** Using the 464 case cohort, a final signature of 23 genes was identified, consisting of 13 genes involved in immune signaling and cell differentiation and 9 housekeeping genes. In the second cohort of 437 lesions, the signature was validated to differentiate benign nevi from malignant melanoma with a sensitivity of 90% and a specificity of 91%. **Conclusions:** The predominance of genes that regulate melanocyte differentiation and immune response in the final signature indicates that these pathways represent critical differences between benign and malignant melanocytic lesions. The performance, objectivity, reliability, and minimal tissue requirements of this diagnostic test make it well-suited for clinical use as an adjunct to histopathology. Integration of this assay into current practice has the potential to enhance patient care through more definitive diagnoses of melanocytic lesions.

**9022 Poster Highlights Session (Board #37), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Gene expression profile test (GEP) prediction of metastasis-free (MFS) and overall survival (OS) in a cohort of cutaneous melanoma (CM) patients undergoing sentinel lymph node biopsy (SLNB).** *Presenting Author: David H. Lawson, Emory University School of Medicine, Atlanta, GA*

**Background:** We recently validated a GEP test that provides accurate prediction of metastatic risk for CM cases. The GEP of 31 genes provides a binary outcome of Class 1 (low risk of metastasis) or Class 2 (high risk). This study evaluated the prognostic. **Methods:** Of 406 patients with successful GEP results and clinical data, 217 had a documented SLNB. All samples and clinical data were collected under an IRB approved, multicenter protocol. Quantitative PCR analysis was performed to assess expression of the gene signature, and Radial Basis Machine predictive modeling was used to determine risk prediction (Class 1 vs. Class 2). **Results:** SLNB+ status (n=58) was associated with greater median Breslow thickness, increased mitotic rate, and ulceration. Metastasis was reported for 37 of 58 (64%) SLN+ cases and 70 of 159 (44%) SLN- cases. While positive predictive values for Class 2 and SLN+ status were comparable (69% vs. 64%, resp.), negative predictive values of 75% and 49% were observed for low risk Class 1 and SLN- cases, respectively. Kaplan-Meier (K-M) analysis revealed 5-year MFS of 34% and 37%, respectively, for GEP Class 2 and SLN+ cases, and OS of 54% and 62% for the two groups, respectively. K-M analysis of MFS and OS for GEP and SLN in combination resulted in outcomes shown in Table 1. Cox multivariate analysis showed that GEP Class 2 and positive SLN status were significant predictors of MFS (HR=4.9 and 1.7, resp., $p<0.01$), but that GEP, in this group of patients, was the only significant predictor of OS (HR=5.1, $p<0.0001$). **Conclusions:** In this study cohort, GEP provided an objective, non-invasive tool that accurately predicted MFS and OS in SLN eligible patients. Importantly, in the discordant Class 2/SLN- group, predicted outcomes more closely reflected Class 2 status. Incorporation of GEP class in treatment planning may enable improved patient management. MFS and OS association with class and SLN status.

| | N | 5-yr MFS | 5-yr OS |
|---|---|---|---|
| **Class1/SLNB-** | 67 | 83% | 91% |
| **Class1/SLNB+** | 9 | 53% | 78% |
| **Class2/SLNB-** | 92 | 35% | 54% |
| **Class2/SLNB+** | 49 | 33% | 57% |

**9023 Poster Highlights Session (Board #38), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Analysis of *TERT* promoter mutations in pediatric melanoma.** *Presenting Author: Armita Bahrami, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Melanoma is rare in children and adolescents and is divided into a conventional adult-type (CM), a small-cell type, and Spitzoid melanoma/ atypical Spitz tumor (AST). ASTs are a group of melanocytic neoplasms with characteristic morphologic features that often affect patients in the first 2 decades, commonly spread to regional lymph nodes, but rarely metastasize to distant sites. Histological criteria are unreliable at predicting the rare subset of AST that disseminates and to date, genomic changes associated with an aggressive clinical behavior have not been identified. Whole genome sequencing has revealed that most adult melanomas have *TERT* promoter activating mutations that lead to increased telomerase activity. We investigated the frequency of *TERT* promoter mutations in pediatric CM and AST and its correlation with clinical outcome. **Methods:** Genomic DNA was extracted from 12 microns of FFPE sections from 15 CM (all in adolescents) and from 26 AST in 25 patients (18 children; 7 adolescents). A portion of the *TERT* promoter (HG19 coordinates, chr5: 1295151-1295347) was amplified by PCR using conventional methods. The resulting amplicon was Sanger sequenced and analyzed for the presence of heterozygous or homozygous alterations within the amplified region. **Results:** 12 of 15 CM had one of the two most frequently described UV associated *TERT* single nucleotide variants (SNVs) (6 SNVs at position 1295228; 6 SNVs at position 1295250), and 2 were marked as indeterminate. An additional CM had a dinucleotide CC->TT variant at positions 1295242/243. At last follow-up (mean, 30 months), 9 patients had died of disease and 3 were alive with disease. Only 2 of 26 AST samples carried a *TERT* promoter mutation (SNV 1295228) and both patients developed widespread metastasis and died of disease. None of the remaining patients with AST developed extranodal disease spread and all were alive without disease at a mean of 17 months. **Conclusions:** *TERT* promoter UV-signature mutations correlate with aggressive clinical behavior in pediatric patients with melanocytic neoplasms. The findings support a pathogenic role for UV light in pediatric melanoma progression.

**9024 Poster Highlights Session (Board #40), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Clustered genomic variants specific to patients who develop immune-related colitis after ipilimumab for prediction of toxicity.** *Presenting Author: Ahmad A. Tarhini, University of Pittsburgh Medical Center, Pittsburgh, PA*

**Background:** Ipilimumab (Ipi) is approved for metastatic melanoma based on significant survival benefits shown in phase III trials. Ipi can result in immune-mediated effects on various organ systems, leading to adverse events (AE) including diarrhea/colitis reported in 30-40% patients (pts) that can be serious and life-threatening. The ability to predict the risk of this AE may lead to new monitoring and improved management. **Methods:** Targeted, deep sequencing of DNA from the blood of 34 pts who underwent neoadjuvant Ipi for regionally advanced melanoma (*Tarhini et al, PLOS One, 2014*) was performed to detect the 21 pts who experienced diarrhea/ colitis. Sequencing was focused on the coding region of 10 genes and genomic domains surrounding 9 SNPs previously associated with IBS, Crohn's Disease and ulcerative colitis in GWAS studies. Selected amplicon libraries derived from locations on 5 chromosomes were sequenced on Ion Torrent PGM at high base density (318 chip: >1000X) and BAM files interrogated using GATK algorithm (UGT v.2.3, Broad Institute, Boston, MA) to identify SNPs, single base substitutions and INDELs (<5 bases). Variants were selected for specificity to pts with grade 1-3 colitis vs pts without. All calls were verified by manual curation of BAM files using Integrated Genomics Viewer (Broad Institute). **Results:** We identified 132 variants specific to pts with colitis (X =6.1; range=1-20). The most parsimonious variant signature (11 variants, 3 chromosomes) comprised 3 INDELs shared by 13 pts including an intronic 5 base DEL in CDKAL1 gene and 2 INS in KIF21B. While 11 pts were classified by 6 unique INDELs and 2 rare SNPs (rs55770822, rs140589352). Alternatively, a 34Kb chromosome 1 "hot spot" in KIF21B gene captured variants specific to 18 pts including multiple frameshift and other coding mutations predicted to alter protein translation. **Conclusions:** These data suggestthat unique INDELs and SNPs specific to pts with colitis after Ipi may provide a predictive biomarker signature. The predominance of these variants within the KIF21B gene previously implicated in inflammatory bowel disease suggests an important role in Ipi induced colitis. (Supported by NIH award P50CA121973). Clinical trial information: NCT01608594.

**9025^ Poster Highlights Session (Board #41), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Systemic antitumor effect and clinical response in a phase 2 trial of intratumoral electroporation of plasmid interleukin-12 in patients with advanced melanoma.** *Presenting Author: Adil Daud, University of California, San Francisco, San Francisco, CA*

**Background:** Interleukin-12 (IL-12) promotes anti-tumor activity through multiple mechanisms, including augmentation of adaptive and innate immune responses. Intratumoral (IT) delivery of IL-12 via electroporation (EP) avoids systemic toxicity while promoting systemic antitumor immunity. This phase 2 study explores the systemic efficacy, clinical response and safety of IT plasmid IL-12 injection (pIL-12) followed by EP in patients (pts) with advanced melanoma. **Methods:** This single-arm, open-label phase 2 study plans to enroll 30 pts with in-transit or M1a melanoma. One treatment cycle consists of IT pIL-12-EP on days 1, 5, 8 in up to four lesions per cycle. A maximum of four cycles at 12-week intervals are allowed. ORR was assessed by a modification of RECIST for cutaneous lesions with restaging performed every 12 weeks. The primary endpoint is best ORR within 24 weeks of first treatment. Pre- and post-treatment tumor biopsies were obtained in all patients. Ongoing analyses to assess safety and emerging efficacy data are being utilized to inform future studies. **Results:** 29 pts have been enrolled and have received at least one treatment cycle. The ORR is 33% (9/27), with 11% CR (3/27). Regression of non-injected lesions was seen in 62% (13/21) of pts with evaluable lesions. Transient pain (56.5%) and inflammation (17.4%) at the treatment site were the most common grade 1/2 drug-related adverse events (AEs), with no grade 3/4 drug-related AEs. Exploratory analyses indicate a doubling of intratumoral NK cells from pre-treatment through day 11 and at day 39, and increased frequency in activated circulating NK cells. **Conclusions:** Local treatment with pIL-12-EP is well tolerated without severe systemic side effects. Regression of treated and non-treated tumors suggests successful induction of systemic anti-tumor response. Local and systemic increases in NK cells are consistent with the expected pharmacodynamic effect of IL-12. Based on these data, an expansion protocol to evaluate increased treatment frequency is planned for melanoma patients. Clinical trial information: NCT01502293.

**9026 Poster Highlights Session (Board #42), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Patterns of durable response with intralesional talimogene laherparepvec (T-VEC): Results from a phase III trial in patients with stage IIIb-IV melanoma.** *Presenting Author: Merrick I. Ross, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** T-VEC is an intralesional oncolytic immunotherapy comprising a modified HSV-type 1. In the randomized OPTiM phase 3 trial, T-VEC significantly improved DR rate (DRR, continuous partial or complete response for ≥6 mo) by 16% vs 2% and overall RR by 26% vs 6% vs subcutaneous (SC) GM-CSF in patients (pts) with advanced melanoma. We hypothesized that some pts progressed on treatment (tx) prior to DR and sought to determine how such events impacted the durability of response. Here we describe response patterns in T-VEC-treated pts with a DR. **Methods:** 436 pts with Stage IIIB-IV melanoma were randomized 2:1 to receive intralesional T-VEC or SC GM-CSF until clinically significant PD, intolerability, or lack of injectable lesions. Tx was to continue for at least 6 mo during which tx discontinuation for PD was not required. PD prior to response (PPR) was defined as the appearance of a new lesion or >25% increase in baseline tumor burden. Injection of new lesions was allowed. Responders were grouped as 1) PPR or 2) no PPR. PPR was grouped by a) existing lesions (± new lesions) or b) new lesions only. Pts without PPR were grouped by DR onset at ≤6 mo or >6 mo. **Results:** Of 48 T-VEC pts with a DR, 23 (48%) had PPR: 9 (39%) pts had PD in existing lesions (± new lesions) and 14 (61%) had new lesions only. For 25 pts with no PPR, 21 (84%) had a DR beginning within the first 6 mo. 40 (83%) of the DRs remain in remission with a median follow up of over 18.4 mo. **Conclusions:** Similar to other immunotherapies, PPR was common in T-VEC-treated pts. Most PPRs included the development of new lesions, thus T-VEC tx should continue through PD. The quality of DR does not seem to be negatively affected by PPR or the timing of achieving DR. These data reinforce the evolving new paradigm of response criteria when treating pts with melanoma with immunotherapeutic agents. Clinical trial information: NCT00769704.

**DR by PPR Status.**

**Efficacy of intralesional Rose Bengal in patients receiving injection of all existing melanoma in phase II study PV-10-MM-02.** *Presenting Author: Sanjiv S. Agarwala, St. Luke's Hospital and Health Network, Easton, PA*

**Background:** The safety and efficacy of intralesional (IL) treatment of refractory cutaneous melanoma with rose bengal disodium (PV-10) was evaluated in an 80 patient international, multicenter, single arm phase II trial (NCT00521053). Overall, PV-10 was well tolerated and 41 of 80 ITT patients (pts) met the primary endpoint of objective response (CR+PR) in their injected target lesions (51% ORR CI 40-63%, 26% CR). **Methods:** Refractory pts (median of 6 previous interventions, 6.3 cm median sum lesion diameter in biopsy confirmed melanoma) received PV-10 into up to 20 cutaneous and subcutaneous lesions up to 4 times over a 16-week period and were followed for 52 weeks. Best overall response rate (BORR) was assessed by RECIST in up to 10 injected target lesions. Secondary endpoints included assessment of duration of response, BORR of untreated bystander lesions, overall survival and adverse events.Confidence intervals for response rates were based on the exact cumulative probabilities of the binomial distribution (95% confidence intervals). **Results:** In the subgroup of 28 pts who received PV-10 into all existing melanoma lesions (i.e., no uninjected lesions), ORR by-patient was 71% (CI 51-87%) with 50% CR (CI 31-69%). In these pts with all disease injected plus 26 pts with uninjected disease limited to bystanders (i.e. 54 pts with all disease monitored), CR was achieved in 232 of the 363 injected lesions (64% CR): 121 lesions required a single injection for CR, 84 required 2 injections, 22 required 3 injections and 5 required 4 injections. Additionally, 10 of 28 uninjected bystander lesions achieved CR. **Conclusions:** Recurrent locoregional melanoma can be a source of persistent morbidity, including disfigurement frequently accompanied with pain, ulceration, bleeding and infection. The high rate of symptom control in refractory patients, manifest in CR of injected lesions after minimal intervention, is the basis for a breakthrough therapy application based on the 28 patient "all treated" subgroup. Although the primary ablative effect is responsible for CR in injected tumors, durability of response and bystander response implicate an immunologic mechanism of action secondary to ablation. Clinical trial information: NCT00521053.

**9028 Poster Highlights Session (Board #44), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Assessment of immune and clinical efficacy after intralesional PV-10 in injected and uninjected metastatic melanoma lesions.** *Presenting Author: Amod Sarnaik, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Intralesional (IL) therapy is under investigation to treat dermal and subcutaneous metastatic cancer. In our murine model, IL injection of PV-10 (10% Rose Bengal) induced regression of injected and uninjected "bystander" melanomas. We observed a consistent increase in anti-tumor T cell responses following IL PV-10 in the mouse model, supporting an immune-based mechanism by which PV-10 mediates regression of uninjected "bystander" tumors. **Methods:** We translated these findings into a pilot clinical trial that enrolled 8 patients with dermal and/or subcutaneous metastatic melanoma. Two study lesions in each patient were sampled by biopsy pre-treatment; one of the two lesions was injected with IL PV-10, then both residual sites were completely excised. We compared tumors before and after treatment with H&E staining to determine pathologic complete response (pCR), and we confirmed results with MelanA immunohistochemistry. Peripheral blood mononuclear cells (PBMC) before and after IL PV-10 were phenotyped for activation markers by flow cytometry. **Results:** Treatment with IL PV-10 led to pCR in the post-treatment biopsies of both PV10-injected and uninjected study lesions in 4 of the 8 patients, and all 8 exhibited at least partial regression of the injected lesion. IL PV-10 was associated with an increase in circulating cytotoxic $CD3^+/CD8^+$ T cells (paired t test, p=0.008). Pre and post PV-10 treated PBMC from one patient were re-stimulated with autologous tumor in vitro. Compared to pre-treatment, PV-10 treatment produced an increase in tumor-specific interferon-gamma release by ELISA. Six of 8 patients had metastatic disease refractory to previous ipilimumab, anti-PD-1 and/or vemurafenib therapy. Four of these 6 patients exhibited pCR to PV10 in both the injected and uninjected lesions. **Conclusions:** IL PV-10 treatment can lead to systemic anti-melanoma immunity and pCR in injected and uninjected lesions including treatment-refractory tumors. Further studies are ongoing to determine the mechanism by which PV-10 increases tumor-specific T cell responses as well as to establish the interaction of intralesional PV-10 with combination checkpoint protein inhibition. Clinical trial information: NCT01760499.

**9029^ Poster Highlights Session (Board #45), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Primary analysis of a phase 1b multicenter trial to evaluate safety and efficacy of talimogene laherparepvec (T-VEC) and ipilimumab (ipi) in previously untreated, unresected stage IIIB-IV melanoma.** *Presenting Author: Igor Puzanov, Vanderbilt-Ingram Cancer Center, Vanderbilt University, School of Medicine, Nashville, TN*

**Background:** T-VEC, an HSV-1 derived oncolytic immunotherapy designed to induce systemic antitumor immunity, showed a ≥ 6 mos higher durable response rate vs GM-CSF in a phase 3 melanoma trial (Andtbacka et al. ASCO 2013). This phase 1b/2 study will determine the safety and efficacy of T-VEC as a priming regimen when added to ipi. **Methods:** Phase 1b studied the safety of T-VEC+ipi. Objective response rate (ORR) was also evaluated with tumor assessments q12w. Blood was collected pre- and post-treatment (tx) for correlative studies. Key criteria: unresected Stage IIIB-IV melanoma, no prior systemic tx, measurable disease, and ≥1 injectable cutaneous, subcutaneous or nodal lesion. T-VEC was given intralesionally at ≤ 4 mL of $10^6$ PFU/mL at wk 1, then $10^8$ PFU/mL at wk 4 and then q2w. Ipi 3 mg/kg q3w was given as 4 infusions starting wk 6. Tx continued until DLT, intolerance, all injectable tumors disappeared, or disease progression (PD) per Immune Related Response Criteria. DLT was any grade (gr) ≥ 4 adverse event (AE) or gr ≥ 3 immune-related AE within the first 6 wks of ipi tx. **Results:** Of 19 patients (pts) enrolled: 42% men, 42% ≥ 65 yrs, 58% Stage IV M1b/c; 18 pts received T-VEC+ipi. No DLTs were reported. Gr 3/4 AEs occurred in 32%. 2 pts had possible immune-related gr 3/4 AEs: 1 pt had gr 3 hypophysitis (attributed to ipi) and gr 3 adrenal insufficiency and gr 3 diarrhea (both attributed to combination), and 1 pt had gr 4 amylase+lipase attributed to ipi. PD (CNS metastases) led to one gr 5 AE. By 15 Oct 13 (data cutoff), median tx duration of T-VEC was 13.3 wks. Of 17 pts with investigator assessed response, ORR was 41% (24% CR, 18% PR); 35% had SD. Median time to response was 2.9 mos. By flow cytometry, activated CD8 T cells significantly increased from baseline 1.8x after T-VEC alone and 2.9x during T-VEC+ipi tx. **Conclusions:** T-VEC+ipi appears to be tolerable with no DLTs. In consideration with published reports, these data, although preliminary, suggest higher CR and OR rates than either agent alone and earlier responses after ipi initiation during T-VEC+ipi than with ipi alone. Additional immunophenotyping and phase 2 (ipi vs T-VEC+ipi) are ongoing. Clinical trial information: NCT01740297.

**9030 Poster Highlights Session (Board #46), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase I dose-escalation study of the protein kinase C (PKC) inhibitor AEB071 in patients with metastatic uveal melanoma.** *Presenting Author: Sophie Piperno-Neumann, Institut Curie, Paris, France*

**Background:** Uveal melanoma is characterized by frequent mutations in *GNAQ* or *GNA11* that encode for G-protein $\alpha$-subunits (G$\alpha$) which mediate signaling from G-protein coupled receptors to downstream signaling pathways, including PKC. AEB071 (sotrastaurin) is a potent, selective oral inhibitor of the classical ($\alpha$, $\beta$), and novel ($\delta$, $\varepsilon$, $\eta$, $\theta$) isoforms of PKC. Preclinical data shows selective sensitivity of G$\alpha$ mutant uveal melanoma cell lines to AEB071. **Methods:** An open-label, multicenter, single-arm, Phase I study was performed in pts (WHO performance status [PS] $\leq$1) with metastatic uveal melanoma. Dose escalation and estimation of the maximum tolerated dose (MTD) was guided by an adaptive Bayesian logistic regression model with overdose control. **Results:** 118 pts received AEB071 at total daily doses of 450−1400 mg administered in divided doses either BID or TID. Genomic profiling analysis has been completed in 52 pts, 96% of which were found to have activating mutations in either *GNAQ* or *GNA11*. Dose-limiting toxicities (DLTs) were observed in 12 pts (11%) at doses $\geq$800 mg/day total (nausea [7%], vomiting [2%], and fatigue [2%]). The MTD was 800 mg/day and 1400 mg/day on TID and BID dosing schedules, respectively. The most common AEB071-related adverse events (AEs) (all grades, all cohorts, >25%) were nausea (68%), dysgeusia (58%), constipation (48%), vomiting (42%), diarrhea (36%), chromaturia (35%), and asthenia (26%). AEB071 exposure increased with increasing dose and was approximately 1–2x higher at steady state during BID dosing, with a median Tmax of 1–4 hr. Decreases in the PKC substrate phosphorylated myristoylated alanine-rich C kinase substrate (pMARCKS) of approximately 40%–90% were seen by Cycle 1 Day 15 for both dosing regimens. pMARCKS suppression did not correlate with clinical response or time on study. One pt achieved a PR and 55/118 (47%) pts achieved SD and progression-free survival (PFS) ranging from <1–57 weeks and with a median PFS of 15.4 weeks (95% CI 8.3–15.7). **Conclusions:** Preliminary data suggest clinical activity of AEB071 and manageable toxicity at multiple dose levels, with evidence of PKC inhibition in patients with uveal melanoma. Clinical trial information: NCT01430416.

**9031 Poster Highlights Session (Board #47), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Open-label, multicenter, single-arm phase II study (DeCOG-Trial) to further evaluate the efficacy and safety of ipilimumab in patients with cutaneous melanoma and rare subgroups.** *Presenting Author: Lisa Zimmer, Department of Dermatology, University Hospital, University Duisburg-Essen, Essen, Germany*

**Background:** Ipilimumab is a recently approved immunotherapy that has shown an overall survival benefit in previously treated and treatment-naïve patients with metastatic melanoma in two phase III trials. However, results of registrational trials might not address all questions regarding safety and efficacy of ipilimumab in advanced melanoma patients seen in daily routine. We performed a multicenter, phase II clinical trial of ipilimumab in patients with different subtypes of metastatic melanoma. **Methods:** Pretreated patients with unresectable stage III or stage IV with cutaneous, mucosal, ocular or unknown primary melanoma (MUP) were included into this study (CA184-137; supported by BMS). Treatment-naïve patients with metastatic ocular melanoma were eligible, too. Four cycles ipilimumab should be administered at a dose of 3 mg/kg 3 weeks apart. Tumor assessments according to RECIST 1.1 version were conducted at baseline, weeks 12, 24, 36 and 48. Adverse events (AEs), including immune-related AEs were graded according to National Cancer Institute Common Toxicity Criteria v.4.0. Primary endpoint was the overall survival (OS) rate at 12 months. **Results:** Between May 2011 to December 2013, 156 patients were enrolled in 25 German centers and received at least one dose of ipilimumab, including 83 cutaneous, 7 mucosal, 53 ocular melanomas and 13 MUP. After a median follow-up of 7 months (range 0.1-26.4), 12-month OS rates were 37% for cutaneous, 14% for mucosal, and 22% for ocular melanomas and 27% for MUP. The median OS from the first dose of ipilimumab was 6.9 months (95% CI 5.7-8.1). The overall response rates among 104 evaluable patients were 16% for cutaneous, 17% for mucosal, 9% for ocular melanomas and 11% for MUP. There were one patient with complete response (1%), 13 patients with partial response (13%), and 23 patients with stable disease (22%). Treatment-related AEs were observed in 106 patients (68%), including 39 grade 3-4 events (25%). There was a drug-related death due to pancytopenia. **Conclusions:** Ipilimumab is a treatment option for patients with cutaneous, ocular, mucosal and unknown primary melanoma with manageable toxicity. Clinical trial information: NCT01355120.

**9032 Poster Highlights Session (Board #48), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II multicentric uncontrolled national trial assessing the efficacy of nilotinib in the treatment of advanced melanomas with c-KIT mutation or amplification.** *Presenting Author: Celeste Lebbe, Hôpital Saint-Louis, Paris, France*

**Background:** Three phase II trials have shown an overall response rate (ORR) around 20% with imatinib in melanoma carrying KIT mutations. The aim of this study was to study the interest of nilotinib a Kit inhibitor with pharmacological advantages compared to imatinib. **Methods:** this multicenter uncontrolled open Hern's single-stage Phase II study enrolled patients with advanced melanoma and KIT amplifications and/or mutations and no BRAF and NRAS mutation, nor previous Kit targeted therapy or active brain metastasis.Patients received Nilotinib 400 mg bid. ORR was the primary endpoint. Secondary endpoints included disease control, metabolic response rate and biomarkers associated to response . Based on type I and II error rates fixed at 0.05 and 0.10, respectively, a sample size of 25 patients was required to test the level of response, p$\leq$ 7.5% against > 30%, with at least 5 successes tindicating that the treatment was effective. Analysis was based on intent to treat. **Results:** 25 patients were enrolled from 2010-07-27 to 2012-08-27: 13 females (52%); median age 70 years(range, 43-87); 23 (92%) tumors with KIT mutations, 5 (20%) KIT amplifications, and 3 (12%) both. One patient (4%) had primary unresectable melanoma, 3(12%) unresectable stage III melanoma, 21 (84%) stage IV melanoma .13 (52%) patients were chemotherapy naive, 12 (48%) had previously received dacarbazine or fotemustine, 1 immunotherapy . Median follow-up was 3 months ([IQR: 2-7], range 0.3-12).One patient reached CR and 4 partial responses, concluding to treatment effectiveness with an ORR of 20% (95%CI: 6.8-40.7) all in patients with KIT mutation . Six patients died and 1-year overall survival was 68.3% (95%CI: 46.5-1.00).The 25 patients experienced a total of 236 adverse events , 2/3 imputed to the drug mostly of grade 1 (n=146 in 21 patients) and grade 2 (47 in 13 pts), and less frequently of grade 3 (39 in 18 pts) or grade 4 (3 in 3 pts: 2 dyspnea, 1 renal failure) and 1 death. Five patients had drug withdrawal because of toxicity. **Conclusions:** According to our hypothesis, nilotinib is an effective drug in KIT mutated melanoma in the absence of BRAF and NRAS mutations and should be added to our armamentarium. Clinical trial information: NCT01168050.

**9033 Poster Highlights Session (Board #49), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II study evaluating ipilimumab as a single agent in the first-line treatment of adult patients (Pts) with metastatic uveal melanoma (MUM): The GEM-1 trial.** *Presenting Author: Jose Maria Piulats Rodriguez, Institut Català d'Oncologia de l'Hospitalet, Barcelona, Spain*

**Background:** Uveal melanoma is the most common primary intraocular malignant tumor in adults. Overall survival (OS) at 5 years is 62% due to high incidence of liver metastasis that are fatal within 4 -9 months from diagnosis. No standard treatment exists for MUM. Ipilimumab has demonstrated to improve both overall and long-term survival in patients with advanced cutaneous melanoma (Hodi FS, *et al.*, NEJM 2010; Robert C, *et al.*, NEJM 2011). However, MUM patients were excluded in these trials. **Methods:** GEM-1 (EudraCT 2010-024415-14) is an open label, single arm phase 2 trial that evaluates first line ipilimumab in adult pts with MUM.The study was conducted in 5 centers in Spain, belonging to the Spanish Melanoma Group (GEM). Eligible pts had progressive metastatic disease, ECOG-PS 0 or 1, and no prior systemic treatment for MUM. Treatment consisted of ipilimumab 10 mg/kg iv q3 weeks (wk) for 4 doses (induction) followed by q12 wk (maintenance) until progression, intolerance or withdrawal. Primary end point was OS and secondary PFS, OR and safety using immune response criteria. **Results:** 32 pts were enrolled from July 2011 to May 2013. One patient was ineligible due to absence of metastatic disease at baseline. An interim analysis showed preliminary data from the 31 patients. 18 pts were men, mean age (SD) 60 (10). 64.5% (20) and 35.5% (11) of pts were ECOG-PS 0 and 1 respectively and progressive liver metastasis at baseline were present in 25 pts (80.7%) being frequently multiple and affecting both lobes. Ten pts experienced G3 (abdominal pain, hypophysitis (3), emesis, diarrhoea, asthenia, proctalgia, bone pain and urinary tract infection) and 5 pts had G4 toxicities (hepatotoxicity (2), multi-organ failure, altered state of consciousness, and vascular compression). With a median follow-up of 5.5 (CI 95%: 3.4-11.1) months 13 pts were evaluable for response: 1 PR (7.7%) and 6 pts SD (46.2%). Mature OS and PFS data are expected by April 2014. **Conclusions:** This is the first ipilimumab clinical trial showing preliminary activity in MUM pts. Safety profile is similar to prior reports in cutaneous melanoma. Response rate seems promising while mature OS and PFS results are pending. Clinical trial information: 2010-024415-14.

**9034 Poster Highlights Session (Board #50), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Long-term safety and overall survival update for BREAK-2, a phase 2, single-arm, open-label study of dabrafenib in previously treated metastatic melanoma (NCT01153763).** *Presenting Author: Paolo Antonio Ascierto, Istituto Nazionale Tumori Fondazione "G. Pascale", Naples, Italy*

**Background:** Dabrafenib is a potent inhibitor of mutated BRAF kinase in *BRAF* V600E/K mutation–positive metastatic melanoma ($mut^+$ MM). This multicenter, single-arm phase 2 study assessed safety and clinical activity of dabrafenib in *BRAF* V600E/K $mut^+$ MM. We previously reported the primary endpoint of investigator-assessed overall response rate in *BRAF* V600E $mut^+$ MM patients and overall survival (OS; median follow-up 11.9 months). Here we report long term safety data and updated OS (median follow-up 13 months). **Methods:** 92 patients with histologically confirmed stage IV *BRAF* V600E/K $mut^+$ MM received oral dabrafenib 150 mg twice daily until disease progression, death, or unacceptable adverse events (AEs). Secondary endpoints included safety and OS. AEs were summarized by duration of dabrafenib treatment. **Results:** 76 patients with *BRAF* V600E $mut^+$ MM and 16 with *BRAF* V600K $mut^+$ MM were enrolled from August 2010 to February 2011. As of December 2013, 11 patients (12%) had not experienced a progression event and 9 continued to receive dabrafenib. In the *BRAF* V600K group, median OS was 12.9 months (95% CI, 6.9-17.1); 4 patients (25%) were alive beyond 18.8 months (third quartile OS; 95% CI, 12.9-NR). In the *BRAF* V600E group, median OS was 13.1 months (95% CI, 10.4-21.9); 21 patients (28%) were alive beyond 30 months (third quartile OS, NR). The most common AEs in all patients were arthralgia (35%), hyperkeratosis (33%), and pyrexia (29%). Overall, 33 patients (36%) experienced a serious AE; 13 (14%) had cutaneous squamous cell carcinoma. New primary melanoma and other malignancies occurred in 2 patients (2%). For patients on dabrafenib $>$ 24 months ($n = 11$), hyperkeratosis (64%), arthralgia (55%), and pyrexia (45%) were the most common AEs observed during treatment, and 2 patients (18%) experienced serious AEs during treatment. **Conclusions:** 25 patients were alive as of December 2013, and 9 of those patients were receiving treatment with dabrafenib. Median OS was $>$ 1 year in patients with *BRAF* V600E/K $mut^+$ MM treated with dabrafenib. The most common AEs in patients treated with dabrafenib $>$ 24 months were the same as those in patients treated with dabrafenib $<$ 24 months. Clinical trial information: NCT01153763.

**9035 Poster Highlights Session (Board #51), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Treatment patterns and outcomes in BRAF V600E mutant melanoma patients with brain metastases receiving vemurafenib in the real-world setting.** *Presenting Author: Geoffrey Thomas Gibney, Moffitt Cancer Center, Comprehensive Melanoma Research Center, Tampa, FL*

**Background:** Metastatic Melanoma (mM) patients (pts) with brain metastases (BM) have a poor prognosis and median survival of $<$6 months. Selective BRAF inhibitors may play a role in the treatment of BM, but data from the "real-world" setting is limited. This study aimed to investigate treatment and survival patterns among $BRAF^{V600E}$ mM pts with active BM receiving vemurafenib (vem). **Methods:** Clinical data for $BRAF^{V600E}$ mM pts with active BM treated with vem after 8/2011 were reviewed from a panel of US oncologists. Demographic and clinical characteristics, mM treatment history pre- and post- vem, treatment response, and death were recorded. 6-month survival rate was estimated using Kaplan-Meier (K-M) method. Prognostic factors for death were measured prior to vem initiation and assessed using a Cox proportional-hazards regression model. **Results:** 283 $BRAF^{V600E}$ mM pts who received vem after diagnosis (dx) of BM were analyzed. Mean age was 57 years; 60.8% were male; 67.5% were ECOG 0-1. Median follow-up time from vem initiation was 5.7 months. Prior to vem, 109 (38.5%) pts received local treatment and 23 (8.1%) pts received systemic treatment for BM. Median vem treatment duration among pts who discontinued vem was 5.0 months. 21 (7.4%) pts required a dose reduction of vem. Reasons for vem discontinuation included systemic disease progression (42.9%), intracranial progression (18.1%), death (16.4%), and pt decision (5.6%). 136/283 (48.1%) were reported to achieve overall intracranial response (CR/PR). No new safety issues were identified. K-M survival at 6-month was 85.7% (95% CI: 80.1, 89.8). Pts with $\geq$5 BM (HR 3.8; 95% CI: 1.7, 8.5), progressive extracranial metastases (HR 2.6; 95% CI: 1.4, 4.6), and $\geq$2 sites of extracranial metastases (HR 5.3; 95% CI: 1.4, 20.4) were found to be significant prognostic factors for death. **Conclusions:** In the real world setting, the use of vem treatment is associated with clinical benefit in $BRAF^{V600E}$ mM patients with active BM.

**9036 Poster Highlights Session (Board #52), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase II single-arm study of pazopanib and paclitaxel as first-line treatment for patients with advanced melanoma.** *Presenting Author: John P. Fruehauf, UCI Comprehensive Cancer Center, Orange, CA*

**Background:** We designed a phase II single arm, open label clinical trial evaluating pazopanib in combination with metronomic paclitaxel as first line therapy for subjects with unresectable stage III and stage IV melanoma. We collected PK data to determine if pazopanib blood levels were associated with treatment outcomes. **Methods:** Subjects received paclitaxel at 80mg/$m^2$weekly for 3 weeks in a 4 week cycle and pazopanib at 800mg as a continuous daily oral dose. Patients with treated CNS metastases were eligible. It was predetermined that 44 subjects with measurable disease were sufficient to estimate the response probability to within +/- 15% (95% confidence interval). The primary endpoint was 6-month progression free survival. Secondary endpoints included 1-year survival, TTP and median OS. Outcomes were correlated with pazopanib cycle 2 day 1 pre-dose steady state plasma levels. **Results:** We enrolled 51% M1c, 34% M1b, 13% M1a, and 1 patient was IIIc. Nine patients had previously treated CNS metastases. Forty six patients were fully evaluable for response. Six of 7 unevaluable patient's had clinical progression and were considered to have PD. Response rates were: 1 CR, 20 PR's, 26 SD's, and 6 PD's. The overall RR (CR+PR) was 40%. Disease control rate was 89% (CR+PR+SD). Six-month PFS was 70%, 1-year OS was 43%. Median TTP was 210 days and median OS was 403 days. Grade 3-4 AEs included hypertension (25%), transaminitis (23%), and neutropenia (17%). One patient discontinued for grade 4 transaminitis which subsequently resolved completely. Pazopanib was dose reduced in 30% of patient's. Mean pazopanib serum levels were not significantly different ($p=.2$) in patients with stable disease (43.43 + 32.3 ug/ml) compared with responding patients (31.96 + 20.58). A linear regression for drug levels and best response yielded an insignificant $r = 0.27$. **Conclusions:** This phase II study demonstrated that pazopanib in combination with paclitaxel was well tolerated and resulted in a 40% response rate with 6-month PFS of 70%, indicating that this combination is of further interest. There was no association between pazopanib serum levels and treatment response. Clinical trial information: NCT01107665.

**9037 General Poster Session (Board #241), Sat, 8:00 AM-11:45 AM**

**Incidence and survival of dermatofibrosarcoma protuberans in the United States.** *Presenting Author: Kathryn L Kreicher, Case Western Reserve University School of Medicine, Cleveland, OH*

**Background:** Dermatofibrosarcoma protuberans (DFSP) is a rare cutaneous sarcoma of intermediate malignancy. Information on risk factors, incidence, and survival of DFSP is limited. We sought to describe the incidence of and survival from primary DFSP in the United States. **Methods:** We used data from the 18 registries of the Surveillance, Epidemiology, and End Results (SEER) Program from 2000-2010 to calculate the incidence of and survival from primary DFSP. **Results:** 6,817 cases of primary DFSP were reported from 2000-2010. Overall incidence was 0.41 per 100,000 person years. Incidence remained steady over the study period. The trunk was the most common anatomic site for all age groups except for men over the age of 80. Incidence among women was 1.14 times higher than men (95% CI of rate ratio: 1.07-1.22). Incidence among blacks was almost 2 times the rate among whites (95% CI of rate ratio: 1.8-2.1). 10-year relative survival of DFSP was 99.1% (95% CI: 97.6% - 99.7%). Increasing age, male sex, and black race were associated with higher all-cause mortality. Anatomic location of the upper limb, lower limb, and head were associated with higher mortality as compared to the most common location of the trunk. **Conclusions:** The epidemiology of DFSP differs from most skin cancers. Our data show that incidence of DFSP has not changed over the last decade. Incidence among blacks is almost twice that of whites. This is the first report showing statistically higher incidence among women than men. Worse survival is associated with increased age, male sex, black race and anatomic location of the limbs and head.

**9038 General Poster Session (Board #242), Sat, 8:00 AM-11:45 AM**

**Prognostic significance of PD-L1 expression, angiogenesis, and hypoxia in melanoma brain metastases (MBM): A histopathologic analysis.** *Presenting Author: Stergios J. Moschos, Department of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** We have previously shown that presence of intratumoral hemorrhage and absence of immune infiltrates in craniotomy specimens of MBM are associated with shorter overall survival (OS), defined as time from craniotomy to death (Hamilton Cancer 2013). We hypothesize that immune checkpoint protein(s), angiogenic factors, cytokines, hypoxia, and the density of mature vs. immature blood vessels (MBV, IBV) are important prognostic factors. **Methods:** Clinicopathologically annotated craniotomy tumor specimens were stained for angiogenic/hypoxic factors (bFGF, VEGF, HIF1$\alpha$), blood vessel density (CD31), PD-L1, and for vessels (>50 $\mu$m2) that are IBV (CD31+SMA—) or MBV (CD31+SMA+). The Aperio imaging system and Definiens Tissue Studio were used to analyze expression of each marker in different compartments within the tumor (tumor, reactive glia, normal brain, mononuclear cell clusters). **Results:** An average of 44 cases were analyzed for each of the 7 stains. When each variable was treated as continuous using Cox proportional hazards models, no variable was associated with OS. When survival information was used to define the optimal cut-point for each variable between those with long versus short OS, high tumor expression of PD-L1 and bFGF, and low tumor expression of HIF1$\alpha$ were associated with worse OS (unadjusted $p<0.05$; hazard ratios 1.92, 2.2, 2.1 respectively). PD-L1 expression was significantly higher in tumor compared to normal brain, but insignificantly different between tumor and reactive glia or immune infiltrates. There was a significant inverse association between tumor PD-L1 expression and immune infiltrate. **Conclusions:** This unique dataset suggests that neither the density nor the quality of blood vessels within MBM is a significant prognostic factor nor correlates with tumor hemorrhage. Tumor response to hypoxia by upregulation of HIF1$\alpha$ may paradoxically be a favorable prognostic factor. More important, high expression of PD-L1 in MBM is an adverse prognostic factor, and could be derived from its immunosuppressive effects in the brain microenviroment. Targeting PD1/PD-L1 pathway in patients with MBM is reasonable on the basis of these findings.

**9039 General Poster Session (Board #243), Sat, 8:00 AM-11:45 AM**

**The FAM-GEM-1 study: Frequency and characteristics of familial melanoma in Spain.** *Presenting Author: Ivan Marquez Rodas, Medical Oncology, Instituto de Investigación Sanitaria Gregorio Marañon, Universidad Complutense, Madrid, Spain*

**Background:** Melanoma risk is determined by environmental, phenotypical and familial background. Literature describes a 5-10% of melanoma cases in a familial setting. Familial melanoma (FM) is classically defined as >2 first degree relatives with melanoma in a family. Multiple melanomas (MM), pancreatic cancer (PC) in family and multiple nevi are also risk criteria. In Spain, there are several local studies about epidemiology and characteristics of FM, but there are no studies exploring all the territory **Methods:** FAM-GEM-1 is a national, observational, 2 years-registry study (2011-2013), conducted by the Spanish Multidisciplinary Melanoma Group (GEM), whose principal objective was to assess the rate of patients with FM in Spain. Secondary objectives were to analyze if FM patients are different in terms of clinical, pathological and/or molecular features; and to create a registry of FM for further studies. We present the final results of the 1,049 patients registered. **Results:** In Spanish population, according to this representative sample, 7%patients meet FM criteria**.** In the univariate analysis, FM patients have more frequently MM, and less Breslow index, positive mitosis and positive nodes. No differences in other prognosis factors or characteristics were found (Table). **Conclusions:** Although FM seem to have better prognosis characteristics, it is not clear if these differences are due to a bias (more concern that leads these patients to earlier diagnosis) or to real molecular differences. Further studies are needed to elucidate it.

| * Fisher or t student p< 0.05 vs non-FM (%): for valid data | FM N (%) 73 (7) | Non-FM N (%) 976 (93) |

**9040 General Poster Session (Board #244), Sat, 8:00 AM-11:45 AM**

**Effect of restoration of microRNA-18a on improvement of imatinib therapy on secondary imatinib-resistance metastatic melanoma.** *Presenting Author: Jun Guo, Peking University Cancer Hospital & Institute, Beijing, China*

**Background:** Imatinib generated remarkable clinical response in melanomas harboring c-kit mutation. However, melanoma resistance to imatinib develops rather quickly in most of the patients. It has been shown that gene mutations, translocations, deletions, amplifications, and epigenetic changes are involved in the process of secondary imatinib-resistance in GI stromal tumor. But imatinib resistance in melanoma has not been well evaluated. **Methods:** The level of miRNAs expression was initially discovered through miRNA profiling using pretreatment and post treatment imatinib resistant melanoma tissues, and then confirmed by quantitative PCR. Scratch wound and in vitro invasion assays were performed to evaluate cell migration and invasion. Luciferase reporter assays, immunoblots, and immunohistochemistry analyses were conducted to examine the association between miR-18a and their targets in imatinib-resistant cell and specimens. **Results:** miR-18a was dramatically down-regulated in secondary imatinib-resistant melanoma tissues. Reintroduction of miR-18a led to imatinib-resistant cells become sensitive to imatinib treatment. Cell cycle and apoptosis analysis indicated that miR-18a overexpression in combination with imatinib treatment resulted in a decrease of cell numbers of S-phase and an increase of apoptotic cells, respectively. Wound healing assay and in vitro invasion assay indicated enforced expression of miR-18a, as well as imatinib treatment dampened the capacity of melanoma cell migration and metastasis. CCND2 and Notch2 were validated as bona fide effectors of miR-18a in melanoma cells. Furthermore, rescued assay was performed to probe the interaction among miR-18a, CCND2/Notch2, and phenotypic alterations, which demonstrated that the sensitivity of imatinib therapy on imatinib-resistant cell line was improved through miR-18a mediated regulation of CCND2/Notch2. **Conclusions:** Targeting of miR-18a is sufficient to enhance the therapeutic effect of imatinib on melanoma treatment, suggesting that restoration of miR-18a may be a promising strategy for the prevention of melanoma patients from developing secondary resistance.

**9041^ General Poster Session (Board #245), Sat, 8:00 AM-11:45 AM**

**Intralesional treatment of stage III metastatic melanoma patients with L19-IL2: Clinical and systemic immunological responses.** *Presenting Author: Dario Neri, Federal Institute of Technology, Zurich, Switzerland*

**Background:** In previous studies, intralesional injection with interleukin-2 (IL2) showed efficacy for the intratumoral treatment of cutaneous/subcutaneous metastases in advanced melanoma patients. Objectives of this multicenter study (ClinicalTrials.gov Id.: NCT01253096) were to investigate whether intralesional delivery of L19-IL2, a targeted form of IL2, would yield similar results with reduced injection frequency and treatment duration and whether systemic immune responses were induced by the local treatment. L19-IL2 is a recombinant fusion protein, consisting of IL2 fused to a single-chain monoclonal antibody (L19) directed against extradomain B of fibronectin, a well-characterized marker of angiogenesis. **Methods:** Twenty-five patients with unresectable Stage IIIB/IIIC melanoma and cutaneous/subcutaneous injectable metastases received intratumoral injections of L19-IL2 once per week at a maximum daily dose of 10 MIU for 4 consecutive weeks. Tumor response was evaluated twelve weeks after the first treatment. **Results:** Twenty-four of 25 enrolled patients were evaluable. Toxicities were mild and comparable to that of free IL2. No serious adverse event was recorded. A complete response of all metastases was achieved in 6 patients (25%), which was long-lasting in most cases (5 patients $\geq$ 24 months). Analysis of progression rates for these patients seems to show an effect of intratumoral injection of L19-IL2 in retarding spread of the disease to distant lymph nodes or appearance of visceral metastases, as compared to historical controls. A significant temporary increase of peripheral regulatory T cells and a sustained decrease of myeloid-derived suppressor cells was observed upon treatment. **Conclusions:** Intratumoral L19-IL2 treatment elicited objective responses in a high percentage of lesions. The targeted form of IL2 yielded results similar to those of the untargeted cytokine, but at lower cumulative doses and more favorable schedule and treatment duration. Analysis of progression and survival rates for these patients indicates a substantial advantage, compared to historical controls, in terms of overall survival and distant metastasis-free survival. Clinical trial information: NCT01253096.

**9042 General Poster Session (Board #246), Sat, 8:00 AM-11:45 AM**

**Incidence and characteristics of melanoma brain metastases appearing during vemurafenib treatment.** *Presenting Author: Lucie Peuvrel, Dermato-Cancerology department, Nantes University Hospital, Nantes, France*

**Background:** Melanoma brain metastases are frequent and severe. We studied their characteristics in a retrospective cohort of patients treated with vemurafenib, a BRAF inhibitor indicated in V600-mutant metastatic melanoma. **Methods:** We included in this study all patients receiving vemurafenib in our department between November 2010 and November 2013 without melanoma brain metastases at initiation of treatment. Brain scans were performed after 2 months, and then every 3 months or in case of neurologic symptoms. RMI could be performed to confirm scan result. Our primary endpoint was the brain metastases incidence. Secondary endpoints were associated risk factors, onset modalities and clinical evolution. **Results:** In our cohort of 86 patients, incidence of brain metastases was 20% after a median follow-up of 9 months (1 to 26 months). They appeared after a mean of 5.3 months of vemurafenib exposure (1 to 15 months). The only identified risk factor was a high number of metastases before treatment (p=0.045). Radiological exams revealed 41% of miliary brain metastases. Occurence of brain metastases was associated with a trend toward a decrease in overall survival from 12.8 months (95% CI: 9.2-16.7) to 8.5 months (95% CI: 4.5-11.5) (p=0.07) and with a significant decrease in progression free survival from 7 months (95% CI: 5-8) to 5 months (95% CI: 3-8) (p=0.04). Among patients with brain metastases, 82% were died at time of analysis after a median of 2.7 months (0.2 to 7.2 months). Comparatively, only 58% of the patients without brain metastases died during the same period. The extra cerebral disease was well controlled in 59% of patients at the time of diagnosis of brain metastases. **Conclusions:** Our study shows that melanoma brain metastases appearing in patients during vemurafenib are frequent in real life conditions and associated with a very poor prognosis. Systematic brain explorations must thus be performed during vemurafenib treatment, even in patients with good extra cerebral responses. RMI should be preferred to scan due to the high frequency of miliary metastases. Specific resistance mechanisms are likely in this location due to the high number of dissociated responses between cerebral and extra cerebral metastases.

**9043 General Poster Session (Board #247), Sat, 8:00 AM-11:45 AM**

**Landscape of genetic alterations in patients with metastatic uveal melanoma.** *Presenting Author: Sophie Piperno-Neumann, Institut Curie, Paris, France*

**Background:** Uveal melanoma (UM) is a rare type of cancer with a mutational profile distinct from skin melanoma and poor prognosis in a metastatic setting. In the context of a dose-escalation clinical trial of the PKC inhibitor AEB071 (sotrastaurin) in UM we conducted genomic profiling of 52 formalin-fixed, paraffin-embedded biopsies from metastatic patients (pts), primarily from liver. **Methods:** Massively parallel sequencing of 288 clinically-relevant cancer genes was performed by Foundation Medicine at high depth (median 646X) to characterize mutations, amplifications (≥6 copies) and homozygous deletions. **Results:** Alterations of known or likely functional significance were frequent only in genes previously implicated in UM but two novel patterns were observed. All but two pts (96%) had a known activating mutation in either GNAQ (63%; Q209P/L/R or R183Q) or GNA11 (33%; Q209L). While this mutually exclusive pattern is a known feature of UM the higher prevalence reported here is likely due to the sequencing depth, as evidenced by low allele frequencies in some pts even after correcting for tumor purity. In addition truncations or splice site mutations in BAP1 were observed frequently (62%), in line with previous reports. The tumors harbored nearly complete mutual exclusivity between partial or putatively complete amplifications of chromosome 8q (52%) and recurrent mutations in SF3B1 (19%; R625C/H or V701F), a pattern previously unreported. In addition BAP1 mutations were frequent in 8q-amplification pts (23/25 [85%]) but rare in SF3B1-mutant pts (2/10 [20%]), suggesting complementary and redundant consequences of these lesions with BAP1 mutations respectively. Mutations of known or likely functional impact were otherwise rare. P53 and SMARCA4 were mutated in two pts each and 15 genes were mutated in a single pt. We then investigated the effect of genetic subtype on the baseline levels of pMARCKS as an indicator of PKC activity. No relationship with any gene or within GNAQ/GNA11 mutant subtypes was observed. However, pMARCKS levels were attenuated upon AEB071 treatment. **Conclusions:** High-depth sequencing of clinical pt metastases sheds new light on the interplay among the small group of genetic alterations observed in uveal melanoma.

**9044 General Poster Session (Board #248), Sat, 8:00 AM-11:45 AM**

**A pilot trial of hu14.18-IL2 in patients with completely resectable recurrent stage III or stage IV melanoma.** *Presenting Author: Mark R. Albertini, University of Wisconsin, Madison, WI*

**Background:** Phase I testing of the hu14.18-IL2 immunocytokine (IC), a mAb reactive with GD2 disialoganglioside, linked to IL2, in patients (pts) with melanoma showed immune activation, reversible toxicities, and a maximal tolerated dose of 7.5 mg/m$^2$/day. Preclinical data in IC-treated tumor bearing mice with low tumor burden documents striking antitumor effects. Thus, we studied IC in melanoma pts in remission but at high risk for recurrence. **Methods:** Pts with completely resectable recurrent stage III or stage IV melanoma were scheduled to receive 3 cycles of IC at 6 mg/m$^2$/d IV over 4 hours on days 1, 2 and 3 of each 28-day cycle. Pts were randomized to surgical resection of all sites of disease either following (Group A) or prior to (Group B) IC cycle 1. Primary objectives were to evaluate histological evidence of IC anti-tumor activity, time to recurrence, and overall survival (OS). **Results:** Twenty melanoma pts (11 recurrent stage III, 8 stage IV, one unknown primary) were randomized to Group A (11 pts) or B (9 pts). Two Group B pts did not receive IC due to persistent disease following surgery. Seven of 18 IC-treated pts remain free of recurrence, with median recurrence-free survival of 5.8 months (95% confidence interval: 2.3 months, not yet reached). Eleven of 18 IC-treated pts are still alive (median follow-up of surviving pts: 34.6 months (range: 19.8-47.5 months)). Toxicities were similar to those previously reported for IC. Immunohistologic evaluations of resected tumors showed variable inflammation and tumor necrosis between pts and no clear differences between Groups A and B. Predominant inflammatory cells were CD3+ T cells and CD163/CD68+ macrophages. Twelve pts had evaluable tumor samples for GD2 analysis and 6/12 showed expression of GD2 on melanoma cells (high (2 pts); low/moderate (4 pts); and undetectable (6 pts)). There was no correlation between GD2 expression (positive vs negative) and time to recurrence (logrank p-value=0.572). **Conclusions:** Prolonged tumor-free survival was seen in melanoma pts at high risk for recurrence who were treated with IC. GD2 expression was detected in 50% of pts. The immunological activation by IC with manageable toxicities suggests potential for combination treatments. Clinical trial information: nct00590824.

**9045 General Poster Session (Board #249), Sat, 8:00 AM-11:45 AM**

**Final overall survival from a phase 3 trial of *nab*-paclitaxel versus dacarbazine (DTIC) in chemotherapy-naive patients with metastatic melanoma.** *Presenting Author: Evan Hersh, University of Arizona Cancer Center, Tucson, AZ*

**Background:** In a phase 3 trial, *nab*-paclitaxel significantly improved progression-free survival (PFS) compared with DTIC (4.8 vs 2.5 months; hazard ratio [HR] 0.792; $P = 0.044$) in chemotherapy-naive patients with metastatic melanoma thereby meeting the primary study endpoint. A trend toward improved overall survival (OS; HR 0.831; $P= 0.094$) at the interim analysis (64% of patients with an event) was also shown. Here we report the final OS analysis. **Methods:** 529 patients with chemotherapy-naive, stage IV melanoma (M1c, 65%; elevated lactate dehydrogenase [LDH], 28%) and an Eastern Cooperative Oncology Group performance status of 0-1 were randomized to receive *nab*-paclitaxel 150 mg/m$^2$ on days 1, 8, and 15 of a 28-day cycle (n = 264) or DTIC 1000 mg/m$^2$ on day 1 of each 21-day cycle (n = 265). The randomization was stratified by metastatic stage, region, and baseline LDH. *BRAF* status was known in 67% of patients; of these, 37% had mutant and 63% had wild-type *BRAF* melanoma. September 20, 2013, was the clinical cutoff date for the final OS analysis. **Results:** At the final OS analysis (median follow-up, ≈ 30 months for censored patients), 427 patient deaths occurred: 215 (81%) in the *nab*-paclitaxel vs 212 (80%) in the DTIC arm. Median OS trended in favor of *nab*-paclitaxel, but did not reach statistical significance vs DTIC (12.6 vs 10.5 months; HR 0.897;95% CI 0.738 - 1.089; $P = 0.271$. OS favored *nab*-paclitaxel vs DTIC across most patient subgroups, including patients aged ≥ 65 years and those with M1c stage disease, elevated LDH, and any *BRAF* status melanoma. The use of poststudy anticancer therapy did not differ by treatment arm, with 77% vs 73% of patients in the *nab*-paclitaxel arm vs DTIC arm receiving poststudy therapy. The use of a BRAF inhibitor (13% vs 10%) or ipilimumab (31% vs 32%) was also similar between treatment arms. As previously reported, the most common grade ≥ 3 adverse events with *nab*-paclitaxel were peripheral neuropathy (25% vs 0% with DTIC) and neutropenia (20% vs 10% with DTIC). **Conclusions:** The study met the primary endpoint with a significant improvement in PFS. At final analysis, *nab*-paclitaxel continued to demonstrate a trend toward improved OS vs DTIC. Clinical trial information: NCT00864253.

**9046 General Poster Session (Board #250), Sat, 8:00 AM-11:45 AM**

**Clinical utility of serum miRNAs for the prediction and early detection of recurrence in melanoma patients.** *Presenting Author: Nathaniel H. Fleming, Ronald O. Perelman Department of Dermatology, NYU Langone Medical Center, New York, NY*

**Background:** The improvement of recurrence risk assessment at the time of primary melanoma diagnosis and the development of better surveillance strategies to monitor recurrence remain critical challenges in melanoma patient care. In the current study, we examine the ability of serum-based miRNAs to 1) improve patient risk stratification and 2) improve early detection of melanoma recurrence. **Methods:** Sera levels of 12 miRNAs were measured using qRT-PCR (Exiqon) in serum prospectively collected at diagnosis from 201 melanoma patients (median FU of survivors 91 months). A multivariate logistic regression model that includes miRNAs in combination with stage was built using the training cohort and evaluated in an independent validation cohort of 82 patients (median FU of survivors 39 months). Sera levels of the most informative miRNA signature were assessed longitudinally in a subset of patients (n=82) with samples drawn pre- and post-recurrence when applicable (n=225 samples). An L1 penalized regression approach (Lasso) was performed on TCGA melanoma data to predict the biological role of the miRNA signature. **Results:** A risk score that included four miRNAs (miR-15b, miR-30d, miR-150, and miR-425) in addition to stage significantly separated recurrence-free and overall survival in both the training and validation cohorts (training RFS and OS $P<0.001$, validation RFS $P<0.001$, OS $P=0.005$). The model improved prediction of recurrence over stage alone, increasing AUC from 0.70 to 0.76 (training) and from 0.76 to 0.79 (validation). Normalized serum levels of miR-15b significantly increased over time in recurrent patients ($P<0.001$), but not in non-recurrent patients ($P=0.17$). Serum levels of miR-15b increased in the three months prior to evident recurrence, peaking at recurrence diagnosis and falling after treatment. In TCGA data, miR-15b was predicted to be associated with mRNAs such as AURKB and CNPA involved in the cell cycle, mitotic regulation, and DNA replication ($P<0.001$ for all). **Conclusions:** The addition of serum-based miRNAs can improve prediction of recurrence at time of primary diagnosis. Our data also revealed that dynamic serum miRNA levels can be useful in informing the timing of imaging studies.

**9047 General Poster Session (Board #251), Sat, 8:00 AM-11:45 AM**

**Biochemotherapy with interleukin-2 for metastatic melanoma: Long-term results in 100 patients.** *Presenting Author: David R. Minor, California Pacific Medical Center Research Institute, San Francisco, CA*

**Background:** As the limitations of new melanoma treatments are seen, we felt an evaluation of long-term results of biochemotherapy (BC) for metastatic melanoma (MM) would be useful. **Methods:** Retrospective single-institution review of 100 consecutive patients (pts) who began therapy between 9/30/2002 and 6/20/2006. Median follow-up is 9 years. Staging: IIIC-1; M1A-17; M1B-35; M1C-47. Patients were treated with the O'Day regimen which is similar to ECOG BC except Temozolomide 150mg/m2 used for DTIC; 6 cycles of BC given, not 4; decrescendo IL-2 dosing 36-18-9-9 miu/day dosing not based on BSA; and patients received maintenance inpatient "pulse IL-2" 108miu/42 hrs monthly for 6-18 months after BC. **Results:** 28 pts are still alive, all without evidence of melanoma (NED). One patient died NED due to a pulmonary embolus, one died from sepsis during BC, and 70 died from MM. 17 pts achieved CR with BC and never relapsed. Two patients achieved PR, had surgery for solitary sites of residual disease, and are NED. 6 pts progressed soon after BC, received ipilimumab (ipi) on various schedules, and are now NED. Two patients had late relapses over 3 years after BC. The first received ipi and is now NED off therapy. The second responded to ipi, progressed, and is now NED on therapy with anti-PD-1. One patient received BC in 2005, relapsed in 2007 and is NED after multiple continuous treatments over 7 years with chemo, RT, surgery, ipi, and vemurafenib. Of the 28 patients alive, only the last two are currently receiving therapy. **Conclusions:** First-line decrescendo BC can give durable remissions in many patients; late relapses are uncommon. Durable responses to ipilimumab may follow progression with BC. Biochemotherapy should now be systematically studied as second line or consolidation therapy.

**9048 General Poster Session (Board #252), Sat, 8:00 AM-11:45 AM**

**microRNA (miRNA) expression profiling predicts clinical outcome of carboplatin/paclitaxel-based therapy (CP) in metastatic melanoma (MM) treated on the intergroup trial E2603.** *Presenting Author: Liza Cosca Villaruz, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** Chemotherapy continues to be a commonly used modality in MM despite the recent successes of immunotherapy and targeted therapy. CP with or without sorafenib (S) results in objective response rates of 16-18% in unselected chemotherapy-naïve patients (intergroup trial E2603). Our primary objective was to identify molecular predictors of survival and response to CP-based chemotherapy in MM. **Methods:** E2603 randomized 823 MM pts to CP+S vs CP alone. This analysis was performed on pre-treatment formalin fixed paraffin-embedded (FFPE) tumor tissues from 115 pts balanced across treatment arms, *BRAF* status, and clinical outcome. We used technology optimized for FFPE samples: Nanostring miRNA expression array and DASL/Illumina microarrays (HT12 v4) for mRNA expression. Integrative analysis was performed using a novel Tree-guided Recursive Cluster Selection (T-ReCS) algorithm to select the most informative features/genes; TargetScan Human v6.2 for miRNA target prediction and mirConnX for network inference. **Results:** High quality miRNA and mRNA expression data were generated from legacy samples from 115 MM pts treated in E2603 (median progression-free survival (PFS) 4.4 mos). T-ReCS identified *miR-659-3p* as the primary miRNA associated positively with PFS together with *miR-219-1-3p*, *miR-516a-5p*. *miR-659-3p* was differentially expressed based on PFS but not on treatment arm (CP+S vs CP; $p=0.6$), *BRAF* status ($p=0.3$), or *NRAS* status ($p=0.6$). Dichotomized by PFS $<$ 4 mos vs $>$ 4 mos, higher *miR-659-3p* expression remained prognostic of longer PFS ($p=0.03$). High *miR-659-3p* expression distinguished patients with responsive disease (complete or partial) from patients with stable disease ($p=0.04$.) Predicted gene targets using TargetScan and mirConnX included *BRAF*, *PIK3C2A*, *FGF12*, *FGF18* and *RAC1*. **Conclusions:** Novel integrative analysis reveals *miR-659-3p* as a predictive biomarker in MM pts treated with platinum-based chemotherapy and may serve to improve patient selection. Validation in an independent population is ongoing and functional studies to elucidate the mechanisms underlying this observation are planned.

**9049 General Poster Session (Board #253), Sat, 8:00 AM-11:45 AM**

**Role of platinum-based chemotherapy for Merkel cell tumor in adjuvant and metastatic settings.** *Presenting Author: Shailesh R. Satpute, Indiana University Simon Cancer Center, Indianapolis, IN*

**Background:** Merkel Cell Carcinoma (MCC) is a rare, highly aggressive primary neuroendocrine carcinoma of skin. The tumor always stains positive for CK20. Chemotherapy for metastatic disease has been platinum plus etoposide, based upon small cell lung cancer studies. The role of adjuvant chemotherapy in resected high risk disease is controversial. The principles of adjuvant chemotherapy in solid tumors are demonstration of activity in the metastatic setting and a probability for postoperative relapse. **Methods:** We reviewed, retrospectively, 41 patients with MCC seen and followed at Indiana University Simon Cancer Center from 2000 – 2013. Most of these patients received cisplatin or carboplatin plus etoposide for 4-6 cycles. Demographics, disease variables, treatments and outcomes were analyzed. **Results:** Median age was 68 years with 64% males. Primary sites affected were extremities (21), head and neck (11) or others including lymph node only disease with unknown primary (9). 12 patients received chemotherapy for metastatic disease at presentation. 10 of 12 (83%) achieved a RECIST response to chemotherapy. Median duration of remission with chemotherapy was 4 months. 27 patients initially underwent wide local excision with sentinel lymph node biopsy followed by lymph node dissection, if clinically indicated. 2 did not receive any definitive therapy. 15 of these 27 patients received adjuvant chemotherapy based upon high risk features including lymph node involvement (8), positive surgical margins (2), bulky primary tumor (2) or rapid growth (3). 11 of these 15 patients remain continuously progression free with median of 3 years. 12 patients did not receive adjuvant chemotherapy. 5 of 12 remain disease free. 21 patients received adjuvant radiation either as their only therapy (9) or in addition to adjuvant chemotherapy (12). 21 of 41 patients remain alive and disease free, 3 are alive with disease, 13 died from metastatic MCC and 4 died of unrelated causes. Median follow up was 3 years. **Conclusions:** Platinum-based combination chemotherapy is active in metastatic MCC. We recommend adjuvant chemotherapy for MCC with high risk features.

**9050 General Poster Session (Board #254), Sat, 8:00 AM-11:45 AM**

**Randomized, double-blind phase II trial of NY-ESO-1 ISCOMATRIX vaccine and ISCOMATRIX adjuvant alone in patients with resected stage IIc, III, or IV malignant melanoma.** *Presenting Author: Jonathan S. Cebon, Ludwig Institute for Cancer Research, Melbourne, Australia*

**Background:** The cancer testis antigen NY-ESO-1 (ESO) has been evaluated as a biomarker and a therapeutic immunologic cancer target. Preliminary data from a phase I clinical trial of ESO and ISCOMATRIX adjuvant (ESO vaccine) suggested this treatment could prevent relapse in patients (pts) with high risk resected malignant melanoma (MEL). **Methods:** We compared ESO vaccine to adjuvant alone in a randomized double-blind phase II study in pts with MEL. Pts with resected stage IIc, IIIb, IIIc, or IV melanoma expressing ESO were randomized 1:1 to ESO vaccine or adjuvant x3 q4w followed by a 4th dose at 6m. Primary endpoint was rate of RFS at 18m in the intent-to-treat (ITT) population and two per protocol (PP) populations, consisting of all relapses regardless of location. Secondary objectives included RFS and Overall Survival (OS) over the entire period of observation (study defined plus off-study follow-up), safety and ESO immunity. **Results:** Of 111 pts screened with ESO-expressing MEL, 110 comprised the ITT population, with 56 randomized to the ESO vaccine arm and 54 to adjuvant (96% and 87%, respectively, were at stage ≥IIIa at entry). There were no significant differences between the two arms for the ITT population during the 18m observation period for median time to relapse, 139 vs 176 days($p=0.296$), or relapse rate, 27 (48.2%) vs 26 (48.1%) (HR=0.913; 95% CI, 0.402 to 2.231), respectively. RFS and OS for the entire period of observation were similar between the two arms. After the third immunization, a significantly larger percentage of pts in the ESO vaccine arm developed a strong positive antibody (Ab) & cellular immune response (IR) to ESO ($p<0.001$); this difference remained for the duration of the study. A total of 17 out of the 31 pts (55%) who had a vaccine-induced IR (Ab against ESO) and no pre-existing immunity were relapse-free at the end of 18m on study. **Conclusions:** The ESO vaccine was safe, well tolerated, elicited strong Ab and cellular responses but did not affect relapse free survival. Optimal efficacy may require combining it with other immunotherapy modalities. Clinical trial information: NCT00199901.

**9051 General Poster Session (Board #255), Sat, 8:00 AM-11:45 AM**

**A phase 1b dose-escalation study of BYL719 plus binimetinib (MEK162) in patients with selected advanced solid tumors.** *Presenting Author: Dejan Juric, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

**Background:** The MAPK and PI3K pathways share common upstream activators and contribute to cell proliferation, differentiation, and survival. Due to compensatory signaling, only partial tumor growth inhibition may occur when targeting either pathway alone. Preclinically-observed synergistic effects of combined PI3K and MEK inhibitors suggest that dual inhibition may be more effective. **Methods:** This phase 1b, open-label study (CMEK162X2109) is evaluating the PI3K$\alpha$ inhibitor BYL719 combined with MEK inhibitor binimetinib (MEK162) in patients (pts) with *RAS*- or *BRAF*-mutant advanced solid malignancies (> 10 types). The objective for dose escalation was estimation of the maximum-tolerated dose (MTD) and/or recommended dose for expansion (RDE), guided by the Bayesian logistic regression model. **Results:** As of September 2, 2013, 58 pts were enrolled and BYL719 was orally co-administered at 80, 120, 160, 200, 220, or 270 mg once-daily (QD) with binimetinib at 30 or 45 mg twice-daily (BID) in 28-day cycles. Thirty two pts (55%) had ≥3 prior anticancer regimens. Median exposure was 7.4 wks. Common adverse events (AEs), regardless of study drug relationship, were diarrhea (86%), nausea (66%), vomiting (52%), reduced appetite (50%), rash (48%), pyrexia (41%), fatigue (38%), and hyperglycemia (36%). Grade 3/4 AEs occurred in 46 individual pts (79%), most commonly diarrhea (12%) and elevated creatine phosphokinase (10%). Dose-limiting toxicities were observed in 9 pts (19%), out of which 4 had grade 3/4 AEs including gastrointestinal and skin disorders. The MTD of the combination was determined to be BYL719 200 mg QD plus binimetinib 45 mg BID, at which 3/6 pts had grade 3/4 AEs. Of 4 ovarian cancer pts with *KRAS*-mutant status, 3 had confirmed partial responses (PRs). PRs were also observed in 1 pt with *NRAS*-mutant melanoma (confirmed) and 1 with *KRAS*-mutant endometrial cancer (unconfirmed). Stable disease lasting > 6 weeks was reported as best response for 18 pts (31%). **Conclusions:** The MTD/RDE for combined BYL719 and binimetinib was reached, and the preliminary safety and efficacy profile justifies further exploration, particularly in pts with *RAS*-mutant ovarian cancer. Clinical trial information: NCT01449058.

**9052 General Poster Session (Board #256), Sat, 8:00 AM-11:45 AM**

**Analysis of recurrence patterns in acral versus non-acral melanoma: Should histologic subtype influence treatment guidelines?** *Presenting Author: Priyanka Gumaste, Ronald O. Perelman Department of Dermatology, NYU Langone Medical Center, New York, NY*

**Background:** Current surgical treatment of primary melanoma is uniform for all histo-subtypes, although certain types of melanoma, such as acral lentiginous melanoma (ALM), are biologically distinct. To our knowledge, no study has explored the effectiveness of standard melanoma treatment guidelines in ALM compared to non-acral melanoma (NAM). **Methods:** Study subjects were selected from a prospectively enrolled cohort of primary melanoma patients at NYU. All patients received wide local excisions with standard margins and a sentinel node biopsy if indicated by accepted practice guidelines. ALM patients were matched to NAM patients (1:3) by gender and melanoma stage, including substage. Logistic regression models were used to compare recurrence and survival outcomes in both cohorts. **Results:** 244 patients were included in this study (ALM=61, NAM=183; median follow-up: ALM= 33 months, NAM=58 months). ALM histologic subtype was an independent negative predictor of recurrence-free survival (HR = 2.45, $p < 0.001$) and melanoma-specific survival (HR= 2.64, $p = 0.001$) compared to NAM. Recurrence was significantly more common in ALM compared to NAM (49% versus 30%, $p=0.007$). When comparing recurrence rates by tumor thickness in both groups, there was no significant difference in recurrence in tumors greater than 2mm (ALM: 64%, NAM: 47%, $p= 0.12$); in tumors less than 2mm, there was a significantly higher recurrence rate in ALM (28%) versus NAM (10%, $p=0.048$). Of note, the rate of loco-regional recurrence was nearly double in ALM (39%) compared to NAM (19%, $p=0.001$). **Conclusions**: Our data revealed a high rate of loco-regional failure in ALM compared to NAM when controlling for AJCC stage. ALM may require wider surgical margins than non- acral cutaneous melanomas of equal thickness, particularly in tumors less than 2mm thick. Revision of surgical margin recommendations based on larger multicenter cohorts may need to be considered.

**9053 General Poster Session (Board #257), Sat, 8:00 AM-11:45 AM**

**Phase I/II study of weekly LOC-paclitaxel (LOC-pac) injection in patients (pts) with metastatic melanoma (MM).** *Presenting Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background**: LOC-paclitaxel (LOC-pac) is a covalent conjugate of paclitaxel linked to an omega-6 fatty acid designed to enhance uptake of paclitaxel into tumors leading to higher intra-cellular drug concentrations and potentially enhance anti-tumor activity of paclitaxel. This is a first in human, phase I, open label, dose-escalating clinical study of LOC-pac administered weekly in patients (pts) with metastatic melanoma (MM). **Methods**: Adult MM pts who were refractory to prior systemic therapy or were ineligible for other therapy of higher priority with normal organ function and ECOG PS 0-2 were eligible for this trial. Patients with baseline peripheral neuropathy over grade 1, prior exposure to taxane chemotherapy, hypersensitivity to cremaphor or with serious concurrent medical conditions were excluded. LOC-pac was given intravenously over 1 hour on days 1, 8, 15, 22 and 29 every 42 days. LOC-pac dosing was escalated from 100mg/m2 to 1000mg/m2 after safety of the prior dose level was confirmed in cohorts of 3 pts each. Responses were assessed by RECIST every 6 weeks. Toxicity was evaluated using CTCAE v3. **Results:** A total of 33 patients were treated in phase I. Median age was 69 years, median ECOG PS was 0 and 79% of enrolled patients were male. Tumor stages were IIIc/M1a/M1b/M1c in 3/3/7/20 patients respectively. The MTD is 1000mg/m2 and the recommended phase 2 dose is 880mg/m2. DLTs were primarily related to infection including pneumonia and pyelonephritis. Other common toxicities included fatigue, nausea, vomiting, pruritus, peripheral neuropathy and stomatitis. No alopecia or nail changes were appreciated. Of the 33 evaluable patients for best response, 16 had PD, 14 had SD, and 3 had PR. All 3 PRs were confirmed. One patient with PR completed 8 cycles of therapy and then underwent metastectomy showing no viable residual tumor and remains without evidence of disease over 144 weeks. **Conclusions**: Our phase I study demonstrated that LOC-pac is safe and is associated with milder toxicities including neuropathy, nail changes and alopecia when compared with paclitaxel. An ongoing dose expansion study will further define the anti-tumor activity of LOC-pac in MM. Clinical trial information: NCT01039844.

**9054 General Poster Session (Board #258), Sat, 8:00 AM-11:45 AM**

**Improved median overall survival (OS) in patients with metastatic melanoma (mM) treated with high-dose (HD) IL-2: Analysis of the PROCLAIM 2007-2012 national registry.** *Presenting Author: Gregory A. Daniels, UC San Diego Moores Cancer Center, La Jolla, CA*

**Background:** HD IL-2 has been reported to have a overall response rate (ORR) for mM of 16% and a median OS 11.4 months (Atkins,1999), however, the studies that led to its regulatory approval are >15 years old and were performed in an era predating checkpoint inhibition and targeted therapies. **Methods:** The PROCLAIM registry (www.proclaimregistry.com), a HD IL-2 observational database currently with over 30 participating sites, consists of a retrospective cohort (treated 2007-2012) informing an ongoing prospective cohort (~600 patients). We report on the retrospective mM subjects (n=170, 11 sites) with survival status determined as of 11/2013 and a median follow-up of 30.5 months. Sites were encouraged to enroll patients sequentially. Inclusion criteria required that patients have received at least one dose of HD IL-2. **Results:** The ORR for mM in the database was similar to the historical rates. All 170 subjects were accounted for, 98 were deceased and 72 were known to be alive. Median OS was 21 months for mM compared to a median OS range of 6.4-13.6 months for other single agent FDA-approved drugs (Bhatia, 2009; Kaufman, 2005; Hodi, 2010; Chapman, 2012). Among patients with stable disease (SD), median OS was 36.6 months compared to 15.4 months in patients with progressive disease (PD). Median OS has not been reached for patients with complete response (CR) or partial response (PR). Comparison of patients who received HD IL-2 as 1st or 2ndline (n=138, 32, respectively) showed no significant difference in OS between these patients. No deaths due to IL-2 related toxicity were reported in the retrospective cohort. **Conclusions:** The PROCLAIM registry documents an improvement in OS for patients treated with HD IL-2 as compared to the historical reference standards. Response to HD IL-2 traditionally defined as CR or PR and, according to this data, should also include SD, which can be very durable. The observation that 1st and 2nd line HD IL-2 possessed similar OS raises intriguing hypotheses about the sequencing of immunotherapy and targeted therapy in mM, and the utility of IL-2 as a salvage option - all of which are currently under examination in the prospective database.

**9055 General Poster Session (Board #259), Sat, 8:00 AM-11:45 AM**

**Tumor-infiltrating lymphocytes (TILs) and expression of PD-L1 in melanoma brain metastases (BM).** *Presenting Author: Anna Sophie Berghoff, Institute of Neurology, Medical University of Vienna, Vienna, Austria*

**Background:** The brain is considered as an immuno-privileged organ and little is known about the inflammatory response to melanoma BM. **Methods:** Patients with neurosurgical resected and histologically verified melanoma BM were identified. Investigation of PD1, PD-L1, CD3, CD8, CD45RO and BRAF V600E were performed by immunohistochemistry and analyzed using previously published semiquantitative evaluation criteria. **Results:** Forty-six specimens (28/46; 60.9% BRAF V600E positive) were available. Forty-one/46 (89.1%) specimens presented with TIL infiltration. CD3+ TILs were evident in 35/46 (76.1%), CD8+ TILs in 28/46 (60.9%), CD45RO+ TILs in 32/46 (69.6%) and PD1+ TILs in 28/46 (60.9%) specimens. The Table lists details of TIL infiltration density. PD-L1 expression on melanoma BM tumor cells was observed in 21/46 (45.7%) specimens. Median H-score for PD-L1 was 3 (range 1–90). Eight/21 (38.1%) PD-L1 positive specimens presented with an H score over 5 %. PD-L1 expression on tumor cells was associated with higher density of PD1+ (p=0.002), CD3+ (p=0.024) and CD8+ (p=0.050) TIL infiltration. Furthermore, density of CD3+ TILs was associated with density of CD8+ (p<0.001), PD1+ (p<0.001) and CD45RO+ (p<0.001) TILs, respectively. No association of previous systemic antineoplastic therapy (including chemotherapy and interferon) and expression of PD-L1, PD1, CD3 or CD45RO could be observed (p=n.s). Expression of PD-L1 on tumor cells or density of PD1+, CD3+, CD8+ or CD45RO+ TILs did not correlate with BRAF V600E status (p=n.s.) or survival from first diagnosis of BM (p=n.s.). **Conclusions:** Melanoma BM show considerable inflammatory infiltrates and expression of PD1 and PD-L1. Clinical studies should investigate the value of checkpoint inhibitors in patients with melanoma brain metastases.

**9056 General Poster Session (Board #260), Sat, 8:00 AM-11:45 AM**

**Ipilimumab in acral melanoma: A retrospective review.** *Presenting Author: Douglas Buckner Johnson, Vanderbilt-Ingram Cancer Center, Nashville, TN*

**Background:** Ipilimumab (Ipi) improves overall survival (OS) in advanced melanoma. Retrospective studies suggest inferior outcomes for Ipi in atypical cohorts of melanoma (uveal, mucosal) compared to unselected populations. Acral melanoma (AM) is an uncommon subtype of melanoma with a poor prognosis. The clinical activity of Ipi has not been well defined in advanced AM. **Methods:** To assess the activity of Ipi in this cohort, we retrospectively reviewed the demographics, treatment history, and clinical outcomes for all patients (pts) with AM treated with Ipi from two centers between February 2006 and June 2013. Using Cox proportional hazards models, we assessed for factors that correlated with OS. **Results:** Of 35 patients with advanced AM who received Ipi, 28 were Caucasian, 6 were black, and 1 was Hispanic. Primary tumors arose on the volar surfaces in 28 and subungual sites in 7. Of 31 genotyped patients, 3 had mutations in *BRAF*$^{V600E}$, 2 in *NRAS*, and 4 in *CKIT*. Stage IVc disease was present in 19 pts, IVb in 6, IVa in 5, and III in 5; 45% had elevated LDH. Median number of prior therapies was 1 (range 0-3) including targeted agents in 6 pts and immune-based therapies in 5. The median number of Ipi doses received was 4 (33 pts with 3mg/kg dosing and 2 with 10mg/kg). Best response by immune-related response criteria (irRC) was complete response in 1 pt, partial response in 3, and stable disease (SD) in 5 for an objective response rate (ORR) of 11.4% and clinical benefit (ORR + SD) at 24 weeks of 25.7%. Median progression-free survival (PFS) from initiation of Ipi was 2.6 months (mo) (95% CI 2.2-3 mo); median OS was 16.7 mo (95% CI 11-22.5 mo). Normal LDH and absolute lymphocyte count ≥1000 at 7 weeks predicted longer OS; metastatic stage, and timing or site of initial recurrence did not influence OS. Toxicities were similar to previous Ipi trials; 16 pts had an immune-related adverse event (irAE) and 7 pts had grade 3 irAEs (colitis in 2, hypophysitis in 3, and hepatitis and dermatitis in 1 each). **Conclusions:** Ipi induced clinical responses in pts with AM with similar ORR, PFS, and OS compared to unselected populations. Treatment was generally well-tolerated with a comparable toxicity profile to previous trials. Ipi remains an appropriate therapy option for pts with advanced AM.

**9057 General Poster Session (Board #261), Sat, 8:00 AM-11:45 AM**

**Vitamin D level at diagnosis and its variation during follow-up as prognostic factor of cutaneous melanoma.** *Presenting Author: Philippe Saiag, Hospital Ambroise Pare, APHP, University Versailles-SQY, Boulogne-Billancourt, France*

**Background:** Low 25-hydroxyvitamin D3 (25(OH)D3) serum concentration at diagnosis of melanoma might be associated with worse survival. We prospectively studied the prognostic value of 25(OH)D3 at diagnosis and during follow-up. **Methods:** Melancohort is a cohort of patients recruited in Paris hospitals in 2003-08 within 1-3 months after diagnosis of AJCC stage I-II, III or IV invasive melanoma and followed until 06/2011. Blood 25(OH)D3 was measured by mass spectrometry. 25(OH)D3 levels were standardized on month of blood drawn, age, sex and body mass index (BMI). Role of 25(OH)D3 level at inclusion and change through time on disease-free survival (DFS) were analyzed in a time dependent covariates Cox model adjusting for age, sex, BMI and AJCC stage. **Results:** 1,171 patients were included, with 411 first relapses during follow-up and 303 deaths. On average 3.25 measures per patient were performed. Median 25(OH)D3 serum concentration at inclusion was 47.2 nmol/L (interquartile range 30.65-63.18). 25(OH)D3 levels at inclusion were inversely correlated with prognostic factors such as AJCC stage (p<0.0001 Kruskal-Wallis), Breslow's thickness (p<0.0001 spearman correlation), and ulceration (p=0.0004 Kruskal-Wallis), but were not associated with DFS in the Cox model, either as a continuous (p=0.747) or categorical variable. Changes in 25(OH)D3 levels during follow-up were significantly associated with worse DFS: with a third quartile Q3 of average change per year (-0.3;4.6nmol/L/Y) used as reference, HR were for Q1 (<-5.25nmol/L/Y) 1.94 95%CI(1.36-2.76), for Q2 (-5.25;-0.30nmol/L/Y) 1.23 95%CI(0.85-1.78), and for Q4 (>4.60nmol/L/Y) 1.61 95%CI(1.14-2.28). In sensitivity analyses, no changes were observed either by AJCC stage or by number of 25(OH)D3 measures performed. Analyses performed on overall survival yielded similar results. **Conclusions:** We show that 25(OH)D3 variation during follow-up is an independent melanoma prognostic marker, but not its level at diagnosis. The biological significance of this finding should be investigated. Previously reported association between low 25(OH)D3 level at diagnosis and poor prognosis were probably due to insufficient adjustment for prognostic factors. Clinical trial information: NCT00839410.

**9058 General Poster Session (Board #262), Sat, 8:00 AM-11:45 AM**

**Dissecting the effect of age on immune response in melanoma patients.** *Presenting Author: Nathaniel H. Fleming, Ronald O. Perelman Department of Dermatology, NYU Langone Medical Center, New York, NY*

**Background:** Older ageat diagnosis has been shown to be an independent negative prognostic factor in melanoma. Nevertheless, no biological basis for the impact of age on melanoma has been defined. In this study, we examined the impact of patient age on cellular immune response as well as response to immunotherapy treatment in the adjuvant setting in a well-studied cohort of melanoma patients. **Methods:** A prospectively-enrolled cohort of patients presenting with stage III melanoma at NYU was studied. Associations between age at diagnosis and presence of tumor-infiltrating lymphocytes (TILs), response to immunotherapy, and stage IV progression-free survival (PFS) and overall survival (OS) were tested by log rank test. In addition, checkpoint PD-L1 expression was tested in pre-treatment tumor specimens in a subset of patients. **Results:** 316 patients (median follow-up for survivors: 45 months) were studied and categorized into two groups by age at diagnosis: ≤60 years (n=163) and >60 years (n=153). The two groups were well matched by clinical substage at presentation. Patients in the older group had significantly shorter OS compared to the younger group (P=0.039). TILs were absent in a significantly larger proportion of the older compared to younger group (35% versus 21%, respectively; P=0.017). Among patients who received adjuvant immunotherapies (n=86), patients in the older group had significantly shorter OS (P=0.048), with a similar trend for PFS (P=0.059). No significant survival differences were observed among patients who received non-immunotherapy treatments (n=57) or no adjuvant treatment (n=165). We reasoned that PD-L1 expression could explain the difference in response to immunotherapy treatment by age; however, no significant difference was observed in PD-L1 expression by age among 66 cases tested at the time of submission. **Conclusions:** Data suggest that decreased immune response and a consequent lack of response to immunotherapy might be contributing, at least in part, to the worse prognosis of older melanoma patients. PD-L1, a key inhibitory receptor, does not seem to be responsible for the observed impaired immune response. Treatment strategies for melanoma patients may need to account for biological differences by patient age.

**9059 General Poster Session (Board #263), Sat, 8:00 AM-11:45 AM**

**Clinicopathologic characteristics and management trends of cutaneous melanoma among older patients: A National Cancer Data Base (NCDB) analysis.** *Presenting Author: Vijaya Raj Bhatt, University of Nebraska Medical Center, Omaha, NE*

**Background:** The incidence and mortality of elderly melanoma are expected to increase. Prior studies have shown poor outcomes in elderly melanoma patients. **Methods:** This is a retrospective study of adult patients diagnosed with cutaneous melanoma between 2000 and 2011 in the NCDB. NCDB contains ~70% of new cancer diagnosis from >1,500 American College of Surgeons-accredited cancer programs in the US and Puerto Rico. Characteristics and management of elderly melanoma (≥60 years) was compared to younger patients (20-59 years) using Chi-square test. **Results:** Of 476,623 total cases, 54% (n=258,153) were diagnosed among older patients. The annual incidence in the older patients increased by 174% (15,910 in 2000 vs. 27,669 in 2011). The majority were white (96%), males (65%), early-stage disease (75% stage 0-II), superficial spreading melanoma histology (39%), and received care in non-academic centers (70%). Elderly patients, compared to younger patients, were more likely to be male, and have in-situ melanoma, less likely to have nodal metastases, receive care in academic centers, undergo wide excision or major amputation for stage I-III disease and systemic therapy for stage III and IV disease (all p<.0001; Table). **Conclusions:** Our study demonstrates a near-doubling of the incidence of melanoma in elderly in the last decade, which disproportionately affects white men. To our knowledge, this is the largest study to demonstrate that the elderly melanoma patients are less likely to receive care in academic centers, undergo wide-excision for stage I-III disease and receive systemic therapy for Stage III-IV. Particularly, the utilization of systemic therapy was markedly lower. All or some of these health care discrepancies may contribute to decreased survival of elderly patients with melanoma.

**Is transhepatic chemoembolization with CPT-11 charged microbeads in combination with systemic fotemustine (f-TACE) effective in uveal melanoma liver metastases? A retrospective analysis of 127 consecutive patients.** *Presenting Author: Sara Valpione, Veneto Research Oncology Institute, Padova, Italy*

**Background:** Uveal melanoma is a rare cancer, it represents 5% to 6% of all melanoma diagnoses (annual incidence approximately 0.5-0.7:100000). Up to 50% of patients with UM will develop metastatic disease within 15 years from the treatment of primary tumor. The preferred spread is hematogenous and the liver is the first or prevalent site of metastatic disease in up to 95% of the recurring patients. The median survival time of metastatic uveal melanoma is generally poor, with reported median life expectancy from 3.6 to 15 months and no standard therapy established so far. **Methods:** We retrospectively reviewed our database of patients treated at Veneto Region Oncology Research Institute for metastatic uveal melanoma, grouped by liver replacement percentage, to evaluate the benefit of treatment with transarterial chemoembolization with CPT-11 charged microbeads combined with systemic fotemustine (f-TACE) in this set of patients. From 1990 to 2013, 156 patients were treated for metastatic uveal melanoma in our Centre. Among them, 147 patients had liver metastases and 127 had enough information recorded to perform the study and were analyzed. **Results:** Among 127 patients with liver metastases, 49 were treated with f-TACE as first line-therapy. The cohort of patients treated with f-TACE and the cohort that did not receive f-TACE were not significantly different for prognostic factors. The treatment with f-TACE conferred a survival advantage (20.6 vs 14.7 months, respectively; p=.050); the advantage was maintained when analysis was performed with stratification for liver metastatic substitution (HR= 0.58, p=.002). The treatment was not affected by severe toxicities. **Conclusions:** F-TACE seems a tolerable regimen that confers an improvement in survival of uveal melanoma patients with liver metastases. Our data prompt for the conduction of perspective comparative studies confirming the efficacy of f-TACE and, in the future, we advise combination treatments with targeted drugs.

**9061 General Poster Session (Board #265), Sat, 8:00 AM-11:45 AM**

**Vemurafenib treatment in patients with BRAF-mutated melanoma failing MEK inhibition with trametinib.** *Presenting Author: Helen Gogas, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece*

**Background:** Trametinib was shown to improve progression-free and overall survival in patients with metastatic melanoma with a BRAF V600E or V600K mutation as compared with chemotherapy in the METRIC trial. However, the median duration of response was 5.5 months and median progression-free survival was 4.8 months in the Trametinib group. Vemurafenib and Ipilimumab were still investigational when this trial was initiated but were available in clinical trials for post-protocol treatment. **Methods:** In this phase III trial 98 patients out of the 322 patients of the intent to treat population who had metastatic melanoma with a V600E or V600K mutation received Vemurafenib (960mg twice daily orally). We present data of patients with complete information on initiation and discontinuation date of Vemurafenib and investigator reported response. **Results:** With a median follow-up of 18.3 months, the median progression free survival (PFS) was 5.2 months with 95% CI 3.7-5.7 and a range of 0.5-27.5+ months. The 6 months PFS was 40.1%. The median overall survival (OS) was 8.3 months with 95% CI 7.1-10.6 and a range of 0.5-27.5+. The 6 months OS was 68.1%. Nineteen patients achieved a partial response and one a complete response. **Conclusions:** Treatment with vemurafenib had an impact on progression free survival post trametinib treatment in patients receiving a MEK inhibitor in first or second line setting. Sequencing BRAF inhibitors with MEK inhibitors and combinations are currently under investigation.

**9062 General Poster Session (Board #266), Sat, 8:00 AM-11:45 AM**

**Effect of the BRAF inhibitor LGX818 on endoplasmic reticulum stress and sensitivity of NRAS-mutant melanoma cells to the MEK inhibitor binimetinib.** *Presenting Author: Friedegund Elke Meier, University of Tuebingen, Tuebingen, Germany*

**Background:** The BRAF inhibitors vemurafenib and dabrafenib have demonstrated antitumor activity in patients with metastatic BRAFV600-mutant melanoma. However, patients with BRAF wild-type, in particular patients with aggressive NRAS-mutant melanoma, do not benefit. In a phase 2 trial, the MEK inhibitor binimetinib showed activity in patients with NRAS-mutant melanoma with overall response rates of >20%. In a previous study, we showed that the BRAF inhibitor vemurafenib induces apoptosis in BRAFV600-mutant melanoma cells through a mechanism involving induction of endoplasmic reticulum (ER) stress. ER stress induction appeared to be an off-target effect of vemurafenib that remarkably enhances its pro-apoptotic activity in BRAFV600-mutant melanoma. **Methods:** In this study, we investigated whether it is possible to take advantage of ER stress induction to establish effective combination therapies for patients with NRAS-mutant melanoma. **Results:** BRAF-mutant and NRAS-mutant metastatic melanoma cell lines were treated with the BRAF inhibitors vemurafenib, dabrafenib and LGX818, and the classical ER stress inducer thapsigargin, and were subjected to electron microscopy. Of note, LGX818 induced morphological features of ER stress, including a significant dilation of the ER in both BRAF-mutant and NRAS-mutant melanoma cell lines. As expected, LGX818 inhibited phosphorylation of ERK and growth and induced apoptosis in BRAF-mutant but not in NRAS-mutant melanoma cells. However, LGX818 significantly enhanced growth inhibition and apoptosis induced by the MEK inhibitor binimetinib in NRAS-mutant melanoma cells. Moreover, LGX818 in combination with binimetinib induced the expression of the ER stress-related factors p8, ATF4, ATF3, CHOP and TRB3 in NRAS-mutant melanoma cells. siRNA inhibition of ATF4 reduced melanoma cell apoptosis induced by LGX818 combined with binimetinib. **Conclusions:** These data suggest that the BRAF inhibitor LGX818 induces endoplasmic reticulum stress and potentiates the antitumor activity of MEK inhibitors in NRAS-mutant melanoma.

**9063 General Poster Session (Board #267), Sat, 8:00 AM-11:45 AM**

**Effect of pregnant sera and a pregnancy-associated metalloproteinase (PAPP-A) on melanoma in vitro and in vivo: Insights into melanoma progression during pregnancy and potential new therapeutic targets.** *Presenting Author: Prashanth Prithviraj, LUDWIG INSTITUTE FOR CANCER RESEARCH, Heidelberg, Australia*

**Background:** At $45/10^5$pregnancies, Malignant Melanoma (MM) is the commonest cancer diagnosed in pregnant women. An aggressive course & poor outcomes are recognised to occur during pregnancy. IGF1 plays an important role in embryogenesis & cancer progression. IGF1 circulates as a complex with IGFBP4, which is cleaved by Pregnancy-Associated Plasma Protein-A (PAPP-A), resulting in release of IGF1. PAPP-A serum levels increase exponentially during pregnancy. **Methods:** 8 MM cell lines were cultured with pregnant & normal sera. Effect on proliferation (MTS) & invasion/migration (wound healing & matrigel transwell assays) were analysed. PAPP-A expression in human MM & cell lines was analysed by PCR, ELISA & IHC. Transient siRNA knock-down of PAPP-A & downstream gene/protein expression were confirmed. Functional assays were performed after PAPP-A knockdown at 24, 48 & 72hrs. An avian neural crest cell migration assay was used to confirm effects in-vivo. Furthermore, effect of PAPP-A neutralising Ab on cell motility & migration induced by sera was analysed. **Results:** PAPP-A is widely expressed in MM tumors and cell lines. While the proliferation of MM cells did not change with PAPP-A knockdown, migratory & invasive capacity was significantly decreased (>40% $p<0.05$). This effect was confirmed in-vivo. The neutralizing Ab attenuated invasion and migration of MM cells, confirming the knockdown results. PAPP-A levels in pregnant sera were 70-fold higher than in control sera. Treatment of MM cells with this serum led to decreased proliferation, but enhanced migration & invasion of MM cells in-vitro. Using an antibody against PAPP-A to evaluate its role in this, we detected a reversion of pregnant serum-induced invasion and migration. **Conclusions:** Pregnant sera enhances the migratory & invasive behaviour of MM cells in-vitro, which can be effectively attenuated by Ab against PAPP-A. Reduced invasion & migration after PAPP-A knockdown suggests a potential therapeutic target in treatment of MM. This study also gives an indication towards a biological mechanism (PAPP-A) involved in MM progression during pregnancy.

**9064 General Poster Session (Board #268), Sat, 8:00 AM-11:45 AM**

**Is extensive lymphadenectomy necessary for regional control of stage III cutaneous melanoma?** *Presenting Author: Manabu Fujita, John Wayne Cancer Institute, Santa Monica, CA*

**Background:** The extent of regional lymphadenectomy in stage III melanoma is still controversial because most recommendations are not based on statistical analysis of the minimum number of excised nodes necessary to minimize regional recurrence. **Methods:** We used our center's melanoma database to identify all patients diagnosed with stage III neck, axillary or inguinal regional metastasis of cutaneous melanoma between 1971 and 2010. We then excluded cases with multiple tumor-involved nodal basins, multiple primaries, <4 removed nodes, or local/ in-transit recurrence. Univariate and multivariate analyses assessed the prognostic significance of demographic and tumor-related variables, including basin site and number of excised nodes, with respect to rates of 5-year regional recurrence-free survival (RRFS) and 10-year melanoma-specific survival (MSS). **Results:** Of 2,748 patients, 785 with regional neck (N=152), axillary (N=387) or inguinal (N=246) metastasis were eligible for study. These patients underwent removal of 4-79 neck nodes (mean 28.8), 4-65 axillary nodes (mean 18.6), or 4-64 inguinal nodes (mean 16.4). Neck, axillary and inguinal regional recurrence rates were 11.8% (18/152), 6.5% (25/387), and 9.8% (24/246), respectively. By multivariate analysis, 5-year RRFS was significantly improved when 20 or more nodes were removed ($p=0.02$) in neck basins, when 10 or more nodes were removed in inguinal basins ($p=0.01$), or when nodes were not palpable in neck ($p=0.05$) or axillary basins ($p=0.02$). The most significant prognostic factor for 10-year MSS was regional recurrence in any of the three sites ($p<0.01$). **Conclusions:** Removal of at least 10 nodes from groin basins and at least 20 nodes from neck basins should minimize regional recurrence in patients with stage III cutaneous melanoma. Comparable recommendations for the axillary basin will likely require meta-analyses that incorporate extracapsular extension and genomic biomarkers.

**9065 General Poster Session (Board #269), Sat, 8:00 AM-11:45 AM**

**A comparison of cutaneous melanoma patients who recur following a negative sentinel lymph node biopsy to those with a positive sentinel lymph node biopsy.** *Presenting Author: Edward L Jones, University of Colorado, Aurora, CO*

**Background:** Sentinel lymph node biopsy (SLNB) for cutaneous melanoma yields powerful prognostic information. Patients with a negative SLNB who recur experience worse outcomes than those with a positive SLNB based upon subgroup analysis in the Multicenter Selective Lymphadenectomy Trial (MSLT-1). The PURPOSE of this study was to compare our patients who recur following a negative SLNB to those with a positive SLNB. **Methods:** Retrospective chart review of a prospectively created database of patients with cutaneous melanoma undergoing SLNB from February 1995 to January 2013. **Results:** Of 1017 patients who underwent SLNB, 170 (17%) recurred after a negative biopsy: 60 (35%) were local/in-transit recurrences, 33 (19%) regional and 73 (43%) distant at a median 27 months (range 15-50 months). One hundred and fifty-seven (15%) patients had a positive SLNB of which 131 (77%) underwent completion lymph node dissection (CLND). Fifty-six (36%) of those patients recurred a median 14 months later (range 8-30 months). The median length of follow-up for entire cohort was 43 months (range 1-170 months). Patients with recurrence after a negative SLNB were more likely to be male (64% vs. 50%, $p=0.02$) but age, Breslow depth, ulceration, mitotic activity and the use of adjuvant therapy were not statistically different. Twenty-nine (88%) of the 33 patients with regional recurrence after a negative SLNB underwent CLND. These patients had significantly more positive nodes in the CLND specimens than those undergoing CLND for a positive SLNB (69% vs. 22%, $p<0.001$). While disease-specific survival was not significantly different between patients with recurrence after a negative SLNB versus a positive SLNB at 5 years (56% vs.77%, $p=0.14$) this became significant at 10 years (28% vs. 68%, $p<0.001$). **Conclusions:** Patients with cutaneous melanoma who recur following a negative sentinel lymph node biopsy have worse survival when compared to those with a positive biopsy. These findings support the subgroup analysis of the MSLT-1 trial and suggest that patients with recurrence following a negative sentinel lymph node biopsy exhibit aggressive tumor biology.

**9066 General Poster Session (Board #270), Sat, 8:00 AM-11:45 AM**

**A randomized phase II study of ipilimumab (IPI) with carboplatin and paclitaxel (CP) in patients with unresectable stage III or IV metastatic melanoma (MM).** *Presenting Author: Rahima Jamal, Centre Hospitalier de l'Université de Montréal - Hopital Notre-Dame, Montreal, QC, Canada*

**Background:** MM has been one of the most treatment-resistant human malignancies. Recently, IPI, a fully human anti-CTLA4 monoclonal antibody has been widely approved for patients (pts) with MM on the basis of increased overall survival (OS). CP is one of few therapies available to pts with BRAF wild type MM that is progressing rapidly. We hypothesized that cytoreduction by CP might both provide time for IPI response, as well as expose immune cells to tumor antigens. In addition to safety and anti-tumor activity, immune biomarker studies were performed. **Methods:** Thirty pts with no prior treatment or one BRAF targeted regimen were randomized in a 1:2 ratio to either concurrent (arm A) or sequential (arm B) CP (AUC6 + 175mg/m$^2$ x 5) with IPI (3mg/kg x 4) given every 3 weeks either concurrently or delayed by one week. Tumor assessments were conducted at week 8, 16 and 24. **Results:** We enrolled 24 cutaneous, 2 mucosal, 3 ocular and 1 unknown primary melanoma. Median age was 55 years and 6 of 8 BRAF mutated pts previously received vemurafenib. Twenty-five pts (83%) received all 5 cycles of CP while 28 pts (93%) completed IPI induction. Two pts died prior to week 16 of disease progression, while 3 patients discontinued CP because of toxicity. Overall median follow-up was 24 weeks (8-24). Response rates (RR) and disease control rates (DCR) for 14 evaluable patients at 24 weeks were 21.4% and 42.9% by mWHO, and 35.7% and 64.3% by irRC, respectively. There were no treatment-related deaths on trial. Grade 3-4 AEs regardless of causality were seen in 63% of pts. CP-related Grade 3-4 AEs were found in 47% of pts in the form of hepatotoxity, electrolyte imbalances, myelosuppression and infections. Grade 3-4 anemia occurred in 3 pts while thrombocytopenia occurred in 2 pts. The rate of febrile neutropenia was 7% (2/30). Seventeen per cent (5/30) of patients received steroids for an immune-related (ir) AE: 2 pts with Grade 3 colitis, 2 pts with Grade 2 endocrinopathy, and 1 pt with Grade 2 rash. **Conclusions:** Safety results suggest manageable toxicity when CP is added to IPI, with most patients completing the full course of treatment. Updated ORR, DCR, 6 month OS, and immune biomarker studies will be presented. Clinical trial information: NCT01676649.

**9067 General Poster Session (Board #271), Sat, 8:00 AM-11:45 AM**

**Predictive importance of ulceration on the efficacy of adjuvant interferon-a (IFN): An individual patient data (IPD) meta-analysis of 15 randomized trials in more than 7,500 melanoma patients (pts).** *Presenting Author: Stefan Suciu, EORTC Headquarters, Brussels, Belgium*

**Background:** Many randomised trials have evaluated the role of adjuvant IFN in high-risk melanoma, some suggesting benefit and others not. To assess the evidence of IFN vs. no IFN, an IPD meta-analysis of these trials was performed. **Methods:** Standard IPD meta-analysis methods were used to assess event-free (EFS) and overall survival (OS), with odds ratios (OR) and confidence intervals (CI) calculated. Trials were divided by dose of IFN – high (10-20MU/m$^2$), Peg-IFN (3-6$\mu$g/Kg), intermediate (5-10MU flat), low (3MU flat) and very low (1MU). **Results:** IPD was provided for 11 of 15 reported trials of IFN vs. no IFN (for the other 4 trials published data were used). Over 7500 pts were included in the analysis, with over 4700 and 3800 events for EFS and OS. There was benefit for IFN for both EFS ($P$<0.00001) and OS ($P$=0.003) (Table). This translated into increased 5-year OS from 46.1% to 49.1%. There was no evidence of differences according to dose, duration of IFN, gender, Breslow thickness or disease stage, but ulceration status impacted the IFN benefit regarding EFS (interaction test: $P$=0.04) and OS ($P$=0.002) (Table). For the ulcerated melanoma, IFN increased the OS from 38.1% to 46.0%, at 5 yrs, and from 28.0% to 38.5%, at 10 yrs. **Conclusions:** This meta-analysis provides evidence that adjuvant IFN significantly reduces the risk of relapse and improves overall survival. This analysis does not identify the optimal dose or duration of IFN. OS benefit was confined to pts with ulcerated tumours. The biological basis of this action is incompletely defined, and being studied in the ongoing study (EORTC 18081 and ECOG-ACRIN Intergroup Trial E1609).

**Detection of BRAF mutations in the plasma of melanoma patients as an early marker of treatment efficiency.** *Presenting Author: Marc G. Denis, Department of Biochemistry, Nantes University Hospital, Nantes, France*

**Background:** Mutant BRAF DNA can be detected in plasma of melanoma patients bearing a mutation in their tumor. Detection of these genetic alterations in circulating DNA has potential clinical applications. We investigated the relationship between mutant BRAF in plasma DNA and treatment response. **Methods:** DNA was extracted from plasma using the iPrep PureLink Virus Kit on an iPrep purification system (Invitrogen). BRAF mutations were detected using the Therascreen BRAF RGQ kit (Qiagen). **Results:** Seventeen patients (1 stage IIIC and 16 stage IV) with a mutated BRAF melanoma (V600E in all cases) were included. Pretreatment plasma samples were available in 10 of them, and the BRAF mutation was detected in 8 samples (80% sensitivity). Twelve patients were treated with a BRAF inhibitor, 4 with a combination of a BRAF inhibitor and a MEK inhibitor, and one patient was treated with chemotherapy (DTIC). After 3 months of melanoma treatment, the BRAF V600 mutation was detected in the plasma of 9 patients (9/17; 53,9%). The presence of mutant BRAF in plasma DNA was compared to the clinical response of patients. The BRAF mutation was present in the plasma of 6 out of the 7 patients who did not respond to treatment. In contrast, mutant BRAF DNA was absent from plasma in 7 out of the 10 patients with partial response to treatment (Fisher's exact test : p = 0.04977). Mutant BRAF in circulating DNA was not associated with the number of metastatic sites at the same time (mean 2.625 in patients with mutant BRAF, and 2.22 in patients without mutant BRAF; p = 0.4266, Wilcoxon's test). **Conclusions:** The sensitive detection of mutant BRAF in plasma would be useful for predicting treatment response to targeted therapy. Supported in part by a grant from Roche.

**9070 General Poster Session (Board #274), Sat, 8:00 AM-11:45 AM**

**RAGE ligand S100A8/A9 as a novel prognostic biomarker for high-risk melanoma patients.** *Presenting Author: Christoffer Gebhardt, German Cancer Research Center (DKFZ), Heidelberg, and University Medical Center Mannheim, Ruprecht-Karl University of Heidelberg, Mannheim, Germany*

**Background:** We have recently demonstrated that the receptor for advanced glycation end-products (RAGE) is a central driver of tumorigenesis by sustaining a chronic inflammatory tumor microenvironment. This study aimed at identifying novel prognostic biomarkers for melanoma by a hypothesis-driven approach linking RAGE signaling-related serum markers with clinical outcome of melanoma patients. **Methods:** Plasma concentrations of the soluble form of RAGE (sRAGE) were analyzed in 173 plasma samples of stage I-IV melanoma patients (cohort 1). Serum concentration of RAGE-related markers sRAGE, S100B, S100A8/A9, and HMGB1 were measured in an independent second cohort of 240 metastasized stage III-IV patients and compared to established prognostic markers including sub-stage and lactate dehydrogenase (LDH). All analyses were performed by enzyme-linked immunosorbent assays. **Results:** sRAGE was strongly associated with overall survival (OS) and progression-free survival (PFS) in cohort 1. A detailed analysis of different RAGE-related serum markers was thereafter performed in cohort 2. Analysis of OS of stage III patients showed that elevated S100A8/A9 independently increased mortal risk in addition to sub-stage IIIB or sub-stage IIIC as compared to sub-stage IIIA. Increased S100B, S100A8/A9, and HMGB1 were independently indicating worse PFS in stage III/IV patients. The analysis of S100A8/A9 and S100B was the best combination to predict PFS and improved the sensitivity to identify patients with later progression from 34.2% (S100B) to 58.2% (S100A8/A9 + S100B). **Conclusions:** The RAGE ligand S100A8/A9 is a powerful independent prognostic marker for OS of stage III patients and contributes substantially to standard biomarker S100B for the identification of patients with high risk for progression.

**9071 General Poster Session (Board #275), Sat, 8:00 AM-11:45 AM**

**Adjuvant therapy with pegylated interferon alfa-2a (PEG-IFN) versus low-dose interferon alfa-2a (IFN) in patients with malignant melanoma in stages IIa(T3a): IIIb (AJCC 2002)—Decog-trial.** *Presenting Author: Thomas K. Eigentler, Department of Dermatology, University of Tübingen, Tübingen, Germany*

**Background:** Adjuvant treatment with IFN improved disease free survival (DFS) and showed a trend for improving overall survival (OS). PEG-IFN has a prolonged half life time and is just given once weekly. This trial was designed to examine if PEG-IFN is superior to IFN in regard to distant metastasis free survival (DMFS), DFS and OS. **Methods:** In this multicenter, open-label, prospective randomized phase III trial, patients (pts) with resected cutaneous melanoma stage IIA(T3a)-IIIB (AJCC 2002) were randomized to receive IFN (3 MU subcutaneously [sc] 3x/week; 24 months) or to PEG-IFN (180 mcg sc 1x/week; 24 months). Randomization was stratified for tumor stage, number of metastatic nodes, patient's age and previous interferon treatment. Primary endpoint was DMFS, secondary endpoints were OS, DFS, quality of life and tolerability. Sample size (880 pts) was calculated on an expected difference of 55% *vs* 45% in the 5 years DMFS rate and assuming 80% power (2-sided, significance level 5%). Non-parametric survival models using log-rank tests and Cox regression models were performed on the ITT population. **Results:** Of 909 pts enrolled, 907 (451 PEG, 458 IFN) were eligible for evaluation after a median follow-up of 5.0 years. Neither DMFS (PEG-IFN 65.1% *vs* IFN 70.2%, p=0.18; HR, 1.16; 95% CI, 0.92-1.5) nor OS (74.2% *vs* 74.8%, p=0.13; HR, 1.05; 95% CI, 0.81-1.37) nor DFS (57.9% *vs* 60.8%, p=0.49; HR, 1.06; 95% CI, 0.86 to 1.31) showed significant differences. Subgroup analyses of PEG-IFN *vs* IFN in pts +/- ulcerated primaries and of different tumor stages did not find differences in DMFS, OS or DFS. 118 pts (26.1%) in the PEG-IFN and 61 pts (13.3%) in the IFN population did not receive the scheduled full dose and length of treatment due to adverse events ($p<0.001$). Leucopenia (CTC grade 2+) and elevation of liver enzymes (grade 2+) were more frequent in the PEG-IFN arm (56% *vs* 23.5% LCP; 19.1% *vs* 9.4 % AST; 33.0% *vs* 16.5% ALT). **Conclusions:** PEG-IFN did not improve the outcome parameters over conventional IFN. CTC grade 2+ toxicity was significantly more pronounced and a higher percentage of pts under PEG-IFN discontinued treatment prematurely. Clinical trial information: NCT00204529.

**9072 General Poster Session (Board #276), Sat, 8:00 AM-11:45 AM**

**Preclinical testing supports combined BET and BRAF inhibition as a promising therapeutic strategy for melanoma.** *Presenting Author: Luca Paoluzzi, NYU Cancer Institute, NYU Langone Medical Center, New York, NY*

**Background:** Manipulation of key epigenetic regulators is emerging as a new therapeutic strategy in cancer. Our group recently reported a role for BRD4, a Bromodomain-containing protein and BET family member, in melanoma maintenance (Segura MF et al, Cancer Research 2013). BET inhibition impaired melanoma cell proliferation in vitro and tumor growth and metastatic behavior in vivo. Here we investigated the effect of combining the BET inhibitor JQ-1 with the B-RAF inhibitor Vemurafenib in in vitro and in vivo models of B-RAF mutated melanoma. **Methods:** We performed cytotoxicity and apoptosis assays, and a xenograft mouse model to explore the in vitro and in vivoactivity of JQ-1 alone or in combination with Vemurafenib in melanoma. We conducted RNA sequencing of xenograft tumors, quantitative RT-PCR and immunoblottings to investigate the mechanisms underlying the effects of combined BET and B-RAF inhibition. **Results:** In vitro, the BET-inhibitor JQ-1 exhibited time and concentration-dependent cytotoxicity against a panel of B-RAF mutant melanoma cell lines. When combined with JQ-1, Vemurafenib showed synergism and significant apoptosis in vitro. In a xenograft mouse model of melanoma, the addition of JQ-1 to Vemurafenib enhanced the ability of either drug alone to suppress tumor growth and significantly improved survival. Tumors treated with BET and B-RAF inhibitors had reduced proliferative index, as revealed by Ki67 immunostaining. Pathway analysis of RNA sequencing data of mouse tumor tissues showed a significant impact on transcriptional programs controlling cell growth, proliferation, angiogenesis, cell-cycle regulation and differentiation. **Conclusions:** Collectively, our data provide a rationale for combined BET and B-raf inhibition as a novel strategy for the treatment of melanoma.

**9073 General Poster Session (Board #277), Sat, 8:00 AM-11:45 AM**

**The Memorial Sloan Kettering Cancer Center (MSKCC) experience of systemic therapy in mucosal melanoma.** *Presenting Author: Christiana Bitas, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Mucosal melanoma (MM) is a molecular and clinical subset of melanoma distinct from cutaneous melanoma (CM). The activity of systemic therapy (tx) in MM has not been rigorously evaluated. We performed a retrospective, single center analysis of MM patients (pts) treated with systemic tx. **Methods:** Using institutional databases, we identified pts with MM who were 1) treated at MSKCC between 1998-2012; 2) developed unresectable or metastatic disease (dz); 3) received ≥1 non-adjuvant systemic tx; 4) had scans available for blinded central radiology review using RECIST 1.1. Pt demographics and clinical outcomes were extracted. **Results:** 61 pts met inclusion criteria. Median age at diagnosis 64 years (range, 35-84); 71% female; primary site: 28 anorectal, 19 vulvovaginal, 13 head/neck, 1 gallbladder. Mutation (mut) status: 8/35 KIT mut (7 exon 11; 1 exon 13); 3/33 BRAF mut (all non V600mut); 3/33 NRAS mut. At time of 1st tx, 55 had metastatic dz (10 M1a, 6 M1b, 39 M1c) and 6 had locally advanced dz. Pts received 106 1st or 2nd-line systemic tx: 81 cytotoxic (24 single-agent alkylators [eg. TMZ, DTIC]; 47 alkylator-based combinations [eg. Cisplatin/Vinblastine/TMZ]; 10 other combinations); 11 immunotherapy [7 ipilimumab, 2 high-dose IL-2, 2 other]; 9 targeted [8 KIT inhibitors, 1 BRAF inhibitor]; 4 biochemotherapy; 1 other investigational tx. Overall response rate (RR) rate to 1st and 2nd-line tx was 16% and 13%, respectively, with no complete responses. 24-week (wk) dz control rate with 1st and 2nd-line tx was 20%, and 9%, respectively. RR in either 1st or 2nd-line to single-agent and combination alkylator tx was 8% (2/24), and 15% (7/47), respectively (p=0.71). RR to targeted tx and immunotherapy was 33% (3/9), and 9% (1/11), respectively. Median time to treatment failure (earlier of date of progression or change in therapy) was 11 wks (95% confidence interval [CI] 8-14 wks) for both 1st and 2nd line tx. Median overall survival (OS) from initiation of 1st-line tx was 11 mo (95% CI 8-13 mo). **Conclusions:** The efficacy of systemic tx in MM is modest and appears similar to that seen in CM. Clinical outcomes for this pt population are poor. Further investigation into the biology and treatment of MM is needed.

**9074 General Poster Session (Board #278), Sat, 8:00 AM-11:45 AM**

**Assessment of overall survival from time of metastastasis in mucosal, uveal, and cutaneous melanoma.** *Presenting Author: Michael Andrew Postow, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Rarer subtypes of melanoma such as mucosal melanoma (MM) and uveal melanoma (UM) are thought to be associated with worse prognoses than cutaneous melanoma (CM). Comparison of OS in pts with MM, UM and CM after diagnosis of stage IV disease, however, has not been rigorously evaluated. **Methods:** We conducted a single-center, retrospective analysis of 2920 pts diagnosed with stage IV melanoma between 2000 and 2013 identified from a prospectively maintained database. Melanoma subtype, date of diagnosis of stage IV disease and date of death were extracted, as were established prognostic variables including age at diagnosis of metastasis, gender and M-stage. **Results:** MM (n=237): median (med) age 66 years (yrs; range 26-91); 65% female; M1a/b/c - 8%/21%/71%. UM (n=286): med age 63 yrs (range 16-86); 46% female; M1a/b/c - 5%/8%/87%. CM (n=2397): med age 62 yrs (range 3-97); 34% female; M1a/b/c - 14%/31%/55%. Differences in age, gender and M-stage were significantly different between groups (p=0.002, $p<0.0001$ and $p<0.0001$, respectively). With a median followup of 46.6 months (mos) and 2192 deaths, the median OS for MM, UM and CM was 9.0 mos (range 0.4-108.1), 13.4 mos (range 0.4-144.0), and 11.7 mos (range 0.1-139.8), respectively. Pts with UM and CM had similar OS (HR: 1.02, p=0.82), but pts with MM had worse OS compared to pts with UM (HR: 1.41, $p<0.001$) and CM (HR: 1.44, $p<0.001$). Pts diagnosed with stage IV melanoma between 2006-2013 (n=1148) had a better OS compared to pts diagnosed between 2000-2005 (n=1773; 13.59 vs. 9.77 mos; $p < 0.001$). In a multivariate model taking into account year of stage IV diagnosis (2000-2005 vs. 2006-2013), age, gender, and M-stage, pts with MM had inferior OS compared to UM and CM. **Conclusions:** MM is an independent poor prognostic factor in pts with stage IV melanoma. Despite distinct tumor biology, similar survivals were observed in stage IV UM and CM. Improved OS in pts treated between 2006-2013 may reflect the efficacy of newer therapies. Stratification by melanoma subtype is warranted in trials including MM.

**9075^ General Poster Session (Board #279), Sat, 8:00 AM-11:45 AM**

**Phase II study of vemurafenib in patients with locally advanced, unresectable stage IIIc or metastatic melanoma and activating exon 15 *BRAF* mutations other than V600E.** *Presenting Author: Sigrun Hallmeyer, Oncology Specialists, SC, Niles, IL*

**Background:** Approximately 50% of metastatic melanoma are activating *BRAF* mutation-positive, most commonly in codon V600. Vemurafenib (VEM), an inhibitor of oncogenic BRAF kinase, has been shown to improve progression-free survival (PFS) and overall survival (OS) in pts with advanced V600E-mutated melanoma (Chapman et al, 2011; NEJM). An open-label phase II trial (NCT01586195) is being conducted to determine the activity and safety of VEM in previously treated or untreated stage IIIC or IV melanoma pts with measurable disease and an activating, non-V600E *BRAF* mutation at exon 15 detected by centralized DNA sequencing. **Methods:** Eligible pts received oral VEM (960 mg bid) until disease progression, unmanageable toxicity, pt request for discontinuation, or other protocol-specified criteria. Tumor responses were evaluated per RECIST v1.1. The primary endpoint was investigator-assessed objective response rate. Time to response, duration of response, PFS and OS, 6- and 12-month survival rates, and safety were additional endpoints. **Results:** As of October 2013, 10 US sites had enrolled 29 pts: 12 with V600K (cohort 1) and 17 with non-V600K mutations (cohort 2 [7 V600R, 3 L597S, 7 others]). Median (range) age was 61 (33-88) years, 86% were male, 45% were stage M1c and 17% unresectable stage IIIC, 28% had brain metastases, and 10% had ECOG PS 2 (the remainder were ECOG PS 0-1). 7% of pts were treatment naive. In pts who had prior therapy for advanced disease, the median (range) number of therapies was 2 (1-6). At this interim analysis, 12/29 pts (41%) had an unconfirmed response (5 V600K, 3 V600R, 4 other). Confirmed responses were observed in 3 pts (all PRs; V600K, V600R, and D594G); there were no CRs. Overall toxicity profile is consistent with the reported experience in melanoma, with the following AEs reported most frequently: fatigue (52%), rash (48%), and arthralgia (38%). 11 pts had ≥1 grade 3-5 AEs, irrespective of causality. We plan to present an updated data cut at ASCO. **Conclusions:** Preliminary results show objective responses in this population of advanced melanoma pts with rarer non-V600E *BRAF* mutations; however, additional follow-up is required. Clinical trial information: NCT01586195.

**9076 General Poster Session (Board #280), Sat, 8:00 AM-11:45 AM**

**Outcome with stereotactic radiosurgery (SRS) and ipilimumab (Ipi) for malignant melanoma brain metastases (mets).** *Presenting Author: Sana Shoukat, Internal Medicine, Emory University School of Medicine, Atlanta, GA*

**Background:** SRS with Ipi for melanoma brain mets has been explored for overall survival (OS). We present the first retrospective analysis to determine if this combination is safe and improves OS, while accounting for lactate dehydrogenase (LDH). **Methods:** Patients with melanoma brain mets who underwent SRS between 1998-2012 (n=176) were compared with those who additionally received Ipi (n=38). The primary endpoint was median OS from time of SRS, calculated using Kaplan-Meier method. Cox proportional hazard model was performed for univariate and multivariable survival analysis. The secondary endpoints were local control (LC), anywhere intra-cranial failure, repeat SRS, and toxicity. Additionally, Propensity Score (PS) method was used to match treatment groups based on patient and disease characteristics, and comparison was made among matched sample. **Results:** Median OS for the cohort was 9.0 months and median follow up was 41.2 months. Patients in the Ipi group had median OS of 28.0 vs. 7.0 months in the non-Ipi group ($p < 0.001$). No difference was noted in LC or anywhere intracranial failures. There was no increased toxicity (radionecrosis, hemorrhage, patient reported memory deficits), or need for repeated SRS in the Ipi group. Multivariate Analysis (Table 1) showed that Ipi independently predicted for improved OS even when taking into account LDH and ECOG performance status. After PS matching, the groups did not differ significantly and multivariable analysis remained unchanged {HR = 2.56 (1.29 – 5.05) ($p = 0.007$)}. **Conclusions:** Use of SRS with Ipi appears to be safe and associated with an increase in OS in patients with melanoma brain mets; this combination should be further investigated.

**Lesion-specific patterns of response and progression with anti-PD-1 treatment in metastatic melanoma (MM).** *Presenting Author: Megan Kate Lyle, Melanoma Institute Australia and University of Sydney, North Sydney, Australia*

**Background:** Anti-PD-1 therapy has demonstrated activity in MM but current data may not fully reflect patterns of response and relapse as discerned by comprehensive lesion-specific analysis. **Methods:** Bidimensional measurements of every metastasis (met) ≥5mm (≥15mm short axis for lymph nodes [LN]) in MM pts enrolled in the MK3475-001 phase 1 trial at a single center were obtained on CT scan at baseline, 12 wks and thereafter. Response of each individual met was determined by change in product of longest perpendicular diameters (POD) and classified as complete (CR, disappearance or <10mm short axis for LN), partial (PR, ≥50% reduction in POD), stable (SD, neither CR/PR/PD) or progressive (PD, ≥25% increase in POD and ≥5mm in 1 axis). Overall pt response was investigator determined using standard immune related response criteria (irRC). **Results:** 27 evaluable pts with med. follow up of 54 wks had a total of 442 discrete mets at baseline (med. 10/pt; range 2-68/pt; med. POD 129mm$^2$). 13/27 (48%) pts had an irRC objective response (OR), 11 (85%) by first scan. Med. time to best response in pts with OR was 24 wks. Although only 1/27 pts had CR (3.7%), 228/442 (52%) individual mets underwent CR and 81% of pts (22/27) had ≥1 CR met at first scan. CR mets were smaller than non-CR [med. POD 80 vs 246mm$^2$($p<0.05$)] but 92/244 mets (38%) ≥100mm$^2$ reached CR. CR rate was highest in lung vs other sites combined ($p<0.05$) (Table). Only 1 CR met subsequently progressed. Of 12 (44%) pts who progressed only 1 had prior OR. 10 (83%) of these pts PD in new and existing mets simultaneously. No site of PD predominated; only 1 pt (8%) PD in brain. 98/442 baseline mets (22%) progressed and most (74%) had PD as best response. Of 80 new or growing mets at first scan, only 4 (5%) subsequently had OR. **Conclusions:** Response to anti-PD1 therapy is rare in mets that are new or growing at first scan. CR in individual mets is common, sustained, and influenced by site and size. These results have implications for the biology of PD-1 inhibition, resistance, biomarker development and patient selection.

**9078 General Poster Session (Board #282), Sat, 8:00 AM-11:45 AM**

**Safety and clinical activity of combining systemic ipilimumab with isolated limb infusion in patients with in-transit melanoma.** *Presenting Author: Charlotte Eielson Ariyan, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Isolated limb infusion(ILI) for melanoma results in a limb response(CR + PR) of 50%, with 11% of patients progression free(PFS) at one year. Ipilimumab(10mg/kg) for M0 melanoma has an overall response rate of 8.3% (95% CI, 0.2-38.5). This phase II trial evaluated the safety and efficacy of ILI with melphalan and dactinomycin followed by systemic ipilimumab(IPI). **Methods:** Melanoma patients with regional disease (stage IIIb/c ) alone or in combination with distant disease (Stage IV) underwent ILI (melphalan + dactinomycin,7.5mg and 75 mcg/kg/limb volume). Within a median of 12 days (range 7-15) after limb infusion, patients received systemic IPI(10mg/kg) q3w x 4 doses. Patients received maintenance IPI (q3months x 2 years) if there was disease control and no limiting toxicity. The primary endpoint was PFS at one year, secondary endpoints were limb response and toxicity. **Results:** As of January 2014, 18 patients were enrolled; 88% of patients were stage IIIB/C and 12% were Stage IV. Weiderbink grade 2--3 limb toxicity was seen in all patients; no patient required a fasciotomy or amputation. Related adverse events(rAE) for sequential therapy occurred in 78% of patients (grade1-3). rAE included colitis (n=8, grade 2-3), hypophysitis (n=5, grade 2), and rash (n=6, grade 1-2); all were medically managed. At 3 months, 89% of patients had a limb response, 65% of which were complete (CR) and 24% were partial responses(PR). One patient had SD, and one patient had POD. With a median follow-up of 18 months, OS is 78%, 2 patients died of melanoma, one died of a pulmonary embolus 60 days after ILI, and one died of complications of pneumonia 6 months after ILI. PFS at one year is 57%. Of the 11 patients with a CR in the limb, 1 subsequently progressed in the limb and 1 progressed outside of the limb. The ALC and eosinophils increased in all patients (ALC mean of .99 after ILI to 1.8 after IPI, eosinphils mean 1.5 to 10.3 during therapy with IPI, $p<0.05$). **Conclusions:** Combination treatment with ILI and Ipilimumab is safe , with no limb threatening toxicity. The response rates and progression free survival are encouraging and support further studies of limb infusion in combination with immune checkpoint blockade. Clinical trial information: NCT01323517.

**9079 General Poster Session (Board #283), Sat, 8:00 AM-11:45 AM**

**Treatment with tumor-infiltrating lymphocytes (TIL) in metastatic melanoma and clinical benefit regardless of site of origin, mutation status, or prior checkpoint blockade.** *Presenting Author: Isabella Claudia Glitza, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** In this report we describe the association of specific patient attributes, such as mutation status, prior treatment with checkpoint blockade, and location of primary tumor with treatment response to therapy TIL therapy. **Methods:** Stage IIIc-IV patients (pts) were enrolled and treated in an ongoing non-randomized phase II TIL trial at MD Anderson Cancer Center. Cox proportional hazards regression (overall survival (OS), progression-free survival (PFS)) and logistic regression (response) were used to assess the association between outcomes and covariates of interest. **Results:** 56 (19 female, 37 male) pts were enrolled. Most common site of origin was cutaneous (N=45), while a subgroup of pts had melanoma derived of acral (N=7) or mucosal origin (N=3). Staging (69% MIc), mutational status (BRAF V600, NRAS mutations) or the presence of brain metastasis did not significantly impact the odds of response or survival (OS, PFS). Overall response rate was 44% (2 pts CR, 22 pts PR) in 54 pts available for analysis, while stable disease was observed in 20 pts. 22 pts received prior checkpoint blockade with ipilimumab and/or anti-PD1. Among subgroups of pts, 30% of the acral/mucosal melanoma pts, 30% of the pts with previous checkpoint blockade and 53% of patients with BRAF V600 mutations responded. Higher numbers of CD8+ T-cells infused was significantly associated with greater likelihood of response (p=0.03) and longer PFS (p=0.01). PFS was significantly worse (p=0.01) after prior checkpoint blockade (1-year PFS: 14% versus 27%) and with higher pre-treatment LDH level (p= <0.001) and ECOG PS score (p=0.002). OS was not affected by site of origin (1-year OS: 68% acral/mucosal), BRAF V600 status (62%), or prior checkpoint blockade (61%). Higher ECOG PS score (p=<0.001) and LDH level (p=<0.001) were associated with greater risk of death. **Conclusions:** Patients with BRAF V600 mutations and with mucosal or acral origin do benefit from TIL therapy. Despite shorter PFS**,** patients that had previously failed checkpoint blockade therapy still experience benefit from TIL therapy, arguing its use in this highly refractory population.

**9080 General Poster Session (Board #284), Sat, 8:00 AM-11:45 AM**

**The impact of clinical response to anti-CTLA4 treatment on overall survival (OS) in metastatic melanoma (MM).** *Presenting Author: Xiaolan Feng, Tom Baker Cancer Centre, Calgary, AB, Canada*

**Background:** It is well known that response to anti-cytotoxic T lymphocyte antigen 4 (anti-CTLA4) treatment can be durable in patients with MM. But it is not known whether clinical response to induction anti-CTLA4 treatment would translate into an OS benefit. Furthermore, predictors of response to anti-CTLA4 agents are not well-established. **Methods:** We performed a retrospective analysis on one hundred patients treated with anti-CTLA4 agents from 2006-2013 in two tertiary cancer centers in Alberta, Canada. Clinical and tumor characteristics, treatment response, toxicity, and survival data were collected through chart review. Clinicians evaluated response based on immune related response criteria. We performed Kaplan-Meier survival analysis, log-rank test and cox proportional hazards model to compare variable groups and univariable analysis using logistic regression to look for factors associated with clinical response to anti-CTLA4 agents. All statistical analyses were carried out using SAS software. **Results:** Striking differences in median OS (mOS) were observed in responders, defined as complete response (CR) plus partial response (PR), and non-responders defined as stable disease (SD) plus progressive disease (PD) (not reached; greater than 36.1 versus 6.9 months, 95% confidence interval (CI) 3.6-10.9, p<0.0001, respectively). A 9 fold difference in mOS was seen between patients with disease control (CR+PR+SD) and those with PD on induction treatment: 36.1 months (95%CI: 22.9-51.4) versus 4.0 months (95%CI: 3-6.7), respectively (p <0.0001). Only host-tumor immunological parameters were associated with a response to anti-CTLA4 treatment. Brisk, as opposed to non-brisk, tumor infiltrating lymphocytes in the primary tumor (p=0.003) and immune mediated side effects (p=0.048) were associated with response in univariable analysis. **Conclusions:** Our retrospective study, although limited by small population size, reveals that response to induction anti-CTLA4 agents is a dominant predictor for survival. Host-tumor immunological parameters may be important determinants for response to anti-CTLA4 agents, although these need to be prospectively validated.

**9081 General Poster Session (Board #285), Sat, 8:00 AM-11:45 AM**

**Vismodegib for advanced basal cell carcinoma: Duration of response after vismodegib discontinuation and response to vismodegib retreatment upon disease progression.** *Presenting Author: Aleksandar Sekulic, Mayo Clinic, Scottsdale, AZ*

**Background:** Vismodegib (VISMO) (Erivedge) is a first-in-class Hedgehog pathway inhibitor (HPI) approved for advanced basal cell carcinoma (aBCC). In the ERIVANCE trial, VISMO-treated patients (pts) demonstrated objective response rates (ORRs) by independent review of 30% in metastatic BCC (mBCC; n=33) and 43% in locally advanced BCC (laBCC; n=63). ORRs by investigator (INV) review were 45% (mBCC) and 60% (laBCC). Treatment on VISMO may be prolonged, and a number of pts discontinued treatment prior to progression on therapy. Here we provide results from a survey designed to assess durability of response in laBCC pts from ERIVANCE who discontinued VISMO while experiencing a response or stable disease (SD). We also determined whether they responded to retreatment with VISMO. **Methods:** As of May 28, 2012, we identified 13 pts who did not have progressive disease (PD) at the time of study discontinuation and were still alive and available for follow-up.In Oct 2012, a survey was sent to INVs to determine pt outcome (disease status and additional treatments) based on the most recent pt assessment. **Results:** Of the 13 pts identified, 11 had stopped VISMO with an INV assessment of response; 2 had SD. Reasons for discontinuation were pt decision (n=7), adverse event (n=4), and physician decision (n=2).The INV or the referring dermatologist assessed 12 pts within ≤7 months of Oct 2012; 1 pt visited a primary care physician in January 2009. 6 of 13 pts remain progression free. For the other 7 pts with PD, duration of treatment-free interval ranged from 89 to ~725 days. 5 pts were treated with excision and/or Mohs surgery and 2 were retreated with VISMO. Best responses in the 2 pts retreated with VISMO were SD and unconfirmed partial response. Overall, 8 of 13 pts did not have PD for >1 year after discontinuation of VISMO. **Conclusions:** VISMO discontinuation after achieving tumor stabilization did not lead to rapid tumor recurrence; pts may maintain response for >1 year. Among pts who experience PD after discontinuation, additional treatment (Mohs or surgery) may be possible. Pts who discontinue VISMO prior to disease progression may benefit from retreatment upon progression. Clinical trial information: NCT00833417.

**9082 General Poster Session (Board #286), Sat, 8:00 AM-11:45 AM**

**Quantitative assessment of melanoma spread in sentinel and non-sentinel lymph nodes and survival.** *Presenting Author: Anja Ulmer, Department of Dermatology, University of Tübingen, Tübingen, Germany*

**Background:** We have recently shown that quantification of cancer dissemination from melanoma to sentinel nodes is feasible and can be combined with other characteristics of the primary tumor to improve outcome prediction. Here we asked whether quantitative assessment of cancer spread to non-sentinel nodes could further improve outcome prediction. **Methods:** The study includes 128 melanoma patients with microscopic positive sentinel nodes who underwent complete lymph node dissection at the University of Tübingen. We analyzed 267 sentinel nodes and 1129 non-sentinel nodes from these patients by pathology and by quantitative immunocytology. For immunocytology half of the node was disaggregated mechanically, single cell suspensions were dispensed onto slides, stained with the melanoma specific antibody gp100. For each node we recorded the disseminated cancer cell (DCC) density, defined as the number of gp100 positive cells per million lymph node cells examined. **Results:** Quantitative immunocytology showed melanoma spread in non-sentinel nodes in 101 of 128 patients (79%), pathology was positive in 23 of 128 patients (18%). At a median follow-up of 67 months (range 3 to 136 months) 45 patients (35%) had died from melanoma. DCC densities in the sentinel node predicted outcome by univariable and multivariable analyses. Additional quantitative assessment of DCC densities in non-sentinel nodes did not significantly improve outcome prediction. A model based on DCC density in the sentinel node and thickness of melanoma predicted outcome even more precisely than a model based on the current AJCC staging system that includes information about the total number of histopathologically positive nodes. **Conclusions:** Quantitative reporting of the sentinel node status allows accurate prediction of melanoma outcome without knowledge of the status of non-sentinel nodes. Routine measurement of DCC densities in sentinel nodes may improve patient stratification for clinical trials and facilitate treatment decisions at the time of sentinel node biopsy when the complete nodal status is unknown.

**9083 General Poster Session (Board #287), Sat, 8:00 AM-11:45 AM**

**On-demand Gamma Knife combined with BRAF inhibitors for the treatment of melanoma brain metastases.** *Presenting Author: Caroline Gaudy-Marqueste, Dermatology and skin cancers Department, UMR911 CRO2 Hôpital Timone, Aix Marseille University, Marseille, France*

**Background:** Both Gamma-Knife radiosurgery (GKRS) and BRAF-inhibitors (BRAF-I) have been shown to be useful in melanoma patients with brain metastases (BM), thus suggesting that it could be interesting to combine their respective advantages. However cases of radiosensitization following conventional radiation therapy in BRAF-I treated patients have raised serious concerns about the real feasibility and risk/benefit ratio of this combination. **Methods:** Blind review by 2 independent observers of brain MRI follow-up pictures and survival assessment in all patients who had been treated by GKRS and BRAF-I at a single institution. **Results:** Among53 GKRS performed in 30 patients who ever received BRAF-I and GKRS, 33 GKRS were performed in 24 patients while under BRAF-I treatment, from which only 4 with an interruption of BRAF-I. The 20 other GKRS were performed in 15 patients (including 9 of the 24) before initiation of BRAF-I treatment. Out of the 263 BM treated, only 3 edemas and 3 hemorrhages were detected within 2 months after GKRS and 4 edemas and 7 hemorrhages were detected later. No case of BM radiation necrosis and no scalp radiation dermatitis occurred. Neither the MRI features nor the incidence of the rare adverse events were deemed unexpected in such a population of melanoma BM. Median survival from first GKRS and first dose of BRAF-I was 24.7, and 48.8 weeks, respectively. **Conclusions:** This series does not show immediate radiotoxicity nor radiation-recall, in melanoma patients with BRAF-I whose BM are treated by GKRS. Interrupting BRAF-I for stereotactic radiosurgery of BM seems useless, although it is still advised for other radiation therapies. Overall very favorable survival figures suggest to test the potential benefit of combining stereotactic radiosurgery and BRAF-I.

**9084 General Poster Session (Board #288), Sat, 8:00 AM-11:45 AM**

**Polymorphisms in the apoptosis pathway and prognosis in cutaneous melanoma.** *Presenting Author: Cristiane Oliveira, Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil*

**Background:** Cutaneous melanoma (CM) is notorious for its poor prognosis and resistance to conventional chemotherapy. Genes involved in the apoptosis pathway, such as *P53*, (tumor suppressor gene), *MDM2* (p53 inhibitor), *BAX* (proapoptotic) and *BCL2* (anti-apoptotic) are important for survival and tumor growth. The polymorphisms *P53* Arg72Pro, *MDM2* T309G, *BAX* G(-248)A and *BCL2* C(-938)A alter the expression of the respective encoded proteins. The aim of this study was to evaluate whether these polymorphisms are associated with overall survival (OS) and relapse free survival (RFS) of CM patients. **Methods:** Our analysis included 185 consecutive CM patients at diagnosis seen at our University Hospital from December 1989 to November 2012. Genomic DNA from peripheral blood of patients was analyzed by polymerase chain reaction followed by enzymatic digestion for discrimination of pertinent genotypes. OS and RFS were calculated using the Kaplan-Meier estimate probabilities, and differences between survival curves were analysed by the log-rank test. OS was calculated from date of first diagnosis until the date of death or last follow-up. RFS was defined as the time to beginning of treatment until the date of the first relapse. **Results:** The median period of observation of patients in study were 61 months (range: 3-283). We observed at 120 months of segment, that the OS in CM patients with the *BAX* GA+AA was higher than in those with the GG genotypes (100% *versus* 79%, $P=0.01$). The OS were also higher with in patients with *BAX* GA+AA plus *BCL2* CC+CA combined genotype than in those with *BAX* GG plus *BCL2* AA (100% *versus* 76.7%, $P=0.02$) and *BAX* GA+AA plus *MDM2* TT+TG than *BAX* GG plus *MDM2* GG (100% *versus* 58.3%, $P=0.006$). No difference in RFS was seen in patients with the distinct genotypes of the above referred genes. **Conclusions:** The data suggest, for the first time, that polymorphism *BAX* gene may independent or jointly with *BCL2* and *MDM2* polymorphisms, modulate OS outcome of CM patients. Additional studies will provide some promising guidance for clinical management and tailored or personalized therapeutics in treating for CM.

**9085 General Poster Session (Board #289), Sat, 8:00 AM-11:45 AM**

**Correlation of tumor-derived circulating cell free DNA (cfDNA) measured by digital PCR (DigPCR) with tumor burden measured radiographically in patients (pts) with $BRAF^{V600E}$ mutated melanoma (mel) treated with RAF inhibitor (RAFi) and/or ipilimumab (Ipi).** *Presenting Author: Parisa Momtaz, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** We hypothesized that tumor-derived cfDNA in plasma may reflect accurately total tumor burden. DigPCR is a quantitative technique that carries out individual PCR reactions simultaneously in thousands of droplets. By utilizing fluorescently-labeled probes specific for a unique tumor-specific mutation (e.g. $BRAF^{V600E}$) it is possible to quantify mutated and wild-type (WT) DNA in plasma with high sensitivity (1 copy of $BRAF^{V600E}$/ml plasma). **Methods:** Plasma from 11 pts with $BRAF^{V600E}$ mutated mel treated with vemurafenib, or dabrafenib, and/or Ipi were collected at various time points. cfDNA extraction from pt plasma was performed and the ratio of the concentration of mutant $BRAF^{V600E}$ to WT cfDNA was determined using DigPCR. The ratio of $BRAF^{V600E}$ /$BRAF^{WT}$ cfDNA was correlated with tumor burden measured radiographically as the sum of target lesion diameters. **Results**: 1 pt had a complete response, 8 had partial responses, and 2 had stable disease. 6 pts progressed after responding. All 4 pts assessed at the time when they were free of disease radiographically had undetectable cfDNA. False negative readings were seen in some samples from 2 pts (radiographic evidence of tumor but no detectable tumor-derived cfDNA despite adequate amount of cfDNA). In 1 pt, cfDNA levels increased despite a decrease in the sum of target lesions but this pt had progression in non-target bone metastases indicating that in some situations, cfDNA may more accurately reflect tumor burden than traditional radiographic measurements. In a pt undergoing resection of bulky metastatic melanoma, we measured the half-life of cfDNA to be approximately 3.5 hours. **Conclusions**: Tumor-derived cfDNA appears to correlate well with tumor burden measured by radiographic imaging. We are currently analyzing our retrospective plasma collection as well as prospectively collecting plasma on $BRAF^{V600E}$mutated mel patients treated with RAFi and/or Ipi to assess more formally the value of cfDNA in reflecting tumor volume. Support: Rohan Melanoma Res. Fund.

**9086 General Poster Session (Board #290), Sat, 8:00 AM-11:45 AM**

**Phase I/II study of resiquimod as an immunologic adjuvant for NY-ESO-1 protein vaccination in patients with melanoma.** *Presenting Author: Rachel Lubong Sabado, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** The TLR 7/8 agonist, Resiquimod has been shown to induce local activation of immune cells, production of cytokines, and antigen-presentation by dendritic cells, features desirable for cancer vaccine adjuvants. In this study, we evaluated the safety and immunogenicity of vaccination with NY-ESO-1 protein emulsified in Montanide ISA-51 VG when given with or without Resiquimod in surgically resected stage IIB-IV melanoma patients. **Methods:** This is a two-part study design. Part I represents an open-label dose-escalation with Resiquimod using 2 cohorts treated with 100ug NY-ESO-1 protein emulsified in 1.25mL Montanide (day1) followed by topical application of 1000mg of the 0.2% Resiquimod gel on days 1 and 3 for cohort-1 (N=3) or days 1, 3, and 5 for cohort-2 (N=3). The cycles were repeated every 3 weeks, total of 4 cycles. For part II of the study, patients were blindly randomized to receive 100ug NY-ESO-1 protein emulsified in 1.25mL Montanide (day1) followed by topical application of placebo gel (Arm-A; N=8) or 1000mg of 0.2% Resiquimod gel (Arm-B; N=12) using the dosing regimen established in Part I. Blood samples were collected at baseline, one week after each cycle of vaccination, and at follow-up visit for the assessment of NY-ESO-1-specific humoral and cellular immune responses. **Results:** The vaccine was generally well-tolerated, with no grade 4 adverse events or study-related deaths. Most study participants experienced mild adverse reactions reported as Grade 1 or 2 per CTCAE criteria v. 4. One patient experienced a grade 3 syncopal episode that was unrelated to the study drugs and another patient had a grade 3 injection site necrosis that was possibly related to the study drugs. NY-ESO-1 specific antibody responses were induced in both study arms although higher mean antibody titers were observed in Arm B. NY-ESO-1 specific CD4+ T cell responses were induced in patients in both study arms. However, significant NY-ESO-1 CD8+ T cell responses were detected only in Arm B. **Conclusions:** The current study shows that Resiquimod is safe and contributes to the induction of immune responses in patients. Clinical trial information: NCT00821652.

**9087 General Poster Session (Board #291), Sat, 8:00 AM-11:45 AM**

**A unique gene expression signature in tumor positive or negative sentinel lymph nodes in patients with melanoma.** *Presenting Author: Ahmad A. Tarhini, University of Pittsburgh Medical Center, Pittsburgh, PA*

**Background:** Molecular characterization through gene expression (exp) profiling of node positive and node negative sentinel lymph nodes (SLNs) in patients with clinical stage I-II melanoma may improve the understanding of mechanisms of metastasis and identify gene signatures for SLN+/SLN- that correlate with clinical outcome. **Methods:** Gene exp profiling was performed on SLN biopsies of 48 (24 SLN+, 24 SLN-) patients (T3a/b, T4a/b) who underwent SLN for staging using transcriptome profiling analysis on 5$\mu$ sections of fresh LN. U133A 2.0 Affymetrix gene chips were used. SAMR used to test the association between gene exp level and SLN status. Genes with fold change>1.5 and q value <0.05 were considered differentially expressed. Pathway analysis was performed using Ingenuity Pathway Analysis. Benjamini and Hochberg method was used to adjust for multiple testing in pathway analysis. **Results:** We identified 45 significantly increased transcripts (1.5-27 fold). Upon pathway analysis, 25 genes were commonly significantly expressed among the most significant and biologically relevant canonical pathways. Top pathways and associated genes were notably related to melanoma microenvironment and signaling pathways implicated in immunosuppression and development of cancer. **Conclusions:** Gene exp profiling identified pathways enriched with genes significantly differentially expressed in SLN+ vs SLN-. These findings warrant investigation in relation to diagnosis and prediction of outcome.

**9088 General Poster Session (Board #292), Sat, 8:00 AM-11:45 AM**

**Sentinel lymph node biopsy among elderly patients with melanoma.** *Presenting Author: Michael S. Sabel, University of Michigan, Ann Arbor, MI*

**Background:** While SLN biopsy is considered standard of care for melanoma ≥1mm in depth, its use among the elderly population is more controversial. To examine this, we reviewed our experience at the University of Michigan with melanoma patients ≥ 75 years of age. **Methods:** A prospective database was used to identify 952 melanoma patients ≥ 75 years of age from 1996 to 2011. In addition to clinicopathologic features and recurrence and survival data, co-morbidity data was collected to calculate the Charlson co-morbidity index (CCI). Univariate and multivariate Cox regression analysis was performed to characterize predictors of outcome. Kaplan Meier analysis was used to generate survival curves. **Results:** Among 553 clinically node negative patients with melanoma ≥1mm in Breslow thickness, 213 had wide excision alone while 340 had excision and SLN biopsy, with 83 (24%) having a positive SLN. Predictors of not performing a SLN biopsy included only older age (p<.0001) and head and neck location (p=.007), but not pathologic features or co-morbidity index. A final multiple variable model predicting SLN involvement included female gender [OR 2.15 (95%CI:1.20-3.85) p=.009], Breslow thickness [OR 1.23 for each 1mm increase (95%CI:1.07-1.42) p=0.004] and satellitosis [OR 4.43 (95%CI 1.61-12.21), p=.004]. Distant disease-specific survival was negatively associated with male gender (OR 1.5 (1.12-2.02), p=.007), increasing age (OR 1.05 per year [1.02-1.08, p<.001]), increasing Breslow thickness (OR 1.07 per year [95% CI 1.01-1.13, p=.013), ulceration (OR 1.51 [95%CI 1.14-2] p=.004), a positive SLN (OR 2.61 [95% CI 1.79-3.82], p<.001) and not having a SLN biopsy (OR 1.72 [1.28-2.33], p<.001). CCI did not predict worse disease-free or melanoma specific survival. **Conclusions:** Among elderly patients with clinically node negative melanoma ≥1mm, 24% harbor SLN metastases. SLN biopsy was not only strongly prognostic, but WLE + SLN biopsy, compared with WLE alone, was associated with improved distant disease-specific survival and a trend towards improved melanoma-specific survival, even after factoring for age and co-morbidities. If otherwise healthy, SLN biopsy should be strongly considered for this population.

**9089 General Poster Session (Board #293), Sat, 8:00 AM-11:45 AM**

**New graded prognostic index (GPI) for melanoma patients with brain metastasis (MBM).** *Presenting Author: Vyshak Alva Venur, Fairview Hospital, Cleveland Clinic, Cleveland, OH*

**Background:** Melanoma is the third most common cause of brain metastasis (BM) and graded prognostic assessment (GPA) is used as a prognostic index for MBM. We evaluated prognostic factors that predict overall survival (OS) in MBM treated at a single tertiary care institution. A preliminary data was presented at ASCO 2013. **Methods:** With IRB approval, the Cleveland Clinic Brain Tumor and Neuro-Oncology Center's database was used to identify MBM treated between 1999 and 2011. OS from the diagnosis of MBM was the primary end point.Cox proportional hazard models were used for data analysis. Stepwise variable selection was used to identify independent prognostic factors. **Results:** 176 MBM charts were reviewed and 159 were included for analysis. Primary site of melanoma was head and neck in 27 (22%), trunk and abdomen in 48 (39%), limbs in 46 (37%) and uvea in 2 (2%) patients. Karnofsky performance scale (KPS) was 90-100 in 67 patients (44%), 70-80 in 70 (46%) and <70 in 15 (10%) patients. Single BM was noted in 48 (31%), 2-3 BM in 52 (34%) and more than 3 was seen in 55 (35%) patients. One hundred, twenty two patients (76%) were symptomatic at diagnosis. One hundred, eight (68%) patients had supratentorial BM, 45 (28%) had both supra-and infratentorial and 6 (4%) had only infratentorial BM. Initial therapy included stereotactic radiosurgery (SRS) in 50 (31%) patients, whole brain radiation (WBRT) in 36 (23%), surgery (S) + WBRT in 30 (19%), WBRT + SRS in 24 (15%) and S + SRS in 9 (6%) patients, while 3 patients underwent only S, 6 patients were observed. Median OS from diagnosis of BM was 5.7 months (95% C.I. 4.4-6.8). The conventional disease specific GPA for MBM that includes KPS and number of brain metastasis was prognostic for survival (p<.0001). On multivariate analysis, the number of extracranial metastasis (ECM) at diagnosis of BM was prognostic for OS. **Conclusions:** A new GPI for MBM with KPS, number of BM and number of ECM is proposed.

| Factor | Median Survival (months) | p value |
|---|---|---|
| KPS | | |
| 90-100 | 7.2 | 0.001 |
| 70-80 | 5.3 | |
| <70 | 2.1 | |
| Number of BM | | |
| 1 | 7.4 | 0.002 |
| 2-3 | 6.7 | |
| >3 | 4.4 | |
| Number of ECM | | |
| 0 | 8.9 | <0.001 |
| 1-2 | 6.7 | |
| 3 | 4.4 | |
| >4 | 2.6 | |

**9090 General Poster Session (Board #294), Sat, 8:00 AM-11:45 AM**

**Efficacy of two ipilimumab (IPI) doses (10 vs. 3 mg/kg) in Alberta, Canada, tertiary cancer centers.** *Presenting Author: Richard M. Lee-Ying, Tom Baker Cancer Centre, Calgary, AB, Canada*

**Background:** The efficacy of IPI for the treatment of metastatic melanoma (MM) has been demonstrated in randomized phase 3 trials. Response rates in the initial dose-finding phase 2 trial indicated the highest overall response rate (ORR) in the 10mg/kg group. Prior studies have identified that the degree of drug exposure during induction is statistically significant in predicting response. The optimal dosing is currently under investigation with a 10 vs. 3mg/kg trial (NCT01515189). **Methods:** Two cohorts were identified in the province of Alberta, one received 10mg/kg, while the second received 3mg/kg inductions. Treatment responses were determined by clinical immune-related response criteria. Fisher's exact test was used to compare response rates. **Results:** A total of 97 patients were identified from 2006-2013, with 31 patients in the 10mg/kg group and 66 patients in the 3mg/kg group. The median follow-up was 15.7 vs. 11.7 months, respectively. The complete response (CR) rate is 19.4% (6/31) and 1.5% (1/66), which significantly favors the 10mg/kg group, p=0.006. The partial response (PR) rates are 19.4% (6/31) and 19.7% (13/66), p=0.97 and the stable disease (SD) rates are 22.6% (7/31) and 12.1% (8/66), p=0.09. Progressive disease (PD) rates are lower in the 10mg/kg group, 32.3% (10/31), vs. 63.6% (42/66) p=0.004. A trend towards improved response rate favored the 10 vs. 3mg/kg group (38.7%, 12/31 vs. 21.2%, 14/66) p=0.07, while the clinical benefit rate (CBR) (CR, PR and SD) was statistically significant, 61.3% (19/31) vs. 33.3% (22/66) p=0.01. An additional 3 patients in the 10mg/kg and 2 patients in the 3mg/kg group are alive with no evidence of disease after subsequent therapy. The frequency of immune-related side effects was not significantly different between groups, despite higher dosing in the 10 vs. 3mg/kg group, p=0.79. **Conclusions:** IPI used at 10mg/kg produces a better CBR than 3mg/kg in this study. This benefit is largely due to marked improvement in CR rates in the 10mg/kg group, and lower rates of PD. These findings are limited by the small sample size, retrospective nature and limited follow-up. Our results support the importance of dose exposure with IPI for MM, and will be explored further in a phase III trial.

**9091 General Poster Session (Board #295), Sat, 8:00 AM-11:45 AM**

**Response rate and durability of chemotherapy for metastatic Merkel cell carcinoma among 62 patients.** *Presenting Author: Jayasri G Iyer, University of Washington, Seattle, WA*

**Background:** Merkel cell carcinoma (MCC) is an aggressive skin cancer with a high propensity to metastasize (> 30%). Distant metastatic MCC is often treated using chemotherapy but its efficacy is unclear because the existing literature: 1) intermingles adjuvant and therapeutic chemotherapy cases and, 2) often includes combined chemo-radiation. **Methods:** To assess the efficacy of chemotherapy on MCC we performed a retrospective analysis of 62 patients in our cohort with distant MCC metastases evaluable for response to chemotherapy alone.Tumor responses were characterized as complete remission (CR), partial remission (PR), stable disease (SD) or progressive disease (PD) per RECIST. Overall survival (OS), durability of response and progression-free survival (PFS) were also analyzed. **Results:** Median age of this cohort was 68 years (range: 47 – 96). Median OS from the start of chemotherapy was 9.5 months. Platinum plus etoposide was the most common first line regimen administered to 69% of the patients. Objective response rate (ORR) with front-line chemotherapy was 54% (34/62) with CR in 15% (9/62) of the patients. 7 of 9 patients with CR eventually progressed. The median progression free survival (PFS) for all patients from start of chemotherapy was 93.5 days with 90% of patients progressing by 290 days. Among responders (CR + PR), median PFS was 161 days, median durability of response was 103 days (range: 12 – 522) and 90% progressed in this subgroup by 428 days. Among 30 patients who received a second line chemotherapy regimen, the ORR was 23% (7/30 with 1 CR, 6 PR). Median PFS from start of second line chemotherapy (n=30) was 61 days (range: 11 – 364). Topotecan was the most commonly used second-line regimen (23%). **Conclusions:** The results of our study suggest that responses to cytotoxic chemotherapy for MCC are frequent but of limited durability. While subject to selection bias in a retrospective study, these data may be useful as a basis for comparison as the "control arm" for trials of new therapeutic modalities in this rare malignancy lacking data from prospective trials.

**9092 General Poster Session (Board #296), Sat, 8:00 AM-11:45 AM**

**Severe skin rash during vemurafenib treatment: A predictive factor of early positive response in metastatic melanoma?** *Presenting Author: Nora Kramkimel, Assistance Publique–Hôpitaux de Paris, Hôpital Cochin, Paris, France*

**Background:** Interindividual variability in pharmacokinetics may influence clinical benefit or toxicity of vemurafenib (VMF) in metastatic melanoma (MM) and identification of predictive factors of response and toxicity are mandatory. **Methods:** From Nov. 2011 to Dec. 2013, VMF plasma concentration was assayed at different times within the first 65 days of treatment, after informed consent, in 55 patients treated with VMF for MM in 3 French Dermatologic Departments. Baseline clinical and biologic characteristics, average VMF plasma concentration per patient for tumor response analysis and absolute exposure at the day of the toxicity, tumor response (PFS, OS, early response rate evaluated after 2 months of VMF) according to RECIST criteria and toxicities (grade ≥2 rash and renal failure, any grade≥3 adverse events) graded using the NCI 4.0 scale, were tested univariately. Candidate variables with p<0.1 were studied in multivariate analysis. **Results:** Mean age was 55 years (25-84). 92.7% had stage IV MM, 25.5% had brain metastasis and 76% were PS 0-1. 90.7% of tumor had *BRAF* V600E mutation and 2.5% V600K. VMF was the first line treatment in 66.7%. Early response rate (i.e CR, PR and SD) was 61.5%. Mean PFS was 5.4 months (0.3-17) and mean OS was 9.0 months (0.3-24+). Mean VMF concentration (n=118) was 47.5 ± 20.4 mg/L. Interindividual variability in dose-normalized VMF exposure was 43%. In multivariate analysis, higher average VMF dose was associated with longer PFS (OR: 0.998 [0.997-0.999], p=0.0025). Grade ≥2 rash, observed in 29.6%, (OR: 5.64 [1.004-31.696], p =0.0495) and daily VMF dose regimen (OR: 1.29 [1.032-1.612],p=0.0256) were associated with early 2-month response. BMI (OR: 0.75 [0.592-0.95], p=0.0173) and VMF plasma concentration (OR: 1.061 [1.017-1.108], p =0.0065) were associated with grade ≥2 rash. **Conclusions:** This is the first study that highlights correlation between grade≥2 rash and early MM response under VMF. Moreover, relationship between PFS and high VMF average dose underlines importance to keep highest VMF dose even after adverse event. Finally, low BMI and high VMF plasma exposure were identified as risk factors for development of grade≥2 rash.

**9093 General Poster Session (Board #297), Sat, 8:00 AM-11:45 AM**

**Efficacy and safety of mechlorethamine (MCH) 0.04% gel in mycosis fungoides (MF) after treatment with topical MCH 0.02%.** *Presenting Author: Youn H. Kim, Stanford Cancer Institute, Stanford, CA*

**Background:** MF, the most common form of cutaneous T-cell lymphoma, is characterized by infiltration of the skin by malignant T cells and can further progress to other organs. Early stage disease (limited/localized skin involvement) is managed with skin-directed therapies. The first FDA approved topical formulation of MCH, MCH 0.02% gel (equivalent to 0.016% w/w MCH, mechlorethamine) was noninferior to MCH-Aquaphor (AP) 0.02% in a 12 mo study (Study 201). In clinical practice, patients (pts) who tolerate MCH 0.02% without complete response (CR) may have their dose increased to maximize response. Study 202 tested the efficacy and safety of MCH 0.04% gel after MCH 0.02%. **Methods:** Pts eligible for this 7 mo phase 2 extension study completed 12 mos of treatment with MCH 0.02% gel or AP without CR. All pts applied a thin layer of MCH 0.04% gel once daily. Application frequency could be reduced for toxicity. Primary endpoint was response rate defined as ≥ 50% improvement in composite assessment of index lesions score (CAILS) of up to 5 lesions, confirmed ≥ 4 weeks later. **Results:** 98 of 100 enrolled pts were treated in Study 202 (MCH 0.04%); 86.7% completed the trial. 26 pts (26.5% [18.6-35.9]) achieved confirmed CAILS response from Study 202 baseline, including 6 CR. Additionally, 14 pts (14.3%) had their first response at final visit—unconfirmed response rate, 40.8% (31.5-50.7). There was no difference in response by age, race, or gender. CAILS response rates were also assessed from Study 201 (MCH 0.02%) baseline for index lesions identified at the start of that trial, with confirmed responses occurring in 74 pts (75.5% [66.3-83.2]). By week 88, 33 pts (84.4%) who had previously received MCH 0.02% gel and 39 pts (67.9%) who had previously received MCH 0.02% AP in Study 201 had responses over the course of these sequential studies. Drug related skin adverse events in Study 202 were mostly mild to moderate and were reported by 31 pts (31.6%); the most common were skin irritation (11.2%), erythema (10.2%), and pruritus (6.1%). **Conclusions:** Pts with stage I or IIA MF who did not achieve CR after 12 mos of daily topical MCH 0.02% had additional clinical benefit with up to 7 mos of treatment with MCH 0.04% gel, which was well tolerated in these pts. Clinical trial information: NCT00535470.

**9094 General Poster Session (Board #298), Sat, 8:00 AM-11:45 AM**

**The genetic variants in interleukin locus at 1q32.1 as markers of melanoma survival.** *Presenting Author: Justin Rendleman, New York University School of Medicine, New York, NY*

**Background:** Interleukins play a critical role in immune regulation of tumor development. Because melanoma is a highly immunogenic cancer, and its progression often correlates with immune-related factors, in this study we have tested whether inherited genetic variants in interleukin pathways affect the clinical outcomes of melanoma patients. **Methods:** We performed a two-stage association analysis of 94 SNPs tagging 32 interleukin genes in 1,200 melanoma patients, ascertained at the New York University Medical Center between 2001-2013. The two stages (discovery and validation) were matched by tumor characteristics, age, and gender. Multivariate Cox regression models tested the associations with recurrence-free and overall survival (RFS and OS, respectively), including age, gender, stage, thickness, ulceration status, anatomic site, and histological subtypes as covariates. **Results:** A region within 1q32.1 containing *IL10*, *IL19*, *IL20*, *IL24* was significantly associated with melanoma OS. Specifically, two SNPs in *IL10* (rs3024493 and rs2222202) showed the strongest associations with OS (HR=5.82, 95% CI=2.08-16.3, p=0.0009; HR=0.47, 95% CI=0.28-0.80, p=0.006 respectively). The association between rs3024493 and OS replicated among both stages (stage 1 p=0.028, stage 2 p=0.017). In addition, SNPs tagging *IL16* were associated with both RFS and OS in the aggregate analysis of both stage 1 and 2 (p=0.04). **Conclusions:** The study has identified novel associations of germline genetic risk variants in an interleukin locus at 1q32.1 with melanoma outcomes (rs3024493), and validated the associations from previous smaller studies that showed germline variants in *IL10* (rs2222202) associate with worse OS. Pending multi-institutional meta-analysis and further genetic and functional investigations, this study strongly suggests that germline variants in the interleukin locus at 1q32.1 should be considered as novel prognostic markers with potential clinical utility.

**9095 General Poster Session (Board #299), Sat, 8:00 AM-11:45 AM**

**Integration of melanoma genotyping in clinical care.** *Presenting Author: Ines Esteves Domingues Pires Da Silva, Ronald O. Perelman Department of Dermatology, NYU Langone Medical Center, New York, NY*

**Background:** Molecularly targeted therapy is improving response rates and overall survival in subsets of melanoma patients. However, targeted therapy for "triple negative" patients (BRAF, NRAS and c-KIT wild type) is not yet defined. In addition, new evidence suggests that germline variants may have an impact in melanoma progression and response to therapy. In this study, we attempt to define the utility of a recently developed clinical assay that encompasses targeted sequencing of 50 genes with known impact on cancer progression. **Methods:** We used the AmpliSeq Cancer Panel HotSpot.V2 from Ion Torrent. The panel targets sequencing of Hotspot regions including 2,800 COSMIC mutations within 50 oncogenes and tumor suppressor genes. Tumor and blood germline DNAs were studied. All identified mutations were independently validated by Sanger sequencing. We then linked the molecular profile to extensive clinicopathological information including treatment and prospective clinical follow-up. **Results:** We examined 35 tumor samples from 33 melanoma patients (2 patients had 2 specimens). 14/35 (40%) had BRAF mutations, 12/35 (34%) had NRAS mutations (one patient had both BRAF and NRAS mutated) and 2 had c-KIT mutant tumor. Eight patients were triple negative and presented with mutations in KRAS (n=2), TP53 (n=5), ERBB4 (n=1), PI3K (n=3), RB1 (n=1), NOTCH (n=1), EZH2 (n=1), APC (n=5) and KDR (VEGFR2; n=2). We detected germline variants in TP53 (40%), KDR (34%), APC (29%), KIT (23%) and PIK3CA (14%) genes. Notably, KDR Q472H has been shown to affect VEGFR2 function. Patients with KDR Q742H had higher microvessel density, higher VEGF production and a shorter survival (15.1 months compared to 54.6 months). **Conclusions:** Sequencing using a validated clinical assay was informative of several targetable mutations in triple negative melanoma. Inhibitors targeting some of these mutations are already FDA approved for non-melanoma and others are currently tested in clinical trials. Our data also revealed a role of germline variant KDR Q472H in melanoma progression, that was not reported before, suggesting that further functional studies are warranted.

**9096 General Poster Session (Board #300), Sat, 8:00 AM-11:45 AM**

**Correlation of absolute and relative eosinophil counts with immune-related adverse events in melanoma patients treated with ipilimumab.** *Presenting Author: Katja Schindler, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** Ipilimumab (ipi) has shown significant improvements in overall survival (OS) for patients (pts) with advanced melanoma in randomized phase III trials. Easily obtainable pre- or on-treatment biomarkers would be helpful to optimize this therapy. In a prior analysis, IL-17 levels correlated with immune-related adverse events (irAEs), and IL-17 and eosinophils are immunologically related. In one prior single institution study of 73 ipi-treated pts, an increase in absolute eosinophil count (AEC) was associated with improved OS. Whether this finding correlates with other clinical outcomes such as immune-related adverse events (irAEs) or is reproducible in larger, multicenter analyses remains unknown. **Methods:** 156 pts with advanced melanoma treated with ipi at the approved standard dose of 3mg/kg in 4 institutions (Medical University of Vienna, University of Zurich, University of Lausanne, and Memorial Sloan-Kettering Cancer Center) between 2010 and 2013 were retrospectively analyzed. Baseline (B/L), week (W) 4 and W7 absolute and relative eosinophil (AEC and REC) counts and occurrence of irAEs were noted. Wilcoxon rank-sum test was performed for analyzing the association of AEC and REC with irAEs. OS was calculated from date of first ipi dose to date of death or last followup. The association between B/L, W4 and W7 levels of AEC and REC and OS was assessed using Cox proportional hazards regression. **Results:** The change in AEC from B/L to W4 and from B/L to W7 was significantly associated with the occurrence of any irAE (p=0.032 and p=0.007, respectively). As continuous variables at W4, AEC and REC were significantly associated with irAEs (p=0.018 and p=0.275, respectively). At W7 AEC was significantly associated with irAEs (p=0.019) but REC was not (p=0.074). Neither AEC nor REC at B/L was significantly associated with irAEs. Neither the change in AEC nor REC from B/L to W4 was associated with OS. **Conclusions:** Eosinophils were associated with irAEs but not OS during ipi treatment. Given functional links between IL-17 and eosinophils, and the correlation of both IL-17 and eosinophils with irAEs, further study of the mechanistic role of this pathway in pts with irAEs is warranted.

**9097 General Poster Session (Board #301), Sat, 8:00 AM-11:45 AM**

**Interobserver variability in ultrasound (US) guided fine needle aspiration cytology (FNAC) of sentinel nodes (SN): Experience in 1,000 melanoma patients.** *Presenting Author: Christiane A. Voit, Charité-Universitätsmedizin Berlin, Berlin, Germany*

**Background:** FNAC is used to determine nature of suspected lesions that are either clinically apparent (palpable) or discovered by imaging (non-palpable) with the same high sensitivity (Voit et al.JNCI 2011). However, there seems to be interobserver variability. **Methods:** Morphology criteria (Voit et al. JCO 2010) were tested in 3 pre-SLNB-US examiners. US criteria, FNAC results were collected in a prospective database.Positive cytology was confirmed by histopathology. Examiner #1 had a long US-FNAC experience, 2 others were learners, #2 with a long US, but not FNAC experience, #3 new to both. **Results:** In 1,000 consecutive prospective patients mean/median Breslow thickness was 2.58/1.57mm. Mean/median follow-up was 56 / 53 months (1 – 132). SN positivity rate was 21%. Overall US-FNAC sensitivity was 71%(US only) and 51%(US-FNAC). Sensitivity of US-FNAC was highest for T4 (76%) and ulcerated melanomas (63%). #1 performed 724(72%), #2 202(20%), #3 74(7%). US validation of #1 was 431/724(59.9%) benign, in 227/724(31.4%) suspicious and in 66/724(9.1%) malignant. #2 estimated in 144/202(71.3%) benign, in 50/202(24,7%) suspicious and in 8/202(4%) malignant; #3 in 57(77%) benign, in 8/75 (10.8%) suspicious and in 9/74 (12.2%) malignant (p<0.001). #1 detects early sign peripheral perfusion(PP) in 32%, #2 in 21% and #3 in 22%. #1 performed FNAC in 291(40%), #2 in 55(25%) and #3 in17(15%)(p<0.001). #1 had sensitivity of 86/157(55%), spec of 99%, PPV of 99% and NPV of 89% (p<0.001). #2 had 34%,100%,100% and 88%,#3 56%, 100%,100% and 89% respectively(p<0.001). Detected sentinel node Tuburden <1mm was successfully FNACed in 45% by #1 and in 20% by #2 and#3 respectively. **Conclusions:** This largest database covering FNACs in SN of melanoma patients showed no difference between ultrasonographists with regard to performing a FNAC if a late sign, baloonshape (BS) or loss of central echoes (LCE), was seen. An examiner experienced in both US and FNAC sees more PP, performs more FNACs and has more positive FNACs. Examiners not used to FNAC tend to not perform FNACS. Interobserver difference is due to a significantly lower detection rate of PP.

**9098 General Poster Session (Board #302), Sat, 8:00 AM-11:45 AM**

**A phase IB study of ipilimumab with peginterferon alfa-2b for patients with unresectable stages IIIB/C/IV melanoma.** *Presenting Author: Ragini Reiney Kudchadkar, Comprehensive Melanoma Research Center, Moffitt Cancer Center, Tampa, FL*

**Background:** Peginterferon alfa-2b (Sylatron) as adjuvant therapy has been shown to benefit patients with resected melanoma and interferon studies have shown that the induction of autoantibodies may correlate with benefit. Ipilimumab (IPI, Yervoy) is an anti-CTLA-4 antibody that induces immune-related toxicity that may correlate with clinical benefit. This abstract is an update of previously presented data. **Methods:** This studycombined IPI at 3mg/kg every 3 weeks for 4 doses along with concurrent peginterferon alfa-2b at 3 mcg/kg weekly for up to 156 weeks or until disease progression, unacceptable toxicity, or patient decision to discontinue. The study was designed to obtain toxicity, tolerability, and autoimmune antibody data and to define a well-tolerated dose of the combination. **Results:** 31 patients were treated with13 female and 18 male subjects. Median age was 65. There were 2 CRs, 9 PRs, 3 with stable disease, and 12 with progressive disease in 26 pts evaluable for response thus far. Five pts have not yet completed cycle 1 and therefore are not evaluable for response at the time of this publication but will be presented. Toxicities from peginterferon alfa-2b 3mcg/kg were dose-limiting with 7 pts requiring dose reduction in peginterferon alfa-2b secondary to toxicity. The grade 3 events leading to dose reductions were nausea and vomiting, leucopenia, dehydration, and hyponatremia. Peginterferon alfa-2b was dose reduced to 2 mcg/kg weekly in future pts after these toxicities were noted. In the subsequent patients grade 3 related events included rash (n = 4), pruritis (2), colitis (1), fatigue (2), and hypothyroidism (1). There was no significant change in the presence autoantibodies (ANA, anti-double stranded DNA, antithyroglobulin, antimicrosomal antibodies, and anticardiolipin antibodies) between responders and nonresponders in the evaluable pts. **Conclusions:** Peginterferon alfa-2b added to IPI results in an excellent response rate of 42.3% in this population. Peginterferon alpha-2b at 2 mcg/kg weekly with IPI at 3 mg/kg every 3 weeks is tolerated well though 20% of patients treated at this dose experienced grade 3 rash. Based on a clinical benefit rate (CR + PR + SD) of 53.8 %, this combination warrants further exploration. Clinical trial information: NCT01496807.

**9099 General Poster Session (Board #303), Sat, 8:00 AM-11:45 AM**

**Association of natural killer (NK) cell exhaustion with melanoma progression.** *Presenting Author: Ines Esteves Domingues Pires Da Silva, Ronald O. Perelman Department of Dermatology, NYU Langone Medical Center, New York, NY*

**Background:** Recent success of immunotherapies targeting the exhaustion markers CTLA-4 and PD-1 has inforced the role of $CD8^+$T cell exhaustion in advanced melanoma patients. T cell exhaustion, has been extensively studied, however little is known about NK cell exhaustion in the same context. In this project, we defined NK cells phenotype in different stages of melanoma to examine its role in melanoma progression. **Methods:** NK cells were purified from the peripheral blood of a prospectively-enrolled cohort of 100 melanoma patients: stage I (n=56), stage II (n=21) and stages III/IV (n=23); in addition to 25 healthy donors. NK cells were characterized for the expression of activating (NKG2D and NKp46) and inhibitory receptors (Tim-3, KIRB1 and KIRNKAT2), function (cytotoxicity, IFN-$\gamma$ production and proliferation) and the intracellular expression of the transcription factors (T-bet and Eomes). We then tested the association between NK cell phenotype and clinicopathological variables associated with melanoma prognosis. Unpaired T test was used to compare two groups, and ANOVA to compare more than two groups. **Results:** NK cells gradually develop a phenotypic and functional profile consistent with progressive exhaustion, from stage I to stage IV characterized by: 1) up-regulation of inhibitory receptors (Tim-3, KIRB1 and KIRNKAT2); 2) down-regulation of activating receptors (NKG2D and NKp46) and transcription factors (T-bet and Eomes); 3) loss of IFN-$\gamma$ production,proliferation and cytotoxicity. Interestingly, the expression of Tim-3 and KIRB1 is higher, while the cytotoxic ability is reduced in patients with melanomas thicker than 1mm (Tim-3 – p=0.007; KIRB1 – p=0.03; cytotoxicity – p=0.05). Higher Tim-3 expression is associated with ulceration (p=0.009) and with mitosis (p=0.001). Moreover, higher expression of Tim-3 and KIRB1, and a lower cytotoxic ability is associated with local or distant metastases (Tim-3 – P=0.002; KIRB1 – p=0.0009; cytotoxicity – p=0.0005). **Conclusions:** Data demonstrate that NK cells become progressively exhausted in the context of melanoma progression. NK cells start acquiring this phenotype in early stages which suggests that targeting them earlier can be be a novel therapeutic strategy.

**9100 General Poster Session (Board #304), Sat, 8:00 AM-11:45 AM**

**Clinical characteristics of patients with non-*V600 BRAF* mutant melanomas.** *Presenting Author: Dae Won Kim, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** *V600E* and *V600K* mutations are the most common *BRAF* mutations in melanoma. We previously showed that non-*V600 BRAF* mutations account for 12% of all *BRAF* mutations in melanoma. Limited clinical data are available for non-*V600 BRAF* mutant melanomas. To better understand non-*V600 BRAF* mutations in melanoma, characteristics of tumor and clinical outcomes were investigated. **Methods:** Clinical and pathologic data were collected retrospectively in patients (pts) with melanoma who had multi-gene mutation analysis (next-gene sequencing) at MD Anderson Cancer Center. Fisher's exact test was used for all comparisons. **Results:** We found 52 pts with non-*V600 BRAF* mutations, among whom 8 had *NRAS*/non-*V600* co-mutations. Common non-*V600* mutations were *K601E* (17.3%), *G469E* (15.4%), *G469R* (7.7%), *D594G* (5.8%), *L597S* (5.8%), and *S467L* (5.8%). Compared with *V600E* mutations as a control (n=82) , the presence of a non-*V600* mutations was significantly associated with older age (median, 58 years vs 50; P=0.001), less superficial spreading type (13.6% vs 32.9%; P=0.02), more lentigo maligna type (20% vs 1.2%; P=0.001), more mucosal subtype (9.1% vs 1.2%; P=0.03), more head/neck primary tumor location (36.4% vs 15.9%; P=0.03), less lower extremity primary tumor location (4.5% vs 24.4%; P=0.003), more co-mutations with *NRAS* (15.4% vs 2.4%, p=0.005) and stage IV disease at initial diagnosis (31.8% vs 7.3%; P=0.0003). Among the 33 pts with non-*V600* mutant metastatic melanoma, 7 received selective BRAF inhibitor (BRAFi). Of the 5 evaluable patients (2 could not tolerate treatment), all had disease progression within 2 months. **Conclusions:** *Non-V600 BRAF* mutant melanomas have more aggressive clinical characteristics, more likely to have co-mutations with *NRAS*, and not responsive to selective BRAFi than *V600E* mutations. A larger cohort and a longer follow-up will better define the prognostic indication of non-*V600* mutated melanoma.

**9101 General Poster Session (Board #305), Sat, 8:00 AM-11:45 AM**

**A phase I trial of BKM120 combined with vemurafenib in $BRAFV600^{E/k}$ mutant advanced melanoma.** *Presenting Author: Alain Patrick Algazi, University of California, San Francisco, San Francisco, CA*

**Background:** Vemurafenib induces transient objective responses in half of $BRAF^{V600E}$mutant melanoma patients and a median PFS of 5.3 months. PTEN loss and PI3K activation are common in BRAF mutant metastatic melanoma, and PI3K activation has been implicated as a cause acquired resistance to BRAF inhibitors. This phase I study tested the safety of combining the BRAF inhibitor, vemurafenib, with the PI3K inhibitor, BKM120, in patients with metastatic BRAF mutant melanoma. **Methods:** Vemurafenib-naïve patients receive a single dose of oral BKM120 (d -7) then vemurafenib twice daily with BKM120 daily (starting on c1d1). Patients with prior progression on vemurafenib received both vemurafenib and BKM120 starting on c1d1 after a vemurafenib washout of at least 14 days. Serial biopsies prior to treatment, on cycle 1 day 15, and at progression were obtained for pharmacodynamics analysis in patients with visible or palpable tumors. 3 + 3 dose escalation was planned starting at vemurafenib 720 mg PO twice daily with BKM120 60 mg daily. **Results:** Four BRAF inhibitor naïve patients andfour BRAF inhibitor refractory patients were treated on study with vemurafenib 720 mg PO bid and BKM120 60 mg PO daily. Two BRAF inhibitor naïve patient experienced DLTs (myalgias, DRESS syndrome). One vemurafenib naïve patient was inevaluable due to non-compliance and had minimal exposure to study drug. Two of four BRAF inhibitor refractory patients experienced DLTs (myalgias, febrile neutropenia). One BRAF inhibitor-resistant patient had a mixed response to treatment with a 35.9% reduction in target lesions and two new small subcutaneous lesions. **Conclusions:** Combination therapy with vemurafenib and BKM120 in BRAF-V600E/K mutant melanoma was not tolerated in either BRAF inhibitor naïve or BRAF inhibitor resistant patients. Clinical trial information: NCT01512251.

**TPS9102 General Poster Session (Board #306A), Sat, 8:00 AM-11:45 AM**

**NEMO: A phase 3 trial of binimetinib (MEK162) versus dacarbazine in patients with untreated or progressed after first-line immunotherapy unresectable or metastatic *NRAS*-mutant cutaneous melanoma.** *Presenting Author: Keith Flaherty, Massachusetts General Hospital, Boston, MA*

**Background:** Melanoma tumors often harbor mutations in the mitogen-activated protein kinase-signaling pathway family members BRAF or NRAS. *NRAS* mutations, observed in about 15% of patients with melanoma, are associated with higher tumor proliferation and poorer prognoses. A large retrospective analysis (n = 677) demonstrated that *NRAS* mutations are independently predictive of poor survival in patients with cutaneous melanoma (Jakob *et al.*, 2011). With no approved targeted therapies for melanoma patients with *NRAS*-mutant tumors, treatments are currently limited to chemotherapy and/or immunotherapy. Binimetinib (MEK162), a potent and selective inhibitor of MEK1/2, has demonstrated promising phase 2 clinical activity in this patient subset. Here we describe the "NRAS mElanoma and MEK inhibitOr" (NEMO) trial, an ongoing phase 3 study designed to compare the efficacy of binimetinib vs dacarbazine in patients with metastatic *NRAS*-mutant cutaneous melanoma (NCT01763164). **Methods:** NEMO is a 2-arm, open-label, 2:1 randomized trial of binimetinib vs dacarbazine. Eligible patients must have advanced unresectable or metastatic cutaneous melanoma with a documented *NRAS* Q61 mutation (by central molecular screening) that was previously untreated or has progressed after 1 line of immunotherapy. Patients are stratified by stage, performance status, and prior immunotherapy. The primary endpoint of the study is progression-free survival, and secondary endpoints include overall survival, overall response, disease control rate, safety, and quality of life. Binimetinib is administered orally at 45 mg twice daily and dacarbazine is dosed intravenously at 1000 $mg/m^2$ once every 3 weeks, until disease progression or unacceptable toxicity. Patient crossover from the dacarbazine arm to the binimetinib arm is not permitted. This phase 3 trial is designed to enroll 393 patients and is currently recruiting patients at more than 150 centers worldwide. Clinical trial information: NCT01763164.

**TPS9103^ General Poster Session (Board #306B), Sat, 8:00 AM-11:45 AM**

**A phase II study of intratumoral application of L19IL2/L19TNF in melanoma patients in clinical stage III or stage IV M1a with presence of injectable cutaneous and/or subcutaneous lesions.** *Presenting Author: Riccardo Danielli, Medical Oncology and Immunotherapy, University Hospital of Siena, Siena, Italy*

**Background:** Preclinical studies in three different murine models of subcutaneous tumors have shown that a single intratumoral injection of a combination of two immunocytokines, L19-IL2 and L19-TNF is more effective than each immunocytokine in monotherapy and is curative in 100% of animals. Furthermore, in the clinical setting intralesional delivery of L19-IL2 elicited objective responses in >50% of Stage III melanoma patients, with a possible benefit in terms of distant metastases-free survival rates for these patients and evidence of systemic immune responses in most evaluable patients. L19-IL2 and L19-TNF are recombinant fusion proteins, consisting of the single-chain monoclonal antibody (L19) directed against extradomain B of fibronectin, a well-characterized marker of angiogenesis, fused to IL2 or TNF cytokines, respectively. **Methods:** A Phase II, uncontrolled, multicenter, prospective study is ongoing at two centers in Italy (EudraCT Number: 2012-001991-13). Twenty patients with unresectable Stage IIIC/IVM1a melanoma and cutaneous or subcutaneous injectable metastases will receive intratumoral injections of L19-IL2 (10 Mio IU maximum daily dose) in combination with L19TNF (312 $\mu$g) once per week for 4 consecutive weeks. Primary objective is the assessment of efficacy measured as the rate of patients with complete response (CR) of L19IL2/L19TNF-treated lesions at week 12. Secondary objectives include ORR and DCR of treated lesions at week 12, and ORR and disease control rate (DCR) at weeks 12, 24 and 36 of treated and non-treated lesions. Additional secondary endpoints include duration of OR and DCR of treated and treated-non treated lesions, median overall survival (mOS) and safety of study drugs. Tumor assessment is performed according to RECIST vs 1.1 and modified (m) mRECIST criteria at baseline and at weeks 6, 12, 24 and 36. Adverse events will be collected according to the CTCAE v. 4.02. The study is ongoing and fifteen patients have been enrolled so far. Clinical trial information: 2012-001991-13.

**TPS9104 General Poster Session (Board #307A), Sat, 8:00 AM-11:45 AM**

**A phase II study to assess vismodegib in the neoadjuvant treatment of locally advanced basal cell carcinoma (laBCC): The Vismodegib Neoadjuvant (VISMONEO) study.** *Presenting Author: Laurent Mortier, Dermatology, CHRU of Lille, Lille, France*

**Background**: BCC is the most common skin malignancy. Surgery cures most cases, but a few patients may exhibit progression to life-threatening, unresectable, locally advanced disease or metastatic tumors and there is no standard therapy for this condition. Vismodegib is a small molecule antagonist of the Hedgehog signalling pathway newly approved in this indication. It showed in a phase II study (ERIVANCE BCC), a tumor response rate of 43% (95%CI: 31 to 56; p<0.001) in laBCC (complete responses 21%). We intend to assess vismodegib in the neo-adjuvant treatment of BCC aiming at reducing the BCC size which will allow a lower surgical stage and preserve the functional and the aesthetic appearance of the affected area. **Methods:** This is an open-label, non-comparative, multicenter, phase II study of vismodegib in patients with laBCC conducted in 33 centers in France. Main eligibility criteria are: age≥ 18 years, histologically confirmed diagnosis of laBCC, BCC with a diameter ≥ 3 cm in areas of intermediate risk of tumor recurrence and ≥ 2 cm in areas of higher risk of tumor recurrence, measurable and/or non-measurable disease, adequate liver and hematological functions. Enrolled patients receive vismodegib 150 mg once-daily po continuously. One cycle of therapy is defined as 28 days of treatment. All patients receive study drug until best overall response, within a maximum treatment period of 10 months. The primary endpoint is the proportion of BCC patients with a down-staging of the initial surgical stage following vismodegib neoadjuvant treatment. Surgical stage, validated by the Reconstructive Surgery teams of three University Hospitals in France, includes tumor size and surgical procedure planned. Secondary endpoints are safety, clinical benefit (assessed by an independent panel of experts), quality of life (Skindex-16 Questionnaire at baseline, after Cycle 1, Cycle 3, Cycle 6, end of treatment), and medico-economical assessment. A total of 50 patients will be recruited; they will be followed-up for 3 years after surgery. Clinical trial information: 2013-004338-13.

**TPS9105 General Poster Session (Board #307B), Sat, 8:00 AM-11:45 AM**

**Phase I-II study of the combination vemurafenib plus peg-interferon in advanced melanoma patients harboring the V600BRAF mutation.** *Presenting Author: Paolo Antonio Ascierto, Unit of Melanoma, Cancer Immunotherapy and Innovative Therapy, Istituto Nazionale Tumori Fondazione, Naples, Italy*

**Background:** Preliminary evidence in the literature suggests that interferon receptor subunit IFNAR1 is down-regulated in melanoma cells harboring a mutated active BRAF. This possibility is supported by our own finding that inhibition of the BRAF-MAPK signaling pathway by vemurafenib up-regulates IFNAR1 expression in BRAF mutated melanoma cells. Moreover, vemurafenib and IFN$\alpha$-2b combination enhances HLA class I antigen expression which is associated with an increased recognition of melanoma cells by cognate T cells. A preclinical study has also showed the ability of vemurafenib and IFN$\alpha$-2b combination to significantly prolong the survival of mice grafted with BRAF mutated melanoma cells. These findings have provided the rationale for designing a novel clinical trial. The study end-points include the evaluation of safety and efficacy of vemurafenib/PEG-interferon (PEG-IFN) combination. **Methods:** VEMUPLINT is an open-label, single-arm, phase I/II trial. Advanced melanoma patients with BRAF V600 mutation will be treated with vemurafenib and PEG-IFN combination (NCT01959633). Eligible patients include unresectable or metastatic melanoma, who have either not been treated or have received no more than 1 line of treatment. The primary end-point is the maximum tolerated dose (MTD) for the phase I study, while is the efficacy, assessed as durable response rate lasting > 32 weeks, for the phase II study. Primary end-points include also evaluation of IFNAR1 up-regulation. Secondary end-points are incidence of grade 3-4 toxicities, disease control rate, time to response, time to progression of brain metastases and overall survival. In the phase I study, groups of 3 patients for each cohort (9 patients) will be entered at each dose level (vemurafenib 960 mg b.i.d. + PEG-IFN 1/2/3 micrograms/Kg). The MTD will be considered the recommended dose for the phase II study. The phase II study will be conducted in approximately 10 investigational sites located in Italy; a total of 42 patients will be enrolled (including 3 patients from the phase I study). This phase I-II trial is currently recruiting patients for the phase I study at the Istituto Nazionale Tumori of Naples, Naples, Italy. Clinical trial information: NCT01959633.

**TPS9106 General Poster Session (Board #308A), Sat, 8:00 AM-11:45 AM**

**Phase II, open-label study of dabrafenib plus trametinib in patients with BRAF mutation-positive melanoma brain metastases: A GSK-sponsored trial.** *Presenting Author: Michael A. Davies, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Data from BREAK-MB (phase II, metastatic melanoma, BRAF V600 mutation positive, with brain metastases, dabrafenib monotherapy) demonstrated a 39.2% overall intracranial response rate and a 81.1% intracranial disease control in cohort A (no prior local therapy), and a 30.8% overall intracranial response rate and a 89.2% intracranial disease control in cohort B (previous local therapy). Median survival was 33.1 and 31.4 weeks for cohorts A and B, respectively. [Long G, et al. *Lancet Oncol*. 2012;13:1087-95]. Data from BRF113220 (phase I/II, metastatic melanoma, BRAF V600 mutation-positive, brain metastasis patients excluded, dabrafenib + trametinib) reported a median progression-free survival (PFS) of 9.4 months with dabrafenib 150mg BID and trametinib 2mg QD combination therapy (150/2), and 5.8 months with dabrafenib monotherapy (HR 0.39, $p$<0.0001). [Flaherty K, et al. *N Engl J Med*. 2012;367(18):1694-703] The median overall survival for the 150/2 therapy was 23.8 months compared with 20.2 months for dabrafenib monotherapy (HR 0.73, not significant). [Daud A, et al. Presented at the Society for Melanoma Research Congress, 2013]. This trial is expected to build the body of evidence regarding the safety and efficacy of dabrafenib plus trametinib combination therapy in patients with BRAF V600 mutation positive, unresectable melanoma brain metastases (MBM). **Methods:** This study will evaluate the safety and efficacy of 4 cohorts. A) V600E, asymptomatic MBM, no prior local therapy; B) V600E, asymptomatic MBM, prior local therapy; C) V600D/K/R, asymptomatic MBM, with or without prior local therapy; D) V600D/E/K/R, symptomatic MBM, with or without prior local therapy. Patients will receive dabrafenib 150 mg BID + trametinib 2 mg QD therapy. 120 patients will be enrolled beginning in January 2014. The primary objective of the study is intracranial response in cohort A patients. Secondary endpoints include; intracranial response in patients in cohorts B, C and D; intracranial disease control; extracranial response; overall response; duration of intracranial, extracranial and overall response; PFS; overall survival; and safety. Clinical trial information: NCT02039947.

**TPS9107 General Poster Session (Board #308B), Sat, 8:00 AM-11:45 AM**

**Targeted modified IL-2 (NHS-IL2, MSB0010445) combined with stereotactic body radiation in advanced melanoma patients after progression on ipilimumab: Assessment of safety, clinical, and biologic activity in a phase 2a study.** *Presenting Author: Howard L Kaufman, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

**Background:** Advanced melanoma patients (pts) can benefit from IL-2 therapy, but treatment is often limited by severe toxicities. The immunocytokine NHS-IL2 is a fusion protein composed of genetically modified IL-2 that preferentially binds to the high-affinity IL-2 receptor, and of a human IgG2 antibody targeting DNA exposed in necrotic tumor regions (NHS76). In preclinical studies, NHS-IL2 showed antitumor activity; in phase 1 trials it was biologically active and well tolerated, both as a monotherapy and in a sequential combination with radiotherapy (Gillessen et al. *Eur J Cancer* 2013; van den Heuvel et al. submitted). This phase 2a, open-label, parallel-group dose-escalation trial investigates safety, clinical and biologic activity of NHS-IL2 following stereotactic body radiation(SBRT) in pts with advanced melanoma (NCT01973608). **Methods:** The primary study objective is to determine the maximum tolerated dose of NHS-IL2 combined with SBRT. Exploratory study objectives are safety, biologic and clinical activity of the combination, and immunogenicity and pharmacokinetics of NHS-IL2. Pts with advanced unresectable or metastatic melanoma that has progressed after ipilimumab as immediately preceding treatment are eligible. Main exclusion criteria: active brain metastases and concurrent systemic immunosuppressive therapy. Up to 86 pts will be enrolled to receive $\leq$3 SBRT (up to 20 Gy on max. 3 lesions or up to 16 Gy if irradiated lesion is located in the thorax), followed by NHS-IL2 iv every 3 weeks in 3 arms: fixed doses of 0.3 mg/kg and 1.0 mg/kg; and dose escalation at 1.8–3.6 mg/kg (standard 3+3 design). If safety allows, up to 14 pts per arm will be enrolled to assess biologic activity, defined by the changes in infiltration of $CD8^+$ and regulatory T cells into the tumor before and during therapy. Depending on the biologic activity, trial arms will be expanded or pooled to determine objective response in 40 pts treated with an active dose. Combination treatment will be continued until disease progression, unacceptable toxicity, or withdrawal of consent. As of Jan 31, 2014, 2 pts are enrolled. Clinical trial information: NCT01973608.

**TPS9108 General Poster Session (Board #309A), Sat, 8:00 AM-11:45 AM**

**Phase 1 study of MEDI4736, an anti-PD-L1 antibody, in combination with dabrafenib and trametinib or trametinib alone in patients with unresectable or metastatic melanoma.** *Presenting Author: Michael S. Gordon, Pinnacle Oncology Hematology, Scottsdale, AZ*

**Background:** Greater understanding of tumor immunology in melanoma has led to the development of targeted treatments with improved outcomes in patients (pts) with metastatic melanoma (MM). Dabrafenib, a V600E BRAF inhibitor, combined with trametinib, a MEK inhibitor, resulted in high response rates, progression-free survival (PFS) of 9.4 mo in *BRAF* mutation-positive melanoma and is now an FDA-approved combination. Adding an immunomodulator may further improve outcomes. MEDI4736, a highly potent anti-PD-L1 antibody, showed clinical activity in a phase 1 study of pts with solid tumors including MM and is being evaluated in combination with dabrafenib/trametinib or trametinib alone in *BRAF* mutation-positive or *BRAF*mutation-negative melanoma. **Methods:** This global, multicenter, open-label phase 1b study (NCT02027961) is enrolling adults with unresectable or MM and ECOG performance status 0-1 into 3 cohorts. In cohort A, *BRAF* V600E or V600K mutation-positive (*BRAF*-MP) pts receive dabrafenib orally (PO) twice daily, trametinib PO once daily (QD) and MEDI4736 intravenously (IV) every 2 wks (q2w), given concomitantly followed by continued dabrafenib/trametinib until progressive disease (PD). In cohorts B and C, *BRAF* V600E or V600K mutation-negative (*BRAF*-WT) pts receive trametinib PO QD and MEDI4736 IV q2w according to 2 different treatment schedules until PD. Primary objectives are determination of maximum tolerated dose (dose-limiting toxicity) and safety profile (adverse events, laboratory evaluations, physical exams, echocardiograms/electrocardiograms) of MEDI4736 in combination with dabrafenib/trametinib or trametinib alone. Secondary objectives include antitumor activity (objective response based on RECIST, duration of response, PFS, and overall survival), pharmacokinetic profile, and immunogenicity of the combination. Exploratory objectives include biomarkers, patient-reported outcomes, and tumor growth parameters. Recruitment is ongoing (target: 69 pts). Clinical trial information: NCT02027961.

**TPS9109 General Poster Session (Board #309B), Sat, 8:00 AM-11:45 AM**

**BeyPro1: A phase II single-arm study for the treatment after recurrence of advanced melanoma patients harboring the $^{V600}$BRAF mutation and pretreated with vemurafenib, with the association of vemurafenib plus fotemustine.** *Presenting Author: Paola Queirolo, Department of Medical Oncology A, National Institute for Cancer Research, Genoa, Italy*

**Background:** BRAF-inhibitor Vemurafenib achieves high response rate and a statistically significant improvement in overall survival (OS) in patients (pts) with unresectable stage III and IV melanoma. However, clinical resistance to this agent eventually arises in most pts. In a Phase I study of Vemurafenib, among 48 pts with progressive disease (PD), 18 pts were treated beyond progression (TBP) $>$ 30 days after local therapy of PD lesions: median OS had not been reached at a median follow-up of 15.5 months from initiation of Vemurafenib, with a median treatment duration beyond initial PD of 3.5 months. Conversely, in pts who were not TBP, median OS was 1.4 months (Kim et al. ASCO 2011). In a series of 112 patients treated with BRAF-inhibitors (Chan et al. ASCO 2013), 36/92 were TBP: median OS from commencement of BRAF-inhibitors in those TBP was longer than those not TBP (15.0 vs 6.5 months, $p<0.001$), as was OS from PD (7.4 vs 1.9 mo, $p=0.001$). These findings suggest that one possible approach to improve the prognostic outlook in pts progressing during Vemurafenib treatment may be continuing the drug in combination with chemotherapy: resistance is not caused by acquisition of secondary BRAF mutations but rather by up-regulation in some cell populations of other proliferative signals with the creation of heterogeneous cell populations partly resistant to BRAF inhibition, and a cytotoxic drug such as Fotemustine (FTM) might act on those proliferating clones. FTM was chosen because it has shown an effect on brain metastases: in a phase III study (Avril et al. JCO 2004) comparing FTM with dacarbazine, the median time of occurrence of brain metastases was longer in the FTM group (22.7 months) than in the dacarbazine group (7.2 months). **Methods:** Thirty pts progressing while on Vemurafenib were enrolled in the study between January and October 2013. The primary objective is to assess the activity of Vemurafenib plus FTM in pts harboring the $^{V600}$BRAF mutation and recurred while on treatment with Vemurafenib. The primary endpoint is PFS. Treatment with FTM plus Vemurafenib will be continued until PD or unacceptable toxicity. Clinical trial information: NCT01983124.

**TPS9110 General Poster Session (Board #310A), Sat, 8:00 AM-11:45 AM**

**Dose-seeking and efficacy study of combination BRAFi and high-dose IFN (HDI) for therapy of advanced melanoma.** *Presenting Author: Diwakar Davar, University of Pittsburgh, Pittsburgh, PA*

**Background:** New immunotherapies and BRAF inhibitors (BRAFi) have improved the prognosis of advanced melanoma. Although BRAFi induce regression in ~50% of patients (pts), responses are incomplete and progression typically occurs at 6 months. Intrinsic/acquired resistance mechanisms represent limitations to single agent BRAFi use. Conversely, immunotherapies benefit only 18-30% of patients. In vitro and in vivo studies suggest that treating BRAF mutated melanoma cells with BRAFi increases sensitivity to IFN. We planned a dose-selection and dose-expansion study to evaluate the novel sequential combination of BRAFi followed after 2 weeks by concurrent BRAFi/IFN$\alpha$. **Methods:** Study will enroll pts with BRAF V600E recurrent/inoperable stage III/IV melanoma. Primary objectives are to evaluate safety/toxicity, identify a phase II dose (RP2D) of combination, and improve progression free survival (PFS). Secondary objectives include improving response rates and documenting evidence of immune modulation. Pts will initially receive vemurafenib at 960 mg twice daily with a 2 week lead-in to exploit immunomodulatory effects. HDI will commence in week 3 with standard induction (4 weeks) and maintenance (48 weeks) schedules employed for adjuvant therapy. Intravenous IFN will be administered 5 days weekly for 4 weeks at 3 escalating dosage levels - 10, 15, and 20 MU/m2/d. Subcutaneous IFN will be administered thrice weekly for 48 weeks at 3 dose levels - 5, 7.5, and 10 MU/m2/d. As combination has not previously been evaluated, HDI will be escalated in 3 fixed dose levels using Storer's modified "up and down" scheme to minimize toxicity. Accrual target in the dose expansion phase is 36 patients treated at RP2D. Prior to study and at serial points during, biopsies of accessible lesions will be obtained. We expect that this combination will increase immune recognition of melanoma cells by CD8+ tumor-infiltrating T cells (TILs) through: 1) upregulation of IFN-$\alpha$R1 and HLA class I APM component expression; 2) inhibition of STAT signaling pathways; and 3) modulation of PD-L1 expression by melanoma cells. Clinical trial information: NCT01943422.

**TPS9111 General Poster Session (Board #310B), Sat, 8:00 AM-11:45 AM**

**The influence of a gene expression signature on the diagnosis and recommended treatment of melanocytic tumors by dermatopathologists.** *Presenting Author: Loren E Clarke, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

**Background:** Many studies have documented suboptimal accuracy and reproducibility in the diagnosis of melanocytic lesions by histopathology, even by experienced dermatopathologists. Therefore, adjunctive methods that provide objective and reliable data have been sought. Recently, a 23-gene expression signature that assesses immune signaling and cell differentiation and uses quantitative reverse-transcription polymerase chain reaction was developed using a cohort of 464 melanocytic neoplasms. (*J Cutan Pathol.* 2014; 41:144-275 [abstr 292263]) The assay has been clinically validated to differentiate benign nevi from malignant melanoma with a sensitivity of 90% and a specificity of 91% in a second, independent cohort of 437 melanocytic lesions representing a broad spectrum of histopathologic types. (*Pending publication*) This study aims to quantify the impact of this assay on diagnosis and management recommendations made by dermatopathologists. **Methods:** Forty-nine dermatopathologists submitted 821 representative histological sections of difficult to diagnose melanocytic lesions encountered during routine practice to a clinical laboratory for gene expression testing. Currently, 513 cases are eligible for study inclusion based upon completed pre- and post-test surveys accompanying each case. Surveys document the physician's diagnosis, predicted biologic behavior (benign, malignant, or indeterminate), level of confidence, and recommendations for management. Study endpoints include the measured level of change in diagnosis, confidence, and treatment recommendations between the pre- and post-test surveys.

**TPS9112 General Poster Session (Board #311A), Sat, 8:00 AM-11:45 AM**

**Pharmacokinetic and pharmacodynamic analysis of preoperative therapy with dabrafenib alone and in combination with trametinib in patients with BRAF mutation–positive melanoma with metastases to the brain (BRV116521).** *Presenting Author: Michael A. Davies, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Dabrafenib (D) has clinical activity in patients (pts) with *BRAF* V600E/K mutation–positive melanoma brain metastases (MBM). The combination of D and trametinib (T) has increased activity in pts with *BRAF*V600E/K mutation–positive melanoma with extracranial metastases (ECM). It is not known whether the activity of D in MBM pts is due to blood-brain barrier penetration of the D parent compound or 1 (or more) of its active metabolites. In addition, the relationships between drug levels (parent compound and metabolites) achieved in MBM, and (1) peripheral exposure and (2) target inhibition in plasma and ECM are unknown. **Methods:** This international, open-label study will enroll up to 30 evaluable pts with stage IV *BRAF*V600E/K metastatic melanoma with untreated, resectable MBM (1-4 cm) and accessible ECM. Pts will be treated with D 150 mg twice daily (BID) for 7-14 days (cohort A, n=15) or D 150 mg BID + T 2 mg once daily for 7-14 days (cohort B, n=15), followed by resection of intracranial lesion(s) and biopsy or resection of accessible ECM(s). Blood (mandatory) and cerebrospinal fluid (CSF; optional) will also be collected on the day of surgery. If clinically indicated, pts in both cohorts will be treated with D + T starting 72 hours postsurgery until disease progression. MBM and ECM tumor tissue will be studied for levels of D (parent and metabolites) and T; expression and activation of pharmacodynamic markers and oncogenic signaling networks (protein, mRNA); DNA mutations and methylation; and immune cell infiltrates. Plasma and CSF will be studied for pharmacokinetics (PK). Blood will also be studied for circulating immune cells and cytokines. The primary objective is to assess PK in MBM, ECM and peripheral blood. Safety and efficacy will also be evaluated. The trial is currently open for accrual in the United States and Australia. Clinical trial information: NCT01978236.

**TPS9113^ General Poster Session (Board #311B), Sat, 8:00 AM-11:45 AM**

**The GERMELATOX DeCOG-trial: German melanoma patients and their attitude toward toxicity during adjuvant interferon treatment.** *Presenting Author: Katharina C. Kaehler, Department of Obstetrics and Gynecology, University Hospital Kiel, Kiel, Germany*

**Background:** Although trials of adjuvant interferon alfa-2b (IFN alpha-2b) in high-risk melanoma patients suggest improvement in disease-free survival (DFS), a metaanalysis could only show a marginal OS survival benefit (OS). Widespread use of adjuvant IFN alpha-2b has been decreased by its significant toxicity.In 2001 Kilbridge et al. (J Clin Oncol 2001) asked US-patients about the degree of improvement in 5-year DFS they would expect to tolerate IFN. At least half of the patients were willing to tolerate mild to moderate and severe IFNa-2b toxicity for 4% and 10% improvements of DFS. On average, patients rated quality of life (QoL) with melanoma recurrence much lower than even severe IFNa-2b toxicity.To date, no data exist on willingness of German melanoma patients to be treated with IFNa-2b. In Germany, melanoma patients are managed by specialized skin cancer units mainly located in certified skin cancer centers and core university hospitals. The willingness of dermatologists to use IFN depends strongly on their experience and capacity to manage IFN-related side effects.A comparison between a German cohort and the US-cohort of Kilbridge would allow new insights into country specific treatment differences. So far no direct comparison has been made between willingness of patients compared to their physicians. **Methods:** In this multicenter non-interventional trial ("GERMELATOX trial") of the Dermatologic Cooperative Oncology Group we assessed preferences and utilities for health outcomes associated with adjuvant IFN among 200 melanoma patients not eligible for IFN due to the low-risk features of their melanoma and 100 dermatooncologists from 10 different melanoma units using the standard gamble technique supported by the willingness to pay mode. The trial described four typical IFN alpha-2b toxicity scenarios and the following three posttreatment outcomes: disease-free health and melanoma recurrence (with or without IFN alpha-2b) leading to cancer death. We also asked patients the improvement in 5-year disease-free survival they would require to tolerate IFN toxicities.The recruitment of the study will be completed in mid 2014.

**TPS9114^ General Poster Session (Board #312A), Sat, 8:00 AM-11:45 AM**

**Biomarker study evaluating the combination of dabrafenib (D) with trametinib (T) versus the combination after 8 weeks of monotherapy with dabrafenib or trametinib in patients with metastatic and unresectable stage IIIC or IV melanoma: GSK study 116613.** *Presenting Author: Christine Mateus, Gustave Roussy Institute, Villejuif, France*

**Background:** Both D and T have demonstrated clinical activity as monotherapies and in combination in *BRAF* mutation–positive melanoma. However, the mechanism of acquired drug resistance and toxicity are not fully understood. We plan to investigate the sequential effects of BRAF and MEK inhibition on skin, blood, and tumor biomarkers, as well as to study correlations between biomarkers and response to treatment and toxicity. **Methods:** This is a 3-arm, open-label, randomized, phase 2 biomarker study in France, comparing the upfront combination of D with T versus their combination after 8 weeks of monotherapy treatment with D or T. As of the end of January 2014, 1 patient was randomized. Approximately 54 eligible patients, ≥ 18 years of age, with histologically confirmed stage IIIc or IV cutaneous melanoma and *BRAF* V600E/K mutation-positive disease will be randomized 1:1:1 to one of three treatment arms. In the monotherapy arms, treatment will be given for 8 weeks continuously (D 150 mg BID or T 2 mg QD) before other drug is dosed. In the combination arm, both drugs, at the respective doses above, will be given upfront. All treatments will be given until disease progression, death, or unacceptable toxicity. The primary objective of this trial is to evaluate biomarkers linked to treatment response, resistance, and toxicity when D and T are given as monotherapy and/or in combination. The secondary objectives are to evaluate the clinical response (overall response rate), as well as the exposures of the 3 arms in connection to clinical response and toxicity, and to characterize the safety profile of D and T in monotherapy and/or in combination. In addition, exploratory objectives are to evaluate changes in inflammation, the impact of the 2 drugs, separately and in combination, on the immune system, progression-free survival, and duration of response. The primary endpoint will be analyzed with a descriptive intent only. Hence, no hypothesis testing will be performed. Clinical trial information: EudraCT number 2012-004577-12.

**TPS9115 General Poster Session (Board #312B), Sat, 8:00 AM-11:45 AM**

**NLG-0304: A phase 2B study of ipilimumab with or without dorgenmeltucel-L (HyperAcute-Melanoma) immunotherapy for patients with stage IV melanoma.** *Presenting Author: Adam I Riker, Advocate Christ Medical Center, Advocate Cancer Institute, Oak Lawn, IL*

**Background:** Dorgenmeltucel-L immunotherapy consists of allogeneic melanoma cells that have been genetically modified to express the carbohydrate $\alpha(1,3)$Gal, to which humans have an inherent pre-existing immunity. It is $\alpha$Gal that is primarily responsible for the hyperacute rejection of foreign tissue via this potent immune defense mechanism in humans. Dorgenmeltucel-L leverages this mechanism to educate the immune system towards components of the patients' own tumor cells. In prior Phase 1 and 2 studies of dorgenmeltucel-L, there have been no grade 3 or higher immunotherapy related adverse events. In the Phase 2 study in combination with pegylated interferon, all evaluable patients developed autoimmune antibodies and 4 developed vitiligo which correlated with either CR or durable post resection NED state. Ipilimumab has now become standard therapy for advanced melanoma patients, particularly those that are BRAF negative. Preclinical data has demonstrated synergy between therapeutic vaccination and anti-CTLA-4 therapy. This study is designed to determine if there is benefit to adding dorgenmeltucel-L to standard ipilimumab therapy. **Methods:** This is a randomized Phase 2B study for patients with stage 4 metastatic melanoma. 100 patients will be randomized to receive either standard ipilimumab therapy (3mg/kg q 3 weeks x 4) or standard ipilimumab plus dorgenmeltucel-L 300 million cells per each immunization, given weekly x 4, then biweekly for 5 months, monthly for 6 months, and every 3 months for an additional year. Patients receiving dorgenmeltucel-L and ipilimumab will start ipilimumab with the $4^{th}$ dose of dorgenmeltucel-L. Primary endpoint is the overall clinical response rate. Secondary endpoints include Disease free survival (DFS), Progression-free survival (PFS), and Overall survival (OS), Duration of Complete Response (CR), Duration of Stable Disease (SD), and immunologic correlates. Clinical trial information: NCT02054520.

**TPS9116^ General Poster Session (Board #313A), Sat, 8:00 AM-11:45 AM**

**A phase II, single-armed, multicenter trial of neoadjuvant vismodegib in patients with large and/or recurrent basal cell carcinoma: NICCI.** *Presenting Author: Ulrike Leiter, Department of Dermatooncology, University of Tuebingen, Tuebingen, Germany*

**Background:** Vismodegib is useful to treat locally advanced or metastatic basal cell carcinoma (BCC) but has not been evaluated for use in a neoadjuvant setting to shrink BCCs before surgery. This multicenter, non-randomized, single-armed phase II clinical study is performed to evaluate the efficacy of neoadjuvant vismodegib in patients with large or large recurrent basal cell carcinoma (BCC). **Methods:** The primary endpoint is to evaluate the efficacy of vismodegib as measured by the percentage of basal cell carcinomas that reach complete remission (CR, as determined by histopathology), partial remission (PR), or stable disease (SD) versus progressive disease (PD) after 12 weeks of treatment. Secondary endpoints include the assessment of i) size-reduction of BCC in $cm^2$ as intended for excision (baseline vs. 12 weeks of treatment by planimetrics), ii) treatment-induced changes assessed by non-invasive imaging techniques (optional: in vivo confocal laserscan-microscopy, optical coherence tomography, high resolution ultrasonography) in correlation with histopathology, and iii) toxicity and tolerability including health-related quality of life questionnaire (Skindex-16) Study design: 75 patients with a BCC or recurrent BCC ($\geq$ 2 cm in diameter in head/neck region, $\geq$ 5 cm for trunk/extremities plus at increased risk for cosmetic disfigurement or functional defects) will be enrolled. After 12 weeks of treatment with vismodegib 150mg/d all patients will receive micrographic excision of the remaining tumor area. Patients will be observed for one year. Documentation of the two-dimensional tumor size (in $cm^2$) as intended for excision will be performed by planimetrics at the time of study inclusion, at week 13 before surgery and at the end of study. Clinical trial information: 2013-004767-31.

**TPS9117 General Poster Session (Board #313B), Sat, 8:00 AM-11:45 AM**

**Phase 1/2 trial of the indoleamine 2,3-dioxygenase pathway (IDO) inhibitor indoximod plus ipilimumab for the treatment of unresectable stage 3 or 4 melanoma.** *Presenting Author: Eugene Kennedy, NewLink Genetics, Ames, IA*

**Background:** IDO is an enzyme that catalyzes the initial and rate limiting step in the conversion of tryptophan to kynurenine. Tryptophan depletion enhances the number and function of the Treg (suppressive) arm of the immune system and inhibits the effector T cell (stimulatory) arm. In addition, it has been shown that kynurenine metabolites may augment the suppressive effects on inflammation and immune responses. The main function of IDO is the regulation of acquired local and peripheral immune tolerance in normal and pathological conditions. In cancer, IDO can either be expressed directly by the tumor cells themselves, or induced indirectly in host antigen presenting cells by the presence of tumor. In these settings, IDO mediates an acquired immune tolerance towards tumors, allowing tumors to thwart an immune response by the host. Therefore, IDO is an attractive target. Ipilimumab is a monoclonal antibody that blocks the immunosuppressive receptor CTLA-4 on T cells, thus enhancing immune responses against tumors. Tumor models have shown synergistic effects with anti-CTLA-4 treatment in combination with indoximod providing a rationale for combination therapy for the treatment of melanoma. **Methods:** This is a Phase 1/2 study of indoximod dose escalation in combination with ipilimumab (3mg/kg q3 weeks x 4 doses) in a standard 3+3 design during the Phase 1 portion. Eligible patients will have unresectable Stage 3 or 4 melanoma. Up to 12 patients will be enrolled in the Phase 1 portion. Indoximod will be administered concurrently with ipilimumab as a twice daily oral dose, continuously for each 21 day cycle. Treatment with indoximod will continue beyond treatment with ipilimumab (halted either due to reaching 4 doses or toxicity) until disease progression or toxicity. The Phase 2 portion will enroll up to 80 patients in a non-randomized study. Patients will receive ipilimumab at the standard dose with concurrent indoximod at the dose determined in Phase 1. Primary endpoints for the Phase 1 portion include safety, toxicity, and determination of a Phase 2 dose. Primary endpoints for the Phase 2 portion will be to evaluate safety and efficacy. Clinical trial information: NCT02073123.

**TPS9118^ General Poster Session (Board #314A), Sat, 8:00 AM-11:45 AM**

**BRIM8: A phase III, randomized, double-blind, placebo-controlled study of vemurafenib adjuvant therapy in patients with surgically resected, cutaneous BRAF-mutant melanoma at high risk for recurrence (NCT01667419).** *Presenting Author: Karl D. Lewis, University of Colorado Cancer Center, Aurora, CO*

**Background:** Approximately 50% of melanomas carry a mutation in the *BRAF* gene. The oral BRAF inhibitor vemurafenib (VEM) has demonstrated meaningful clinical benefit in $BRAF^{V600}$ mutation-positive, locally advanced/unresectable or metastatic melanoma. For patients (pts) with resected melanoma, interferon alfa-2b represents the only widely approved adjuvant therapy; however, its use is limited by a modest improvement in disease recurrence and a high incidence of severe adverse effects that lead to treatment discontinuation in up to a third of pts. BRIM8 is a phase III, international, multicenter, double-blind, randomized, placebo-controlled study designed to evaluate the safety and efficacy of VEM in pts with resected cutaneous melanoma at high risk (>50%) for recurrence (stage IIC and III disease). **Methods:** Pts aged ≥18 yrs with histologically confirmed stage IIC or III $BRAF^{V600}$mutation-positive (by cobas testing) melanoma of cutaneous origin that has been completely resected are eligible. Pts without clinical or radiologic evidence of regional lymph node involvement must undergo sentinel lymph node biopsy, and those with evidence of regional or sentinel lymph node involvement must undergo complete regional lymphadenectomy. Pts with a history of systemic therapy for treatment or prevention of melanoma (including interferon alfa-2b) are ineligible. Two cohorts (C) will enroll ~ 725 pts: C1—500 pts with completely resected stage IIC, IIIA (one or more nodal metastasis >1 mm in diameter, per Rotterdam classification), or IIIB cutaneous melanoma; C2—225 pts with stage IIIC cutaneous melanoma. Pts will be randomized 1:1 to receive VEM (960 mg bid) or placebo for 52 weeks with randomization stratified by pathologic stage and region (C1) and by region (C2). Primary efficacy outcome measure is investigator-assessed disease-free survival. Secondary efficacy outcome measures include overall and distant metastasis-free survival. Safety, pharmacokinetic, and pt-reported outcomes will also be assessed. As of 13 Jan 2014, 179/196 sites are active and 154 pts have been randomized (C1: 89; C2: 65). Clinical trial information: NCT01667419.

**TPS9119 General Poster Session (Board #314B), Sat, 8:00 AM-11:45 AM**

**Phase I/II study of the TLR3 agonist poly-ICLC as an adjuvant for NY-ESO-1 protein vaccination with or without Montanide ISA-51 vg in patients with melanoma.** *Presenting Author: Rachel Lubong Sabado, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** Poly-ICLC is a synthetic dsRNA complex which directly activates DCs and also triggers NK cells to kill tumor cells. Compared to LPS and R848, Poly-ICLC is the most potent TLR adjuvant due to its induction of cytokines such as IL-12 in the absence of IL-10, and maintenance of high levels of CD80 and CD86 in DCs. This study assessed the therapeutic potential of TLR3 activation by adding Poly-ICLC to a NY-ESO-1 protein vaccine with and without Montanide in surgically resected stage IIB-IV melanoma patients. **Methods:** In Phase I of the study, patients received subcutaneous injection of 100$\mu$g NY-ESO-1 protein and 1.1mL Montanide emulsified in escalating doses of Poly-ICLC: 0.35mg (cohort 1; N=3), 0.70mg (cohort 2; N=3), or 1.4mg (cohort 3; N=3). The cycles of vaccination were repeated every 3 weeks for a total of 4 cycles. In Phase II of the study, patients were randomized to subcutaneous vaccination of 100$\mu$g NY-ESO-1 protein with 1.4 mg Poly-ICLC, the dose established in the Phase I of the study, (Arm A; N=12) or with 100$\mu$g NY-ESO-1 protein, 1.4mg Poly-ICLC and 1.1ml Montanide (Arm B; N=12). The cycles of vaccination were repeated every 3 weeks for a total of 4 cycles. Blood samples were collected at baseline, one week after each cycle of vaccination, and at follow-up visit for the assessment of NY-ESO-1-specific humoral and cellular immune responses. Clinical trial information: NCT01079741.

**TPS9120 General Poster Session (Board #315A), Sat, 8:00 AM-11:45 AM**

**NCI 8628: A randomized phase II study of ziv-aflibercept (Z) and high-dose interleukin-2 (HD IL-2) or HD IL-2 alone for inoperable stage III or IV melanoma—Efficacy and biomarker study.** *Presenting Author: Madeeha Ashraf, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** IL-2 plays a central role in immunity affecting the proliferation and survival of effectors of antitumor response. IL-2 at high bolus IV dosage gives a 16% response rate and durable responses in 4-5% of patients (pts) with metastatic melanoma. VEGF plays a critical role in angiogenesis and host innate and adaptive immunity. VEGF blocks maturation of dendritic cells and inhibits priming of T cell responses. High baseline serum VEGF was reported to be a predictor of non-response to HD IL-2. We developed a strategy to deplete VEGF prior to HD IL-2 to reverse the immunosuppressive impact of VEGF and enhance antitumor T cell response. Z (known as aflibercept outside the US) is a high-affinity soluble decoy VEGF receptor and potent angiogenesis inhibitor. Our phase II study of Z alone for advanced melanoma showed median OS of 16.3 months and PFS 3.7 months. **Methods:** NCI 8628 is a phase II trial of Z and HD IL-2 (Arm A) versus HD IL-2 alone (Arm B) randomized 2:1 respectively with accrual goal 105 pts. Arm A: consists of 3 courses (maximum) and each course consists of 2 cycles of HD IL-2 at 600,000 IU/kg IV every 8 hours for up to 14 doses (1$^{st}$ cycle), followed by a rest period of 1-2 weeks' (wk) rest and readmission for HD IL-2 (2$^{nd}$ cycle). Z is given concurrently at 3 mg/kg IV every 2 wk, starting 2 wk prior to IL-2 in course 1. In the absence of disease progression, maintenance Z is given at 4 mg/kg every 2 wk after completion of IL-2. Arm B: patients receive HD IL-2 alone for a maximum of 3 courses (6 cycles). Eligible pts: Stage III inoperable or Stage IV (any M) melanoma . ECOG performance status of 0/1 and adequate organ function for HD IL-2. Up to two prior regimens for metastatic melanoma are allowed, and stable treated brain metastases. Response assessment follows RECIST v.1.1. Blood and tumor specimens are being collected prospectively for biomarker and mechanistic studies. Clinical trial information: NCT01258855.

**TPS9121 General Poster Session (Board #315B), Sat, 8:00 AM-11:45 AM**

**MIKIE: A randomized, double-blind, regimen-controlled, phase II, multicenter study to assess the efficacy and safety of two different vismodegib regimens in patients with multiple basal cell carcinomas.** *Presenting Author: Rainer Kunstfeld, Medical University of Vienna, Vienna, Austria*

**Background:** Vismodegib, a Hedgehog signaling pathway inhibitor, is FDA and EMA approved for patients (pts) with advanced basal cell carcinoma (BCC) who are not candidates for surgery or radiotherapy. While vismodegib reduces BCC tumor burden and blocks growth of new BCCs in pts with basal cell carcinoma nevus syndrome (BCCNS), further studies are required to optimize the therapeutic index of long-term (chronic) therapy. The MIKIE study (NCT01815840) assesses the efficacy and safety of 2 intermittent vismodegib dosing regimens in pts with multiple BCCs. **Methods:** MIKIE is a randomized, double-blind, regimen-controlled phase II study, in adults with multiple BCCs (including BCCNS) ≥18 years with ≥1 histopathologically confirmed BCC and ≥6 clinically evident BCCs (at least three ≥5 mm in diameter). 200 pts are planned to be randomized (1:1) to regimen A or B and stratified by BCCNS status, geographic region, and immunosuppression status. In regimen A, pts receive 3 courses of vismodegib (150 mg/d) for 12 weeks followed by placebo for 8 weeks, followed by a final 12-week course of vismodegib. In regimen B, pts receive vismodegib (150 mg/d) for 24 weeks, followed by 3 alternating courses of placebo (8 weeks) followed by vismodegib (8 weeks). Total duration of treatment will be 72 weeks in both arms, with 52 weeks of follow up. Major inclusion criteria include ECOG performance status 0–2; adequate hematopoietic, hepatic, and renal function; and signed written informed consent. Major exclusion criteria include inoperable metastatic or locally advanced BCC. Primary objective includes the percentage reduction from baseline in the number of clinically evident BCCs after 72 weeks of treatment in the 2 regimens. Secondary objectives include the percentage reduction in overall size of 3 largest BCCs, the proportion of pts with a 50% reduction in BCCs, the number of pts with new BCCs, recurrence rate, and safety and tolerability (including dropout rate due to tolerability). Skindex-16 quality of life and pharmacokinetic assessments will be conducted at selected sites. The first patient was enrolled in March 2013; the study is ongoing. Clinical trial information: NCT01815840.

**Effect of denosumab versus zoledronic acid (ZA) in preventing skeletal-related events (SREs) in patients with metastatic bone disease: Subgroup analyses by baseline characteristics.** *Presenting Author: Allan Lipton, Penn State Hershey Medical Center, Hershey, PA*

**Background:** There is an interest in identifying patients at risk for SREs who may benefit most from treatment with bone-targeted agents (BTA). Previous results from a subgroup analysis of three phase 3 trials demonstrated denosumab was superior to ZA in preventing SREs (pathologic fracture, radiation or surgery to bone, or spinal cord compression) regardless of baseline clinical pain symptoms or prior SRE status. This analysis assesses if denosumab is superior to ZA in delaying patients' time to SREs across relevant baseline characteristics. **Methods:** Patients with metastatic bone disease were randomized 1:1 to receive either SC denosumab 120 mg + IV placebo (n=2,862) or IV ZA 4 mg (adjusted for CrCl) + SC placebo Q4W (n=2,861) in double-blinded phase 3 studies. Time to first on study SRE and time to first and subsequent SRE were evaluated in patients by several baseline variables: location of skeletal metastases (mets) (axial vs appendicular), presence of visceral mets (yes/no), urinary N-telopeptide (uNTx) level (median; ≥43.5 vs <43.5 nmol/mmol), number of bone mets(<2 or ≥2), and ECOG performance status (0 or ≥1). **Results:** Denosumab significantly delayed time to first SRE compared to ZA regardless of patients' baseline characteristics. Similar results were noted in preventing first and subsequent SREs in all subgroups. **Conclusions:** Denosumab significantly delayed patients' time to SREs compared to ZA regardless of patient's baseline status. Clinical trial information: NCT00321464, NCT00330759, NCT00321620.

**Benefit of denosumab vs ZA on time to first on-study SRE.**

| Baseline characteristic | HR (95% CI) | *P*-value |
|---|---|---|
| Axial bone mets only (n=1,422) | 0.83 (0.70,1.00) | 0.046 |
| Appendicular bone mets only (n=753) | 0.78 (0.61,0.99) | 0.042 |
| Both axial & appendicular bone mets (n=1,695) | 0.83 (0.71, 0.97) | 0.022 |
| ≥2 bone mets (n=2,234) | 0.81 (0.71,0.93) | 0.003 |
| <2 bone mets (n=3,489) | 0.84 (0.74,0.94) | 0.003 |
| Visceral mets (n=2,341) | 0.80 (0.69,0.93) | 0.003 |
| No visceral mets (n=3,382) | 0.84 (0.75,0.94) | 0.002 |
| High uNTx (n=2,553) | 0.86 (0.76,0.98) | 0.028 |
| Low uNTx (n=2,553) | 0.75 (0.65, 0.86) | <0.001 |
| ECOG 0 (n=2,312) | 0.82 (0.71,0.94) | 0.006 |
| ECOG ≥1 (n=3,398) | 0.84 (0.75,0.94) | 0.002 |

**Phase 3 study of NEPA, a fixed-dose combination of netupitant and palonosetron, for prevention of chemotherapy-induced nausea and vomiting during repeated moderately emetogenic chemotherapy (MEC) cycles.** *Presenting Author: Matti S. Aapro, Clinique de Genolier, Genolier, Switzerland*

**Background:** Antiemetic guidelines recommend co-administration of targeted prophylactic medications aimed at inhibiting several molecular pathways involved in emesis. NEPA is a novel, fixed-dose combination of a new $NK_1$ receptor antagonist (RA), netupitant (NETU 300 mg), and palonosetron (PALO 0.50 mg), a pharmacologically distinct 5-$HT_3$RA. NEPA was previously shown to be superior to PALO after a single chemotherapy (CT) cycle in this study; maintenance of efficacy/safety over continuing cycles has been evaluated as a secondary objective. **Methods:** This multinational, randomized, double-blind, parallel group study assessed the efficacy/safety of single oral doses of NEPA versus PALO in chemotherapy-naive patients (pts) receiving multiple cycles of anthracycline-based CT. All pts also received oral dexamethasone (DEX) 12 mg (NEPA) or 20 mg (PALO) on Day 1. Efficacy endpoints were complete response (CR: no emesis, no rescue medication) and no significant nausea (<25 mm on 100 mm VAS). **Results:** 1,455 pts were randomized; 1286 participated in the multiple cycle extension. Patients participated in 5969 total CT cycles; 76% completed at least 4 cycles. Treatment groups were comparable; female (98%), white (80%), mean age of 54 yrs. The superiority of NEPA over PALO for overall (0-120 hr) CR during Cycle 1 was maintained over multiple CT cycles. A greater proportion of NEPA-treated pts also had no significant nausea over repeated cycles. Most frequently reported study drug-related adverse events (AEs) for NEPA included headache (3.5%) and constipation (2.0%) during the multiple cycle extension. The type/incidence of AEs were similar for NEPA and PALO. **Conclusions:** NEPA, a novel, fixed-dose combination targeting dual antiemetic pathways, is highly effective and safe over multiple cycles of MEC. A single dose of NEPA + DEX on Day 1 of CT offers guideline-based prophylaxis with a convenient, single-day treatment. Clinical trial information: NCT01339260.

| Overall CR rates (% patients) | NEPA | PALO | P value |
|---|---|---|---|
| Cycle 1 | N = 724<br>74.3% | N = 725<br>66.6% | 0.001 |
| Cycle 2 | N = 635<br>80.3% | N = 651<br>66.7% | <0.0001 |
| Cycle 3 | N = 598<br>83.8% | N = 606<br>70.3% | <0.0001 |
| Cycle 4 | N = 551<br>83.8% | N = 560<br>74.6% | <0.0001 |

**9503** **Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Aprepitant versus metoclopramide, both combined with dexamethasone, for preventing cisplatin-induced delayed emesis: A randomized, double-blind study.** *Presenting Author: Fausto Roila, Oncologia Medica, Ospedale S. Maria, Terni, Italy*

**Background:** A combination of aprepitant, a 5-HT3 receptor antagonist, and dexamethasone is recommended for the prophylaxis of cisplatin-induced nausea and vomiting in acute phase, and aprepitant+dexamethasone (A+D) in delayed phase. Aim of this study was to verify if A+D is superior to metoclopramide plus dexamethasone (M+D) in preventing delayed emesis in cancer patients receiving the same prophylaxis for acute emesis. **Methods:** A randomized double-blind study comparing A+D versus M+D was completed in previously untreated cancer patients. Before chemotherapy, all patients were treated with intravenous palonosetron 0.25 mg, dexamethasone 8 mg, and oral aprepitant 125 mg. On day 2-4 patients randomly received oral dexamethasone 8 mg qd plus aprepitant 80 mg qd (days 2-3) or metoclopramide 20 mg qid plus dexamethasone 8 mg bid. Primary endpoint was rate of complete response (no vomiting, no rescue treatment) in day 2-5 after chemotherapy. **Results:** Of 303 enrolled patients 288 were evaluable, 147 receiving A+D, 137 M+D. Day 1 results were similar inboth arms. On day 2-5, complete response rate was not significantly different (80.3% with A+D versus 82.5% with M+D, p<0.38, respectively), and all secondary endpoints were also similar (complete protection, total control, no vomiting, no nausea, score of Functional Living Index-Emesis; p<0.24). Adverse events incidence was not significantly different between the two treatments. **Conclusions:** In cancer patients submitted to cisplatin-based chemotherapy, receiving the same antiemetic prophylaxis foracute emesis, A+D is not superior to M+D in preventing delayed emesis, and both treatments present similar toxicity. Clinical trial information: NCT00869310.

**9504 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Long-term risk of heart failure associated with adjuvant trastuzumab in breast cancer patients.** *Presenting Author: Hart Goldhar, University of Toronto, Toronto, ON, Canada*

**Background:** The late cardiac effect of adjuvant trastuzumab (T) and its potential interaction with anthracycline in the general population have not been well studied. The purpose of this retrospective population-based cohort study was to determine the long-term risk of heart failure (HF) associated with adjuvant T and chemotherapy, compared to chemotherapy alone. **Methods:** Female breast cancer patients in Ontario, diagnosed between 2003 and 2009 were identified by the Ontario Cancer Registry and linked to administrative databases to ascertain demographics, cardiac risk factors, comorbidities, and use of adjuvant T and other chemotherapy. Patients with pre-existing HF were excluded. The main endpoint was new diagnosis of HF, obtained using an algorithm of admission and physician claims data. Group differences were assessed by the Kaplan-Meier (KM) method and multivariable piecewise Cox regression. Competing risk analysis using the Fine and Gray method and propensity score matching analysis were performed. **Results:** 19,074 women with breast cancer treated with adjuvant chemotherapy were identified, of whom 3 371 (17.7%) also received adjuvant T. Anthracycline use was 84.9% overall. The groups did not differ significantly in demographics, comorbidities, or cardiac risk factors. After a median follow-up of 5.9 years, patients treated with T and chemotherapy were more likely to develop HF than patients on chemotherapy alone (5-year KM estimates of 5.3% vs. 2.6%; $p<0.0001$ (log-rank)). After adjusting for confounders, adjuvant T remained independently associated with incident HF in the first 1.5 years (HR=5.77, 95% CI 4.38-7.62, p=0.0004), but not thereafter (HR=0.87, 95% CI 0.57-1.33, p=0.53). Anthracycline did not increase the risk of HF with T synergistically (interaction p=0.23). Competing risk and propensity score analyses revealed similar results. **Conclusions:** In this large population-based cohort study of breast cancer patients with long-term follow-up, adjuvant T was associated with increased risk of HF in breast cancer survivors, within the first 1.5 years of initiating treatment, but not thereafter. This provides reassurance about the long-term cardiac safety of adjuvant T in the general population.

**9505 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Cardiovascular diseases after Hodgkin lymphoma treatment: 35-year disease risk and sequence of events.** *Presenting Author: Frederika A. van Nimwegen, Department of Psychosocial Oncology and Epidemiology,The Netherlands Cancer Institute, Amsterdam, Netherlands*

**Background:** Hodgkin lymphoma (HL) survivors are known to be at increased risk of cardiovascular disease (CVD), causing excess morbidity and mortality. It is unclear, however, whether the increased risk persists after 35 years and whether there are specific patterns in the sequence of multiple CVDs in individual patients. **Methods:** A cohort study was performed including 2,528 5-year HL survivors, diagnosed before age 51 and treated between 1965-1995. We assessed CVD endpoints (ischemic heart disease [IHD], congestive heart failure and cardiomyopathy [HF] and valvular heart disease [VHD]) up to October 2013 through questionnaires to GPs and cardiologists. Cumulative incidence of CVDs was estimated accounting for death as a competing risk. Risk factors were evaluated using Cox regression. Standardized Incidence Ratios (SIRs) were estimated to compare CVD risk with the general population. **Results:** We identified 1,419 CVDs in 752 patients, after a median follow-up of 21 years. Following mediastinal radiation (medRT), 35-year cumulative incidence of CVD was 46.3% (95%CI: 43.5%-49.1%), compared to 18.6% in patients not treated with medRT (14.3%-23.4%). The most frequently diagnosed first cardiac event was IHD (49%), followed by VHD (40%). 49% of CVD patients developed multiple CVDs; 92% of these patients received medRT; among patients with one CVD and patients without any CVDs, this was 90% and 77%, respectively ($p<0.001$). HF was mostly diagnosed as last CVD (67% of HF). Both medRT (Hazard Ratio (HR): 3.6, 95%CI: 2.8-4.7) and anthracycline-containing chemotherapy (HR: 1.6, 95%CI: 1.3-1.9) increased the risk of any CVD independently. More than 35 years after HL diagnosis, our patients had a 2.1–fold increased SIR of primary IHD or HF (95%CI: 1.1-3.7), compared to the general population, corresponding to 126 excess cases per 10,000 person years. 9.4% of patients who died, died from CVDs. Median survival time after a first CVD was 5.1 years. **Conclusions:** The risk of CVD is strongly increased for at least 35 years following HL treatment, especially after medRT. Multiple CVDs are frequently observed. Physicians should be aware of the persistently increased risk of CVDs and the increased risk of developing subsequent CVDs.

**9506 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Increasing cardiovascular screening in at-risk adult survivors of pediatric malignancies: A randomized controlled trial.** *Presenting Author: Melissa M. Hudson, St. Jude Children's Research Hospital, Memphis, TN*

**Background:** Adults treated with anthracycline chemotherapy and/or chest radiation for pediatric malignancies are at increased risk of cardiomyopathy. Left ventricular function (LVF) screening provides opportunities for early detection and intervention that may preserve heart function. The objective of the ECHOS study was to determine whether the addition of advanced practice nurse (APN) telephone counseling to a print survivorship care plan (SCP) significantly increases the proportion of at-risk survivors who complete cardiomyopathy screening. **Methods:** Survivors currently age $>$ 25 years participating in the Childhood Cancer Survivor Study who received cardiotoxic therapy and reported no history of cardiac screening during the past 5 years were eligible for enrollment. The 472 participants (mean age 40.1, range 25.0-59.0; 53.3% females) were randomized to: 1) standard care consisting of SCP summarizing cancer treatment and cardiac health screening recommendations (n=234) or 2) standard care plus two APN telephone counseling sessions (n=238). The primary outcome, completion of a LVF assessment within 1 year, was validated by medical records and compared between the two arms using adjusted relative risks (RR) with 95% confidence intervals (CI). **Results:** Participants in the standard and APN counseling groups did not differ by demographic or clinical characteristics. At the time of 1-year follow-up (411 participants completing the study), 107/205 (52.2%) of the survivors in the APN group completed screening compared to 46/206 (22.3%) in the non-APN group ($p<0.0001$). With adjustment for gender, age ($<30$, $30+$) and Children's Oncology Group recommended screening frequency group (annual, 2 years, 5 years), survivors in the APN-group were more than two times more likely than the control group to have the recommended cardiovascular screening (RR 2.31; 95% CI: 1.74-3.07). **Conclusions:** The addition of telephone counseling to a SCP with cardiac health screening recommendations increases cardiac screening in at-risk survivors. These strategies can be adapted to support other types of health-protective screening in other at-risk survivor populations. Clinical trial information: NCT01003574.

**9507 Oral Abstract Session, Mon, 3:00 PM-6:00 PM**

**Impact of vaginal dehydroepiandosterone (DHEA) on vaginal symptoms in female cancer survivors: Trial N10C1 (Alliance).** *Presenting Author: Debra L. Barton, Mayo Clinic, Rochester, MN*
