**Background:** Cancer immunotherapy (CIT) based on Dendritic Cells (DC) is developing into a more mature therapy option as clinical trials progress. Our approach involves the microbial danger molecule Lipopolysaccharide (LPS) in connection with Interferon-Gamma (IFNg) to generate mature DCs that release Interleukin-12 (IL12). As the IL12 production is limited to a timespan of about twenty-four hours, we inject DCs that have been exposed to LPS/IFNg for six hours in order to ensure that IL12 release is still ongoing during the in vivo interaction with T cells. **Methods:** We here report an analysis of 27 patients with advanced solid extra-cranial metastatic malignancies that received our DC CIT approximately ten years ago. The patients come from two phase I clinical trials and were age-matched and disease-matched. To explore potential factors contributing to the extended survival of certain patient groups, we studied a set of immunological variables in the peripheral blood mononuclear cells and the vaccine, where available from these patients. Methods used were flow cytometry, Elispot assays, Cytometric Bead Arrays and qRT-PCR. Statistical techniques included Student's T test, Pearson's correlation, Kaplan-Meier curves and Cox regression. **Results:** Of the total 27 study participants, six (~22%) were still alive. 20 patients of one of those two phase I trials have already been reported in an interim analysis in 2007. In spring 2013, which is approximately ten years after the advent of the trial, five of the twenty (1/4=25%) were still alive. Immunological variables with significantly different values in patients alive at the time of review include RORgt mRNA levels, GATA3 mRNA levels, CD94+ cells and IL-17 production. **Conclusions:** Long-term survival has been reached in a subset of patients with advanced metastatic disease that received our DC CIT approximately ten years ago. The immunological variables we studied might be a first hint at future biomarkers that can identify potential long-term survivors. Further studies with an increased number of patients are needed to consolidate our observations.

**3097 General Poster Session (Board #164), Sun, 8:00 AM-11:45 AM**

**Phase I/IIa study of therapeutic p16$^{INK4a}$ vaccination in patients with HPV-associated cancers.** *Presenting Author: Miriam Reuschenbach, Department of Applied Tumor Biology, Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany*

**Background:** Therapeutic strategies specifically targeting HPV-associated cancers are lacking. The cellular protein p16$^{INK4a}$ is strongly overexpressed in HPV-associated cancers, while in normal tissues p16$^{INK4a}$ expression is barely detectable. Therefore targeting of p16$^{INK4a}$ by vaccination could represent an interesting immune therapeutic approach for patients with HPV-associated cancers. We performed a phase I/IIa trial to monitor toxicity and immunogenicity of p16$^{INK4a}$vaccination (Vicoryx). **Methods:** Patients with advanced p16$^{INK4a}$-overexpressing, HPV DNA-positive cancer (anogenital region, head and neck) were included after completion of standard treatment. The protocolcomprised a total of 12 subcutaneous injections of a synthetic p16$^{INK4}$ peptide mixed with Montanide ISA-51 VG in weekly intervals. Objectives of the trial were clinical safety and changes of humoral and cellular immune responses against the p16$^{INK4a}$peptide. T cell responses were monitored by interferon-gamma ELISpot and antibodies by ELISA from peripheral blood. **Results:** Phase I is completed with 10 patients, phase IIa is ongoing with 14 patients recruited of 16 planned. No toxicity was observed during and after vaccination that was regarded as related to vaccination with the auto-antigen p16$^{INK4a}$ in any of the patients. While pre-existing baseline T cell and antibody responses against the p16$^{INK4a}$ peptide were rare, p16$^{INK4a}$-reactive T cells and antibodies were successfully induced in 8 of 16 patients analyzed to date. So far one head and neck cancer patient with lung metastases completed the entire study protocol with stable disease for now 18 months after the last vaccination. The remaining 9 patients of phase I had progressive disease. **Conclusions:** This is the first study demonstrating that p16$^{INK4a}$ peptide vaccination is safe and well tolerated and that immune responses against p16$^{INK4a}$ can be induced by p16$^{INK4a}$ peptide vaccination and are not accompanied by clinical autoimmune symptoms. Further trials will be designed to assess whether this approach may be an adjuvant therapeutic strategy for patients with HPV-associated cancers. Clinical trial information: NCT01462838.

**3098 General Poster Session (Board #165), Sun, 8:00 AM-11:45 AM**

**Synthetic IL-33 DNA as anti-tumor adjuvant in vivo.** *Presenting Author: Daniel Villarreal, University of Pennsylvania, Philadelphia, PA*

**Background:** Antigen specific CD4+ and CD8+ T cell responses have been generated in 78-90% of volunteers in two recent HPV and HIV clinical studies using our highly optimized DNA immunogens delivered using *in vivo* electroporation. IL-12 DNA was shown to augment T-cell responses in a prophylactic HIV clinical trial as compared to using antigen alone (increase in response rates of 36.4% and 18.6% in the CD4+ and CD8+ T cell compartments respectively) which could prove critical as available FDA-licensed adjuvants are limited, and include aluminum salts, or more recently, LPS formulations and do not improve CD8$^+$T cell immunity. **Methods:** Here we describe an advance to augment the immune responses of DNA delivered by electroporation in the cancer immunotherapy arena. IL-33 has two different biologically active forms known as full-length IL-33 and mature IL-33. **Results:** Full-length IL-33 is thought to be the biologically most active form to promote inflammation, while the function of the mature cleaved form of IL-33 in modulating the immune responses remains more elusive. The potential ability of both isoforms to influence the adaptive immune response and act as an adjuvant has not previously been explored. We show that both isoforms of IL-33 are capable of enhancing potent antigen specific effector and memory T cell immunity in vivo when used in a DNA immunotherapy for HPV16. We also show that while both forms of IL-33 drove robust HPV specific IFNy responses (~2000 SFU), neither form drove high secretion of IL-4 (<250 SFU). Moreover, both isoforms augmented polyfunctional CD4$^+$ and CD8$^+$ T cell responses when compared to antigen alone (24-25% vs 18% and 66-67% vs 56%, respectively) and resulted in higher antigen-specific CD8$^+$ degranulation. Co-administration with IL-33 conferred 100% protection against challenge with HPV E6/E7-expressing tumors (TC1 cell challenge). Both the full length and mature IL-33 adjuvant isoforms prevented or delayed the growth of tumors and/or expedited the rate of complete tumor regression and cured 10/10 and 9/10 animals, respectively. **Conclusions:** The data support that IL-33 DNA can act as a novel adjuvant for HPV-specific DNA immunotherapy, and is a strong candidate to be examined clinically in the context of anti-tumor immune-based therapy.

**3099 General Poster Session (Board #166), Sun, 8:00 AM-11:45 AM**

**Cancer immunotherapy of patients with the biochemical relapse of the prostate cancer using dendritic cell-based vaccine DCVAC/PCa.** *Presenting Author: Radek Spisek, Sotio, Prague, Czech Republic*

**Background:** Effect of cancer immunotherapy at the minimal residual disease stage can be evaluated in patients with the biochemical relapse of the prostate cancer. We performed a Phase I/II clinical trial in patients with the biochemical relapse of the prostate cancer using autologous mature dendritic cells pulsed with killed LNCap prostate cancer cell line, DCVAC/PCa. **Methods:** Eligible patients had a biochemical relapse of the prostate cancer after primary prostatectomy or after radical prostatectomy and salvage radiotherapy. Absence of hormonal therapy was required. DCVAC/PCa treatment consisted of twelve doses of 1x10$^7$dendritic cells injected s.c. Treatment comprised of initial 2 doses in 2 weeks interval and DCVAC/PCa was then administered every four weeks for a total of twelve doses. Patients experiencing significant prolongation/stabilization of PSA-DT were eligible for an additional treatment cycle. Primary goal of the study was to assess safety. Secondary goals were PSA kinetics and presence of tumor specific immunity. **Results:** Twenty one patients were evaluated after receiving 12 doses of DCVAC/PCa. Administration of DCVAC/PCa did not lead to any significant side effects. Continuous cancer immunotherapy by DCVAC/PCa significantly prolonged the PSA doubling time (PSA-DT) in all treated patients. Median PSA-DT increased from 7,86 months prior to the treatment, to 26,08 months after completing 12 doses of DCVAC/PCa, $p<0.001$. Eight of 21 patients had stable PSA levels during the treatment duration (PSA-DT>36 months) and PSA-DT remained stable during the additional cycle of the treatment (average PSA-DT of 48,13 months). Long-term administration of DCVAC/PCa led to the induction and maintenance of T cells specific against multiple tumor antigens including PSA, MAGE-A1 and MAGE-A3. **Conclusions:** This study indicates that the cancer immunotherapy with DCVAC/PCa represents a promising approach for prostate cancer patients with biochemical relapse. This study supports the use of immunotherapy early in the course of the disease, provided that relevant surrogate endpoints predictive of improved prognosis of early stage patients will be identified. Clinical trial information: 2009-017259-91.

**3100 General Poster Session (Board #167), Sun, 8:00 AM-11:45 AM**

**Antitumor effects of a nanoparticle-based vaccine targeted at human aspartyl (Asparaginyl) $\beta$-hydroxylase (HAAH).** *Presenting Author: Hossein A. Ghanbari, Panacea Pharmaceuticals, Inc., Gaithersburg, MD*

**Background:** HAAH is an established target for cancer therapy. It is over-expressed on cancer cells and plays a role in cancer cell growth, motility and invasiveness. Treatment of cancer cells to inhibit HAAH expression (siRNA) or neutralize its activity (mAb) returns cells to a normal phenotype. Moreover, tumor growth in xenograft models of human cancer is significantly (>80%) inhibited by anti-HAAH mAbs. HAAH is an oncofetal protein, important during development but not adult life, and thus, is a promising target for immunotherapy. However, as a self antigen, standard vaccination methods are ineffective in eliciting a sufficient immune response. **Methods:** We have designed and developed a nanoparticle based anti-cancer vaccine targeting HAAH. This vaccine incorporates a segment of the extracellular domain of HAAH fused to the gpD protein of $\lambda$-phage which is known to help to overcome immune tolerance. **Results:** The manufactured vaccine demonstrated high levels of immunogenicity in mice. Animals injected with 5x10$^7$-5x10$^9$ nanoparticles showed dose-dependent HAAH-specific antibody responses after 3 injections (day 0, 7, and 14). Sera from these animals demonstrated antigen specific binding to HAAH presented as either recombinant protein (ELISA) or on the surface of tumor cells (ELISA and FACS). The nanoparticle-based vaccine was further tested for efficacy against a mouse hepatocellular cancer line (BNLT3) injected subcutaneously into BALB/c mice in both a prophylactic and treatment modality. In the prophylactic model, mice (n=20) were vaccinated with 5 subcutaneous doses of nanoparticles (5x10$^{10}$) on days 0, 7, 14, 46, and 62 and were challenged with 5x10$^4$ BNLT3 cells on day 46. By day 70, 100% of control mice (n=5) had developed tumors with a mean tumor volume of >300mm$^3$. In contrast, only 85% of vaccinated mice had tumors, with a mean tumor volume of <100mm$^3$. In the treatment model, tumor cells (5x10$^3$) and vaccine (10$^{10}$) were co-administered on day 0 and animals were boosted on days 7 and 14. By day 50, 60% of control mice (n=5) had developed tumors with a mean volume of >20mm$^3$, while none of the vaccinated mice had palpable tumors. **Conclusions:** These data support further development of this novel nanoparticle vaccine.

**3101 General Poster Session (Board #168), Sun, 8:00 AM-11:45 AM**

**Boosting of cellular and humoral immune responses to HPV16/18 antigens by VGX-3100: A follow-on phase I trial.** *Presenting Author: Matthew P Morrow, Inovio Pharmaceuticals, Blue Bell, PA*

**Background:** Despite the development of highly effective prophylactic vaccines against human papillomavirus (HPV) types 16 and 18, prevention of cervical dysplasia and cancer in women infected with high-risk HPV types remains an unmet medical need. We have previously reported data from a phase 1 dose escalation study for a therapeutic HPV16/18 vaccine, VGX-3100, delivered by in vivo electroporation (EP). Immunization in that study drove seroconversion as gauged by ELISA to at least one vaccine antigen in 100% of patients while 78% mounted an Interferon Gamma (IFNg)ELISpot response to the vaccine antigens.. **Methods:** Of the 18 patients enrolled in that trial, 13 were rolled into a second phase 1 immunogenicity trial entailing a single 6.0mg boost of VGX-3100 administered using EP. **Results:** Increases in immune reactivity following the boost were noted, as eleven patients showed boost-driven increases in ELISA titers and the mean ELISpot magnitude increased by at least 2-fold in seven patients irrespective of the dose of VGX-3100 they received in the first clinical trial. Additional Flow Cytometric analyses of cellular responses revealed increased HPV specific IFNg and TNFa production as compared to prior to the boost (0.34% to 0.57% and 0.27% to 0.60%, respectively) with contribution from both the CD4+ and CD8+ T cell compartments. Additionally, HPV specific CD8+ T cells expressing Fas Ligand concomitantly with either cytokine or the degranulation marker CD107a increased from 0.19% to 0.28% following the boost. Employment of staining for the activation marker CD137 (41BB) showed that patient CD8+ T cells continued to activate efficiently in response to HPV antigens following the boost, including a statistically significant increase in co-expression of Granzyme B and Perforin within the activated T cell subset ($p=0.026$). **Conclusions:** Taken together these data suggest that immunization with VGX-3100 drives immune responses that have the ability to be further boosted by additional administrations. Current studies are underway in an untreated HPV 16/18 associated CIN2/3 setting to assess whether these significant immune responses can translate into clinically effective treatment options to surgery. Clinical trial information: NCT01188850.

**3102 General Poster Session (Board #169), Sun, 8:00 AM-11:45 AM**

**Impact of new oncolytic herpes simplex virus vector armed with interleukine-12 for cervical cancer therapy.** *Presenting Author: Masahiro Kagabu, Iwate Medical University School of Medicine, Morioka, Japan*

**Background:** Cervical cancer is the third most common cancer in women, and the seventh overall, the incidence and mortality of cervical cancer in the world was approximately 530,000 and 275,000 respectively according to a database of the Agency for Research on Cancer (IARC) in 2008. Requirement of new treatments it is mandatory to improve the outcome of the pathology. Replication-selective oncolytic herpes simplex viruses (oHSV) have emerged as a new platform for cancer therapy. Accumulating evidence indicates that, aside from the extent of replication capability within the tumor, the efficacy of an oncolytic HSV-1 depends on the extent of induction of host antitumor immune responses. We analyzed therapeutic potential of third-generation of oncolytic HSV-1 termed T-01 and Replication-competent HSV-1 vectors expressing IL-12 (T-mfIL12) for cervical cancer in mouse model. **Methods:** (1) In vitro, we investigated cytotoxicity reaction of human and mouse cervical cancer cell lines (TC-1, SKG-IIIa, CaSki, HeLa). (2) In vivo, we analyzed TC-1 cell lines in immune-competent models. Animals were challenged with a lethal dose of TC-1, 17 days after the first intratumoral (i.t.) administration of T-01 or T-mfIL12 was performed. Intratumoral administration of T-01 or T-mfIL12 were performed 4-5 days interval total 6 times. **Results:** T-01 and T-mfIL12 has great cytotoxicity for human and mouse cervical cancer cell lines. In addition, our results indicate that administration of T-01 and T-mfIL12 produced greatest antitumor effects in cervical cancer models. Furthermore, in immune-competent models, we found an increase of the number of cancer specific CD8+ T-cell in spleen of mice treated with T-01 in comparison with the control treated mice. **Conclusions:** Our data suggest that administration of T-01 and T-mfIL12 is an effective treatment against cervical cancer model. It may potentially be translated into the clinical area.

**3103 General Poster Session (Board #170), Sun, 8:00 AM-11:45 AM**

**A first-in-class, first-in-human phase I study of enadenotucirev, an oncolytic Ad11/Ad3 chimeric group B adenovirus, administered intravenously in patients with metastatic epithelial tumors.** *Presenting Author: Emiliano Calvo, START Madrid, Centro Integral Oncológico Clara Campal, Hospital Universitario Norte Sanchinarro, Madrid, Spain*

**Background:** Enadenotucirev (E) is an Ad11/Ad3 group B adenovirus, selective for killing cancer cells with little or no activity expected in normal tissue. E shows a broad anti-tumor activity in preclinical models. **Methods:** Main objectives of this study were to evaluate safety, pharmacokinetics (PK), pharmacodynamics (PD) of E delivered intravenously (IV) on Day (D) 1, 3 and 5 as single cycle and to recommend a dose for phase 2 (DP2). Once determined, DP2 was confirmed with up to 4 repeat cycles. A ″3 + 3″ dose escalation design was employed in patients (pts) with epithelial tumors having no standard treatment options. **Results:** 34 pts were treated as shown in Table. Tumor origin included colorectal (26 pts), parotid (3 pts) and oropharynx, liver, stomach, gall bladder and breast (1 pt each). At a dose of 1e13 viral particles (vp) over 5 min, DLTs were observed in 2 pts, a reversible Grade (Gr) 3 acute lung injury and dyspnea with hypoxia, hence defining the Maximally Administered Dose. Adverse events (AEs) seen in ≥ 10% pts were pyrexia, chills, flu like illness, nausea, vomiting, diarrhea, anorexia, asthenia, musculoskeletal pain, thrombocytopenia and increased transaminase (incr transa) and gammaGT (GGT). Gr 3 AEs seen in 3 pts were asthenia, hypertension, neutropenia, lymphopenia, thrombocytopenia and incr alkaline phosphatase and transa; Gr 3 incr GGT occurred in 5 pts, Gr 4 incr transa was seen in 1 pt (already with a DLT). AEs were reversible and short lasting. Significant increase in cytokines (TNF, interferon gamma, IL6, IL12) occurred on D1 at ≥ 3 e12 vp but were attenuated with D3 and 5 dosing and with prolonged infusion duration. The proposed DP2 is 6e12 vp over 40 min, every three weeks. Preliminary PK and PD data suggest that E remains active in the blood and replicates in some pts when administered at the DP2. Antiviral antibody responses suggest that repeat cycles are feasible. **Conclusions:** E can be safely administered to cancer pts and a biologically relevant dose and schedule have been determined for Phase 2 study. Clinical trial information: NCT02028442, EUDRACT 2012-001067-79.

**3104 General Poster Session (Board #171), Sun, 8:00 AM-11:45 AM**

**Oncolytic wild-type reovirus infection in brain tumors following intravenous administration in patients.** *Presenting Author: Adel Jebar, University of Leeds, Leeds, United Kingdom*

**Background:** Oncolytic viruses preferentially replicate in, and kill cancerous cells. Wild-type reovirus is a proprietary isolate of reovirus type 3 Dearing, a double-stranded RNA human reovirus. In two trials using intralesional administration in gliomas and recurrent brain tumours, wild-type reovirus has been well tolerated, with early signs of efficacy. A recently completed trial in Leeds, UK (Adair *et al.* 2012 *Sci Transl Med*) has proven that intravenous wild-type reovirus accesses colorectal cancer liver metastases. Intravenous delivery to brain tumours would be easier, cheaper and more acceptable to patients than intralesional administration. To date, no oncolytic virus has been shown to infect brain tumours following intravenous delivery. This trial aims to identify whether wild-type reovirus can cross the blood brain barrier and infect brain tumours following intravenous administration. **Methods:** This is an open-label, non-randomised, single centre study of intravenous wild-type reovirus administered to patients prior to planned surgery for recurrent high grade glioma or metastatic brain tumours. In total, 12 patients will be treated with a single infusion of $1x10^{10}$ $TCID_{50}$of wild-type reovirus. The primary objective is the presence of wild-type reovirus in the resected tumours as assessed by immunohistochemistry, RNA in-situ hybridization and retrieval of infectious virions. **Results:** Three patients have completed the study to date, including one glioblastoma multiforme, one grade 3 oligodendroglioma and one colorectal brain metastasis. Two of the 3 patients were taking high dose steroids. All 3 resected patient tumours contained wild-type reovirus RNA and protein. There was evidence for wild-type reovirus productive infection in 2 of the tumours. Grade 3-4 adverse reactions were neutropaenia in 1 patient and lymphopaenia in all 3 patients. **Conclusions:** We have shown for the first time that an oncolytic virus, wild-type reovirus, infects and replicates in brain tumours following intravenous administration. This trial will pave the way for phase I/II trials and combination studies using wild-type reovirus in patients with high grade gliomas and brain metastases. Clinical trial information: ISRCTN70443973.

**3105 General Poster Session (Board #172), Sun, 8:00 AM-11:45 AM**

**Oncolytic viral therapy for malignant gliomas using myxoma virus deleted for antiapoptotic M11L gene.** *Presenting Author: Peter A. J. Forsyth, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Malignant gliomas (MGs) remain largely incurable with a poor prognosis and an average survival of approximately 1 year. They are resistant to radiotherapy (RT) and temozolomide (TMZ). Clearly more effective treatments for MGs are needed. Oncolytic viruses are promising new agents used against experimental models of MGs and are now in several clinical trials. Myxoma virus is an excellent oncolytic virus because it is safe, selectively infecting and killing only cancer cells. We have shown that myxoma virus is efficacious in MGs and brain tumor initiating cells (BTICs) in vitro and in vivo, but the effect on survival in BTICs is not striking and only seen when combined with rapamycin. We think that manipulating myxoma virus will improve its therapeutic efficacy in MG, and hypothesize that genetic deletion of the anti-apoptotic gene M11L in Myxoma virus will enhance cell killing in MGs/BTICs and may be synergistic with TMZ and RT. **Methods:** We created the myxoma M11L knockout virus (M11L-KO) and tested its ability to kill MG cells and BTICs isolated from fresh human malignant gliomas. We have also examined the efficacy of M11L-KO virus on killing of BTICs when combined with TMZ and RT. **Results:** We found that M11L-KO is superior to WT-myxoma, produces a productive infection, and kills glioma cells and BTICs via apoptosis as shown by cleavage of PARP and caspase-3. As expected, the M11L protein in the WT virus does associate with the mitochondria, which is consistent with its role in inhibiting apoptosis. We have also found an additive effect of TMZ and RT with the M11L-KO virus compared to WT-myxoma. Finally, a microarray screen in BTICs showed several promising candidates in the intrinsic and extrinsic apoptosis pathways that are down- or up-regulated by M11L in WT-myxoma. Interestingly, our microarray data showed that TNFSF10 is up-regulated in BTICs infected with M11L-KO myxoma compared to cells infected with WT-myxoma, indicating its possible role in Myxv-M11L-KO-mediated killing of BTICs. **Conclusions:** These results will have clinical significance in the development of an experimental treatment in MGs patients.

**3106 General Poster Session (Board #173), Sun, 8:00 AM-11:45 AM**

**Activity of IMMU-130 anti-CEACAM5-SN-38 antibody-drug conjugate (ADC) on metastatic colorectal cancer (mCRC) having relapsed after CPT-11: Phase I study.** *Presenting Author: Efrat Dotan, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** IMMU-130 is an ADC of the humanized anti-CEACAM5 antibody, labetuzumab, linked to the active metabolite of CPT-11, SN-38 (drug-antibody ratio=7.6). In an every other week dosing schedule, neutropenia was dose-limiting. Multiple doses of 12 mg/kg were tolerated with modest activity (1 PR). We are now examining a more frequent dose schedule. **Methods:** Patients with mCRC refractory to standard therapy, including CPT-11, with elevated blood CEA (>5 ng/mL) enrolled in this phase I trial. Two regimens are under evaluation: 1 x or 2 x weekly for 2 weeks in a 3-week cycle to assess safety and efficacy, and to determine a safe dose for multiple treatment cycles. **Results:** Thirteen patients were treated twice-weekly at 4, 6, 9, and 12 mg/kg/dose (n = 3, 6, 3, and 1, respectively). Neutropenia is dose-limiting (6 ≥ G2), with manageable G1-2 nausea (7), fatigue (6), vomiting (3), and diarrhea (2 G1-2, 1 G3) observed during treatment. At 12 or 9 mg/kg, dose reductions/delay were required due to ≥ G2 neutropenia. Two patients dosed at 9 mg/kg required dose reduction to 4.5 mg/kg, one completing 21 doses, with a 24% reduction in the target lesions and another with SD after 32 doses. Two of 6 pts in the 6 mg/kg cohort showed a treatment effect following dose reduction for toxicity; one with a 28% reduction in target lesions after 38 doses, and another with 63% reduction in the target lesions (RECIST1.1 PR) after continuing treatment at 3 mg/kg for 27 doses. A 4.0 mg/kg twice-weekly dose level is now under study. In the once-weekly schedule, 3 pts completed 1 cycle at 8 mg/kg, with 1 pt experiencing dose delay/reduction in the subsequent cycle due to Gr 4 neutropenia; 3 more pts are enrolled. CEA blood titers correlated with response. There have been no anti-antibody or anti-SN-38 antibody reactions based on ELISA tests. The Phase II will expand patients at optimal dosing and will assess PK and UGTA1A genotypes. **Conclusions:** These early results indicate therapeutic activity of IMMU-130 in advanced mCRC patients during Phase I extended dosing, even in patients who are relapsed/refractive to CPT-11, and with manageable neutropenia and GI toxicities. Clinical trial information: NCT1605318.

**3107 General Poster Session (Board #174), Sun, 8:00 AM-11:45 AM**

**Characterization of an anti-Trop-2-SN-38 antibody-drug conjugate (IMMU-132) with potent activity against solid cancers.** *Presenting Author: David M. Goldenberg, Immunomedics, Inc., Morris Plains, NJ*

**Background:** IMMU-132 is an antibody-drug conjugate (ADC) made from a humanized anti-Trop-2 mAb (hRS7) coupled through a linker to SN-38, the active metabolite of CPT-11. Trop-2 is found in a wide range of tumor, including gastric, pancreatic, triple-negative breast (TNBC), colonic, prostate, and lung. Current Phase I/II clinical trials confirm the anticancer activity of IMMU-132 in cancers expressing Trop-2. The current studies further characterize IMMU-132 in terms of conjugation, mechanism of action (MoA), and efficacy. **Methods:** SN-38 conjugation to hRS7 was analyzed by HIC, LC-MS, and HPLC. MoA was assessed by comparisons in binding, ADCC, and pro-apoptotic signaling pathways. Efficacy studies were performed in mice bearing human tumor xenografts. **Results:** IMMU-132 has a drug to antibody ratio of 7.6, <1% aggregation, and no loss in binding to cells or to a Trop-2 chip (cells: $K_D$ = 0.63 ± 0.26 nM *v* 0.54 ± 0.17 nM; BIACore: 0.26 ± 0.14 *v* 0.51 ± 0.04 nM, IMMU-132 and hRS7, respectively). Linkage chemistry should preserve the active lactone ring form; initial *in vivo* data suggest that conjugated SN-38 may not be glucuronidated until released. IMMU-132 retains binding to the neonatal receptor, but lost 65% of ADCC activity. Free SN-38 and IMMU-132 mediated the same signaling pathways in cells, with $p21^{WAF1/Cip1}$ up-regulation, cleavage of caspase 3 and 9, and poly-ADP-ribose polymerase cleavage. IMMU-132 treatment of gastric cancer xenografts (17.5 mg/kg; 2xwk x 4wks) result in significant anti-tumor effects compared to non-specific control ADC ($P$<0.0001). In tumors not typically treated with irinotecan as a single agent (pancreatic and TNBC), IMMU-132 provided significant tumor growth inhibition. Mice with a TNBC xenograft treated with 12.5 mg/kg IMMU-132 (q4dx4) resulted in 7/8 mice alive at study conclusion (day 105) *v* only 1/9 in saline-control group ($P$=0.001). Tumor regressions occur in mice bearing aggressive pancreatic tumor xenografts (untreated median survival = 11 d) when clinically relevant doses of IMMU-132 is given (HED=8 mg/kg; $P$=0.0003). **Conclusions:** Conjugation of SN-38 to hRS7 results in a potent ADC that retains characteristics of both the antibody and the drug.

**3108 General Poster Session (Board #175), Sun, 8:00 AM-11:45 AM**

**Activation of the human natural killer cells NK-92 with a lymphocyte-derived cytokine-rich supernatant.** *Presenting Author: Ioannis F. Voutsas, Department of Animal and Human Physiology, Faculty of Biology, University of Athens, Athens, Greece*

**Background:** *Ex vivo* activated NK cells adoptively transferred to cancer patients were among the first lymphocyte populations used in immunotherapeutic protocols. To enhance NK cell cytotoxicity, individual cytokines, as well as cytokine combinations have been tested. In an effort to achieve optimal cytokine combinations, conditioned media collected upon stimulation of immune cells have also been assessed. Human lymphocytes activated *in vitro* with anti-CD3 mAb secrete various immunomodulatory agents in their culture supernatant (ACD3S). We tested the *in vivo* efficacy of ACD3S-activated NK-92 cells in an adoptive cell transfer cancer immunotherapeutic model in mice. **Methods:** ACD3S was collected by stimulating normal peripheral blood mononuclear cells for 3 days with immobilized anti-CD3. IL-2-depleted NK-92 cells were *in vitro* reactivated with ACD3S for 24 hours and their cytotoxic activity was determined using standard $^{51}$Cr-release assay against K562, FM-3 and MCF-7 targets. Perforin production was assessed by FACS. SCID mice subcutaneously inoculated with human tumor cells (FM-3 and MCF-7) were intraperitoneally administered 3 doses of ACD3S-activated NK-92 cells. Tumor growth and overall survival of the animals were recorded. **Results:** IL-2-depleted NK-92 cells showed reduced cytotoxicity againstK562, FM-3 and MCF-7 target cells. Brief exposure of NK-92 cells to ACD3S resulted in a statistically significant enhancement of their lytic ability against the same targets and their intracellular perforin production was restored to levels comparable to standard NK-92 cells. When ACD3S-activated NK-92 cells were administered to FM-3 or MCF-7 tumor-bearing SCID mice, a statistically significant delay in tumor growth was recorded. Moreover, adoptive transfer of *ex vivo* ACD3S-activated NK-92 cells was well tolerated and prolonged the survival of mice. **Conclusions:** We propose an alternative method for the *in vitro* enhancement of NK-92 cell cytotoxicity, which is retained after their adoptive transfer in animals. The protocol used for NK-92 cell activation is brief, of low cost and of low risk for side-effects, and thus could eventually be considered for the treatment of solid tumors.

**3109 General Poster Session (Board #176), Sun, 8:00 AM-11:45 AM**

**The prognostic significance of ErbB-1 (EGFR), ErbB-2 (HER2), and c-MET overexpression in resectable gastric carcinoma (GC).** *Presenting Author: Aleksandra A. Paliga, The Ottawa Hospital, Ottawa, ON, Canada*

**Background:** This study investigates the prognostic value of overexpression of EGFR, HER2 and c-Met by immunohistochemistry (IHC) in Canadian patients with GC and correlates expression with clinicopathologic characteristics. **Methods:** Tissue microarrays (TMA) containing 4 cores/tumor were constructed from 120 consecutive GC resected between 2002-2008, stained for EGFR, HER2 and c-Met by IHC, and scored by 3 pathologists, from 0-3+, based on membranous and cytoplasmic staining intensity respectively. EGFR and c-Met score greater than 2 and HER2 3+ was considered overexpressed. Receptors' expression was compared with clinicopathological characteristics and survival. **Results:** Of 113 evaluable cases – median age 64 (range 29-94), 72% were male, histologic type: intestinal 76%, diffuse 14%, mixed 10%. We observed no correlation between T, N stage and EGFR, HER2 or c-Met overexpression. Differences were observed according to histologic type: intestinal type expressed more frequently HER 2 (10/12; p=0.26) and c-Met (51/65; p=0.02). EGFR and c-Met positive and HER2 negative trended to inferior overall survival (OS). As previously reported, the prognostic effect of c-Met overexpression was time-dependent, with OS curves separating after 26 months, trending to inferior OS in the c-Met + group. **Conclusions:** In our study, HER2 overexpression in GC trended to superior OS, while EGFR and/or c-Met overexpression trended to poor OS. However, only the group of EGFR+/c-Met+/HER2-, although quite small, reached statistical significance. Larger studies to confirm our findings are warranted, since targeted therapy may provide a major therapeutic advance.

| IHC expression | n/% | Median OS in months | | HR [95% CI], p-value |
|---|---|---|---|---|
| | | Present | Absent | |
| **EGFR overexpression** | 17/15 | 15 | 30 | 1.60 [0.89-2.87], p=0.11 |
| **HER2 overexpression** | 12/11 | 85 | 29 | 0.51 [0.22-1.18], p=0.11 |
| **c-Met overexpression** | 65/58 | 28 | 48 | 1.17 [ 0.74-1.87], p=0.49 |

**3110 General Poster Session (Board #177), Sun, 8:00 AM-11:45 AM**

**Combining radiotherapy and immunotherapy in the treatment of advanced cancer: A limited meta-analysis.** *Presenting Author: Christine Zhou, Rochester Institute of Technology, Rochester, NY*

**Background:** A majority of patients with advanced cancer expire from uncontrolled disseminated disease due to lack of effective systemic treatment. Radiation (RT) serves a limited role as palliative therapy. Recently, a unique synergy between RT and immunotherapeutics (IT) has been noted. This study assesses currently published clinical data combining RT and IT (cRIT) to exam the effect of such combination treatment on patient survival and toxicity. **Methods:** Eligible studies were found through PubMed. Keywords included radiation, radiotherapy, metastasis, advanced cancer, immunotherapy, interleukin, interferon, dendritic cells, and NK cells. Criteria included clinical studies combining any RT and IT in patients with diagnosed advanced disease published since Jan 1, 1999, excluding studies that also combined chemotherapy. Patient survival and toxicity data was captured and analyzed. The primary endpoints included treatment response rates and median survivals. **Results:** Eleven studies were eligible with a total of 525 patients. Of those patients, 397 received cRIT; 110 and 41 patients received RT or IT alone, respectively. RT methods included conventional radiation, intensely modulated radiation therapy, and stereotactic radiotherapy. IT agents included interleukin 2, interferon $\alpha/\beta$, thalidomide, and dendritic cells. Pooled data from seven studies (309 patients) reported response rates of complete response as 21.4% (95% CI 0-49.4%), partial response as 19.5% (95% CI 0-39.9%), stable disease as 19.7% (95% CI 1.7-37.6%), and progressive disease as 30.0% (95% CI 10.7-49.4%). The disease-free survival in cRIT patients was 18.9 (90% CI 1.8-35.9) months and overall survival was 21.7 (95% CI 6.0-37.3) months. Most common toxicities included skin reactions (49.5%), esophagitis (81.2%), anemia (21.8%), anorexia (21.2%), and liver dysfunction (19.1%). Pooled data does not show any significant increase in toxicity level with combined therapy. **Conclusions:** Based on this limited pooled analysis, cRIT appeared to be effective and safe in certain patients with advanced cancers. Randomized trials are needed to further assess the value of this new treatment modality and the best combination of RT and IT.

**TPS3111 General Poster Session (Board #178A), Sun, 8:00 AM-11:45 AM**

**RANIDO: A phase III clinical trial of racotumomab-alum or nimotuzumab versus docetaxel in advanced non-small cell lung cancer patients.** *Presenting Author: Maurenis Hernandez, Center of Molecular Immunology, Havana, Cuba*

**Background:** Despite extensive research in NSCLC treatment, overall survival remains insufficient. Immunotherapy has become a viable treatment to help the immune system to control or eliminate cancer.Racotumomab-alum is an anti-idiotypic vaccine that induce an inmunological response against N-glycolilated gangliosides in NSCLC patients. Several studies have demonstrated its antitumoral effect and safety. Nimotuzumab is an anti-EGFR monoclonal antibody that has shown promising activity in NSCLC patients without skin toxicity. The aim of this study is to evaluate safety and efficacy of racotumomab-alum or nimotuzumab versus docetaxel as second line or switch maintenance therapy for advanced NSCLC. **Methods:** This phase III, randomized clinical trial will include 670 patients with histologically confirmed stage III-IV NSCLC, after first line therapy, with PS 0-2,aged>18 years, with written informed consent. The primary endpoint will be overall survival, and also we will assess quality of life, safety and immunological response. Patient will be randomized with 2:2:1 ratio to 3 arms: racotumomab-alum, nimotuzumab or docetaxel, in 2 strata: progressive patients that will receive the treatment as second line, and non-progressive patients that will receive it as switch maintenance. Racotumomab-alum treatment consists in 5 bi-weekly intradermal immunizations and re-immunizations every 4 weeks. Nimotuzumab arm will receive 6 weekly infusions followed by bi-weekly doses .Both drugs will be given until severe worsening of PS or toxicity. Treatment will not be interrupted at disease progression, even when other therapy line will be administered concomitantly. Docetaxel will be used at 75 mg/m$^2$ for six cycles, if no progressive disease after 3$^{rd}$ cycle. In the progressive setting racotumomab-alum and nimotuzumab will be considered as non-inferior to docetaxel if 1- year OS rate is 23.1% (HR 0.75) considering a 10 % non-inferiority margin. As switch maintenance therapy both drugs will be equivalent to docetaxel, if 1- year OS rate is 36% (HR 0.62) using a 15% non- inferiority margin. An interim analysis will be done when half the patients in each arm has completed 1 year follow-up.

**TPS3112 General Poster Session (Board #178B), Sun, 8:00 AM-11:45 AM**

**A phase 1 mechanism of action study of intratumoral or intravenous administration of enadenotucirev, an oncolytic Ad11/Ad3 chimeric group B adenovirus in colon cancer patients undergoing resection of primary tumor.** *Presenting Author: Rocio Garcia-Carbonero, Hospital Universitario Virgen del Rocio, Instituto de Biomedicina de Sevilla, Sevilla, Spain*

**Background:** To date convincing clinical success with oncolytic viruses tends to be associated with intra-tumoral (IT) administration and evidence for successful systemic delivery of viruses to tumor cells by intravenous (IV) infusion remains sparse. Enadenotucirev (E or ColoAd1) is a tumor selective Ad11/Ad3 group B adenovirus that has demonstrated preclinical activity in a metastatic model of colorectal cancer (CRC) and in human tumor biopsies ex-vivo [Kuhn et al, PLoS ONE 2008; 3 (6):e2409]. Serological studies suggest that the prevalence of neutralising antibodies against group B adenoviruses is low, which may permit systemic delivery [Holterman et al, J Virol. 2004 Dec; 78(23):13207-15]. CRC patients (Pts) scheduled for resection of primary tumor present a pre-surgical window of opportunity to evaluate IV and IT delivery to tumor, lymph nodes and normal margins in resected tissues. **Methods:** Pts with histologically confirmed CRC scheduled for surgical removal of primary tumor receive E delivered either IV on day (D) 1, 3 and 5 at a dose of 1e12 viral particles (vp) over 5 min (5 pts); or IT at a dose of 1e11 vp/mL with a variable volume injected based on the tumor surface area (5 pts). Surgery is performed 7 – 15 days post first dose of E. The primary objective is to assess the pattern and extent of E spread in the tumor, normal tissue and draining lymph nodes as visualised by IHC staining of E hexon protein. Evidence of immune modulation associated with virus activity is assessed by co-staining for markers including CD8, CD11b, CD57 and CD25. Additional staining includes the primary uptake receptors of E (CD46, DSG-2) and markers of endothelial cells (CD31) and myofibroblasts (SMA) that may influence viral delivery or spread. Additional analyses include electron microscopy and qPCR. Other objectives are assessment of safety, viral kinetics and immune response following IV and IT administration. Correlation with routine tumor biomarkers e.g. K-ras, BRAF, PI3K, PTEN, SPARC will also be evaluated. To date 3 pts have been treated, 1 IT and 2 IV, and 3 pts are scheduled for treatment. Clinical trial information: EUDRACT 2013-000562-11.

**TPS3113 General Poster Session (Board #179A), Sun, 8:00 AM-11:45 AM**

**Phase II study with immunotherapy with dendritic cells (DC) and intratumoral hiltonol in patients with advanced solid tumors.** *Presenting Author: José María López-Picazo, Department of Oncology, Clinica Universidad de Navarra, Pamplona, Spain*

**Background:** DC vaccines have proved efficacy in the treatment of cancer and combination strategies are expected to increase anti-tumor activity. Our study explores the efficacy of intratumoral Hiltonol, a potent TLR3 agonist in combination with an autologous vaccine of DC loaded with self-tumor lysates that we developed in a previous pilot trial (Alfaro C, J Immunology 2011) in patients with solid tumors. Hiltonol is an stabilized form of polyI:C, a nucleic acid that mimics viral RNA. It induces local release of cytokines that promote inflammation, induce type I interferon and favour traffic of leukocytes to infiltrate the tissue. Preclinical data indicates that intratumoral administration of Hiltonol triggers pro-inflammatory changes that increase the efficacy of DC vaccination. **Methods:** In this phase II study, 25 patients with advanced solid tumors non-amenable for conventional treatment are being treated with Hiltonol and DC vaccinations. The vaccination protocol includes the following strategies: (1) pretreatment with cyclophosphamide to decrease regulatory T cells; (2) maturation and activation of DC with TNF-alpha, interferon-alpha and *poly I:C*, a potent inducer of type I interferon; (3) use of autologous tumor as antigenic source to expose DC to antigens that are exclusive of tumor cells; and (4) daily intradermal doses vaccinations during four consecutive days in 2 cycles every 4 weeks. Two intratumoral ultrasound-guided injections of Hiltonol 0.25 mg are administered on alternate days the week following each DC cycle. Sample size has been calculated using a two-stage Simon´s Minimax design, with alpha error $\alpha = 0.05$ and beta-error=0.10 for $P_0=0.05$ and $P_1=0.25$. The main objective is response rate. Secondary objectives include assessment of toxicity, overall survival and immunologic response (in vitro lymphocyte responses against tumor antigens; delayed hypersensitivity reactions; and assessment of DC maturation by expression of pro-inflammatory cytokines). Clinical trial information: NCT01734564.

**TPS3114 General Poster Session (Board #179B), Sun, 8:00 AM-11:45 AM**

**Phase I/II, open-label study of nivolumab (anti-PD-1; BMS-936558, ONO-4538) as monotherapy or combined with ipilimumab in advanced or metastatic solid tumors.** *Presenting Author: Margaret K. Callahan, Department of Medicine at Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Nivolumab, a fully human IgG4 programmed death-1 (PD-1) immune checkpoint inhibitor antibody, and ipilimumab, a fully human IgG1 cytotoxic T-lymphocyte antigen-4 receptor (CTLA-4) blocking antibody, have shown antitumor activity and durable responses in patients (pts) with solid tumors including melanoma, renal cell cancer and non-small cell lung cancer. Preclinical and clinical data indicate that combined PD-1 and CTLA-4 blockade may improve antitumor activity. We hypothesize that nivolumab alone or combined with ipilimumab may have activity in additional solid tumor types. We describe a phase I/II signal detection, open-label study to analyze the safety and efficacy of these agents in locally advanced or metastatic triple-negative breast, small-cell lung, gastric or pancreatic cancer—areas of significant unmet medical need. **Methods:** The primary and secondary objectives of this study are objective response (OR) rate and safety, respectively. Exploratory objectives include progression-free survival, overall survival, immunogenicity, pt-reported global health outcomes, and analysis of pharmacodynamic activity of nivolumab alone or combined with ipilimumab in peripheral blood and tumor tissue. Additionally, evaluation of putative biomarkers such as PD-1 ligand (PD-L1) expression will be performed. The study uses a modified Simon 2-stage design. In stage 1, 36 pts for each tumor type will be assigned 1:1 to treatment with either nivolumab 3 mg/kg IV Q2W (arm N), or nivolumab 1 mg/kg + ipilimumab 3 mg/kg IV Q3W for 4 doses then nivolumab 3 mg/kg IV Q2W (arm N+I), until progression or toxicity. Responses will be assessed using RECIST criteria at wks 6, 12, 18, 24 and then Q12W. Treatment arms will proceed independently into stage 2 if $\geq$2 pts in a given arm for each tumor type have an OR. In stage 2, an additional 22 pts per tumor type will be assigned to each arm (N or N+I) and receive the stage 1 dosing regimen. Key eligibility criteria include ECOG status $\leq$1, available fresh or archival tumor tissue, measurable disease by CT or MRI (RECIST 1.1), and adequate bone marrow, liver and renal function. Clinical trial information: NCT01928394.

**TPS3115 General Poster Session (Board #180A), Sun, 8:00 AM-11:45 AM**

**A phase I dose escalation and cohort expansion study of lirilumab (anti-KIR; BMS-986015) in combination with nivolumab (anti-PD-1; BMS-936558, ONO-4538) in advanced solid tumors.** *Presenting Author: Neil Howard Segal, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Killer cell immunoglobulin-like receptor (KIR) and programmed death-1 (PD-1) are immune receptors that downregulate natural killer (NK) cell and T-cell activity, respectively. Immune checkpoint blockade is emerging as a novel form of cancer immunotherapy. Lirilumab, an anti-KIR antibody, potentiates NK activity and innate immunity, with only modest side effects (mostly grade 1 or 2) in a phase I monotherapy trial. Nivolumab, a fully human IgG4 PD-1 immune checkpoint inhibitor antibody, potentiates T-cell activity and adaptive immunity, and has shown durable activity in various solid tumors, including melanoma (MEL), kidney cancer and non-small cell lung cancer (NSCLC). We hypothesize that simultaneous KIR and PD-1 blockade will enhance innate and adaptive immunity, resulting in greater clinical activity than with either agent alone. We describe a phase I study of lirilumab and nivolumab in patients (pts) with advanced solid tumors, the first collaborative trial conducted by the International Immuno-Oncology Network. **Methods**: Approximately 150 pts will be treated across dose escalation and expansion. During dose escalation, pts with any solid tumor (excluding primary central nervous system tumors) will receive nivolumab 3 mg/kg IV Q2W plus lirilumab 0.1, 0.3, 1, or 3 mg/kg Q4W in 8-week cycles (max 12 cycles). During cohort expansion, pts with NSCLC (squamous/non-squamous), MEL, select gastrointestinal cancers, head and neck squamous cell carcinoma (SCCHN), and hepatocellular carcinoma will be enrolled at the maximum tolerated dose (MTD), or highest planned dose if no MTD is defined. The primary objectives are to determine the safety, tolerability, dose-limiting toxicities, and MTD of the combination. Secondary objectives are to assess preliminary antitumor activity, pharmacokinetics, and immunogenicity (all pts), and pharmacodynamic effect on tumor-infiltrating lymphocyte subsets (MEL and SCCHN pts). Exploratory objectives include an assessment of innate and adaptive immune responses in peripheral blood and/or tumor specimens and correlation with clinical outcome. Clinical trial information: NCT01714739.

**TPS3116 General Poster Session (Board #180B), Sun, 8:00 AM-11:45 AM**

**A multicohort trial of the safety and efficacy of the PD-1 inhibitor MK-3475 in patients with hematologic malignancies.** *Presenting Author: Guillermo Garcia-Manero, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Hematologic malignancies (HMs) are responsive to immunotherapy, but in some cases appear to usurp the PD-1 pathway for tumor immune escape. MK-3475 is a potent, highly selective, humanized IgG4/kappa isotype, anti-PD-1 monoclonal antibody designed to block PD-1 interaction with PD-L1 and PD-L2. In some patients with solid tumors, MK-3475 enhances anti-tumor immune activity and has demonstrated therapeutic activity. We are testing the safety and preliminary activity of MK-3475 in patients with HMs. **Methods:** This is a multicenter, nonrandomized, open-label phase 1b trial in patients with HMs, enrolling patients in 3 separate cohorts : hypomethylating agent failure myelodysplastic syndrome (MDS); relapsed/refractory (R/R) Hodgkin lymphoma (HL); and primary mediastinal large B cell lymphoma (MLBCL)/PD-L1 positive non-Hodgkin lymphoma (NHL). Approximately 78 pts will be enrolled. The primary objectives are to determine safety, tolerability, and objective response rate or complete remission rate of 10 mg/kg MK-3475 dosed every 2 weeks until disease progression or excessive toxicity. Secondary objectives include analysis of efficacy parameters (DOR/PFS/OS) for each indication, and association between PD-L1 expression and response. Exploratory objectives include PK and the relationship of candidate efficacy/resistance biomarkers and anti-tumor activity. Response will be evaluated using standard criteria. Patients receiving at least 1 dose will be included in the safety analysis. For the primary endpoint, the study provides ~80% power to detect a difference under the null hypothesis in a given cohort (20% difference in ORR for MDS; 20% difference in CRR for HL, 25% difference in ORR for MLBCL/NHL) with one-sided type I error rate of 5%. Clinical trial information: NCT01953692.

**TPS3117 General Poster Session (Board #181A), Sun, 8:00 AM-11:45 AM**

**A phase 1 (Ph1) trial of MK-3475 combined with lenalidomide (Len) and low-dose dexamethasone (Dex) in patients (pts) with relapsed/refractory multiple myeloma (RRMM).** *Presenting Author: David Samuel DiCapua Siegel, John Theurer Cancer Center, Hackensack, NJ*

**Background:** RRMM patients refractory to proteasome inhibitors and immunomodulatory drugs (IMiD) have a very poor outcome. PD-L1 expressed on most MM plasma cells is a potential mechanism of immune evasion. MK-3475 is a potent, highly selective, humanized IgG4/kappa isotype, anti-PD-1 monoclonal antibody designed to block PD-1 interaction with PD-L1 and PD-L2, enhancing lymphocytic activity, tumor regression and immune rejection. **Methods:** This is an open-label, Ph1 multicenter, non-randomized dose escalation trial of MK-3475 combined with Len/Low-dose Dex in RRMM patients failing two lines of prior therapy, including bortezomib and an IMiD, using a modified 3+3 design followed by a toxicity probability interval (TPI) for dose confirmation. Cohorts of 3-6 pts per dose level (DL) will be enrolled sequentially at escalating doses of MK-3475 (2, 5, 10 mg/kg) with Len (25mg) / Low-dose Dex (40mg) until a preliminary maximum tolerated dose (MTD) or maximum administered dose (MAD), is identified. Additional pts will be enrolled at the MTD/MAD in combination with Len/Low-dose Dex to confirm dose and evaluate safety and preliminary efficacy. Primary objectives of the trial are to establish a MTD/MAD and determine safety and tolerability of MK-3475 / Len / Dex in pts with RRMM. Secondary objectivesinclude analysis of efficacy (ORR/CR/sCR/TTP/DOR/PFS/OS), and PD-L1 expression and corresponding efficacy. Exploratory objectives are PK of MK-3475 with Len/Dex and the relationship of candidate efficacy/resistance biomarkers and anti-tumor activity. AEs as categorized in the NCI CTCAE v 4 will be summarized by DL for all pts receiving ≥1 dose. After the TPI, the dose-response relationship (% of subjects with ≥1 dose limiting toxicity (DLT) for each DL selected for confirmation), will be estimated by Bayesian pooling of adjacent violators analysis, using all DLT data. The dose-response profile, along with other tolerability data, will determine the recommended Ph2 dose for the combination. Efficacy endpoints (evaluated using established International Working Group response criteria) will be summarized for each DL using descriptive statistics. Clinical trial information: NCT02036502.

**TPS3118 General Poster Session (Board #181B), Sun, 8:00 AM-11:45 AM**

**A phase I study of adoptive T-cell therapy with or without dendritic cell vaccination in patients with metastatic melanoma.** *Presenting Author: Roger Tell, Department of Oncology-Pathology, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden*

**Background**: The addition of autologous dendritic cell vaccine (DCV) to adoptive T-cell therapy (ACT) may enhance the anti-tumor immune responses in melanoma. **Methods**: Study Population - Patients with advanced malignant melanoma who have tumor that is accessible for core biopsy or is resectable; confirmed progressing metastatic disease; refractory to standard therapy; not having had prior systemic cancer therapy within the past four weeks at the time of the start of the lymphodepletion regimen. Sample Size - 10 patients will be evaluated, 5 patients in each group. Study Desig - A phase I, nonrandomized, multicohort trial will be conducted to enroll patients at a single institution in a modified 5+5 design. Five patients will be assigned to each cohort (A or B) and receive adoptive transfer of in vitro expanded autologous tumor infiltrating lymphocytes (TIL) without (A) or with (B) autologous tumor lysate loaded DCV administered i.d. 3-5 times with weekly intervals. Prior to TIL transfer all patients will be pre-treated with a preconditioning regimen consisting of cyclophosphamide (60 mg/kg per day for 2 days) followed by fludarabine (25 mg/m(2) per day for 5 days). Administration of TIL will be followed by IL-2 administration (100,000 IU/kg intravenously three times a day to a maximum of 14 doses). All subjects will be monitored for 17 weeks. Outcome Measures - (1) The primary objective of the study is to investigate the safety of the T-cell therapy, with and without DCV, as evaluated according to the NCI CTCAE scale version 4.0. (2) The secondary objective is to measure time to disease progression according to RECIST 1.1. (3) TIL will be analyzed for anti-tumor reactivity as a possible predictive biomarker using an autologous melanoma cell line generated from the patient (when possible), or semi-allogeneic melanoma cell line that has at least one matched HLA-A allele, as targets. (4) In order to assess if the addition of DCV post TIL transfer has influenced TIL persistence, TIL and PBMC will be analysed by TCR sequencing. Clinical trial information: NCT01946373.

**TPS3119 General Poster Session (Board #182A), Sun, 8:00 AM-11:45 AM**

**A phase Ib multicohort study of MK-3475 in patients with advanced solid tumors.** *Presenting Author: Rita Nanda, The University of Chicago, Chicago, IL*

**Background:** Immune surveillance is one of the primary mechanisms to prevent neoplastic growth. The PD-1 receptor-ligand pathway can be used by tumors to evade immune surveillance. MK-3475 is a potent, highly selective, humanized IgG4/kappa isotype mAb designed to block PD-1 interaction with its ligands PD-L1 and PD-L2, and can reactivate the immune system to eradicate the host tumor. **Methods:** This is a multicenter, non-randomized, multi-cohort trial of single agent MK-3475 in over 130 patients diagnosed with locally recurrent and/or distant metastatic 1) triple negative breast cancer, 2) head and neck cancer (both HPV and non-HPV associated), 3) urinary tract cancer or 4) gastric cancer. All enrolled patients must express PD-L1 within their tumor microenvironment. MK-3475 is given intravenously at 10 mg/kg every 2 weeks. Primary objectives are to determine (1) safety and tolerability and (2) anti-tumor activity of MK-3475 in patients with PD-L1 positive, advanced solid tumors. Secondary objectives include progression-free survival, overall survival and response duration in treated patients. Radiographic imaging will be obtained every 8 weeks to assess clinical response defined by RECIST 1.1. Tumor biopsies will be available both pre-treatment and during treatment to allow investigation of candidate biomarkers which may predict clinical response to immune checkpoint blockade. Treatment continues for 24 months or until complete response, disease progression, unacceptable toxicity, physician decision, or patient's withdrawal of study consent. Retreatment for patients who progress after a complete response is allowed. AEs will be monitored and graded according to guidelines in the NCI CTCAE v. 4.0. Summary statistics for safety endpoints and the incidence rate of immune-related AEs and of Grade 3-5 AEs will be calculated. Efficacy will be evaluated in each cohort, in patients with baseline and with either ≥1 post-baseline evaluation or who discontinue the trial due to progressive disease or a drug-related AE. Overall response rate assessed by independent radiology review will be used as the primary endpoint for efficacy. Clinical trial information: NCT01848834.

**TPS3120^ General Poster Session (Board #182B), Sun, 8:00 AM-11:45 AM**

**A phase 1 study to evaluate the safety and tolerability of MEDI4736, an anti–PD-L1 antibody, in combination with tremelimumab in patients with advanced solid tumors.** *Presenting Author: Margaret K. Callahan, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** MEDI4736 (M) is a human IgG1 monoclonal antibody that binds specifically to programmed cell death ligand 1 (PD-L1), expressed on immune cells and tumor cells, preventing binding to PD-1 and CD80, expressed on T cells. Tremelimumab (T) is a human IgG2 monoclonal antibody directed against cytotoxic T-lymphocyte-associated protein 4 (CTLA-4). Both PD-1 and CTLA-4 are regulators, or checkpoints, of T cell activation. The mechanisms of activation for these checkpoints are non-redundant, suggesting that targeting both pathways may have additive or synergistic activity. Data from mouse models of transplantable solid tumors support synergistic antitumor activity of combination immunotherapy. **Methods:** This open-label phase I study (NCT01975831) is designed to evaluate the safety of the combination of M and T in patients (pts) with advanced solid tumors. Eligible pts include those with histologically confirmed non-small cell lung, cervical, head and neck, colorectal, ovarian cancers, or renal cell carcinoma with adequate performance status and organ function who are not eligible for, have declined, or have failed standard treatment. The dose escalation phase uses a 3+3 design: M is administered at escalating doses starting at 0.3 mg/kg every 2 wks and T is administered at escalating doses starting at 3 mg/kg (up to 10 mg/kg) every 4 wks for the first 6 cycles, then every 12 wks. An expansion phase will evaluate the combination therapy at the maximum tolerated doses in each tumor type. Treatment may continue for up to 12 months or until progressive disease or unacceptable toxicity. The primary study end points are safety/tolerability and identification of the maximum tolerated dose of the combination. Secondary objectives include pharmacokinetics, immunogenicity, and clinical activity, as assessed by tumor response (RECIST v1.1 and Immune-related Response Criteria), progression-free survival, and overall survival. Exploratory objectives include the evaluation of tumor and serum PD-L1 levels, immune cell phenotypes, and tumor microenvironment. Recruitment is ongoing to a target enrollment of 102 pts. Clinical trial information: NCT01975831.

**TPS3121 General Poster Session (Board #183A), Sun, 8:00 AM-11:45 AM**

**First-in-human phase 1 study of the novel indoleamine-2,3-dioxygenase (IDO) inhibitor NLG-919.** *Presenting Author: Samir Khleif, GRU Cancer Center, Augusta, GA*

**Background:** IDO is an enzyme that catalyzes the initial and rate limiting step in the conversion of tryptophan to kynurenine. Tryptophan depletion enhances the number and function of the Treg (suppressive) arm of the immune system and inhibits the effector T cell (stimulatory) arm. In addition, it has been shown that kynurenine metabolites may augment the suppressive effects on inflammation and immune responses. The main function of IDO is the regulation of acquired local and peripheral immune tolerance in normal and pathological conditions. In cancer, IDO can either be expressed directly by the tumor cells themselves, or induced indirectly in host antigen presenting cells by the tumor. In these settings, IDO mediates an acquired immune tolerance towards tumors, allowing tumors to thwart immune responses by the host. Therefore, IDO is an attractive target in therapeutic interventions aimed at restoring the immune response towards the tumor. NLG-919 inhibits the enzymatic activity of IDO. Agents that inhibit the IDO pathway have been shown to act synergistically with each other as well as with chemotherapy and other checkpoint inhibitors such as anti-CTLA-4, anti-PD-1, and anti-PD-L1. We believe current SOC treatments that incorporate single or multiple IDO pathway inhibitors in combination with other checkpoint inhibitors may add significant benefit to an active immunotherapy regimen. **Methods:** This study is a Phase 1, dose escalation study of NLG-919 for patients with advanced solid tumor malignancies. Eligible patients have pathologically confirmed relapsed or refractory solid tumors for which no approved therapy exists. Up to 36 patients will be enrolled and the dose of NLG-919 will be escalated according to a standard 3+3 design. NLG-919 will be administered orally twice daily for the first 21 days of repeating 28 day cycles. Patients may receive drug until disease progression. Endpoints include safety, toxicity, and determination of a MTD or MBED that can be taken forward into phase 2 studies. Furthermore, additional immunological, pharmacokinetic, and pharmacodynamics tests are also planned. Clinical trial information: NCT02048709.

**TPS3122^ General Poster Session (Board #183B), Sun, 8:00 AM-11:45 AM**

**TREAT-ME 1: Treatment of advanced gastrointestinal cancer in a clinical phase I/II trial with genetically modified mesenchymal stem cells.** *Presenting Author: Jobst von Einem, Department for Hematology and Oncology, Klinikum Großhadern and Comprehensive Cancer Center, LMU Munich, Munich, Germany*

**Background:** Next generation somatic cell-based therapies are at the edge to add another therapeutic modality to clinical oncology particular for malignancies with still high medical need. Based on a vast number of preclinical data, we have initiated a phase I/II clinical trial for the treatment of advanced adenocarcinoma of the gastrointestinal tract applying genetically-modified mesenchymal stem cells (MSC) from the patients' own bone marrow (TREAT-ME 1). **Methods:** Autologous MSC have the capability to home to any (inflammatory) tumor site or metastasis to deliver therapeutic gene products in a highly effective way. Our pharmaceutical product (IND) is a genetically modified somatic cell suspension. The stable integration of the therapeutic gene (here HSV-TK) under the control of a tumor specific promoter (based on the molecular tumor tissue profile) is accomplished through the use of a gamma-retroviral, replication incompetent and self-inactivating (SIN) vector system. The manufactured MSC cell-suspension is applied intravenously for three consecutive weeks, followed by the administration of the prodrug which is activated only in the context of the tumor environment. The study has started to recruit (Oct 2013) and the first patient cohorts are designed to define the optimal cell dose and feasibility. Safety and tolerability will be evaluated and as secondary variables TTP and OS up to one year. Interim results of the phase I safety phase are expected in 2014. In this trial we have already demonstrated that the genetic modification of autologous MSCs from cancer patients and their manufacturing as an IND is feasible and does not alter the typical biological properties of MSCs. The therapeutic administration of genetically modified MSCs as a principle mechanism of a cell-based gene therapy respectively a gene product delivery tool holds promise for the clinical application of a patient-tailored combination of cell- and suicide gene therapy. We expect this innovative medicinal product will provide high local therapeutic activity and low (off-target) toxicity resulting in a positive safety profile.

**TPS3123 General Poster Session (Board #184A), Sun, 8:00 AM-11:45 AM**

**Active8: A randomized, double-blind, placebo-controlled study of chemotherapy plus cetuximab in combination with VTX-2337 in patients with recurrent or metastatic squamous cell carcinoma of the head and neck (SCCHN).** *Presenting Author: Ezra E.W. Cohen, Moores Cancer Center, University of California at San Diego, La Jolla, CA*

**Background:** The potential for synergy between cytotoxic and immunologic agents is an exciting area of exploration in oncology. Many chemotherapeutics like platinum and 5-FU can induce immunogenic antitumor effects. Natural killer (NK) cell-mediated antibody-dependent cellular cytotoxicity (ADCC) is an important mechanism of IgG1 monoclonal antibodies (MAb). VTX-2337 is a novel Toll-like receptor 8 (TLR8) agonist with preclinical data demonstrating synergistic effects with chemotherapy and increased ADCC with MAbs. For recurrent or metastatic SCCHN, the EXTREME regimen adding cetuximab to platinum and 5-FU improved median overall survival (OS) by 2.7 months. While a significant advance, further improvement is needed. Synergy with immunotherapy is one option. A phase Ib study of cetuximab and VTX-2337 in recurrent or metastatic SCCHN patients showed the combination to be tolerable and active. TLR8 activation and NK cell stimulation and mobilization provided a rationale to further assess this combination in SCCHN patients. **Methods:** This randomized, double-blind, placebo-controlled, phase 2 study evaluates the safety and efficacy of VTX-2337 with EXTREME vs. EXTREME alone for first-line treatment of recurrent or metastatic SCCHN. Patients must have a confirmed diagnosis with at least one measurable lesion and no previous systemic therapy for recurrence. Approximately 175 pts will be randomized 1:1 to receive VTX-2337 + EXTREME or placebo + EXTREME for 6 cycles (q3wk), followed by weekly cetuximab with biweekly VTX-2337/placebo. The primary objective is to compare progression-free survival (PFS) according to immune-related response evaluation criteria between the 2 treatment arms as determined by an independent review facility. Secondary objectives include comparisons of safety, OS, objective response rate, duration of best response, disease control rate, and duration of disease control of the two treatment groups. Pharmacodynamics and pharmacokinetics of VTX-2337 as well as translational medicine correlatives will also be evaluated. Enrollment began in October 2013.

**TPS3124 General Poster Session (Board #184B), Sun, 8:00 AM-11:45 AM**

**A phase 2 study of docetaxel in combination with indoximod in metastatic breast cancer.** *Presenting Author: Hatem Hussein Soliman, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Indoleamine 2,3 dioxygenase (IDO) is a tryptophan-catabolizing enzyme that tumors use to create a state of immunosuppression. Indoximod (D-1-methyltryptophan) is a broad IDO pathway inhibitor as it has been shown to potentially interfere with multiple targets within the IDO pathway. Preclinical studies in MMTV-neu mouse models have shown that indoximod combined with chemotherapy was more effective in causing tumor regressions than either agent alone. A phase 1 trial combining docetaxel and indoximod demonstrated safety and responses in metastatic breast cancer patients. Based on this data a phase 2 trial in metastatic breast cancer was initiated. **Methods:** The study is a 1:1 randomized, placebo controlled two arm phase 2 study. The study treatment is docetaxel 75mg/m2 IV D8 plus indoximod 1200mg PO BID D1-14 every 21 days or matching placebo. Primary endpoint is progression free survival. Secondary endpoints include overall survival, response rate per RECIST 1.1, and immune response correlative assays. Patients with measurable, histologically confirmed metastatic breast cancer, no prior chemotherapies for metastatic disease, ER+ or ER – HER2 -, ECOG PS 0-1, no active CNS disease, no active autoimmune disease are eligible. Target enrollment is 154 patients and it is currently enrolling patients in multiple clinical sites all around the US. Clinical trial information: NCT01792050.

**TPS3125 General Poster Session (Board #185A), Sun, 8:00 AM-11:45 AM**

**A phase 2 study of Ad.p53 DC vaccine in combination with indoximod in metastatic solid tumors.** *Presenting Author: Hatem Hussein Soliman, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Indoelamine 2,3 dioxygenase (IDO) is an inducible tryptophan-catabolizing enzyme that downregulates the immune system. Many tumor cell types overexpress IDO to avoid elimination by infiltrating cytotoxic T cells. Indoximod (1-methyl-D-tryptophan/ D1MT) is an IDO pathway inhibitor. Published preclinical data suggests that blockade of IDO with indoximod enhances the immunologic response to dendritic cell (DC) vaccines. Ad.p53 is an adenovirus used for generating DC vaccines directed against p53 epitopes. Ad.p53 when given to previously treated SCLC patients significantly increased their response rate to subsequent chemotherapy. Data showing a similar trend for enhanced response to subsequent chemotherapy was presented in breast cancer patients who were treated in the phase I trial using Ad.p53DC and indoximod. The primary endpoint in phase II is the response rate of indoximod +Ad.p53 in metastatic breast cancer patients. Secondary endpoints include safety, PFS, OS, and immunologic correlates. **Methods:** This Phase 2 study uses a single arm, Simon two stage design. Patients with measurable, metastatic breast cancer, <3 lines of prior chemotherapy in metastatic setting, p53 immunohistochemistry >5% in archival tumor specimen, ECOG 0-2, no autoimmune disease are eligible. Study treatment consists of 1600mg PO BID of indoximod given continuously along with up to 6 fixed doses of Ad.p53DC SQ vaccinations q2weeks. First stage of accrual is 12 patients with one response required for progression into the second stage of 25 additional patients. The study design is based on the alternative hypothesis of a 20% response rate, with 90% power to detect this level of activity with a significance of .09 (assuming a total of 4 responses out of 37 are observed). Accrual to the first stage of this trial is completed and the study remains open with some of the patients still undergoing study treatment. Clinical trial information: NCT01042535.

**TPS3126 General Poster Session (Board #185B), Sun, 8:00 AM-11:45 AM**

**A first-in-human study of pegylated recombinant human IL-10 (AM0010), daily administered for four months in selected advanced solid tumors.** *Presenting Author: Todd Michael Bauer, Sarah Cannon Research Institute/ Tennessee Oncology, PLLC, Nashville, TN*

**Background:** Cancer immunotherapy targets the activation of tumor infiltrating CD8 T cells. Tumor associated inflammation on the other hand is thought to both promote tumor growth and to inhibit the CD8 mediated immune responses. IL-10 directly induces Interferon gamma in tumor resident CD8+ T cells, stimulates the cytotoxic activity of CD8+ T cells, increases the immunoglobulin production of B cells and has strong anti-inflammatory activity. In preclinical studies, PEGylated IL-10 (PEG-IL-10) but not non-PEGylated-IL-10 induces the rejection of large syngeneic tumors and the development of immunological memory against the tumor cells. Maximal antitumor efficacy required daily subcutaneous injections of PEG-IL-10 for 2-4 weeks indicating the need for prolonged stimulation of the immune system. rHuIL-10 was used in previous clinical trials in inflammatory diseases but its short T1/2 prevented a meaningful clinical benefit. AM0010, a PEGylated human IL-10, is safe in preclinical species and a first in human study was started November 2013. **Methods:** This study will be performed in two parts and will enroll approximately 28 patients with advanced solid tumors in the escalation phase, followed by at least one expansion cohort of 15 patients. Patients with melanoma, non-small cell lung cancer, renal cell cancer, colorectal cancer, castrate resistant prostate cancer, ovarian cancer and pancreatic cancer will be enrolled during the dose escalation phase, followed by at least one disease specific expansion cohort. Patients will daily self-administrate subcutaneous doses of AM0010 for four cycles of 1 month without dosing holidays. The primary objectives are to establish the safety and tolerability, dose limiting toxicities, and MTD of AM0010. Secondary objectives are to assess preliminary anti-tumor activity, pharmacokinetics, and immunogenicity of AM0010. The pharmacodynamic effects of AM0010 on innate and adaptive immunity will be evaluated using serum cytokine measurements, immunohistochemistry of tumor infiltrating T cells and humoral and cellular tumor antigen specific responses in the blood of patients. Clinical trial information: NCT02009449.

**TPS3127 General Poster Session (Board #186A), Sun, 8:00 AM-11:45 AM**

**A phase 1b study to assess the safety of PLX3397, a CSF-1 receptor inhibitor, and paclitaxel in patients with advanced solid tumors.** *Presenting Author: Neelesh Sharma, University Hospitals Seidman Cancer Center, Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH*

**Background:** Tumor-associated macrophages (TAMs) mediate resistance to chemotherapy and radiation therapy. Macrophages are regulated in part by colony stimulating factor -1 (CSF-1), which signals through the CSF-1 receptor (CSF-1R) expressed predominantly on TAMs. CSF-1 is expressed by several types of malignancies (including breast and prostate cancer, leiomyosarcoma and glioblastoma) and correlates with extent of TAM presence in tumor parenchyma. Preclinical studies demonstrated that tumor exposure to cytotoxic therapies such as paclitaxel, cisplatin or ionizing radiation lead to increased expression of CSF-1, IL-34 (the other ligand for CSF1R), and chemokines regulating TAM recruitments, CCL8/ MCP2. This is associated with an increased presence of TAMs in residual tumors, resulting in a tumor immune microenvironment favoring malignant cell proliferation and survival. PLX3397 is an orally available small molecule inhibitor of CSF-1R with IC50 of ~17 nM. *In vivo* studies in transgenic MMTV-PyMT mice with late-stage mammary cancer and lung metastases treated with paclitaxel and PLX3397 showed: reduced macrophage infiltration of primary tumor tissue; increased presence of tumor infiltrating $CD8^+$ and $CD4^+$ T-lymphocytes; and reduced tumor growth as well as pulmonary metastases compared to paclitaxel alone (DeNardo et al., 2011). These studies provide clinical rationale to study the combination of PLX3397 and paclitaxel in solid tumors. Safety, pharmacokinetics and pharmacodynamics data of single-agent PLX3397 have been previously presented (Anthony et al., 2011). **Methods:** In this phase Ib trial, patients with advanced solid tumors are treated with weekly paclitaxel and escalating doses of continuous dosing of oral PLX3397 to establish a RP2D of PLX3397. This will be followed by a dose expansion to a total of 15 patients, to further determine safety and preliminary efficacy of this combination. Exploratory objectives include correlating changes in serum CSF-1 levels and identifying novel biomarkers of clinical activity. This study will support further development of the PLX3397/paclitaxel combination in the I-SPY-2 neoadjuvant breast cancer trial. Clinical trial information: NCT01525602.

**TPS3128 General Poster Session (Board #186B), Sun, 8:00 AM-11:45 AM**

**Phase 2 study of programmed death-1 antibody (anti-PD-1, MK-3475) in patients with microsatellite unstable (MSI) tumors.** *Presenting Author: Dung T. Le, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** We hypothesize that a correlation may exist between the number of somatic mutations in individual tumors and the response to immune checkpoint inhibitors since each protein-coding mutation has the potential to serve as a novel antigen for an immune response. This may explain why lung cancers and melanomas, which harbor hundreds of somatic tumors, respond so well to these agents. Microsatellite unstable (MSI) tumors are deficient in DNA mismatch repair which leads to hundreds to thousands of spontaneous mutations. Furthermore, similar to melanoma, MSI positive colon cancers, there is often prominent lymphocyte infiltration. PD-1 is upregulated on activated T cells and provides inhibitory signals to T cells undergoing activation. MK-3475 is a humanized monoclonal IgG4 antibody against PD-1 and is showing activity in multiple tumor types. This study aims to establish the treatment benefit and evaluate MSI as a predictive marker of response to anti-PD-1 blockade. **Methods:** This is an open-label, 2-stage, phase 2 study to evaluate the clinical activity of MK-3475 in 3 cohorts of patients: MSI positive colorectal cancer (CRC); MSI negative CRC; and MSI positive solid tumors but not CRC. MK-3475 will be administered at 10 mg/kg every 14 days. The co-primary endpoints for CRC cohorts are immune-related progression-free survival (irPFS) rate at 20 weeks and objective response rate assessed using immune related response criteria. The primary endpoint for the cohort with other solid tumors is irPFS at 20 weeks. Secondary endpoints include disease control rate, progression-free survival, overall survival and safety. Each MSI positive and MSI negative CRC cohort will evaluate up to 25 patients, and the cohort with MSI positive solid tumors but not CRC will enroll up to 21 patients. Results from exome sequencing and PD-L1 expression using IHC on tumor tissue will be correlated with response. Clinical trial information: NCT01876511.

**TPS3129 General Poster Session (Board #187A), Sun, 8:00 AM-11:45 AM**

**Randomized phase II study with dendritic cell (DC) immunotherapy in patients with resected hepatic metastasis of colorectal carcinoma.** *Presenting Author: Javier Rodriguez, Medical Oncology, Clinica Universidad de Navarra, Pamplona, Spain*

**Background:** Cellular immunotherapy with DC is a feasible strategy with proved activity in the treatment of cancer. Preclinical and clinical data indicate that efficacy of DC immunotherapy is improved when used in clinical settings of minimal residual disease, and Sipuleucel-T is the first approved treatment based in this approach. We are exploring the efficacy of an autologous vaccine of DC loaded with self-tumor antigens that we developed in a previous pilot trial (Alfaro, J Immunology 2011) in patients with colorectal cancer with completely resected hepatic metastasis following standard adjuvant treatment. **Methods:** In this randomized phase II study, patients with colorectal carcinoma with hepatic metastasis treated with complete surgical resection and standard adjuvant chemotherapy are randomized to receive DC vaccine or observation. The two-cycle vaccination protocol includes the following strategies: (1) pretreatment with cyclophosphamide to decrease regulatory T cells; (2) maturation and activation of DC with TNF-alpha, interferon-alpha and *poly I:C*, a potent inducer of type I interferon; (3) use of autologous tumor from resected liver metastasis as antigenic source to load antigens onto DC, including antigens that are exclusive of tumor cells; and (4) administration of daily intradermal vaccines during four consecutive days in 2 cycles every 4 weeks. The strategy is to replicate the immune response induced during an acute viral infection in terms of activation signals and persistence of antigens in lymph nodes. The main objective is progression-free survival. Thirty-six patients will be included, allowing to detect a HR=1.75 (alpha error=0.2, beta error=0.35). Secondary objectives include assessment of toxicity, overall survival and immunologic response (in vitro lymphocyte responses against tumor antigens; delayed hypersensitivity reactions; induction of tumor antibody responses; DC activation parameters including IL-12 and IL-6 production and expression of CD80, CD83, CD86, B7-H1, B7-H4 and B7-DC; assessment of DC maturation by expression of pro-inflammatory cytokines; and DC migration). Clinical trial information: NCT01348256.

**TPS3130 General Poster Session (Board #187B), Sun, 8:00 AM-11:45 AM**

**Safety and immunologic efficacy of personalized multiple HLA class I-restricted peptide vaccines for breast cancer patients in the adjuvant setting.** *Presenting Author: Uhi Toh, Department of Surgery, Kurume University Faculty of Medicine, Kurume, Japan*

**Background:** Despite several attempts to introduce immunotherapy in cancer treatments have been carried out mostly without achieving significant clinical effects for refractory cancer, HER-2+ breast cancer(BC) patients (pts) who received adjuvant trastuzumab(Tz) followed by vaccination with peptide vaccines(PVs) have a lower recurrence rate than adjuvant Tz therapy alone and suggested new adjuvant that can increase the efficacy of the novel immunotherapic strategies.(Sears AK, J Clin Oncol 29: 2011) We previously demonstrated safety, high immunogenicity and clinical benefit for pts with metastatic BC using selected personalized PVs (Toh U, 2013 SABCS), we further conducted a Phase II trial evaluating selected multiple PVs in the adjuvant setting to prevent BC recurrence. The primary endpoint of the study is to evaluate the safety and immunological response to selected multiple peptides vaccination carried out in pts who are in clinical disease free and have completed standard adjuvant chemotherapy, the secondary endpoints were recurrence free survival and overall survival. **Methods:** This single arm, multicentrePhase II trial enrolled each of HLA-A2, A24, A26 or A3 superfamily molecule postoperative BC patients. Pre-vaccination plasma was measured for their IgG levels reactive to each of the previously reported 31 candidate peptides followed by administration subcutaneously of the four peptides at maximum showing higher levels of IgG. Total sixteen vaccinations were given as weekly for initial eight administrations and as biweekly for further eight inoculations. The concurrent adjuvant endocrine therapy was available during vaccinations. Currently 22 pts have been accrued and 17 pts have completed treatment. Follow-up will be carried out for 24 months to register adverse events and to evaluate the immunological effects. Levels of IgG reactive to each peptide in the pre- and post-treatment plasma were measured using LUMNEX system as well as specific T-cell cytotoxicity assessed by Elispot in the pre- and post-treatment peripheral blood lymphocytes at every 6 times of vaccination. Correlation between survival and the immune activity was investigated. Clinical trial information: 000003081.

**TPS3131 General Poster Session (Board #188A), Sun, 8:00 AM-11:45 AM**

**A phase 1A/1B, two-stage study of a PSA/IL-2/GM-CSF vaccine for the treatment of PSA-recurrent prostate cancer in hormone-naive and hormone-independent patients.** *Presenting Author: Gregory A. Daniels, VA San Diego Healthcare System, San Diego, CA*

**Background:** Prostate cancer vaccines demonstrate clinical benefit in hormone refractory metastatic prostate cancer patients. The broader application to earlier disease stages remains both cost prohibitive and of unclear benefit. The aim of this trial evaluates the safety and tolerability of a simple recombinant PSA vaccine in men with either hormone naïve or hormone-independent prostate cancer without evidence of metastasis ("PSA-only"). Secondary aims include changes in PSA doubling time, time to measurable disease and vaccine-induced immunologic assessments. **Methods:** This is a Phase 1A/1B trial of PSA/IL-2/GM-CSF vaccine in recurrent prostate cancer in hormone-naïveand hormone-independent patients**.** Major inclusion criteria include adenocarcinoma of the prostate, rising serum PSA and no measurable disease. Phase 1A examines the rate of dose limiting adverse events (DLAEs) in an initial course of 6 vaccinations ("induction vaccination"). Phase 1B examines the rate of DLAEs with a continued coarse of an additional 6 vaccinations ("maintenance vaccine") in another 28 patients. There will be an interim analysis after the first 20 patients accrue. All patients will receive intradermal injections of the PSA/IL-2/GM-CSF vaccine at weeks 1, 2, 3, 7,11, and 15. Secondary endpoints including serum PSA and prostatic acid phosphatase (PAP) level measurements along withimmunological evaluations. All patients will be evaluated for diseaseprogression at Week 19. If the Phase 1A portion of the trial demonstrates safety of the induction vaccination, 28 additional patients will be enrolled in the Phase 1B portion of the trial. Patients will receive maintenance vaccine alternating every 4 weeks between IL-2 and the complete vaccine (PSA/IL-2/GM-CSF) starting at week 23 and until week 43 (6 injections total). To date, eight of twenty patients have received at least one vaccine injection in the phase IA portion without DLAEs. Enrollment continues in phase IA.

**TPS3132 General Poster Session (Board #188B), Sun, 8:00 AM-11:45 AM**

**A phase I study of BPX-201 vaccine plus AP1903 for chemo-naive metastatic castrate-resistant prostate cancer (mCRPC).** *Presenting Author: Guru Sonpavde, The University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

**Background:** We have reported promising activity, including one RECIST PR and potential synergy with chemotherapy, in a phase I trial of 18 men with mCRPC administered BPX-101 (Bellicum Pharmaceuticals), an autologous antigen presenting cell (APC)-based vaccine, pulsed with PSMA (prostate specific membrane antigen) and transduced with an adenovirus bearing iCD40, with each dose followed by *in vivo* activation by dimerizer drug AP1903 infusion (Slawin KM, Sonpavde G, et al, ASCO 2011). This provided a rationale for the study of our second-generation vaccine, BPX-201, manufactured with APCs transduced with an adenoviral vector bearing genes for iMyD88/CD40, which includes signaling elements from the "universal" adjuvant adapter, MyD88 (Narayanan, et al, JCI 2011), and PSMA, and followed by AP1903 activation. **Methods:** A 3+3 design Phase I dose escalation trial (NCT01823978) evaluating BPX-201 plus AP1903 is ongoing for men with chemo-naive mCRPC in 2 institutions: UAB (University of Alabama, Birmingham, AL) and Baylor Sammons Cancer Center (Dallas, TX). The primary objective is to determine the safety of BPX-201 in doses of 10, 20 and 40 million cells and AP1903 when administered to patients with chemo-naive mCRPC. Six patients will be enrolled per dose cohort (total accrual=18). Secondary objectives are to evaluate efficacy with vaccine and subsequent therapy, pharmacokinetics, and circulating tumor cells for up to 2 years. Extensive immune monitoring is performed during both the vaccination phase and during subsequent therapies. Patients undergo leukapheresis once at baseline followed by therapy with cryopreserved product after 2-3 weeks given intradermally q 2 weeks x 6 doses. AP1903 is administered intravenously 24 hours after each dose of the vaccine. Radiographic evaluation is performed q 3 months or earlier, if required. Post-vaccine systemic therapy is initiated for symptomatic or radiographic progression and not for PSA progression alone. Enrollment on the lowest dose cohort (n=6) is complete without dose limiting toxicities. Cohort 2 started enrolling in January 2014. Clinical trial information: NCT01823978.

**TPS3133 General Poster Session (Board #189A), Sun, 8:00 AM-11:45 AM**

**Local and systemic antitumor effects of activated autologous dendritic cells for intratumoral injection: A phase I/II trial.** *Presenting Author: Vivek Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Dendritic cells (DC) are antigen presenting cells proficient in inducing de novo immune responses, and the presence of intratumoral DCs confers a survival advantage to patients, likely due to an improved balance between the immune system and the growing tumor lesion. We have initiated a Phase I/II clinical trial to exploit this finding, by using partially activated autologous DCs (aDC; DCVax-Direct) for intratumoral injection in inoperable tumors for which limited treatment options exist. These aDC retain antigen uptake and presentation capability and are conditioned to complete the maturation process following injection, resulting in initiation of a broad anti-tumor immune response. Preclinical animal data have demonstrated that these aDC can mobilize both local and systemic immune responses, and effectively clear both injected (local) and non-injected (distal) inoperable tumor lesions. **Methods:** The Phase I component of the trial aims to enroll 6 patients each in following indications: colorectal cancer, lung cancer, breast cancer with brain metastases, pancreatic cancer, melanoma and 'other'. Patients must have had at least one recent anti-tumor treatment other than active immune therapy prior to enrollment into the trial. A dose escalation across indications investigates the safety of 3 dose levels. The aDC are injected intratumorally, using imaging guidance, at days 0, 7 and 14, followed by injections at 8 and 16 weeks. Initial DLT assessments are done following the first three injections. Tumor biopsies are taken at the time of injections to assess local effects on the injection of aDC, and tumor response is assessed using both RECIST and Immune Related Response Criteria, starting 8 weeks after the first injection. The first dose cohort of the Phase I component has completed DLT assessments, and the second dose cohort's enrollment is nearly complete. In addition, the "other" cohort of multiple cancers has been fully enrolled. Correlative immune-biomarkers studies to evaluate response and/or resistance mechanisms are planned. The Phase II component will enroll 24 patients in a selected indication, based on the results obtained in Phase I. Clinical trial information: NCT01882946.

**TPS3134 General Poster Session (Board #189B), Sun, 8:00 AM-11:45 AM**

**Autologous dendritic cell vaccination (DCVAC/OvCa) added to standard of care therapy in three open-label randomized phase 2 studies in women with advanced stage ovarian cancer (OC).** *Presenting Author: Lukas Rob, Department of Gynecology and Obstetrics, Charles University and University Hospital Motol, Prague, Czech Republic*

**Background:** OC is the 5$^{th}$ most common type of cancer in women and the 4$^{th}$most common cause of cancer death in women. Immunotherapy, for induction of tumor cell specific immune responses destroying tumor cells, has emerged as a promising treatment modality in solid malignant tumors. Studies have shown that chemotherapy can be combined with vaccine without blunting the response to the vaccine. **Methods:** The approach tested in the reported trials is a patient specific active cellular immunotherapy using autologous dendritic cells differentiated from peripheral blood monocytes and presenting tumor antigens derived from killed OC cell lines (SK-OV-3, OV-90). A phase 1 trial of DCVAC/OvCa (EudraCT 2010-021462-30) was the basis for the phase 2 program. This includes 3 protocols designed for patients with 1$^{st}$line treatment, relapsed Pt-sensitive and relapsed Pt-resistant advanced stage OC. Immunotherapy is added to standard chemotherapy. *SOV01 (90 pts; EudraCT 2013-001322-26):* A randomized, open-label, three-arm, multi-center Phase II clinical trial evaluating effect of addition of DCVAC/OvCa to first line standard chemotherapy (carboplatin and paclitaxel) in women with newly diagnosed epithelial ovarian carcinoma. *SOV02 (60 pts; EudraCT 2013-001323-38):* A randomized, open-label, parallel group, multi-center Phase II clinical trial evaluating effect of addition of DCVAC/OvCa to standard chemotherapy (carboplatin and gemcitabine) in women with relapsed platinum sensitive epithelial ovarian carcinoma. *SOV03 (60 pts; EudraCT 2013-001325-24):* A randomized, open-label, parallel group, multi-center Phase II clinical trial evaluating effect of addition of DCVAC/OvCa to standard chemotherapy in women with relapsed platinum resistant epithelial ovarian carcinoma. The first patient in the phase 2 program was enrolled November 5, 2013, and all 3 trials are now recruiting patients. As of February 3, 10 patients had been screened and 7 had been randomized. Clinical trial information: EudraCT 2013-001322-26.

**3500 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Preoperative chemoradiotherapy and postoperative chemotherapy with 5-fluorouracil and oxaliplatin versus 5-fluorouracil alone in locally advanced rectal cancer: Results of the German CAO/ARO/AIO-04 randomized phase III trial.** *Presenting Author: Claus Rodel, University of Frankfurt, Frankfurt, Germany*

**Background:** The CAO/ARO/AIO-94 trial established preoperative chemoradiotherapy (CRT), total mesorectal excision (TME) surgery, and adjuvant chemotherapy with 5-FU as standard treatment for locally advanced rectal cancer. The goal of the CAO/ARO/AIO-04 trial was the integrating of more effective systemic treatment. First results of early secondary endpoints have been published (Rödel et al., Lancet Oncol 2012). Here we present the primary endpoint, disease-free survival (DFS) at 3 years. **Patients and Methods:** Patients with cT3/4 or cN+ rectal cancer were randomised into two arms: 1) preoperative 50.4 Gy plus infusional 5-FU 1 g/m$^2$ days 1-5 and 29-33, followed by TME-surgery and 4 cycles of bolus 5-FU 500 mg/m$^2$ for 5 days), and 2) preoperative 50.4 Gy plus infusional 5-FU (250 mg/m$^2$ days 1-14 and 22-35), oxaliplatin (50 mg/m$^2$ days 1, 8, 22, and 29), followed by TME and 8 cycles of adjuvant oxaliplatin (100 mg/m$^2$ day 1), leucovorin (400 mg/m$^2$ day 1) and infusional 5-FU (2,400 mg/m$^2$ day 1-2). The primary endpoint was DFS at 3 years defined as the interval from randomization to incomplete surgical resection, locoregional or metastatic recurrence or death, whichever occurred first. **Results:** A total of 637 patients were randomly assigned to arm 1 and 628 to arm 2. After a median follow-up time of 50 months, 198 patients in arm 1 had had a DFS-related event, as compared with 159 patients in arm 2 (HR 0.79, 95% confidence interval 0.64 to 0.98, P=0.03 by the mixed effects Cox model). The rate of DFS at three years was 71.2% (95% confidence interval, 67.6% to 74.9%) in arm 1 and 75.9% (95% confidence interval, 72.4% to 79.5%) in arm 2 (P=0.03 by the exact stratified log-rank test). Grade 3-4 late overall treatment-related toxicity occurred in 23% in arm 1 and 26% in arm 2 (P=0.14). The incidence of grade 3-4 sensory neuropathy in the oxaliplatin containing arm was 7% during treatment, decreasing to 3% at one year of follow-up. **Conclusions:** Adding oxaliplatin to 5-FU-based neoadjuvant CRT and adjuvant chemotherapy in locally advanced rectal cancer significantly improved DFS. Clinical trial information: NCT00349076.

**3501 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Preoperative chemoradiotherapy and postoperative chemotherapy with capecitabine and oxaliplatin versus capecitabine alone in locally advanced rectal cancer: Disease-free survival results at interim analysis.** *Presenting Author: Hans-Joachim Schmoll, Martin Luther University Halle-Wittenberg, Halle, Germany*

**Background:** The PETACC-6 trial investigates whether the addition of oxaliplatin to preoperative oral fluoropyrimidine-based chemoradiation (CRT) followed by postoperative adjuvant fluoropyrimidine-based chemotherapy (CT) improves disease-free survival (DFS) in locally advanced rectal cancer. **Methods:** Between 11/2008 and 09/2011, patients with rectal adenocarcinoma within 12 cm from the anal verge, T3/4 and/or node-positive, with no evidence of metastatic disease and considered either resectable at the time of entry or expected to become resectable, were randomly assigned to receive 5 weeks of preoperative CRT with capecitabine, followed by 6 cycles of adjuvant CT with capecitabine with (arm 2) or without (arm 1) the addition of oxaliplatin before and after surgery. 440 DFS events were required to have 80% power to detect an improvement in 3-year DFS from 65% with capecitabine alone to 72% with capecitabine and oxaliplatin (HR=0.763) using a two-sided alpha of 5% and owing for an interim analysis for early efficacy at 200 events. The primary analysis was intent-to-treat and adjusted for stratification factors (clinical T category, nodal status, distance from the tumor to the anal verge and method of locoregional staging) except the center. **Results:** 1094 patients were randomized (547 in each arm). 543 eligible patients in arm 1 and 526 in arm 2 started their allocated treatment of whom 67.4% completed protocol treatment in arm 1 vs. 53.8% in arm 2. An independent data monitoring committee reviewed the interim data and recommended the early release of the results. At median follow-up of 31 months, respectively 124 and 121 DFS events were observed in arm 1 and 2 (adjusted HR=1.036, 95% CI: 0.806 -1.331, P=0.781). 3-year DFS was 74.5% (95% CI: 70.1% - 78.3%) in arm 1, which is higher than anticipated vs. 73.9% (95% CI: 69.5% - 77.8%) in arm 2. Conditional power under HR=0.763 is only 7%. **Conclusions:** Interim results indicate that the addition of oxaliplatin to capecitabine plus radiotherapy does not improve DFS. Careful follow-up should continue until the planned 440 events to document any late treatment difference. Clinical trial information: NCT00766155.

**3502 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Adjuvant chemotherapy with oxaliplatin/5-fluorouracil/leucovorin (FOLFOX) versus 5-fluorouracil/leucovorin (FL) for rectal cancer patients whose postoperative yp stage 2 or 3 after preoperative chemoradiotherapy: Updated results of 3-year disease-free survival from a randomized phase II study (The ADORE).** *Presenting Author: Yong Sang Hong, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

**Background:** To report the updated results of 5-fluorouracil (5-FU)/leucovorin (LV) (FL) with or without oxaliplatin (FOLFOX) in patients with curatively resected rectal cancer whose pathologic stages of ypII/III after preoperative chemoradiotherapy (CRT). **Methods:** This is a randomised phase II study accrued patients with curatively resected rectal cancer patients whose postoperative stage ypII (ypT3-4/ypN0) or III (any ypT/ypN1-2) after preoperative CRT with fluoropyrimidines alone. Patients were randomly assigned (1:1) to receive adjuvant chemotherapy either with FL (5-FU 380 mg/m$^2$, LV 20 mg/m$^2$ on days 1-5, every 4 weeks, 4 cycles) or FOLFOX (oxaliplatin 85 mg/m$^2$, LV 200 mg/m$^2$, 5-FU bolus 400 mg/m$^2$ on day 1, 5-FU infusion 2400 mg/m$^2$ for 46 hours, every 2 weeks, 8 cycles). Randomisation was centrally coordinated and stratified by the ypStage and participating sites. The primary endpoint was 3-year disease-free survival (DFS). **Results:** A total of 321 patients were randomly assigned between November 2008 and June 2012; 161 patients to FL and 160 to FOLFOX. The arms were balanced. At a median follow-up of 38.2 months (IQR, 26.4 – 50.6), 3-year DFS rate was 71.6% (95% CI, 64.6 – 78.6) in the FOLFOX arm and 62.9% (95% CI, 55.4 – 70.4) in the FL arm with a hazard ratio (HR) of 0.657 (95% CI, 0.434 – 0.994, $p$=0.047) by intention-to-treat analysis. After adjusting for stratification and prognostic variables, HR remained unchanged favoring FOLFOX (0.560; 95% CI 0.366 – 0.856; $p$=0.007) in terms of 3-year DFS. In the subgroup analysis, patients with ypStage III (HR 0.602 [0.371 – 0.977], $p$=0.040), ypN1b (HR 0.356 [0.132 – 0.960], $p$=0.041), ypN2 (HR 0.414 [0.181 – 0.946], $p$=0.037), and minimally regressed tumors (HR 0.395 [0.188 – 0.831, $p$=0.014] benefited more from FOLFOX than FL. Grade-3 or -4 adverse events were not statistically different between arms. **Conclusions:** Adjuvant FOLFOX demonstrated improved 3-year DFS in curatively resected rectal cancer patients whose postoperative stage of ypII/III after preoperative CRT. Clinical trial information: NCT00807911.

**3503^ Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Maintenance strategy with fluoropyrimidines (FP) plus Bevacizumab (Bev), Bev alone, or no treatment, following a standard combination of FP, oxaliplatin (Ox), and Bev as first-line treatment for patients with metastatic colorectal cancer (mCRC): A phase III non-inferiority trial (AIO KRK 0207).** *Presenting Author: Dirk Arnold, Klinik für Tumorbiologie, Freiburg, Germany*

**Background**: The optimal maintenance strategy following combination chemotherapy plus Bev is still controversial. AIO KRK 0207 investigates whether after a 24-week standard induction with F//Ox/Bev, no continuation of therapy or continuation with Bev alone are non-inferior to FP plus Bev. **Methods:** Pts with mCRC and 'standard' eligibility criteria were enrolled. After 24 weeks of induction treatment with FP/Ox/Bev, pts without disease progression were randomized into one of the following arms: A) standard maintenance treatment with FP plus Bev; B) Bev alone; or C) no treatment. At first progression, re-induction of the initial treatment was planned. The primary endpoint was 'time to failure of strategy' (TFS), comprising maintenance *plus*re-induction after first progression. Sample size was calculated (one-sided alpha of 0.0125; power of 80%) to conclude non-inferiority compared with the FP plus Bev arm. Secondary endpoints included time to first progression (PFS1) and overall survival (OS). **Results:** 840 pts were enrolled, 473 randomized. Median follow-up is 27 months. After induction, 60% of pts had CR/PR, 40% SD. Median PFS1 in arms A, B, C were 6.2, 4.6 and 3.6 months (p< 0.0001; A vs C: HR 2.11, 95% CI 1.63-2.73; A vs B: HR 1.28, 95% CI 0.99-1.65; B vs C: HR 1.56, 95% CI 1.22-1.99), respectively. TFS favored arm A over arm C (HR 1.31, 95% CI 1.01-1.69, p=0.038) but without difference between arms A and B (HR 1.04,95% CI 0.81-1.36, p=0.74). However, upon first progression only 24% in arm A and 47 % in both arms B and C, received re-induction. After 200 documented events, preliminary OS is 23.4 months from randomization, without significant difference between treatment arms (p=0.69). **Conclusions:** Following 24 weeks of induction, active maintenance with both, FP plus Bev or Bev alone, show prolonged TFS over no treatment. Only a minority of patients received re-induction treatment as planned. With currently limited follow up, the different maintenance strategies had no impact on OS. Clinical trial information: NCT00973609.

**3504 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Final results and subgroup analyses of the phase 3 CAIRO3 study: Maintenance treatment with capecitabine + bevacizumab versus observation after induction treatment with chemotherapy + bevacizumab in metastatic colorectal cancer (mCRC).** *Presenting Author: Miriam Koopman, University Medical Center Utrecht, Utrecht, Netherlands*

**Background:** We investigated the efficacy of maintenance treatment with capecitabine (cap) + bev versus observation in mCRC patients (pts) not progressing during induction treatment with cap, oxaliplatin and bev (CAPOX-B). **Methods:** Previously untreated mCRC pts with stable disease or better after 6 cycles of CAPOX-B were randomized between observation (arm A) or maintenance treatment with cap 625 mg/m2 bid daily continuously + bev 7.5 mg/kg iv q 3 weeks (arm B). Upon first progression (PFS1), pts in both arms were to be treated with CAPOX-B until 2nd progression (PFS2, primary endpoint). Secondary endpoints were overall survival (OS) and time to 2nd progression (TTP2), which was defined as the time to progression on any treatment following PFS1, and quality of life (QoL). Preplanned subset analyses were performed. **Results:** A total of 558 pts were randomized. Upon PFS1, CAPOX-B was reintroduced in 61% of pts in arm A and 47% in arm B. There was a significant benefit for maintenance treatment for PFS1, TT2PD and PFS2 with a median of 8.5 m vs 11.7 m, respectively (HR 0.67, p < .0001). Multivariable analysis showed a significant interaction for treatment with OS. Subgroup analysis showed a significant interaction for treatment in pts with synchronous metastases with resected primary tumor (n=180): median OS 18.0 m (A) vs 25.0 m (B) (p <0.0001), and for pts with complete/ partial response to induction treatment before randomization (n=366) with median OS of 18.8 m (A) and 24.1 m (B; p < .0001). QoL was maintained during maintenance treatment, and was clinically not inferior compared to QoL in the observation arm. **Conclusions:** Final CAIRO3 results establish the benefit of maintenance treatment with cap + bev after first-line induction treatment in pts with mCRC. Multivariable analysis shows a significant interaction of treatment with OS. Our finding that the positive effect on survival for maintenance treatment is most pronounced in pts with synchronous disease and resected primary tumor and with PR/CR to induction treatment should be confirmed.

**3505 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Treatment outcome according to tumor *RAS* mutation status in OPUS study patients with metastatic colorectal cancer (mCRC) randomized to FOLFOX4 with/without cetuximab.** *Presenting Author: Carsten Bokemeyer, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

**Background:** The addition of cetuximab to FOLFOX4 significantly improved progression-free survival and response in the first-line treatment of patients (pts) with *KRAS* codon 12/13 (hereinafter exon 2) wild-type (wt) mCRC. Pts with *KRAS*exon 2 tumor mutations showed no such cetuximab benefit, with a trend for worse outcome. **Methods:** Available *KRAS* exon 2 wt tumors from OPUS study pts were screened for 26 mutations (new *RAS*) in 4 additional *KRAS* codons (exons 3 and 4) and 6 *NRAS* codons (exons 2, 3 and 4) using BEAMing technology (5% sensitivity cutoff selected for analysis). Outcome was assessed according to *RAS* mutation status (*KRAS* exon 2 + new *RAS*). **Results:** Mutation status was evaluable in 118/179 (66%) pts with *KRAS* exon 2 wt tumors. New *RAS* mutations were detected in 31/118 (26%) pts. In those with *RAS* wt tumors, response was significantly improved by the addition of cetuximab to FOLFOX4 (Table). The treatment effect for those with new *RAS* tumor mutations could not be definitively assessed due to low pt numbers. In pts with any tumor *RAS* mutation (*KRAS* exon 2 + new *RAS*), no benefit from the addition of cetuximab to FOLFOX4 was seen, with a clear trend for worse outcome. **Conclusions:** Pts with mCRC harboring any activating *RAS* mutation are unlikely to benefit from the addition of cetuximab to FOLFOX4. Restricting cetuximab administration to pts with tumors wt at all such loci might help further tailoring of therapy to maximize pt benefit. Clinical trial information: NCT00125034.

**Treatment outcome according to tumor *RAS* mutation status in CRYSTAL study patients with metastatic colorectal cancer (mCRC) randomized to FOLFIRI with/without cetuximab.** *Presenting Author: Fortunato Ciardiello, Medical Oncology, Second University of Naples, Naples, Italy*

**Background:** The addition of cetuximab to FOLFIRI significantly improved progression-free survival, overall survival and response in the first-line treatment of patients (pts) with *KRAS* codon 12/13 (hereinafter exon 2) wild-type (wt) mCRC. Pts with *KRAS* exon 2 tumor mutations showed no cetuximab treatment benefit. **Methods:** Available *KRAS* exon 2 wt tumors from CRYSTAL study pts were screened for 26 mutations (new *RAS*) in 4 additional *KRAS* codons (exons 3 and 4) and 6 *NRAS* codons (exons 2, 3 and 4) using BEAMing technology (5% sensitivity cutoff selected for analysis). Outcome was assessed according to *RAS* mutation status (*KRAS* exon 2 + new *RAS*). **Results:** Mutation status was evaluable in 430/666 (65%) pts with *KRAS* exon 2 wt tumors. New *RAS* mutations were detected in 63/430 (15%) pts. In those with *RAS* wt tumors, a significant benefit across all endpoints was associated with the addition of cetuximab to FOLFIRI (Table). In pts with new *RAS* tumor mutations, no clear difference in efficacy outcomes between treatment groups was seen. In pts with any tumor *RAS* mutation (*KRAS* exon 2 + new *RAS*), no benefit from the addition of cetuximab to FOLFIRI was apparent. **Conclusions:** In the first-line treatment of mCRC, pts with *RAS* wt tumors derived a marked benefit from the addition of cetuximab to FOLFIRI; pts with *RAS* tumor mutations did not benefit. This finding may allow the further tailoring of cetuximab therapy to maximize pt benefit. Clinical trial information: NCT00154102.

**3507 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Prognostic impact of deficient mismatch repair (dMMR) in 7,803 stage II/III colon cancer (CC) patients (pts): A pooled individual pt data analysis of 17 adjuvant trials in the ACCENT database.** *Presenting Author: Daniel J. Sargent, Mayo Clinic, Rochester, MN*

**Background:** MMR status has been established as an important prognostic factor in CC pts. We determined the association of dMMR status with clinical/pathological features and prognosis using the ACCENT database. **Methods:** Microsatellite instability (MSI, 14 studies) or immunohistochemical analysis (1 study) for MLH1/MSH2/MLH6 proteins was performed on 7,803 stage II/III pts enrolled in 17 trials; 2 studies tested both. 571 pts received surgery alone; 3,878 5FU monotherapy (mrx); 2,299 5FU+oxaliplatin (oxal); and 1,055 5-FU+irinotecan (iri). Tumors with MSI-high or an absent protein were classified as dMMR; remainder were MMR-proficient (pMMR). Median follow-up was 7 years. Outcomes included overall survival (OS) and time to recurrence (TTR). Correlation analyses included all pts; prognostic analyses were limited to pts receiving surgery alone or 5FU mrx excluding pts receiving oxal/iri. **Results:** 524 (23.1%) of 2,270 stage II and 823 (14.9%) of 5,533 stage III pts exhibited dMMR. MMR status was associated with female sex (dMMR, 19% F v 16% M, p=0.004), higher T stage (dMMR, 11% T1/2 v 18% T3 v 21% T4, p < 0.001), and right-sided tumor location (dMMR, left 9% v right 27%, p < 0.001). Compared to pMMR, dMMR was strongly associated with improved OS (HR=0.27, p=0.01) and TTR (HR=0.27, p=0.01) in stage II pts treated with surgery alone (Table). Association of MMR was prognostic although of attenuated impact in 5FU treated stage II and in stage III pts , with significance confined to 5FU-mrx treated stage III pts (HR=0.80, p =0.02 for TTR; HR=0.79, p=0.02 for OS). **Conclusions:** Our study confirms prognostic utility of MMR status in stage II CCs. MMR also impacts outcome in stage III patients, but does not currently alter pt management.

**Impact of adjuvant chemotherapy with 5-FU or FOLFOX in colon cancers with microsatellite instability: An AGEO multicenter study.** *Presenting Author: David Tougeron, Department of Gastroenterology, Poitiers University Hospital, Poitiers, France*

**Background:** Microsatellite instability (MSI) is found in 12% of colon cancers (CC) and associated with a low recurrence rate after curative surgery. Adjuvant chemotherapy with 5-FU seems ineffective, but small studies recently suggest that adjuvant chemotherapy with FOLFOX could be effective (Zaanan et al.). The aim of this study was to analyze efficacy of adjuvant chemotherapy with 5-FU or FOLFOX in relapse-free survival (RFS) of MSI CC. **Methods:** This multicenter retrospective study included patients with stage II or III MSI CC with curative surgery between 2000 and 2012. High-risk stage II CC were defined by one of these criteria: stage T4, bowel obstruction, tumoral perforation, vascular emboli, lymphatic invasion, perinervous invasion, or a number of lymph nodes examined inferior to 10. Prognostic factors of RFS were analyzed in univariate and multivariate analysis using Cox model. **Results:** A total of 433 MSI CC patients were analyzed, including 57% and 43% stage II and III, respectively. Median follow-up was 35 months. Mean age was 70 $\pm$ 17 years. Overall, 61%, 27%, 12% patients had a surgery alone (n=263), adjuvant FOLFOX (n=119) or 5-FU (n=51) respectively. Adjuvant chemotherapy was administered in 17% of stage II (n=41) and 70% of stage III (n=129). Recurrence rates were 6% (n=14) for stage II and 21% (n=39) for stage III. Adjuvant chemotherapy was associated with better RFS in univariate analysis, but only for FOLFOX (HR=0.46, 95%CI 0.23-0.79) and not for 5-FU (HR=1.02, 95%CI 0.60-1.73). Three-years RFS was 75% for surgery alone, 66% for 5-FU and 84% for FOLFOX (p=0.02). In multivariate analysis taking account the other prognosis factors, adjuvant chemotherapy with oxaliplatin remains significantly associated with better RFS (HR=0.29, 95%CI 0.13-0.65 ; p=0.003). In the subgroup analyses, benefit of FOLFOX, as compared to 5-FU and surgery alone, was significant in stage III (HR=0.38, 95%CI 0.21-0.69 ; p=0.0014) and a trend was observed for high-risk stage II (HR=0.141 95%CI 0.02-1.04 ; p=0.0549). **Conclusions:** This multicenter study confirms that adding oxaliplatin to 5-FU can restore the chemosensitivity of MSI CC.

**3509 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM**

**Mutation and copy number discordance in primary versus metastatic colorectal cancer (mCRC).** *Presenting Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Molecular profiling for CRC commonly utilizes formalin-fixed tissue of convenience, which may include tissue obtained from primary or metastatic tumors. While the alterations in *KRAS*have been shown to have a high degree of concordance, a detailed survey of other commonly mutated genes, copy number variations, and the influence of intervening treatment in CRC has not been conducted. **Methods:** Primary and metastatic tissue underwent sequencing on a 46 or 50-gene hotspot AmpliSeq panel (IonTorrent) in a CLIA-compliant setting. For a subset of patients, targeted resequencing of a panel of 202 genes by HiSeq 2000 (Illumina) to an average depth of 800 was performed by the MDACC Institute of Personalized Cancer Therapeutics, with single nucleotide variations and copy number called by in-house algorithms. **Results:** Sequencing was successfully completed on 115 pairs of primary and metastatic tumors (N=107 for 46/50-gene, and N=17 for 202-gene). Forty-six high level amplifications (>4 copies) were found in 28 genes in 11 of 17 pairs, with discordant results in all cases, including discordance in potentially clinically relevant amplifications: *HER2, NOTCH1, FLT3*, and *AURKA*. Overall concordance rate for mutations on the 46/50-gene panel was 78%, but varied substantially by gene. *APC, TP53, NRAS,* and *BRAF* demonstrated concordance similar to *KRAS* (89% concordance), while *PIK3CA* demonstrated a 6.8-fold higher odds of discordance between primary and metastatic site (95% CI of odds ratio (OR) of 2.1 to 22.6, P<0.001). Genes with low prevalence (<10%) such as *FGFR3, STK11*, and *FBXW7* likewise had high levels of discordance (OR 4.4, 95% CI: 1.4 to 14.1, P=0.008). Intervening chemotherapy treatment was associated with a 3.5 fold higher odds of discordance across all genes compared to patients that did not receive therapy between resection of primary and metastatic tumors (95% CI 1.26 to 10.4, P=0.008), including *KRAS, TP53,* and *PIK3CA*(OR of 5.2, 3.5, and 3.3 respectively). **Conclusions:** Rates of discordance between primary and metastases mutations vary substantially by gene and prior treatment in mCRC. Prospective efforts to enrich for biomarkers need to account for tumor site and treatment variability on a gene-by-gene basis.

**3510 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM**

**Analysis of clonal evolution in colorectal cancer.** *Presenting Author: Donna M. Graham, Princess Margaret Cancer Centre/Ontario Cancer Institute, Toronto, ON, Canada*

**Background:** Comparisons of primary tumor and metastases (met) from the same individual patients (pts) highlight intratumor heterogeneity and clonal evolution with treatment. Results of genomic mutation analysis may guide treatment decisions in colorectal cancer (CRC). **Methods:** Ultra-deep (mean 35,000x coverage) amplicon sequencing was performed for hotspot regions of *TP53*, *APC*, *KRAS*, *NRAS, PIK3CA*, and *BRAF* on 36 DNA samples isolated from metachronous FFPE tumor specimens from 15 pts with CRC. The cohort included 10 pts with tissue from the primary and $\geq$1 met, four pts with pairs of mets, and one pt with a recurrent tumor at the primary site. One sample from each pt had prior analysis with a customized 23-gene panel for Sequenom. Samples were compared for presence of mutation and variant allele frequency (all-freq). **Results:** All *KRAS, NRAS, PIK3CA,* and *BRAF* mutations identified using Sequenom were confirmed by ultra-deep sequencing. Analysis for the six pts with *KRAS* codon 12 mutation, three pts with *TP53* mutation, and one pt with *NRAS* mutation confirmed mutation persistence from primary to met. Seven of the 15 pts had interval treatment with chemotherapy +/- bevacizumab. *KRAS* all-freq differed between primary and met based on interval treatment. Elevated all-freq (2.4 fold) between primary and met was found for three pts who received interval chemotherapy compared with a 0.6 fold average change in all-freq for three pts with no interval treatment ($p$=0.05 by Mann-Whitney U test). All-freq of *TP53* R273H mutation also increased (4.2 fold change) between primary and met in one treated pt. No low-frequency *KRAS* mutations or other mutations were identified in either sample of 3 pts previously found to be wild-type for KRAS; none had received anti-epidermal growth factor receptor therapy. One pt with anastomotic recurrence at 5 years had discordant *TP53*, *PIK3CA,* and *BRAF* mutation status from the primary suggesting the possibility of new CRC primary. **Conclusions:** Ultra-deep sequencing confirmed persistent clinically-relevant mutations between CRC primary and met. *KRAS* mutated subclones may be enriched in metastases following systemic chemotherapy. Targeted deep sequencing of driver mutations provides a powerful tool to monitor tumor behavior, and to identify recurrent lesions that are molecularly distinct from primary tumors.

**3511 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM**

**Colorectal Cancer Subtyping Consortium (CRCSC) identification of a consensus of molecular subtypes.** *Presenting Author: Rodrigo Dienstmann, Sage Bionetworks, Seattle, WA*

**Background:** Recently, a number of independent groups reported novel molecular subtypes in colorectal cancer (CRC). A formal comparison across these classifiers is needed to reconcile findings and accelerate clinical translation. The CRCSC was formed to identify a consensus among the subtyping systems through large scale data sharing and meta-analysis. **Methods:** The CRCSC consists of 6 groups (15+ institutions) that analyzed more than 30 patient cohorts with gene expression data, spanning multiple platforms and sample preparation methods. Each of the 6 classifiers (with 3-6 subtypes) was applied to the collection of public and proprietary datasets encompassing over 4,000 samples, mostly stage II-III CRC. Concordance of subtype calls and associations with clinical, molecular and pathway features were assessed centrally by an independent team. **Results:** Despite heterogeneities in cohorts and methods, subtype concordance analysis readily yielded a clear consensus on 4 CRC molecular subtypes (CMS1-4), with significant interconnectivity among the calls from the participating groups. The remaining 16% of samples did not have a consensus assignment, which may be partly explained by an additional mixed subtype with variable epithelial-mesenchymal activation; further refinement is needed. **Conclusions:** This is the first example of a large-scale, community based comparison of cancer subtypes. Within the largest collection of CRC samples we identified recurrent signals of 4 biologically distinct subtype classes enriched for key clinical, pathway and molecular traits. Ongoing efforts are attempting to improve the granularity of these subtypes.

**3512 Clinical Science Symposium, Tue, 9:45 AM-11:15 AM**

**Molecular subtyping of colon cancers and distinct prognostic groups [NCCTG N0147 (Alliance)].** *Presenting Author: Frank A. Sinicrope, Mayo Clinic, Rochester, MN*

**Background:** Categorization of colon cancers (CCs) into subtypes based upon pathways of tumorigenesis may improve prognostication. CCs were studied from a randomized trial of adjuvant FOLFOX ± cetuximab. **Methods:** Stage III CCs (N=3,018) were prospectively analyzed for *BRAF*$^{V600E}$ and *KRAS* (codons 12, 13) mutations by a PCR-based assay. DNA mismatch repair (MMR) proteins (MLH1, MSH2, MSH6) were analyzed; loss of any indicated deficient (dMMR) *vs* proficient MMR (pMMR). Sequencing-based methylation of *MLH1*was performed. Association with 5 yr disease-free survival (DFS) was evaluated using Cox models. **Results:** CCs were categorized into 5 subtypes (Table): Traditional (49%), Alternate (35%), Serrated (6.9%), Serrated dMMR (6.8%) or Familial dMMR (2.6%). Traditional *vs* alternate or serrated pMMR CCs were more likely left-sided (67% *vs* 42% or 24%; p<.0001) and from men (58% *vs* 51% or 41%; p< .0001). Alternate and serrated *vs* traditional pMMR tumors were frequently right-sided [58% and 76% *vs* 33%, p<.0001] and from women (p< .001). Serrated *vs* traditional pMMR CCs had more high grade histology (44% *vs* 19%, p < .0001) and N2 stage (59% *vs* 41%, p<.0001). Serrated *vs* familial dMMR CCs were older and more likely female (p <.0001). Alternate or serrated pMMR (*vs*traditional) tumors showed worse DFS (Table). Compared to alternate CCs, traditional [HR= 0.68 (0.58 -0.79), p<.001], serrated dMMR [HR=0.73 (0.54-.99), p=.042], and familial dMMR [HR=0.51 (0.30-.87), p=.0130] CCs showed favorable DFS. DFS of dMMR and traditional subtypes were similar. **Conclusions:** Subtype categorization of CCs reveals distinct clinical features and prognoses. Alternate and serrated pMMR subtypes show poor DFS whereas more prevalent traditional CCs have favorable DFS that is similar to dMMR CCs.

| Subtype | HR (95% CI) for DFS | P value[a] |
|---|---|---|
| Traditional (pMMR; wild-type *BRAF* and *KRAS*) | Ref | |
| Alternate (pMMR; wild-type *BRAF*, mutant *KRAS* | 1.48 (1.27-1.74) | <.001 |
| Serrated pMMR (mutant *BRAF*$^{V600E}$, wild-type *KRAS*) | 1.43 (1.11-1.85) | .007 |
| Serrated dMMR (mutant *BRAF*$^{V600E}$, wild-type *KRAS*, hypermethylated *MLH1*) | 1.09 (0.80-1.48) | .59 |
| Familial dMMR (wild-type *BRAF*, any *KRAS*, unmethylated *MLH1* | 0.76 (0.45-1.29) | .31 |

**3513 Poster Highlights Session (Board #1), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Antitumor effects of dabrafenib, trametinib, and panitumumab as single agents and in combination in *BRAF*-mutant colorectal carcinoma (CRC) models.** *Presenting Author: LI Liu, GlaxoSmithKline, Oncology, Collegeville, PA*

**Background:** In contrast to *BRAF*-mutant melanoma, the inhibition of *BRAF* or *BRAF*/MEK has been relatively ineffective in the treatment of *BRAF*-mutant CRC, possibly due to EGFR-dependent resistance mechanisms. This study aimed to determine the anti-tumor activities for *BRAF*/MEK inhibition with or without EGFR inhibition in *BRAF*$^{V600E}$ CRC models and to identify biomarkers of response/resistance. **Methods:** We assessed cell growth inhibition, apoptosis and cell signaling changes by inhibitors of *BRAF* (dabrafenib, D), MEK (trametinib, T), and EGFR (panitumumab, P, cetuximab, and erlotinib) dosed as monotherapies and in combination in five *BRAF*$^{V600E}$ human CRC lines (Colo205, HT29, RKO, SW1417 and LS411N). Further, these inhibitors were evaluated for their anti-tumor effects either alone or in combination in two *BRAF*$^{V600E}$ CRC patient derived tumor xenografts (PDXs) established in female nude mice. One patient-derived xenograft (PDX) harbored the PIK3CA$^{H1047R}$ mutation (Co-018) and the other (Co-012) was wildtype for PIK3CA. **Results:** In three out of five lines, all three EGFR inhibitors enhanced cell growth inhibition by D and the combination of D/T. Adding P to D or to the combination of D/T led to sustained suppression of pERK. The triple combination of P/D/T most effectively inhibited both pERK and pS6, and increased PARP cleavage in HT29 cells. P significantly improved the efficacy of either D or D/T in the Co-012 and Co-018 models. The triple combination of P/D/T was highly efficacious in both PDXs, and more effectively delayed tumor growth than the combination of P/D or D/T in Co-018 model, while D and P alone showed little or no activity. Pharmacodynamic changes and baseline characterization including expression levels of EGFR and EGFR ligands are under evaluation, and will be tested in clinical samples. **Conclusions:** While inhibition of MAPK or EGFR signaling has limited activity in *BRAF*-mutant CRC, the combined inhibition of MAPK signaling and EGFR has significant anti-tumor activity, with the triple combination being the most efficacious in preclinical models of *BRAF*$^{V600E}$ CRC. The results support ongoing clinical trials of D/T/P combinations in subjects with V600E BRAF-mutation positive CRC.

**3514 Poster Highlights Session (Board #2), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase I study of the selective BRAF$^{V600}$ inhibitor encorafenib (LGX818) combined with cetuximab and with or without the $\alpha$-specific PI3K inhibitor BYL719 in patients with advanced *BRAF*-mutant colorectal cancer.** *Presenting Author: Robin Van Geel, The Netherlands Cancer Institute, Amsterdam, Netherlands*

**Background:** In contrast to *BRAF*$^{V600}$ mutated (*BRAF*m) advanced melanoma, *BRAF*m colorectal carcinoma (CRC) does not respond to BRAF inhibitors due to strong feedback activation of the epidermal growth factor receptor (EGFR) upon *BRAF* inhibition. However, combining a *BRAF* and an EGFR inhibitor resulted in strong synergistic activity with complete inhibition of tumor growth in vitro and in vivo. The addition of a phosphatidylinositol 3-kinase (PI3K) inhibitor increased synergy. **Methods:** This is a phase I study evaluating safety, tolerability and anti-tumor activity of encorafenib (LGX818), a highly selective *BRAF*$^{V600}$ inhibitor, the EGFR mAb cetuximab, ± the $\alpha$-specificPI3K inhibitor BYL719 in patients (pts) with advanced *BRAF*m/*KRAS* wild-type CRC. Cohorts of pts were treated with escalating doses of oral encorafenib once daily in combination with IV cetuximab (400 mg/m$^2$ loading dose, 250 mg/m$^2$weekly) (dual arm), or with escalating doses of oral encorafenib and oral BYL719 once daily in combination with cetuximab (triple arm). **Results:** By November 08, 2013, 18 pts were enrolled across four dual combination dose levels: 100 (n = 2), 200 (n = 4), 400 (n = 9) and 450 mg (n = 3) encorafenib. Three pts were enrolled in the triple arm at 200 mg encorafenib, 100 mg BYL719 and cetuximab. Dose escalation has been completed in the dual arm where a phase 2 dose has been identified; dose finding is ongoing in the triple arm. In the dual arm, 2 dose-limiting toxicities, vomiting grade 3 (400 mg) and QTc prolongation grade 3 (450 mg), were observed, and fatigue (33%) and vomiting (28%) were the most frequently observed treatment-related adverse events. Three partial responses, including one in the triple arm, have been observed and prolonged disease stabilization was frequently achieved including two pts that have remained on treatment for one year. Decrease in carcinoembryonic antigen (CEA) has also been observed. Updated data from the triple arm will be presented. **Conclusions:** These results indicate that combination treatment of encorafenib and cetuximab ± BYL719 is well tolerated with promising antitumor activity in pts with advanced *BRAF*m CRC who failed standard treatment. Clinical trial information: NCT01719380.

**3515 Poster Highlights Session (Board #3), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Efficacy and tolerability in an open-label phase I/II study of MEK inhibitor trametinib (T), BRAF inhibitor dabrafenib (D), and anti-EGFR antibody panitumumab (P) in combination in patients (pts) with BRAF V600E mutated colorectal cancer (CRC).** *Presenting Author: Johanna C. Bendell, Sarah Cannon Research Institute, Nashville, TN*

**Background:** BRAF V600 mutations occur in 5–10% of CRC and confer poor prognosis. Unlike in BRAF mutant (BRAFm) melanoma, BRAF and MEK inhibitors show limited activity in BRAFm CRC. Preclinical data suggest that EGFR can mediate resistance in BRAFm CRC, which can be overcome by combined inhibition of BRAF and EGFR. Therefore, combined inhibition of the BRAF pathway (with D or D + T and with anti-EGFR agent P) to prevent EGFR-mediated resistance is a rational and promising approach to treat BRAFm CRC. **Methods:** Eligible pts with BRAFm CRC enrolled in Parts 1 and 2 of the ongoing 3-part study, dose escalation (DE; Part 1), cohort expansion (CE; Part 2) and a planned randomized comparison (Part 3), received either the doublet (D + P) or triplet (D + P + T) combination. **Results:** 19 pts received D + P ± T in DE or CE. Doublet: 6 pts received the full doublet dose (D 150 mg twice daily [BID] + P 6 mg/kg every 2 weeks [Q2W]) in Cohort 1 DE and 3 pts received the doublet in Part 2 CE. Triplet: 3 pts received the lowest combination dose of the triplet (D 150 mg BID + P 4.8 mg/kg Q2W + T 1.5 mg once daily [QD]) in Cohort 2. DE Cohorts 3A (D 150 mg BID + P 4.8 mg/kg Q2W + T 2 mg QD), n = 4 and 3B (D 150 mg BID + P 6 mg/kg Q2W + T 1.5 mg QD), n = 3 were opened simultaneously. No dose-limiting toxicities have been seen in any cohorts. Most common drug-related adverse event (AE) was dermatitis acneiform for doublet (5/9 pts, all Grade [Gr] 1) and triplet (5/10 pts, 3 Gr 1 and 2 Gr 2) pts. In the doublet group, no possibly drug-related Gr > 3 events were reported. In the triplet group, Gr > 3 events at least possibly drug-related, included vomiting (n = 1), rash (n = 1) and skin fissures (n = 1). In preliminary efficacy data, partial responses have been seen in 4/6 evaluable pts on the triplet dose (3/4 ongoing, 1 > 7 months) with 2 pts with stable disease (SD; 1 ongoing and 1 discontinued due to AE). Of the 8 evaluable pts on the doublet dose, 7/8 achieved SD (lasting 6–26 weeks; 2 pts ongoing) as the best overall response. Updated results will be presented. **Conclusions:** P can be safely combined with D or D/T. Encouraging evidence of clinical activity has been seen. Clinical trial information: NCT01750918.

**3516 Poster Highlights Session (Board #4), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase 1B study of vemurafenib in combination with irinotecan and cetuximab in patients with *BRAF*-mutated advanced cancers and metastatic colorectal cancer.** *Presenting Author: David S. Hong, Department of Investigational Cancer Therapeutics (Phase I Program), University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** *BRAF V600* mutations, present in 5-10% of patients (pts) with metastatic colorectal cancer (mCRC), are considered poor prognostic markers, and <10% of *BRAF*-mutated mCRC pts respond to a combination of cetuximab (C) and irinotecan (I). Vemurafenib (V), an oral kinase inhibitor to the mutated V600 isoform of BRAF, demonstrated a 5% response rate in a phase I trial with *BRAF*-mutated mCRC. In vitro data in CRC cell lines has shown that blockade of mutated BRAF by vemurafenib triggers compensatory activation of EGFR. Inhibition of EGFR combined with vemurafenib results in synergistic cytotoxicity in preclinical models, further augmented by irinotecan. The safety and efficacy of the combination in pts with *BRAF*-mutated advanced malignancies have not been studied. **Methods:** In this 3+3 phase I study, pts with refractory *BRAF*-mutated cancer received escalating doses of vemurafenib in combination with cetuximab and irinotecan over a 14-day cycle. Radiographic responses were evaluated every 4 cycles by RECIST 1.1. Adverse events (AEs) were assessed by CTCAE 4.0. **Results:** Through 1/2014, 10 pts have been enrolled: 7 at dose level 1(DL) (V- 480mg PO BID, C-250 mg/m2 weekly and I- 180mg/m2 every 14 days) and three at DL 2 (increased to V-720mg PO BID). One dose-limiting toxicity was observed at DL1 (grade 3 arthralgia) and resolved with dose reduction. The most common AEs were rash, nausea, and diarrhea. Of the 6 evaluable pts treated at DL 1, 5 had mCRC and 1 had appendiceal adenocarcinoma. Four of the 5 mCRC pts (80%) achieved a partial response. For the 5 mCRC pts, median best response was a reduction of -44% (range, 0% to -70%) with duration of responses of 5, 5+, 8+, 12+, and 14+ cycles. The appendiceal carcinoma pt had disease progression. PK and PD analysis is planned. **Conclusions:** The combination of vemurafenib with irinotecan and cetuximab seems well tolerated in pts with *BRAF*-mutated mCRC. Even with a low vemurafenib dose, PRs were seen in 4 of 5 evaluable mCRC pts in the first cohort. Additional pts continue to be enrolled at higher dose levels of vemurafenib. A US cooperative group randomized phase II trial of this combination in BRAF-mutated mCRC (SWOG1406) is planned. Clinical trial information: NCT01787500.

**3517 Poster Highlights Session (Board #5), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase 1-2 trial of the BRAF inhibitor dabrafenib (D) plus MEK inhibitor trametinib (T) in BRAF V600 mutant colorectal cancer (CRC): Updated efficacy and biomarker analysis.** *Presenting Author: Ryan Bruce Corcoran, Massachusetts General Hospital, Boston, MA*

**Background:** *BRAF V600* mutations occur in 5-15% of metastatic CRC and predict poor prognosis. Although highly effective in *BRAF* mutant melanoma, BRAF inhibitor monotherapy has shown poor efficacy in *BRAF* mutant CRC. Preclinical data suggest that improved MAPK pathway suppression with combined inhibition of BRAF and MEK may improve efficacy. **Methods:** 43 patients (pts) with *BRAF V600* mutant stage IV CRC were treated with D (150mg BID) and T (2mg QD), 17 of whom were enrolled in a pharmacodynamic cohort with tumor biopsies pre-treatment and after 2 weeks of therapy. Archival tissues were analyzed for microsatellite instability (MSI), PTEN loss, and 487-gene sequencing (Illumina). **Results:** Of 43 pts, 5 (12%) achieved partial response (PR) or better (with or without confirmation), including 1 (2%) pt with complete response (CR) ongoing >22 months. An additional 22 (51%) pts achieved stable disease (SD) at first restaging, of which 11 (26%) pts had a minor response (10% to 30% tumor reduction). 10 (23%) pts remained on study >6 months. All 9 evaluable post-dose biopsies had reduced levels of phospho-ERK relative to pre-dose (average decrease 47% ±24), however, the % pERK inhibition and response did not correlate proportionally. Mutational analysis of 15 subjects has been completed to date. The pt with CR and 2 of 3 evaluable pts with PR had PIK3CA mutation. Neither PTEN loss nor MSI correlated with efficacy. **Conclusions:** The combination of D + T has activity in a subset of *BRAF V600* mutant CRC pts, with several PRs and a durable CR. MAPK signaling was inhibited in all pts evaluated, but to a lesser degree than observed in *BRAF* mutant melanoma with D as a single agent. PIK3CA mutations were identified in responding patients and thus do not preclude response to this regimen, but a definitive correlation between PIK3CA mutations and efficacy cannot be established given the limited pt sample. Biomarker refinement and additional therapeutic combinations may improve clinical activity. Clinical trial information: IND No: 113,557.

**3518^ Poster Highlights Session (Board #6), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**VE-BASKET, a Simon 2-stage adaptive design, phase II, histology-independent study in nonmelanoma solid tumors harboring BRAF V600 mutations (V600m): Activity of vemurafenib (VEM) with or without cetuximab (CTX) in colorectal cancer (CRC).** *Presenting Author: Josep Tabernero, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Low prevalence of V600m in non-melanoma cancers requires novel trial designs to assess the activity of BRAF inhibitors. Based on preclinical models that V600m positive (+) CRC upregulates the EGFR pathway and sensitizes to EGFR inhibitors in response to VEM (Prahallad et al Nature 2012), we investigated the activity of VEM in V600m+ CRC with or without CTX. Here we present preliminary efficacy and safety data for the VEM cohort and VEM + CTX dose-finding cohorts. **Methods:** This multicohort, Simon 2-stage adaptive design, single-proportion study included adult patients (pts) with V600m+ cancers refractory to standard therapy or for whom standard/curative therapy is not available. Pretreated CRC pts received either VEM (960 mg bid) without (cohort 3a) or with CTX (cohort 3b, 3+3 dose escalation) until investigator (INV)-assessed disease progression or unacceptable toxicity. Primary objective was INV-assessed response rate at wk 8 (RECIST v1.1). Maximum tolerated dose (MTD) and recommended dose (RD) were to be determined for the VEM + CTX cohort. **Results:** Median (range) treatment duration was: cohort 3a, 77 (24-225) d; 3b, 114 (36-279) d. At stage I, no responses were observed in cohort 3a (n=10). In cohort 3b, 14 pts have been enrolled for determination of MTD/RD. No dose-limiting toxicities (DLT) have been observed in dose level (DL) 1 (VEM 720 mg bid/CTX 200 mg/m$^2$/wk) and DL 2 (VEM 720 mg bid/CTX 250 mg/m$^2$/wk); 1 pt experienced a DLT (asymptomatic amylase grade 3 and lipase grade 4 elevation) in DL 3 (VEM 960 mg bid/CTX 250 mg/m$^2$/wk). Preliminary response data are in table. DL 3 was selected as the RD. There were no unexpected safety findings in either cohort. **Conclusions:** VEM + CTX show early signs of activity in V600m+ CRC; a formal evaluation of efficacy and safety results will be provided at the meeting. VEM monotherapy is not effective in V600m+ CRC. Clinical trial information: NCT01524978.

**3519 Poster Highlights Session (Board #7), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Subgroup analyses in *RAS* mutant, *BRAF* mutant and all-wt mCRC pts treated with FOLFOXIRI plus bevacizumab (bev) or FOLFIRI plus bev in the TRIBE study.** *Presenting Author: Fotios Loupakis, U.O. Oncologia Medica 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

**Background:** Phase III TRIBE trial demonstrated that first-line FOLFOXIRI plus bev improved PFS and RECIST response and, at adjusted analyses, OS as compared to FOLFIRI plus bev. The prognostic and/or predictive effect to anti-EGFRs of *RAS* and *BRAF*mutation is well established. We conducted this post-hoc analysis in the TRIBE study in order to describe the predictive and prognostic effect of each molecular cathegory. **Methods:** Mutational analyses were centralized at the Coordinating Center. Mutations within *KRAS* and *NRAS* codon 12, 13 and 61 and *BRAF* codon 600 were analyzed by means of pyrosequencing in tumoral DNA extracted from primaries or metastases. Pts not bearing *RAS* or *BRAF*mutations were defined as "all wt". **Results:** Molecular results are available for 375 out of 508 randomized pts (73.8%). *KRAS*, *NRAS* and *BRAF* were found mutated (mut) in 198 (52.8%), 20 (5.3%) and 28 (7.5%) cases, respectively. All wt pts were 129 (34.4%). Predictive analyses: see table. No significant interaction between *RAS* or *BRAF* status and treatment effect was reported in PFS or OS. All wt pts treated with upfront FOLFOXIRI plus bev achieved median PFS and OS of 13.3 and 41.7 mos, respectively. Prognostic analyses: as compared to all wt pts, *BRAF* mut had significantly shorter PFS (HR: 2.29 [1.49-3.52], p=0.0002) and OS (HR: 3.31 [2.03-5.39], p<0.0001) while for *RAS*mut no difference in PFS was detected (HR: 1.15 [0.91-1.45], p=0.256), but OS was significantly shorter (HR: 1.48 [1.09-2.00], p=0.012). **Conclusions:** Benefit from FOLFOXIRI plus bev was independent of *RAS* and *BRAF* mutational status, with a trend toward a larger benefit in *BRAF* mut limited by small subgroup size. All wt pts treated with FOLFOXIRI plus bev achieved impressive PFS and OS results. Independently from the treatment received *RAS* or *BRAF*mut pts had shorter long-term survival. Clinical trial information: NCT00719797.

**Combined epiregulin (EREG) and amphiregulin (AREG) expression levels as a biomarker of prognosis and panitumumab benefit in *RAS*-wt advanced colorectal cancer (aCRC).** *Presenting Author: Jenny F. Seligmann, University of Leeds, Leeds, United Kingdom*

**Background:** RNA expression of epiregulin (EREG) ligands EREG and/or amphiregulin (AREG) has shown correlation with the efficacy of EGFR-targeted therapy in advanced colorectal cancer (aCRC). This finding requires validation, and interaction with MEK-AKT pathway mutations clarified. We examined both ligands and mutations in patients (pts) in a large randomised trial of panitumumab. The *a priori* hypothesis was that high expression of either AREG or EREG, in *RAS*-wild type (wt) pts, would predict panitumumab benefit. **Methods:** AREG and EREG expression and *RAS (KRAS* and *NRAS*) and *BRAF* mutations were assessed in archival tumor from 323 pts randomised to irinotecan (Ir) or irinotecan/panitumumab (IrPan) as second-line treatment of aCRC (PICCOLO trial, Lancet Oncol 14: 749-759). A predefined dichotomous model classified ligand expression as "high" (either EREG or AREG in top tertile for mRNA level) or "low" (neither EREG nor AREG in top tertile). Prognostic effect was assessed, then predictive effect by testing interaction with drug impact. The primary population was *RAS*-wt (n=220); primary endpoint was progression-free survival (PFS). **Results:** High ligand expression was not a significant prognostic marker for PFS (HR 0.93, 95% CI 0.68-1.27, p=0.64) or overall survival (OS) (HR 0.79, 95% CI, 0.58-1.09, p=0.15). However, it was significantly predictive. For *RAS*-wt pts with high ligand expression, median PFS was 8.3 months (IrPan) vs 4.4 months (Ir) (HR=0.62, 95%CI 0.49-0.78, p<0.001). Conversely, *RAS*-wt pts with low expression gained no benefit: 3.2 months (IrPan) vs. 4 months (Ir) (HR=0.97, 95%CI 0.8-1.17, p=0.73). The ligand-treatment interaction was p=0.01. Less effect was seen on the secondary endpoints response rates (interaction p=0.09) and overall survival (interaction p=0.11). Ligand expression was markedly lower in *BRAF*-mutated than all-wt tumours (p<0.001), however ligand expression remained predictive of panitumumab effect following adjustment for *BRAF*. **Conclusions:** The hypothesis was confirmed: high ligand expression predicts panitumumab benefit on PFS in *RAS*-wt pts; there was no evidence of benefit with low ligand expression. Optimisation of the ligand model for clinical use is needed, however this work confirms that EREG and AREG are potentially useful biomarkers for anti-EGFR therapy.

**3521 Poster Highlights Session (Board #9), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Amphiregulin (AREG) SNP rs161511 to predict cetuximab efficacy independent of AREG mRNA levels: Data from FIRE3 (AIO KRK-0306).** *Presenting Author: Sebastian Stintzing, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** Anti-bodies targeting the epidermal growth factor receptor (EGFR) have shown efficacy in metastatic colorectal cancer (mCRC). The extended RAS analysis has further defined EGFR dependent tumors that are more sensitive to EGFR inhibition. Beyond RAS mutations, expression of EGFR ligands (amphiregulin (AREG) and epiregulin (EREG)) have shown predictive values. The challenge to move these biomarkers into clinic are the standardization of quantitative intra-tumor measurements. If germline single nucleotide polymorphisms (SNPs) in AREG and/or EREG would be predictive this could easily used in clinical practice. We have previously shown that rs1615111 associated with time-to-recurrence in gastric cancer. Aim of this study was to test the predictive value of rs1615111 in cetuximab treated mCRC patients. **Methods:** Genomic DNA was isolated from tissue samples of 299 patients (median age 64 years, male 67.2%) treated in first-line with either FOLFIRI cetuximab (n=139) or FOLFIRI bevacizumab (n=160) from the FIRE-3 trial (NCT00433927). In 174 samples, tumor cells were micro-dissected for mRNA extraction. rtPCR was carried out using LightCycler technology. All patients were *KRAS*/*NRAS* wild-type. The bevacizumab arm served as negative control arm. **Results:** The minor allele A of rs1615111 was associated with decreased tumor response (37% vs. 78.4%, two-sided Fisher's p=0.02) shorter progression free survival (5.9 months vs. 10.6 months, logrank p=0.001 HR 3.46) and OS (11.4 months vs. 33.1 months, logrank p=0.001, HR 3.87) in FOLFIRI plus cetuximab treated patients. Low AREG mRNA expression was associated with short OS (3.2 months vs. 33.1 months logrank p<0.001, HR 0.08) but no association with rs1615111 could be established. In FOLFIRI plus bevacizumab treated patients rs1615111 did not have any predictive value. **Conclusions:** AREG SNP rs1615111 is *predictive* for cetuximab treatment. No prognostic value could be established. Biological function of rs1615111 remains unknown as it was not associated with mRNA expression. Beyond RAS mutations and EGFR ligand expression SNPs in AREG are new promising predictive marker for EGFR inhibitors. Prospective studies to validate and confirm these data are warranted.

**3522 Poster Highlights Session (Board #10), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Influence of mRNA expression of *epiregulin (EREG)* and of *amphiregulin (AREG)* and *RAS* mutations on outcome of patients with metastatic colorectal cancer treated with 5-FU/LV plus irinotecan or irinotecan plus oxaliplatin as first-line treatment (FIRE 1-trial).** *Presenting Author: Arndt Stahler, Department of Pathology, University of Munich, Germany, Munich, Germany*

**Background:** Our aim was to investigate the impact of *EREG/AREG* expression and *RAS (KRAS/NRAS)* mutations in patients with metastatic colorectal cancer (mCRC) receiving systemic treatment without monoclonal antibodies. **Methods:** In total, 208 (of 479) patients with mCRC of a randomized trial receiving 5-FU/LV plus irinotecan (FUFIRI) or irinotecan plus oxaliplatin (mIROX) as first-line treatment were included in this analysis. Median progression-free-survival (PFS) and overall survival (OS) of the subset were well comparable to the whole study population. *RAS* mutation detection was performed by pyrosequencing of exons 2-4 of the *KRAS*- and *NRAS*- gene (codons 12, 13, 61 and 146). mRNA expression was quantified by RT-qPCR. To discriminate high and low expression, a ROC analysis resulted in a cut-off value using the maxima of sensitivity and specificity for overall response rate. *RAS* mutation and mRNA expression of *AREG* and *EREG* were correlated with response, PFS and OS. **Results:** In 107 of 208 patients (51.4%) a *RAS* mutation could be detected. mRNA expression was analysed in 192 patients, concerning *AREG* (low: 161 vs high: 31) and *EREG* (low: 103 vs high: 89). *RAS* wild-type tumors were not associated with better PFS (8.7 vs 8.2 months, HR: 0.93, p=0.62) and OS (21.9 vs 18.6 months, HR: 0.88, p=0.41). High compared to low *AREG* expression did not influence outcome concerning PFS (10.0 vs 8.2 months, HR: 0.68, p=0.07) and OS (24.6 vs 18.7 months, HR: 0.72, p=0.11). High compared to low *EREG* expression correlated with prolonged PFS (9.7 vs 7.0 months, HR: 0.58, p<0.01) and OS (25.8 vs 15.5 months, HR: 0.48, p<0.01). The favourable prognostic effect of high *EREG* expression was evident independently of *RAS* mutation (OS: HR wild-type: 0.50, HR mutated: 0.44; p<0.01), and treatment (OS: HR FUFIRI-arm: 0.42, HR mIROX-arm: 0.53; p<0.01). **Conclusions:** *EREG* expression appears as powerful prognostic marker in patients with mCRC receiving systemic therapy without monoclonal antibodies. Neither *RAS* mutations nor *AREG* expression showed a significant correlation with outcome in the FIRE1-trial.

**3523 Poster Highlights Session (Board #11), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Mir-31-3p as a predictive biomarker of cetuximab effects in a post hoc analysis of new EPOC phase III trial.** *Presenting Author: Pierre Laurent-Puig, UMR-S775 Bases Moléculaires de la Réponse aux Xénobiotiques, Paris, France*

**Background:** miR31-3p expression level has been associated with progression free survival (PFS) in *KRAS* wild type metastatic colorectal cancer (mCRC) patients treated with anti-epidermal growth factor receptors (EGFRs). In this study we evaluated its predictive value on PFS in the new EPOC trial by measuring its expression in primary tumors and liver metastases. **Methods:** miR31-3p expression was determined by RT-QPCR in 125 formalin-fixed and paraffin-embedded (FFPE) primary tumor samples from patients. There were 63 patients (control arm) who received oxaliplatin or irinotecan-based chemotherapy and 62 received the above plus cetuximab. Correlations between miRNA expression and survival were performed using an adjusted Cox model. Liver metastasis were available for 58 of the 125 patients and comparison was done using a Pearson correlation on log2 transformed miR31-3p expression value. **Results:** A significant association was found between PFS and miR31-3p expression in the cetuximab arm (p=0.035; HR=1.2, CI95% CI [0.98 – 1.48]), and not in the control arm (p=0.36; HR=0.96, CI95% [0.75 – 1.23]).A predictive model was developed dichotomizing patients with high or low risk of progression. In the cetuximab arm PFS was significantly shorter in patients with high expression than in patients with low expression (p=0.033). In all patients with high miR31-3p expression, PFS was significantly shorter in the cetuximab treated arm than in the control arm (p=0.0177, median PFS: 49.6 and 64.9 weeks respectively), in all patients with low miR31-3p expression, PFS was not different between cetuximab and control arm. Study of miR-31-3p expression in primary tumor and matching metastasis showed a correlation in the control arm (p=0.00004) but not in the cetuximab arm (p=0.55). **Conclusions:** We demonstrated for the first time that miR31-3p expression is predictive of cetuximab effects and replicated association of its expression with PFS in patients receiving cetuximab. Furthermore miR31-3p allowed identification of a subgroup of patients in which cetuximab with chemotherapy had a detrimental effect on PFS. Eventually the correlation of miR31-3p expression in metastases and primary tumors in the control arm, but not in the cetuximab arm, suggests cetuximab has an effect on miR31-3p expression, supporting its involvement in the EGFR pathway.

**3524 Poster Highlights Session (Board #12), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase II study of single-agent cetuximab in *KRAS* G13D mutant metastatic colorectal cancer (mCRC).** *Presenting Author: Marta Schirripa, U.O. Oncologia Medica 2, Azienda Ospedaliero-Universitaria Pisana, Istituto Toscano Tumori, Pisa, Italy*

**Background:** *RAS* mutant metastatic colorectal cancer (mCRC) patients (pts) are excluded from treatment with anti-EGFR monoclonal antibodies. Nevertheless, retrospective data from large phase III trials led to hypothesize a potential benefit from cetuximab in *KRAS* G13D mutant pts both in first and advanced lines of treatment (De Roock *JAMA* 2010, Tejpar *JCO* 2012). In the refractory setting, *KRAS* G13D mutant pts achieved a superior progression free survival (PFS) (4.0 vs. 1.9 months, HR=0.51, p=0.004) and overall survival (OS) (7.6 vs. 5.7 months, HR=0.50, p=0.005) compared to pts with other *KRAS* mutations. We conducted the present trial in order to prospectively confirm those findings and to evaluate the clinical relevance of single agent cetuximab in *KRAS* G13D mutant mCRC pts. **Methods:** According to previously reported results, using a phase 2 Fleming single-stage design, with 90% power and alpha 0.05, setting p0=10% and p1=50%, the study required the inclusion of 12 pts. The alternative hypothesis would have been rejected if 3 or less pts would have been progression-free at four months after treatment start. We prospectively enrolled mCRC patients to receive treatment with cetuximab monotherapy (500 mg/mq bi-weekly). Main eligibility criteria were the following: *KRAS* G13D mutant, measurable metastatic disease, progression after treatment with fluoropyrimidine, oxaliplatin, irinotecan, and bevacizumab or no other valid therapeutic option. Pts were re-evaluated according to RECIST 1.1 criteria. **Results:** Twelve consecutive *KRAS* G13D mutant eligible pts were enrolled. Main pts' characteristics were the following: Male/Female, 6/6; median age, 74 years (range 26-79); Eastern Cooperative Oncology Group performance status 0/1-2, 6/6; synchronous/metachronous disease, 8/4; median number of previous CT lines, 2 (range 0-5). Three patients (25%) showed disease stabilization at four months after treatment start and no RECIST responses were observed. Disease control rate at six months was 0%. Median PFS and OS were 1.9 and 7.2 months, respectively. Grade 3 rash was observed in two (17%) patients and no unexpected toxicities occurred. **Conclusions:** The hypothesis of a clinically relevant benefit with cetuximab monotherapy in *KRAS* G13D mutant mCRC pts was rejected. *KRAS* G13D mutant mCRC pts should not be treated with cetuximab and alternative strategies should be adopted.

**3525 Poster Highlights Session (Board #14), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Overall survival result and outcomes by *KRAS*, *BRAF*, and DNA mismatch repair in relation to primary tumor site in colon cancers from a randomized trial of adjuvant chemotherapy: NCCTG (Alliance) N0147.** *Presenting Author: Frank A. Sinicrope, Mayo Clinic, Rochester, MN*

**Background:** We report mature overall survival (OS) data in stage III colon cancers from a phase III trial of adjuvant mFOLFOX6 ± cetuximab. Biomarkers were analyzed in relation to primary tumor site and OS, and include additional non randomized patients (pts) with *KRAS*mutant tumors. **Methods:** Cancers (N= 3,018) were analyzed prospectively for $BRAF^{V600E}$ (exon 15) and *KRAS* (exon 2;codons 12, 13) mutations, and expression of DNA mismatch repair (MMR) proteins (MLH1, MSH2, and MSH6). Loss of an MMR protein indicated deficient (d) MMR. Tumor site was categorized as proximal *vs*distal (inclusive of the splenic flexure). Median follow-up was 4.9 yrs. Cox proportional hazards models were adjusted for covariates including treatment. **Results:** Consistent with our previously reported DFS data, the addition of cetuximab was associated with worse OS in pts with wild type *KRAS* (p=.0073). Activating $BRAF^{V600E}$ or KRAS mutations were detected in 346/2831 (12.2%) and 1042/2905 (35.9%) tumors, respectively; dMMR was found in 329/2906 (11.3%). dMMR or mutations in $BRAF^{V600E}$ or *KRAS* were more likely to occur in proximal *vs* distal tumors [all p<.0001]. $BRAF^{V600E}$ mutations were associated with older age, female sex, high grade histology, dMMR, and higher T and N stage (all p< 0.01). A tumor site interaction was observed for OS with *KRAS* (p=.0435) and MMR (p=.0097), but not *BRAF*. *KRAS* mutations [HR 1.98 (1.49-2.63); p<.0001] and dMMR [HR 1.85 (0.99-3.46); p=.054] were each associated with worse OS in distal (*vs* proximal) cancers. dMMR predicted favorable OS in proximal tumors [HR 0.71 (0.53-0.97); p=.030]. Tumors with wild type copies of both *BRAF* and *KRAS* showed better OS within proximal [HR 0.74 (0.59-0.93); p=.009] and distal [HR 0.51 (0.39-0.67); p<.0001] cancers compared to those with a $BRAF^{V600E}$ or *KRAS*mutation. **Conclusions:** The addition of cetuximab to mFOLFOX6 resulted in significantly poorer OS. The prognostic impact of biomarkers on OS differed significantly by tumor site. Novel findings include poor OS of *KRAS* mutant tumors that was restricted to the distal colon, and a divergent prognosis for dMMR by primary tumor site. Clinical trial information: NCT00079274.

**3526 Poster Highlights Session (Board #15), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Evolution of heterogeneous mechanisms of acquired resistance to cetuximab-based therapy in colorectal cancer.** *Presenting Author: Clara Montagut, University Hospital del Mar - IMIM, Barcelona, Spain*

**Background:** Anti-EGFR drug resistance is a major challenge in metastatic colorectal cancer (mCRC). The aim of this study was to elucidate molecular mechanisms of acquired resistance in mCRC patients treated with cetuximab-based therapy. **Methods:** 37 mCRC patients with acquired resistance to cetuximab-based therapy with paired tumor samples (prior and at progression to treatment) were prospectively included. In three patients, multiple biopsies were obtained over the course of the disease. Mutations in *EGFR*, *KRAS, NRAS*, *BRAF* and *PIK3CA* genes were evaluated by next-generation pyrosequencing. Gene amplification was evaluated by FISH. Mutations were also assessed in plasma in 7 representative cases. **Results:** Eighty-one percent of patients harbored a molecular event (comprising mutations and amplifications) in post-treatment biopsies. In one third of patients, multiple molecular events (range 2-5) coexisted in the same sample. *RAS* mutations were the most frequent event (40% of patients) and mostly affected exons 3 and 4, followed by mutations in *PIK3CA (19%), BRAF (11%), EGFR* S492R (8%) and novel mutations in *EGFR* ectodomain (5%). Of note, in 9 patients the mutations were already detected at diagnosis by next-generation sequencing. Multiple repeat biopsies revealed that the percentage of mutant alleles increased under drug pressure and became undetectable following drug withdrawal. Mutations were detected in plasma samples in 62% of tested cases. **Conclusions:** We provide comprehensive evidence for the evolution of multiple mechanisms of acquired resistance to cetuximab-based therapy in mCRC. This data establishes the need of routine molecular studies at disease progression to individualize further therapeutic decisions.

**3527 Poster Highlights Session (Board #16), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Surgical resection of primary tumors (SRPT) in asymptomatic patients with stage IV colorectal cancer (CRC): A Canadian province experience.** *Presenting Author: Shahid Ahmed, Department of Medical Oncology, Saskatoon Cancer Centre, Saskatchewan Cancer Agency, University of Saskatchewan, Saskatoon, SK, Canada*

**Background:** Surgical resection of primary tumors (SRPT) in asymptomatic stage IV colorectal cancer (CRC) patients remains controversial. Reported survival benefit in literature has been attributed to selection of younger healthier patients with good performance status (PS). We have shown that SRPT improves survival independent of age, PS, and comorbid illness (JCO 30: 2013;456). This study was conducted to validate prognostic role of SRPT in asymptomatic patients with stage IV CRC. **Methods:** A cohort of newly diagnosed asymptomatic patients with stage IV CRC during 1992-2005, in Saskatchewan, was evaluated. Kaplan-Meier method was used to determine survival. Log-Rank test was done to compare survival. Cox proportional hazard model was performed to determine prognostic importance of SPRT. **Results:** There were834 patients with median age of 70 years (22-93) and male to female ratio of 58:42 were identified. Twenty six percent had Eastern Cooperative Oncology Group (ECOG) PS of >1 and 62% had a comorbid illness. There were 521 (63%) patients who underwent SRPT and 43.3% received chemotherapy. Median overall survival (OS) of patients who received chemotherapy was 16 (95% CI: 13.8-18.2) months. Patients who underwent SRPT had median OS of 19.7 (16.9-22.6) months vs. 8.4 (6.9-10.0) months without surgery (p<0.0001). Patients who received second generation therapy and underwent SRPT had median OS of 29.4 months (24.2-34.5) vs. 16.0 (13.2-18.9) months if they received older regimen. On multivariate analysis 5FU-based chemotherapy (HR 0.43; 95% CI: 0.36-0.53), SRPT (0.47; 0.39-0.57), metastesectomy (0.48; 0.38-0.62), and second line chemotherapy (0.72; 0.58-0.92) were correlated with superior survival whereas, elevated bilirubin (1.48; 1.11-1.62), low albumin (1.48; 1.25-1.75), ECOG PS >1 (1.36; 1.15-1.62), high grade tumor (1.34; 1.06-1.58), leukocytosis (1.30; 1.06-1.58), anemia (1.28;1.09-1.49), and age ≥ 65 years (1.20; 1.02-1.42) were correlated with poor survival. Test for interaction between ≥ 1 metastatic sites and SRPT was significant (p=0.03) suggesting larger benefit of SRPT in stage IVA disease. **Conclusions:** This first large population based cohort study confirmss that SRPT, improves survival independent of chemotherapy, age, functional status and comorbid illness, in asymptomatic patients with stage IV CRC .

**3528 Poster Highlights Session (Board #17), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Surgical outcome for pulmonary metastasis of colorectal cancer in the modern chemotherapy era: Results of a retrospective Japanese multicenter study.** *Presenting Author: Tomoyuki Hishida, Department of Thoracic Surgery, National Cancer Hospital East, Chiba, Japan*

**Background:** There have been few reports of surgical outcome for pulmonary metastasis (PM) of colorectal cancer (CRC) (CRC-PM) in the era of modern effective chemotherapy including oxaliplatin. **Methods:** Clinical and survival data of patients undergoing first metastasectomy for CRC-PM between 2004 and 2008 were collected from 46 institutions. Data cut-off date was August 31, 2013. **Results:** A total of 1,237 patients' (pts') data were collected. After exclusion of ineligible cases including non-R0, 898 pts' data were analyzed. Of these, 161 (18%) pts had synchronous PM with primary tumor. Median number of resected PMs was 1 (range, 1–10) and 124 (14%) had bilateral PMs. The five-year overall survival (OS) and disease-free survival (DFS) were 65.7% (95% CI, 62.3–69.2) and 35.3 % (32.1–38.8) after median follow-up period of 61 months, respectively. According to the status of pre or postoperative adjuvant chemotherapy (Pre-/ Post-C), pts were classified into four groups: A (-/-, n=417), B (-/+, n=368), C (+/-, n=55), and D (+/+, n=58). There were substantial differences in background among four groups. Independent prognostic factors for OS and DFS were elevated carcinoembryonic antigen (CEA) level at the time of lung resection (OS: HR=2.03, 95% CI, 1.61–2.57; DFS: 1.58, 1.32–1.88), and the number of resected PMs (OS: 1.20, 1.10–1.30; DFS: 1.21, 1.13–1.29). The five-year OS and DFS after surgery alone (group A) were 66.8% (62.1–72.0), and 39.3% (34.6–44.6), respectively. After adjusting by above prognostic and background factors among four groups, overall perioperative use of chemotherapy (B+C+D vs. A) was not statistically associated with prolonged OS (HR=0.95, 0.66–1.35) and DFS (0.93, 0.71–1.20). HR of Pre-C (group C vs. A) was 2.26 (95% CI, 1.06–4.81) for OS and 2.26 (1.28–3.98) for DFS. On the other hand, HR of Post-C (B vs. A) was 0.81 (0.55–1.19) for OS and 0.87 (0.66–1.14) for DFS. **Conclusions:** Modern surgical resection for CRC-PM demonstrated favorable prognosis. This retrospective study did not reveal a relevant effect of perioperative chemotherapy on survival. However, HR of Post-C prompted further investigation for adjuvant chemotherapy after resection of CRC-PM.

**3529 Poster Highlights Session (Board #18), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A comparison of survival by site of metastatic resection (MR) in metastatic colorectal cancer (mCRC).** *Presenting Author: Brandon David Bernard, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** MR of liver limited disease is an effective therapy for patients (pts) with mCRC. Despite limited data, this approach has been expanded to include MR in other sites. We compared survival for mCRC pts undergoing MR of liver metastasis vs MR in other sites. **Methods:** Pts with mCRC who underwent MR in British Columbia over 5 time cohorts between 1995 and 2010 were reviewed. Pts without data on the site of MR or survival were excluded. Overall survival (OS) was defined as the time from diagnosis of metastasis to death. Kaplan Meier methodology and log-rank tests were used to compare the impact of site of MR on OS. Multivariate Cox regression was performed to assess for the impact of MR on OS, adjusting for known prognostic factors. **Results:** 2,082 pts with mCRC were identified; 1,197 men (57.5%) and 885 women (42.5%); 236 (1995-96), 206 (2000), 351 (2003-4), 546 (2006), 743 (2009-10). Median age at diagnosis of mCRC was 69 (14-94). 544 pts (30.0%) received a MR: 207 liver (38.1%), 57 lung (10.5%), 11 liver and lung (2.0%), 98 peritoneal (18.0%), 50 ovarian (9.2%), 34 brain (6.3%) and 87 other (16.0%). Pts that did not undergo MR had an OS of 13.4 months (ms) vs 41.8 ms for those that had MR of liver, lung or ovary (HR 0.31 (0.27-0.36); p<0.0001). By MR subgroup, OS was 46.2 ms for liver, 43.0 for lung, 41.2 for liver and lung, 13.4 for peritoneum, 21.8 for ovary, and 15.8 for brain. When compared to MR of liver, no significant difference in OS was observed for MR in lung (p=0.61) or liver and lung (p=0.26). Multivariate OS data are shown in the Table. **Conclusions:** MR of lung and liver and lung appears to confer a comparable survival advantage to MR of liver limited disease. Additional investigation is needed to further select pts most likely to benefit from MR.

| Multivariate analysis for OS | HR | p-value |
|---|---|---|
| MR (liver, lung, or ovar)y | 0.36 (0.31-0.42) | <0.0001 |
| Age (< 65 vs ≥ 65) | 0.89 (0.63-1.27) | 0.54 |
| Sex (M vs F) | 1.03 (0.94-1.13) | 0.51 |
| Primary (colon vs rectum) | 1.11 (1.00-1.20) | 0.03 |
| M1 at presentation (N vs Y) | 0.85 (0.77-0.95) | 0.0016 |
| ChemoTx (Y vs N) | 0.48 (0.24-0.82) | 0.009 |
| Primary resection (Y vs N) | 0.57 (0.49-0.65) | <0.0001 |
| 2000 vs 1995-96 | 1.40 (1.10-1.60) | 0.0012 |

**3530 Poster Highlights Session (Board #19), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Complete neoadjuvant therapy in rectal cancer (CONTRE): A Brown University Oncology Research Group phase II study.** *Presenting Author: Kimberly Perez, Brown University Oncology Research Group, Providence, RI*

**Background:** After preoperative chemoradiation and surgery, many patients (pts) with clinical stage II-III rectal cancer are unable to tolerate adjuvant FOLFOX chemotherapy, which may compromise disease-free and overall survival (DFS/OS). This study was designed to assess treatment delivery, toxicity and impact on pathologic response of administering chemotherapy prior to chemoradiation and surgery. **Methods:** Pts with clinical T3-4 and/or N1-2 rectal cancer, staged by endorectal ultrasound (ERUS) and pelvic MRI, received modified (m) FOLFOX6 every two weeks x eight cycles, followed by 50.4 Gy IMRT with concurrent capecitabine 825mg/m$^2$ BID, 5 days per week, followed by surgery 4-8 weeks later. **Results:** There were 39 pts enrolled between August 2010 and June 2012; median age was 61 (30-79); clinical stage II n=7, stage III n=32. Distance from the anal verge: <3cm n=5; 3-5cm n=5; >5cm n=29. There were four pts presented with lumen obstruction preventing advancement of the endoscope and 31 with rectal bleeding. There were 36 pts (92%) completed eight cycles of mFOLFOX6. Grade 3 toxicities during chemotherapy included diarrhea (n=2), neutropenia (n=6), and renal dysfunction (n=1). There was one pt with a cardiovascular disease had a TIA (grade 4). There was one pt had grade 4 neutropenia. All pts had resolution of bleeding and improvement of obstructive symptoms, with no complications requiring surgical intervention. There as two pts declined radiation after completing chemotherapy, and one withdrew due to grade 3 diarrhea. At surgery, pathologic complete response (ypT0N0) (pCR) was confirmed in 13 pts (33%; 95% CI 18.24%-47.76%), residual stage I in 10 (26%), stage II in seven (18%), and stage III in eight (20%); one pt did not undergo surgery. There was two pts with microsatellite unstable tumors had no evidence of response to treatment. **Conclusions:** Over 90%of pts wereable to complete mFOLFOX6 when administered prior to chemoradiation and surgery. The pCR rate was higher than typically seen with chemoradiation alone. A randomized study would be required to determine if improved delivery of chemotherapy using this approach improves DFS/OS, but CONTRE represents a well-tolerated alternative to the current standard treatment sequence and could serve as a platform for clinical trials in rectal cancer. Clinical trial information: NCT01363843.

**3531 Poster Highlights Session (Board #20), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Neoadjuvant radiotherapy (RT) combined with capecitabine (Cape) and sorafenib (Sor) in patients (pts) with locally advanced, k-ras-mutated rectal cancer (LARC): A phase I/II trial SAKK 41/08.** *Presenting Author: Roger Von Moos, Kantonsspital Graubünden, Chur, Switzerland*

**Background:** K-ras mutation is found in up to 40% of LARC. Sor is a multitarget tyrosine kinase inhibitor including raf and VEGFR and has demonstrated radiosensitizing effects. Sor might improve outcome of standard preoperative radio-chemotherapy in patients with k-ras mutated LARC. **Methods:** Pts with k-ras mutated T3-4 and/or N+, M0 disease by MRI were included. Recommended doses from phase I part consisted of RT 1.8 Gy/day x25 with Cape 825mg/m$^2$bid x 33 in combination with Sor 400mg/d. The primary endpoint for the phase II part was pathological complete response (pCR) prospectively defined as grade 3 (near complete regression) or 4 (complete regression) in the histological grading system according to Dworak (DC). A pCR rate of 8% or lower was considered uninteresting and of 22% or higher was promising. Secondary endpoints included sphincter preservation, R0 resection, downstaging and safety. **Results:** 54 pts were treated in 18 centers in Switzerland und Hungary, 40 pts were included into the single arm phase II part. Median dose intensity per day was 100.0% for RT, 98.6% for Cape and 100.0% for Sor respectively. pCR rate was 60.0% (95%CI: 43.3%, 75.1%) by central independent pathological review (15.0% DC grade 4; 45.0% DC grade 3). Sphincter preservation was achieved in 89.5%, R0 resection in 94.7% and downstaging in 81.6% of the pts. The most common grade 3 toxicities included diarrhea (15.0%), skin toxicity outside of the RT field (12.5%), pain (7.5%), skin toxicity in RT field, proctitis, fatigue and cardiac ischemia (each 5.0%). Laboratory AEs grade 3/4 were neutropenia (1 pt grade 4; 1 grade 3), creatinine elevation (1 pt grade 3). **Conclusions:** The combination of Sor to standard RCT with Cape in k-ras mutated LARC tumors is highly active with acceptable toxicity and deserves further investigation. Clinical trial information: NCT00869570.

**3532 Poster Highlights Session (Board #21), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**External validation of the neoadjuvant rectal (NAR) score and Valentini prediction nomogram (VPN): A multicenter study.** *Presenting Author: Soundouss Raissouni, Tom Baker Cancer Centre, Calgary, AB, Canada*

**Background:** The VPN [JCO 2011;29(23)] is a tool used for individualized prognostication in rectal cancer, and the recently described NAR score [Yothers et al. JCO 32, 2014 abst: 38] has been suggested as a surrogate endpoint for overall survival (OS) in clinical trials. However, these tools have not been validated outside of the clinical trial setting. We assessed these models in a retrospective multi-institution database, to determine their predictive ability for outcome in patients with rectal cancer treated with neoadjuvant chemoradiation (nCRT). **Methods:** Data from patients with locally advanced rectal cancer who received nCRT and had curative intent surgery from 2005 to 2012 were collected from Tom Baker Cancer Center, Cross Cancer Institute, BC Cancer Agency, Ottawa Hospital Cancer Centre and Dr. H. Bliss Murphy Cancer Centre. The NAR score was compared with pathologic complete response (pCR) status for OS and with the VPN for local control (LC), distant control (DC) and OS using Akaike's information criterion (AIC – a tool for comparing models in a dataset). C-index was evaluated for VPN and NAR for OS. **Results:** 1,172 patients were included; pCR was achieved in 16.6%.The median NAR score was 17.36; NAR risk groups included low (22.6%), intermediate (42.6%), and high (34.9%). The 5-year OS in the NAR risk groups were 88.1% (low), 82% (intermediate – HR 1.89, 95% CI 1.13 – 3.1), 59.5% (high – HR 5.05, 95% CI 3.1 – 8.2), and 89.9% for pCR (HR 0.25, 95% CI 0.14 – 0.45) versus 73.1 % for no pCR (log rank p-value $<0.0001$ for both). AIC favoured NAR compared with pCR for OS (2,549.6 v 2,824.0).VPN as a continuous variable predicted LC (HR 0.97, 95% CI 0.95-0.99, p=0.015), DC (HR 0.98, 95% CI 0.98-0.99, $p<0.0001$) and OS (HR 0.96, 95% CI 0.95-0.96, $p<0.0001$). The AIC favoured VPN over NAR for LC (851.2 v 856.5), DC (2,154.5 v 2,160.6) and OS (2,455.3 v 2,549.6). C-index also favoured VPN over NAR for OS (0.697 v 0.66). **Conclusions:** Similar to recent clinical trial data, NAR outperformed pCR in predicting OS, and the VPN was significantly associated with LC, DC and OS in the non-clinical trial setting. VPN appeared to better predict LC, DC, and OS compared with the NAR score and is favoured for individual patient prognostication.

**3533 Poster Highlights Session (Board #22), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Neoadjuvant rectal cancer (RC) score to predict survival: Potential surrogate endpoint for early phase trials.** *Presenting Author: Greg Yothers, National Surgical Adjuvant Breast and Bowel Project Biostatistical Center, and University of Pittsburgh Graduate School of Public Health, Department of Biostatistics, Pittsburgh, PA*

**Background:** Valentini, et al. (J Clin Oncol 29: 2011, 3163-72) developed nomograms for predicting overall survival (OS) based on clinical factors available after neoadjuvant therapy (tx). Pathologic T-stage (pT), N-stage (pN), and clinical T (cT) were the most important independent predictors of OS. We developed a neoadjuvant RC score (NAR score) using pN and downstaging of T (cT – pT) based on relative weights suggested by the nomograms. NSABP's R-04 trial presents an opportunity for independent validation of the NAR score. **Methods:** Pts with clinical stage II/III RC undergoing preoperative RT (4,500cGy in 25 fractions over 5 wks + boost of 540-1080cGy in 3-6 daily fractions) were randomized to one of four regimens in a 2x2 design: CVI 5-FU (225mg/m$^2$ 5 days/wk), with or without oxaliplatin (Ox) (50mg/m$^2$ /wk x 5) or oral capecitabine (825 mg/m$^2$ BID 5 days/wk), with or without Ox. The NAR score is computed as [5 pN – 3 (cT – pT) + 12]$^2$ / 9.61 where: cT in {1, 2, 3, 4}, pT in {0, 1, 2, 3, 4}, and pN in {0, 1, 2}. The NAR score takes values from 0 to 100; higher scores indicate poorer prognosis. Analyses based on the score should be stratified by cT. NAR score is compared to pathologic complete response (ypCR) by Akaike's information criterion (AIC) to determine the better predictor of OS. **Results:** 1,479 pts had data for the NAR score and follow-up for OS. Continuous NAR score was significantly associated with OS (HR/unit 1.04 95% CI 1.03-1.05, $p<0.0001$). Pts were grouped into low, intermediate, and high risk of death categories based on tertiles of the NAR score. Categories were significantly associated with OS ($p<0.0001$) with 5yr OS values of 92, 89, and 68%, respectively. ypCR was also significantly associated with OS (HR 0.37 95% CI 0.24-0.58, $p<0.0001$). Continuous NAR score had a much lower AIC (2902.49) than ypCR (2987.08) suggesting stronger association with OS. **Conclusions:** The NAR score has been validated as a predictor of OS after neoadjuvant tx for RC. AIC of the continuous NAR score suggests it is a better predictor of OS than dichotomous ypCR. NAR score could be used in place of ypCR as a surrogate endpoint for OS in early phase neoadjuvant rectal trials. Support:U10-CA-12027, U10-CA-37377, U10-CA-69651, U-10-CA-69974; Sanofi; Roche. Clinical trial information: NCT00058474.

**3534 Poster Highlights Session (Board #23), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A randomized phase III trial of mFOLFOX6 plus bevacizumab versus FOLFIRI plus bevacizumab as first-line treatment for metastatic colorectal cancer: West Japan Oncology Group study 4407G (WJOG4407G).** *Presenting Author: Kentaro Yamazaki, Divison of Gastrointestinal Oncology, Shizuoka Cancer Center, Shizuoka, Japan*

**Background:** FOLFIRI and FOLFOX showed equivalent efficacy for metastatic colorectal cancer (mCRC), however their combination with bevacizumab (Bev) have not been directly compared. **Methods:** The WJOG4407G study was a randomized, open-label, phase III trial. Patients (pts) with previously untreated mCRC were randomized to receive either mFOLFOX6+Bev (group A; oxaliplatin 85mg/m$^2$, l-leucovorin 200mg/m$^2$, bolus 5-FU 400mg/m$^2$, infusional 5-FU 2,400mg/m$^2$, and Bev 5mg/kg; q2w) or FOLFIRI+Bev (group B; irinotecan 150mg/m$^2$instead of oxaliplatin), stratified by institution, adjuvant chemotherapy, and liver limited disease. The primary objective was to investigate non-inferiority of B to A in progression free survival (PFS) assessed in the full analysis population (all randomized pts without major violation of eligibility criteria); non-inferiority margin of hazard ratio (HR) 1.25 based on the assumption of median PFS 10/11 months in A/B (power 0.85, 1-sided alpha 0.025). The secondary endpoints were response rate, overall survival (OS), safety, and quality of life (QOL). **Results:** From September 2008 to January 2012, 395 (A/B 198/197) of 402 enrolled pts were eligible for efficacy analysis. Data cut-off date was July 2013. Median PFS in A/B were 10.7/12.0 months (HR 0.905, 95% CI 0.723-1.133; p=0.003 for non-inferiority and p=0.427 for superiority; events in 78% pts). There was no interaction effect between the treatment and *KRAS*(codon12, 13) mutation status. Subsequent treatments were performed in 168/157 pts after A/B. Median OS in A/B were 28.9/31.8 months (HR 0.901, 95% CI 0.683-1.189; events in 50% pts), and response rates were 62.2/63.8%. The common grade 3 or 4 adverse events in A/B were leukopenia 4.5/11.3%, neutropenia 35.4/45.6%, diarrhea 5.1/8.7%, febrile neutropenia 1.5/5.1%, peripheral neuropathy 21.7/0%, and venous thromboembolism 1.5/6.2%. The QOL assessed by FACT-C (TOI-PFC) and FACT/GOG-Ntx were favorable for B throughout 18 months. **Conclusions:** FOLFIRI+Bev was non-inferior to mFOLFOX6+Bev with respect to PFS as 1st-line treatment for mCRC, and showed better trend in QOL. Clinical trial information: UMIN000001396.

**3535 Poster Highlights Session (Board #24), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Metformin (M), diabetes (DM), and colorectal cancer (CRC) survival among U.S. veterans.** *Presenting Author: Jessica K Paulus, Tufts Clinical and Translational Science Institute, Boston, MA*

**Background:** Although diabetes (DM) is associated with a worse colorectal cancer (CRC) prognosis, metformin (M) use has been associated with improved overall and CRC-specific survival in several prior studies. We examined the impact of M use on overall survival (OS) in patients with type 2 DM and CRC among US veterans while adjusting for treatment, stage and diabetic severity, offering the largest cohort study examining this issue to date. **Methods:** There were 21,352 patients with CRC were diagnosed between 2001 and 2008 in the US Veterans Health Administration. OS was compared across four groups: patients without DM (n=16,355); patients with DM on M (n= 2,038); patients with DM on anti-DM medications other than M (n=2,136); and patients with DM not on anti-DM medication (n=823). Multivariate Cox proportional hazards models were used to estimate the association between M use, DM and OS while adjusting for age, race, stage, body mass index, HbA1C, comorbidity index, and cancer treatment. **Results:** Median survival was 61 months in non-diabetics, 67 months in metformin users, 45 months in users of other diabetic medications, and 51 months in diabetics not on anti-DM medication. HbA1C levels were 6.9%, 6.8%, and 6.2% in patients with DM on metformin, other, or no anti-DM medication, respectively. In the subset of CRC patients with DM, those patients taking M had a 21% decrease in the risk of death compared to patients with diabetes taking anti-DM medications other than M ($HR_{adj}$ 0.79; 95% CI 0.73-0.86, $p=<0.001$), while diabetic patients not on any anti-DM medications had a 13% decrease in risk of death ($HR_{adj}$ 0.87; 95% CI 0.78-0.97, p=0.02). No interaction between M and BMI was observed (p=0.86). In the entire cohort, patients with DM on anti-DM medications other than M had a statistically significant increase in risk of death compared to non-diabetics ($HR_{adj}$ 1.26; 95% CI 1.19-1.33, $p=<0.0001$). However, patients with DM on M had similar OS as compared to non-diabetics ($HR_{adj}$ 1.05; 95% CI 0.99-1.12, p=0.11), as did patients with DM not on anti-diabetic medication ($HR_{adj}$1.08; 95% CI 0.99-1.18, p=0.07). **Conclusions:** Among diabetics with CRC, M use is associated with improved survival as compared to the use of other medications. Metformin may reduce the survival disadvantage associated with DM among CRC patients.

**3536 Poster Highlights Session (Board #25), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Racial differences in *KRAS*/*BRAF* mutation rates and survival in colon cancer (NCCTG N0147 [Alliance]).** *Presenting Author: Harry H. Yoon, Mayo Clinic, Rochester, MN*

**Background:** It is unknown if racial disparities in colon cancer outcomes persist after controlling for clinicopathologic variables and treatment. Molecular characterization of colon cancers in a North American population that includes Asians has not been reported. **Methods:** *KRAS*/*BRAF* mutation (mt) was determined in stage III colon cancer patients (pts, N = 3305) in the North American phase 3 adjuvant trial N0147. Race categories included Asian (149), black (240), or white (2916). Outcomes were analyzed in 2931 pts randomized to FOLFOX +/- cetuximab. Given a lack of interaction between race and treatment, arms were pooled. Cox models were used to estimate disease-free survival (DFS). **Results:** *BRAF* mt frequency in tumors from whites was twice that of tumors from Asians or blacks; *KRAS* mt rates were highest in tumors from blacks; *KRAS/BRAF* wildtype (wt) rates were highest in tumors from Asians (all $P<.005$; Table). Compared to whites, tumors from blacks were more likely to be N1 (*vs* N2) or low-grade (*vs* high), and tumors from Asians were more likely to be distal (*vs* proximal) (all $P<.003$). Blacks were younger than whites ($P<.001$). Notably, the prognostic impact of race differed based on N stage ($P_{interaction}=.0049$) and age ($P_{interaction}=.012$). Thus, DFS was analyzed by N stage (Table) and age. Blacks had shorter DFS than whites among N1 pts, and Asians had longer DFS among N2 pts, independent of covariates including *KRAS/BRAF* (Table). Among age <50, blacks had shorter DFS than whites (multivariate HR 2.8; 95% CI 1.7-4.6; $P<.0001$). Findings were consistent using time to recurrence as the outcome. **Conclusions:** These data, to our knowledge, are the first to show that Asians have a significantly lower rate of *KRAS/BRAF* mutations than blacks or whites. We also report a novel interaction of race with N stage and age, showing that racial disparities in survival persist despite uniform stage and enrollment in a phase 3 trial.

**Body mass index (BMI) as prognostic in metastatic colorectal cancer (mCRC): A pooled analysis of 21 first-line trials in the ARCAD database.** *Presenting Author: Lindsay A. Renfro, Mayo Clinic, Rochester, MN*

**Background:** Recent retrospective analyses in early CRC showed low and high BMI associated with worse outcomes; limited data exist on BMI as a prognostic or predictive factor in mCRC. **Methods:** Data from 18,564 pts enrolled to 21 first line mCRC trials from 1997-2009 were pooled. BMI was studied as possibly non-linear in Cox models for overall survival (OS) and progression-free survival (PFS); both prognostic and predictive effects were tested. Adjustments for and interactions with age, sex, and performance status (PS) were considered. Subgroup analyses within anti-EGFR vs. anti-angiogenesis were performed. Clinically relevant effects with $p<0.05$ were deemed significant. **Results:** BMI was prognostic for OS ($p<0.0001$) and PFS ($p<0.0001$) with "L" shape risk; i.e., risk of progression and/or death was greatest near BMI = 15, risk decreased as BMI increased to approximately BMI = 28, then plateaued. Relative to obese pts, low BMI pts had 46% increased risk of a PFS event and 85% increased risk of death. Low BMI was associated with poorer survival for males than females (interaction $p=0.0003$); high BMI was associated with worse survival for patients with PS 2+ but not lower PS (interaction $p=0.003$); other interactions and predictive tests were not significant. The BMI effect was similar in anti-EGFR and anti-angiogenesis therapy. **Conclusions:** Low BMI was associated with higher risk of progression or death among the mCRC trial pts studied, with decreased risk for higher BMI, opposite of reports in the adjuvant setting. Possible explanations include cancer cachexia in low BMI pts and increased dose or selection bias in high BMI pts, who may have comorbidities making them ineligible for clinical trials. Further study to understand the mechanisms of this association are warranted.

**3538 General Poster Session (Board #1), Sat, 8:00 AM-11:45 AM**

**Early predictors of prolonged overall survival (OS) in patients (pts) on first-line chemotherapy (CT) for metastatic colorectal cancer (mCRC): An ARCAD study with individual patient data (IPD) on 10,962 pts.** *Presenting Author: Dirkje Willemien Sommeijer, NHMRC Clinical Trials Centre, Sydney; Flevohospital, Almere; Academic Medical Centre, Amsterdam, Netherlands*

**Background:** To expedite drug development and improve treatment (trt) decisions, early indicators of trt efficacy are needed. We evaluated the pt-level association between early tumor shrinkage (ETS; ≥ 20% decrease from baseline), early objective tumor response (EOTR; CR/PR by RECIST), and early nonprogression status (EnPD;CR/PR/SD by RECIST) at 6, 8/9, or 12 weeks (wks) with OS, and compared these with standard endpoints (best overall response [BOR] and confirmed response [ConfR]) in pts treated with 1st-line CT. **Methods:** 16 phase III trials, including 10,962 pts on 5FU-LV/capecitabine alone or with oxaliplatin/irinotecan, from the ARCAD database were analyzed. Associations between early endpoints and OS were tested by stratified Cox models with a landmark approach. Prediction performance was compared by the C-index (c), a measure of relative accuracy to distinguish those at high versus low risk of death (higher value indicates better risk discrimination). **Results:** ETS and EOTR were significant predictors of OS with similar hazard ratios (HRs) to BOR and ConfR ($p<0.0001$; see Table). Pts without early progression (non-PD) showed the largest risk reduction (HRs ~ 0.3). Adjusting for age, performance status, number of metastases, and prior trt, significance remained. C-indices were similar across early endpoints, and similar to those for BOR and ConfR. **Conclusions:** Early responses are significantly associated with prolonged OS in mCRC pts on 1st-line chemotherapy. Early PD strongly correlates with an increased hazard of death. The pt-level prediction accuracy is as strong as for standard endpoints with the advantage of earlier tumor evaluation. Similar performance of ConfR implies the lack of utility for response confirmation. Formal surrogacy testing at trial level is ongoing.

**Correlation of *PI3KCA* and extended *RAS* gene mutation status with outcomes from the phase III AGITG MAX involving capecitabine (C) alone or in combination with bevacizumab (B) with or without mitomycin C (M) in advanced colorectal cancer (CRC).** *Presenting Author: Timothy Jay Price, The Queen Elizabeth Hospital and University of Adelaide, Woodville, Australia*

**Background:** Mutations affecting *RAS* genes are now established predictive markers of non-response to anti-epidermal growth factor receptor (EGFR) antibodies in advanced colorectal cancer (CRC). *PI3KCA* (and *BRAF*) may also be predictive. A previous analysis restricted to *KRAS* exon 2 has not revealed any role for mutation status as a predictive marker for bevacizumab therapy. This analysis assessed the prognostic and predictive impact of extended *RAS and PI3KCA* gene mutation status in patients receiving C +/- B +/- M in the randomised phase III MAX study. **Methods:** DNA was macrodissected from archival formalin fixed paraffin embedded tumor tissue. Mutation status was determined using pyrosequencing and confirmed with Sanger sequencing (for equivocal *RAS*). Mutation status (Wild type/WT v Mutated/MT) was correlated with efficacy outcomes (RR, PFS & OS). Predictive analyses were undertaken using a test for interaction involving both C vs CB + CBM **Results:** Patient demographics and clinical outcomes were comparable between the tissue study population (n=281/60%) and the intention to treat population (n=471). MT in K*RAS* exons 2, 3, 4 and *NRAS* 2, 3, 4 as follows; 32.4%, 4.3%, 3.9%, 1.4%, 0.7% & 0. There were five patients who had more than one *RAS* MT (four with *KRAS* exon 2&4, one *KRAS* exon 2&3*).* The total proportion with any *RAS* MT is 40.9%. *PI3K* MT rate was 7.5% exon 9, and 3.6% exon 20. All *RAS* gene mutation status (WT v MT) had no prognostic impact for PFS, HR 0.92 (0.72-1.17) or OS HR 0.97(0.73-1.27). Using the comparison of C v CB + CBM, *RAS* gene mutation status was not predictive of the effectiveness of B for PFS, HR 0.56 (0.37-0.84) for *RAS* MT and HR 0.69 (0.49-0.97) for *RAS* WT, p for interaction 0.51. RR with *RAS* MT was higher without Bev (C 50% v CB/CBM 37.3%), but RR improved with Bev in the WT group (C 27.3% v CB/CBM 42.3%), p for interaction 0.01. *PI3KCA* mutation was neither predictive for bevacizumab effect nor prognostic. **Conclusions:** An additional 12.6% of MAX study patients who were *KRAS* exon 2 WT had additional RAS mutations. Neither all *RAS* gene mutation status nor *PI3KCA* mutation status was prognostic for progression-free survival or overal survival, or predictive of bevacizumab outcome in patients with advanced CRC. Clinical trial information: NCT00294359.

**3540 General Poster Session (Board #3), Sat, 8:00 AM-11:45 AM**

**Survival outcomes for patients with metastatic colorectal cancer (mCRC) based on primary site, right (R) colon versus left (L) colon versus rectal (Rec) primary: Results from the South Australian Registry of mCRC.** *Presenting Author: Yoko Tomita, The Queen Elizabeth Hospital, Adelaide, Australia*

**Background:** Previous reports have described differences in biology and outcome based on R or L sided primary bowel cancer. Possible differences in response to biological agents have also been reported. **Methods:** We explored the SA mCRC registry to assess differences in patient characteristics, treatment received, and outcomes based on if the primary was R colon (caecum to transverse colon), L colon (splenic flexure to sigmoid), or rectal. KM was used for survival outcomes and Cox proportional hazards regression modeling was used to assess defined prognostic markers. **Results:** 3,121 patients were analysed. 33.5% had R colon, 35.3% L colon and 26.7% rectal primary. Major differences between the groups are shown in the Table. There was no major difference between L and Rec. There were statistically significant differences between both R v L and R v Rec; R occurred more in females and older age, and had more poorly differentiated pathology. Biological agent use, chemotherapy (CT) use, and metastatectomy were all less common in R. KRAS MT rates were greater in R v L (p=0.007). Analysis of systemic therapy revealed similar rates of 1st line therapy, but different 2nd line; R 47% v L 60% v Rec 60% respectively. The mOS for the entire group R v L v Rec was 9.8 v 19.2 v 17.8 months. For the group who had active therapy defined as CT (+/- metastatectomy), mOS was R 15.5 v L 26.2 v Rec 26.3 months. For those (n=168) who underwent liver resection (+/- chemotherapy) 5 year survival was R 55%, L 58% Rec 55%. In patients treated with only CT, mOS was R 10.3 v L 15.1 v Rectal 15 months. **Conclusions:** There were no major differences noted between L colon and Rectal primary. Patients with R primary had more negative prognostic factors and indeed had inferior outcomes when compared to those with L or Rectal primary. Patients who were suitable for hepatic surgery had no difference in outcome.

| | Right | Left | Rectum |

**3541 General Poster Session (Board #4), Sat, 8:00 AM-11:45 AM**

**Survival of high-grade neuroendocrine carcinomas (HGNEC) of the colon and rectum: Analysis of the Surveillance, Epidemiology, and End Results (SEER) database.** *Presenting Author: Hammad Shafqat, Memorial Hospital of Rhode Island, Pawtucket, RI*

**Background**: HGNECs are rare, aggressive colorectal tumors, biologically similar to small cell lung cancer. Their optimal management is unclear and based on case series. Our study sought to compare survival outcomes and the role of surgery in HGNECs and high-grade adenocarcinomas (AC) using the population-based SEER registry. **Methods**: We obtained data on patients (pts) with colorectal HGNEC or AC diagnosed between 1998 and 2011. Relative survival (RS) was the primary endpoint. Trends in incidence and survival were calculated as annual percent change (APC). Associations with prognostic factors and treatment were analyzed in multivariate proportional hazard models, accounting for immortal time bias, and reporting hazard ratios (HR) with 95% confidence intervals (CI). **Results**: Compared with AC ($N$=392,854), HGNECs ($N$=1,455) were more often metastatic (18% *vs.* 54%, respectively) and more commonly located in the cecum or rectum, but rarely in the sigmoid ($P$<.0001). The incidence of HGNEC increased during the study period (APC 2.5%, $P$=.015), while the incidence of AC decreased (APC -3%, $P$<.0001). Survival was significantly worse for HGNECs than for high-grade AC at every stage (Table). No improvement over time in survival of HGNEC was seen (APC, 0.1%, $P$=.88), unlike in AC (APC, 0.9%, $P$<.0001). Stage I-III HGNECs were less likely to undergo resection (84% vs. 91% for AC, $P$<.0001), although the survival benefit (HR 0.50, 95% CI 0.34-0.74) was the same as for AC ($P$ for interaction=.88). Compared with high-grade AC, resected HGNECs were more often node-positive (68% vs. 53%) or >5 cm in size (59% vs. 50%). The number of metastatic nodes was prognostic in HGNEC (HR for N2 vs. N1, 1.94, 95%CI 1.41-2.66). **Conclusions**: The prognosis of HGNEC has not improved over the past decade, despite advances in therapy of AC. HGNECs benefit from surgery similarly to ACs. Pts with stage I-II HGNECs have similar 5-year RS of 51%, warranting studies of adjuvant systemic therapy.

| | High-grade AC | | HGNEC | |
|---|---|---|---|---|

**3542 General Poster Session (Board #5), Sat, 8:00 AM-11:45 AM**

**The effect of chemotherapy delivered until progression versus complete stop on the overall survival of patients with metastatic colorectal cancer: A meta-analysis of randomized trials.** *Presenting Author: Allan Andresson Lima Pereira, Instituto do Câncer do Estado de São Paulo - ICESP/FMUSP, São Paulo, Brazil*

**Background:** The impact of the duration of chemotherapy on the overall survival (OS) of patients with metastatic colorectal cancer (mCRC) is controversial. We performed a systematic review and meta-analysis of randomized controlled trials (RCT) that compared chemotherapy continuously administered until progression versus complete treatment interruption after first line therapy for patients with mCRC **Methods:** We searched medical literature databases and oncology conferences proceedings for RCTs that compared the OS of mCRC patients who received first line chemotherapy until progression with those who were offered complete treatment stop after a fixed number of cycles. RCT that evaluated the role of any kind of maintenance therapy were excluded. A meta-analysis of reported Hazard Ratios for OS, with respective 95% confidence intervals, was performed using the fixed-effect models. **Results:** Our search retrieved 106 trials, of which sox were eligible (N=2373). The meta-analysis (N=2,334) showed a statistically significant OS benefit in favor of chemotherapy delivered until progression (*HR= 0.89, 95%CI= 0.82 to 0.98; p= 0.01; $I^2$ 0%*). The range of chemotherapy-free interval in the complete-stop group across trials was 3.7 – 4.3 months. Only three trials reported quality of life (QoL) data. Chemotherapy administered until progression was associated with more adverse effects and impaired QoL. **Conclusions:** Chemotherapy administered continuously until progression for mCRC patients is associated with a modest but significant improvement in OS. However mCRC is a heterogeneous disease and identification of molecular biomarkers could help clinicians to predict which patients would benefit from continuous or intermittent cancer-directed therapies.

**3543 General Poster Session (Board #6), Sat, 8:00 AM-11:45 AM**

**An internally and externally validated nomogram to predict severe neutropenia in Japanese patients (pts) with advanced colorectal cancer (aCRC) treated with irinotecan (IRI)-based regimens.** *Presenting Author: Wataru Ichikawa, Showa University, Tokyo, Japan*

**Background:** Irinotecan (IRI)-based regimens are one of the standard treatments for advanced colorectal cancer (aCRC). In Asians, *UGT1A1*6* and *UGT1A1*28* are associated with IRI-related severe neutropenia. We conducted a prospective observational study to examine the correlation between *UGT1A1*genotypes and the clinical outcome of IRI-based regimens in Japanese patients (pts) with aCRC (NCT 01039506). We presented the data of the interim safety analysis at the 2013 ASCO annual meeting (Abstract No. 3535) and the European Control Conference (ECC) 2013 (Abstract No. 2364). We developed a final nomogram that predicts severe neutropenia, based on the data from 1,312 pts enrolled into the study, and externally validated it using independent data from 350 pts. **Methods:** From October 2009 to March 2012, pts with histologically confirmed aCRC treated with IRI-based regimens were enrolled into the study. *UGT1A1* genotypes were categorized into three groups: wild (**1/*1*), hetero (**1/*6*, **1/*28*), and homo (**6/*6*, **6/*28*, **28/*28*). Detailed toxicities in the first three months of treatment were prospectively recorded. A nomogram for predicting severe neutropenia was developed using multiple logistic regression that included *UGT1A1*genotypes and non-genetic factors. The nomogram was internally validated using bootstrap resampling, and externally validated using independent cohorts from six sites. **Results:** The final nomogram was developed using the safety data from 1,312 of the 1,376 enrolled pts. The frequencies of *UGT1A1* polymorphisms were 48%, 41%, and 11% for the wild, hetero, and homo groups, respectively. Severe neutropenia was observed in 31% of all pts: 25%, 34%, and 49% for the three groups, respectively. The nomogram integrates important factors such as regimen, initial doses of IRI, age, sex, performance status, *UGT1A1* genotype, pre-treatment neutrophil count, and total bilirubin. The concordance index (c-index) was 0.693, which was higher than that of 0.593 for a model that used just the *UGT1A1*genotype. The nomogram was externally validated with a c-index of 0.702, using independent data from 350 pts. **Conclusions:** This nomogram can be used to accurately predict IRI-related severe neutropenia in Japanese pts with aCRC.

**3544 General Poster Session (Board #7), Sat, 8:00 AM-11:45 AM**

**A phase II trial of combined chemotherapy with oral S-1 and 24-hour infusions of irinotecan plus bevacizumab in patients with metastatic colorectal cancer.** *Presenting Author: Sotaro Sadahiro, Department of Gastroentelogical Surgery, Tokai University School of Medicine, Isehara, Japan*

**Background:** Irinotecan causes S-phase-specific cell killing. Its active metabolite, SN-38, is catalyzed by carboxylesterases. Prolonged exposure to low concentrations of irinotecan is associated with less carboxylesterase saturation, thereby enhancing therapeutic effectiveness (Houghton PJ, 1995, Rothenberg ML, 1998). We previously reported that combined chemotherapy with oral UFT/leucovorin or S-1 plus 24-hour infusions of irinotecan is very effective. We examined the effectiveness and safety of combined chemotherapy with S-1 and 24-hour infusions of irinotecan plus bevacizumab in patients with metastatic colorectal cancer (mCRC). **Methods:** Patients who had mCRC, an age of ≥ 20 years, and an ECOG PS of 0-1 were eligible. S-1 (40 mg/m$^2$) was given orally twice daily on days 1 to 14. Irinotecan was given as continuous 24-hour intravenous infusion on days 1 and 15. On the basis of the results of a previous phase I study, patients who were homozygous for the UGT1A1*28 allele received 100 mg/m$^2$ of irinotecan, and those with other genotypes received 125 mg/m$^2$of irinotecan. Bevacizumab (5 mg/kg) was given intravenously on days 1 and 15, followed by a two-week rest. This four-week regimen was regarded as one cycle and was repeated. The primary endpoint was overall response (OR). The secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety. **Results:** 79 patients were enrolled; median age, 68 years (range, 38-85); 42% female; ECOG PS 0/1, 58%/42%; and first line/second line therapy, 58%/42% (adjuvant chemotherapy, 16%). Three patients (4%) were homozygous for the UGT1A1*28 allele. Median follow-up time was 18.1 months. The median number of treatment cycles was seven. The OR rate was 77.2% (95% confidence interval, 66.4-85.9; first line, 80.4%; second line, 72.7%). Median PFS was 15.7 months (first line, 16.4 months; second line, 16.5 months). Median OS were not reached. Grade 3 or higher adverse events that occurred at an incidence of ≥ 10% were neutropenia (43.0%), leukopenia (20.3%), anorexia (19.0%), and diarrhea (10.1%). **Conclusions:** This regimen appears to be highly active and well tolerated, both as first-line and second-line chemotherapy for mCRC. Clinical trial information: 10R-121.

**3545 General Poster Session (Board #8), Sat, 8:00 AM-11:45 AM**

**Asia-Pacific colorectal screening score and colorectal cancer screening in asymptomatic Asian population.** *Presenting Author: Joseph JY Sung, Institute of Digestive Disease, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

**Background:** There has been a rapid rise in colorectal cancer (CRC) incidence in recent decades in many Asian countries. Age, gender, smoking, and family history are the significant risk factors of CRC. This study would like to develop an Asia-Pacific Colorectal Screening (APCS) score to identify subjects with high-risk for colorectal advanced neoplasia (AN) in Asia. **Methods:** A multicentre study was in 11 Asian cities. A total of 7,463 asymptomatic subjects underwent screening colonoscopy. The first 2,000 subjects were used as a derivation cohort. AN was defined as advanced adenoma and CRC. A multiple logistic regression was applied to the derivation cohort identifying significant risk factors for AN; odds ratios of significant risk factors were then utilized to develop APCS score ranging from 0-6, including age (0=40-49, 1=50-59, 2=60+), gender (0=female, 1=male), family history (0=absent, 1=present), smoking (0=no, 1=current or past), and Body Mass Index (BMI) (0= <23kg/m$^2$, 1= >23kg/m$^2$). Three tiers of risk were defined: 0 'average risk' (AR); 1-3 'moderate risk' (MR); and 4–6 'high risk' (HR). The APCS score was applied to the validation cohort as performance assessment. **Results:** The baseline prevalence of AN were 4.9% and 5.4% in the derivation and validation cohorts. In the validation cohort, 110 subjects (2.0%) were in AR, 4,148 subjects (75.9%) in MR, and 1,205 (22.1%) subjects in HR. Prevalence of AN in AR, MR and HR were 0.9%, 4.1% and 10.5% respectively. Compared with AR, subjects in MR and HR had 4.5-fold and 11.5-fold increased prevalence of AN. **Conclusions:** The APCS score based on age, gender, family history, smoking and BMI is a useful tool in stratifying asymptomatic Asians for priority of CRC screening.

**3546 General Poster Session (Board #9), Sat, 8:00 AM-11:45 AM**

**MLN0264, an investigational antiguanylyl cyclase C (GCC) antibody-drug conjugate (ADC), in patients (pts) with advanced gastrointestinal (GI) malignancies: Phase I study.** *Presenting Author: Cristina Cruz Zambrano, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** This first-in-human study (NCT01577758) assessed the safety and tolerability, dose limiting toxicities (DLTs), maximum tolerated dose (MTD), pharmacokinetics, and preliminary antitumor activity of MLN0264 in adult patients (pts) with advanced gastrointestianl (GI) malignancies expressing the surface antigen guanylyl cyclase C (GCC). Preclinical studies have shown antitumor activity in GI tumor animal models, including GCC-expressing human colorectal cancer (CRC) xenografts. **Methods:** Pts received MLN0264 by IV infusion on day 1 of 21-day cycles. Dose escalation proceeded via a Bayesian continual reassessment method in pts with GI malignancies. At the MTD, pts with metastatic CRC were enrolled to an expansion cohort (including ≥ 6 with high GCC expression). **Results:** As of November 27, 2013, 36 pts have received MLN0264, 19 at 0.3–2.4 mg/kg in the dose-escalation cohorts and 20 (including 3 from dose escalation) in the MTD expansion cohort. Median age was 60 years (30–78); 69% were male; 30 had CRC, two had pancreatic, two had esophageal, one had gastric cancer, and one had small intestine carcinoma. Median time from diagnosis was 37.6 mos. DLTs were seen in four pts: grade 4 neutropenia in two of four pts at 2.1 and the one pt at 2.4 mg/kg (all >MTD), and grade 4 febrile neutropenia in 1 of 6 pts at the MTD of 1.8 mg/kg. Pts received a median of 2 (1–8) cycles. Adverse events (AE) (NCI-CTCAE v4.03) were reported in 86% of pts. Common AEs (all grades) included fatigue (42%), nausea (42%), diarrhea (36%), and decreased appetite (31%); 56% of pts had grade ≥3 AEs, including neutropenia (19%), hypokalemia (11%), diarrhea (8%), and anemia (8%). Four pts discontinued due to AEs. MLN0264 concentration was detectable in all pts in a dose-dependent manner. Antibody drug conjugates (ADC) was detectable in serum at the pre-infusion time of the next cycle (day 21) for pts dosed at ≥1.2 mg/kg. The drug in the ADC, monomethyl auristatin E, was detectable in a dose-dependent manner, with peak concentration occurring approximately 2–3 days after each infusion. One pt (gastric carcinoma, 1.8 mg/kg) had a PR (RECIST 1.1); 13 pts had SD, including three treated for ≥ four cycles. **Conclusions:** The MTD of MLN0264 was determined as 1.8 mg/kg every three weeks. MLN0264 appeared generally well tolerated; preliminary antitumor activity was seen. Further investigation is warranted. Clinical trial information: NCT01577758.

**3547 General Poster Session (Board #10), Sat, 8:00 AM-11:45 AM**

**The 12-gene colon cancer assay validation and utility: Summary of clinical evidence.** *Presenting Author: Emily Burke, Genomic Health, Inc., Redwood City, CA*

**Background:** The 12-gene colon cancer assay is the first commercially available molecular assay to predict the risk of recurrence in stage II/III colon and rectal cancer. Rigorous evidence for clinical validity and utility of an assay is imperative since the result is used for treatment decision-making. This summary outlines the studies that meet an established definition of clinical validation and additional studies that support the utility of the assay. **Methods:** Prospectively designed studies using archival tissue with pre-specified methods, clinical outcomes, and analysis plan were considered clinical validation studies (Simon et al. JNCI 2009). Additional studies that demonstrated the utility of the assay in a clinical setting were considered supportive. **Results:** The assay has been clinically validated in four independent studies with 3,315 patients (2,390 stage II/628 stage III colon and 130 stage II/167 stage III rectal). All four studies demonstrated a significant association ($p<0.05$) between the result and outcome (e.g. recurrence risk and cancer specific survival). The score was examined in the context of other variables, including T and N stage, mismatch repair status, number of nodes examined, lymphovascular invasion, and tumor grade; across all studies, the result consistently contributed to risk stratification beyond these variables. Three clinical utility studies with 502 patients showed that 29-45% of initial treatment recommendations in stage IIA colon cancer were changed, with a net reduction in use of adjuvant chemotherapy. **Conclusions:** Clinical validation of the 12-gene assay followed a now-standard approach of using archived tissue from multiple large, prospectively-designed studies with documented long-term outcomes; the 12-gene colon assay meets level IB evidence criteria. Subsequent studies showed the assay has impact on clinical practice. The underlying tumor biology assessed by the score is relevant in both colon (stage II and III) and rectal cancer, providing information beyond conventional features, and can help guide treatment decisions regarding adjuvant chemotherapy.

**3548 General Poster Session (Board #11), Sat, 8:00 AM-11:45 AM**

**A phase 1b study of VEGFR inhibitor fruquintinib in patients with pretreated advanced colorectal cancer.** *Presenting Author: Jin Li, Fudan University Cancer Hospital, Shanghai, China*

**Background:** Fruquintinib is a novel oral small molecule compound selectively inhibits vascular endothelial growth factor receptors (VEGFR) 1, 2, and 3 with potent inhibitory effects on multiple human tumor xenografts. In the first-in-human phase I study, fruquintinib demonstrated good tolerability and impressive antitumor activity (ORR=38.2% and DCR=82.4%) in patients (pts) with various heavily pre-treated solid tumors including colorectal cancer (CRC) (ASCO 2012 Abs#3038). **Methods:** This phase Ib study was designed to evaluate the safety, pharmacokinetics , and efficacy of two fruquintinib regimens: 4mg once daily continuously (QD) or 5mg once daily for three weeks followed with one week break (3/1 wk), as treatment for pts with advanced CRC who had failed at least two prior systemic therapies. The study consists of two stages: a two-arm 1:1 randomization stage including both QD and 3/1 wk regimens, and an expansion stage with the selected regimen. Tumor response was assessed per RECIST1.1. **Results:** Forty pts were enrolled in the randomization phase, with 20 pts in each QD or 3/1 wk group. Patient characteristics at baseline were similar between the two groups. The median treatment duration was 90 (7-280) days for QD regimen and 119 (14-364) days for 3/1 wk regimen. The most common treatment-related toxicities were hand-foot syndrome (HFS), hoarseness, proteinuria, hypertension and fatigue. The 3/1 wk group had less Grade 3/4 AEs than the QD group, particularly HFS (5% vs. 30%). Thirty-five pts were evaluable for response, 17 in QD and 18 in 3/1 wk. In QD group: DCR=76.2% (2 partial responses or PRs and 2 minor responses or MRs who achieved a 20-30% tumor reduction), 16-wk progression free survival (PFS)=40.0%, and 9-month survival=41.2%. In 3/1 wk group: DCR=83.3% (1 PR and 3 MRs), 16-wk PFS=65.0%, and 9-month survival=53.8%. 5mg 3/1 wk regimen was selected as the recommended regimen and additional 22 CRC pts were enrolled in the expansion stage. **Conclusions:** Fruquintinib administered at 5mg once daily in cycles of three weeks on and one week off was well tolerated and demonstrated encouraging preliminary clinical efficacy in pts with advanced CRC. Further clinical studies are warranted. Clinical trial information: NCT01975077.

**3549 General Poster Session (Board #12), Sat, 8:00 AM-11:45 AM**

**Prognostic value of *KRAS* exon 2 gene mutations in stage III colon cancer: Post hoc analyses of the PETACC8 trial.** *Presenting Author: Julien Taïeb, APHP and Paris Descartes University, Paris, France*

**Background:** Prognostic value of *KRAS* mutations in resected colon adenocarcinoma remains debated. We examined the prognostic impact of *KRAS* exon 2 mutations in stage III patients receiving adjuvant FOLFOX + /-cetuximab patients from the PETACC8 Phase III trial. **Methods:** *KRAS* exon 2 mutations in codon 12 (p.G12V, p.G12R, p.G12S, p.G12A, p.G12C, p.G12D) and codon 13 (p.G13D) were examined in all patients with available material and signed translational research informed consent enrolled in the PETACC8 trial. Analyses were restricted to *BRAF* wild type tumors, since the prognostic impact of BRAFV600E in this population has already been described. Because no benefit or deleterious effect from adjuvant cetuximab was reported in this trial, tumors from both study arms were pooled for analysis. Association between time to recurrence (TTR) and disease-free survival (DFS) and type of *KRAS* mutation was evaluated using Cox proportional hazard model. **Results:** *KRAS* mutations were found in 638/1657 tumors, including 502 codon 12 and 136 codon 13 alterations. *KRAS* mutations in codon 12 (HR: 1.67; 95% confidence interval [CI] [1.35-2.04]; P<0.001) but not in codon 13 (HR: 1.23; 95% confidence interval [CI] [0.85-1.79]; P=0.26) were significantly associated with shorter TTR as compared to patients with *KRAS*/*BRAF* wild-type tumors, independently of other covariates. Similar results were found for DFS. When anatomic sites were taken into account, the impact of *KRAS* mutations on TTR was only found for distal tumors (n=1043) with an increased risk of relapse (HR: 1.96; 95% confidence interval [CI] [1.51-2.56]; P<0.0001) for *KRAS*codon 12 mutated tumors and a trend for codon 13 (HR: 1.59; 95% confidence interval [CI] [1.00-2.56]; P=0.051), as compared to *KRAS/BRAF*wild type patients. Similar results were found for DFS. **Conclusions:** *KRAS* exon 2 mutations are independent predictors of TTR or DFS for patients with stage III distal colon cancer receiving adjuvant therapy. Future clinical trials in the adjuvant setting should consider tumor location and type of *KRAS* mutation as important stratification factors.

**3550^ General Poster Session (Board #13), Sat, 8:00 AM-11:45 AM**

**Survival outcomes in patients (pts) with *KRAS/NRAS* (*RAS*) wild-type (WT) metastatic colorectal cancer (mCRC) and non-liver-limited disease (non-LLD): Data from the PRIME study.** *Presenting Author: Jean-Yves Douillard, Centre René Gauducheau, Nantes, France*

**Background:** ESMO guidelines recommend upfront treatment with an active combination regimen for mCRC pts with multiple metastases and those with more limited disease (Schmoll et al, 2012). Panitumumab (pmab) + FOLFOX4 is an active regimen that improved overall survival (OS) vs FOLFOX4 alone in the 1st-line treatment of *RAS* WT mCRC (PRIME study). In this exploratory analysis of PRIME, we report the efficacy of pmab + FOLFOX4 vs FOLFOX4 in pts with non-LLD. **Methods:** PRIME was a randomized (1:1) phase 3 study comparing the efficacy and safety of pmab 6.0 mg/kg Q2W + FOLFOX4 vs FOLFOX4 in pts with no prior chemotherapy for mCRC. In this exploratory analysis conducted when ≥80% of pts had an OS event, median progression-free (PFS) and OS were estimated for pts with *RAS* WT (*KRAS/NRAS* exons 2-4 assessed, including codon 59) non-LLD. 3-year OS rates were also evaluated. Data were summarised descriptively and tested for significance using Cox's proportional hazards models. **Results:** Of the 505 pts with *RAS* WT mCRC, 416 had non-LLD. Treatment arms were well balanced with respect to baseline sex, age and metastatic sites. Overall, 82% of pts had liver involvement, 51% had ≥3 metastatic sites (median 3 [range 1-6]) and median LDH was 373 (range 4-5780) U/L. Median PFS and OS were longer in *RAS* WT non-LLD pts receiving pmab + FOLFOX4 vs FOLFOX4 (Table). 3-year OS rates were 31% vs 23% for non-LLD pts receiving pmab + FOLFOX4 vs FOLFOX4, respectively. Numeric benefits were also observed in LLD patients receiving pmab + FOLFOX4. **Conclusions:** This post-hoc analysis suggests that the PFS and OS benefits observed with 1st-line pmab + FOLFOX4 vs FOLFOX4 in the overall PRIME population are also seen in the subgroup of pts who have non-LLD. Clinical trial information: NCT00364013.

**3551 General Poster Session (Board #14), Sat, 8:00 AM-11:45 AM**

**Phase 1 study of biweekly (Q2W) anti-EGFR monoclonal antibody (mAb) mixture Sym004 in patients (pts) with metastatic colorectal cancer (mCRC) resistant to previous anti-EGFR treatment.** *Presenting Author: Guillem Argilés, Department of Medical Oncology, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Preclinical models suggest that WT KRAS mCRC may retain EGFR dependency despite resistance developed to anti-EGFR mAb treatment (eg, cetuximab or panitumumab). Sym004 is the first-in-class drug mixture of two mAbs targeting non-overlapping epitopes of EGFR causing augmented receptor degradation. Cohorts of weekly 9 and 12 mg/kg from the multicenter phase 1 trial exploring multiple doses and schedules of Sym004 have recently reported antitumor activity and a tolerable safety profile. **Methods:** We here report safety (primary endpoint) and efficacy (exploratory endpoint) from the two Sym004 Q2W cohorts of this trial. Eligible pts had WT KRAS mCRC with prior clinical benefit to anti-EGFR mAbs and subsequent progression during or within 6 months after treatment cessation. Sym004 was administered until disease progression or unacceptable toxicity. **Results:** A total of 29 pts (median age was 64 years; 62% had liver metastasis [non-]target lesions; 86% had >2 prior lines of therapy) were treated at 12 (N=12) and 18 mg/kg (N=17) Sym004 Q2W. Drug-related AEs were manageable with dose reduction and supportive medication. Grade ≥3 toxicities in 12 and 18 mg/kg cohorts were skin rash (3/12 [25%]; 6/17 [35%]; no grade 4) and hypomagnesemia (3/12 [25%]; 6/17 [35%]). Grade 3 diarrhea was seen in one pt of each cohort (8%; 6%). Infusion-related reactions were observed in 2/29 (7%) pts (grade 1 and 2, each). Efficacy assessments are shown in the Table. **Conclusions:** Single-drug Sym004 was well tolerated and antitumor responses seen at 18 mg/kg Q2W in the first assessment at week 4-8 suggest clinical activity of Sym004 in anti-EGFR mAb resistant WT KRAS mCRC pts. The early benefit:risk profile remained favorable; no new toxicities were found. Clinical trial information: NCT01117428.

**Impact of chemotherapy partner on efficacy of targeted therapy in metastatic colorectal cancer (mCRC): A meta-analysis.** *Presenting Author: David Chan, Royal North Shore Hospital, St Leonards, Australia*

**Background:** In metastatic colorectal cancer (mCRC), the question of whether efficacy of targeted therapy is affected by chemo partner remains unresolved. Studies of chemotherapy (chemo) added to epidermal growth factor receptor (EGFR) inhibitors (EGFRI: cetuximab, panitumumab) and anti-vascular endothelial growth factoragents (VEGF) (bevacizumab, aflibercept) have reported mixed outcomes. We undertook systematic review to explore efficacy of these combinations according to chemotherapy partner. **Methods:** Randomized controlled trials were sought evaluating the combination of chemo with targeted therapy, categorized according to therapy class (EGFR or VEGF) and chemo partner (oxaliplatin (ox) or irinotecan (iri)). The impact of fluoropyrimidine (FP) regimen (bolus, infusional, or oral) was also explored. Only *KRAS* exon 2 wild type (WT) subpopulations were included in EGFR analysis. The primary endpoint was overall survival (OS) with secondary endpoints of progression-free survival (PFS), overall response rate (ORR) and toxicity. Meta-analysis was performed according to CONSORT guidelines and standard methods with hazard ratios (HR) and odds ratios (OR) computed. **Results:** We identified 21 trials evaluating 9,629 patients. For EGFRI, OS (eight trials, 3,499 pts) was improved in combination with iri, HR 0.87 (95% CI 0.78-0.97) but not ox with HR 1.01 (95% CI 0.91-1.13). PFS (n=3473) was also improved with iri with HR 0.74 (95% CI 0.65-0.83) but not ox (HR 0.92, 95% CI 0.83-1.02). Overall response rate (n=3436) OR for iri was 3.09 (95% CI 2.47-3.86) and OR for ox was 1.36 (95% CI 1.12-1.64). The iri-ox interaction p-value was 0.07 for OS, 0.006 for PFS and <0.00001 for ORR. Overall grade 3/4 (all toxicity) OR for iri was 2.53 (95% CI 2.06-3.11) and ox OR 1.89 (95% CI 1.40-2.54). Two trials (n=151) directly compared iri-EGFRI with ox-EGFRI. No significant differences in efficacy were observed. For anti-VEGF therapy (11 studies, 5,290 pts), there was no significant difference in OS, PFS, ORR or toxicity according to chemo regimen used. The choice of FP did not affect efficacy. **Conclusions:** The meta-analysis shows superior efficacy when EGFRI are combined with irinotecan-based chemo regimens compared to oxaliplatin-based regimens. Chemo interaction was not observed with anti-VEGF therapy.

**3553 General Poster Session (Board #16), Sat, 8:00 AM-11:45 AM**

**Pulmonary metastasectomy in colorectal cancer patients with previously resected liver metastasis: Pooled analysis.** *Presenting Author: Samer Salah, Department of Medical Oncology, King Hussein Cancer Center, Amman, Jordan*

**Background:** Data addressing the outcomes and patterns of recurrence following pulmonary metastasectomty (PM) in patients with colorectal cancer (CRC) and previously resected liver metastasis are very limited. **Methods:** We searched the PubMed for studies assessing PM in CRC and gathered individual data for patients who had PM and a previous curative liver resection. The influence of potential factors on overall survival (OS) was analyzed through univariate and multivariate analysis. Furthermore, the influence of patterns of recurrence following PM on post-recurrence survival was investigated. **Results:** Between 1983 and 2009, 146 patients from five studies underwent PM and had previous liver resection. The median interval from resection of liver metastasis until detection of lung metastasis and the median follow up from PM were 23 and 48 months respectively. Sixty seven (46%) underwent intra-operative thoracic lymph node (LN) sampling; nine of them (13%) had pathologically confirmed LN involvement, and 48 (33%) received perioperative chemotherapy. Five-year OS and recurrence free survival following PM were 54% and 29% respectively. Factors predicting inferior OS in univariate analysis included thoracic LN involvement and size of largest lung nodule ≥ two cm. In multivariate analysis, thoracic LN involvement was the only independent factor (HR 4.86, 95% CI: 1.56-15.14, $P = 0.006$). Ninety-three patients had recurrence following PM. Data on dates and pattern of recurrence was available for 74 patients, the five-year post- recurrence survival for patients with lung only recurrence treated with repeated PM (n=21), lung only recurrence treated with chemotherapy (n=20), liver only recurrence (n=10), and all other patterns of recurrence (n=23) were 60%, 0%, 18%, and 5% respectively, $p < 0.0001$. **Conclusions:** PM offers a chance for long term survival in selected patients with CRC and previously resected liver metastasis. Thoracic LN involvement predicted poor prognosis; therefore, significant efforts should be undertaken for adequate staging of the mediastinum prior to PM. Also, adequate intra-operative LN sampling allows proper prognostic stratification and enrollment in novel adjuvant therapy trials.

**3554 General Poster Session (Board #17), Sat, 8:00 AM-11:45 AM**

**Neoadjuvant mFOLFOX6 for stage II/III rectal cancer patients with a T3/T4 tumor.** *Presenting Author: Junichi Koike, Gastroenterological Surgery, Omori Medical Center, Toho University School of Medicine, Tokyo, Japan*

**Background:** The efficacy and safety of neoadjuvant modified FOLFOX6 (mFOLFOX6) therapy in stage II/III rectal cancer patients with a T3/T4 tumor is yet to be determined. **Methods:** Stage II/III (Ra/Rb) rectal cancer patients aged 20–80 years of age with a T3/T4 tumor were enrolled in this phase II multicenter study. Accrual of patient data began in August 2011 with a planned patient population set at 50. All patients had an Eastern Cooperative Oncology Group performance status of 0–1. The primary endpoint was preoperative response rate, and the secondary endpoints were histological effect, R0 resection rate, pCR rate, down-staging rate, neoadjuvant therapy completion rate, occurrence of adverse events, the incidence of postoperative complications, and three-year disease-free survival. Computed tomography was performed after four courses of neoadjuvant mFOLFOX6 therapy. Patients with progression disease (PD) underwent resection of the primary lesion, while those without PD received another two courses of treatment. Treatment was discontinued when resection was not possible in patients with PD. **Results:** Registered patients in July 2013 totaled 53 (male n=41, female n=12) with a mean age of 60 (38–77). The number of patients with T3 and T4 tumors was 42 and 10, and patients at stages II and III were 10 and 42, respectively. One patient withdrew due to consent retraction. Median relative dose intensity of mFOLFOX6 therapy was 93.2% for L-OHP, 5-FU, and l-LV. Treatment completion was achieved in 96.2% and 84.6% for four and six courses, respectively, and withdrawal was due to patient's discretion, not adverse events. Surgery was performed in 78.8% of patients. Serious (grade ≥3) adverse events included neutropenia (n=5), leukopenia (n=1), thrombocytopenia (n=1), febrile neutropenia (n=1), nausea (n=1), vomiting (n=1), and peripheral neuropathy (n=2). The rates of R0 resection, pCR, and sphincter preservation, were 91.0%, 10.3%, and 82.9%, respectively. Postoperative complications included suture failure (n=3), wound infection (n=2), pneumonia (n=1), and intestinal obstruction (n=1). **Conclusions:** Neoadjuvant therapy using mFOLFOX6 is a safe and efficacious treatment option for rectal cancer, especially locally advanced disease. Clinical trial information: UMIN000006583.

**3555 General Poster Session (Board #18), Sat, 8:00 AM-11:45 AM**

**CA 11-19 as a tumor marker for the diagnosis of colorectal cancer.** *Presenting Author: Bergein F Overholt, Gastrointestinal Associates, Knoxville, TN*

**Background:** Colorectal cancer remains the second most frequent cause of cancer deaths in both sexes in the United States. Both fecal and blood tests using tumor related antigens are increasingly being used to monitor treatments and in some cases aid in diagnosing colorectal cancers. However, higher sensitivity and specificity are needed before an acceptable tumor antigen blood test for colon cancer is clinically useful. **Methods:** Using double monoclonal ELISA analysis, a new colon cancer antigen, CA 11-19, (100 kDa glycoprotein) was measured in 670 colonoscopy confirmed patients including normal, benign GI diseases, polyps and colon cancer in a blinded IRB approved study. **Results:** Using a cutoff of below 6.4 units/ml as normal, CA 11-19 was positive (>6.4) in 132 of 139 of colorectal cancer cases. 100% of 63 cases of Stage I and II were positive. Sensitivity of CA 11-19 for diagnosis of colorectal cancer was 95%. Negative results were found in 94% of normals (175/187) and 80% of benign GI diseases (161/202). The specificity for the assay was 80.2% for all benign groups combined (426 negative assays for 531 benign patients). **Conclusions:** Ca 11-19 is a serologic tumor marker for colorectal cancer with a demonstrated sensitivity of 95% and a specificity of 80%. Diagnostically, a positive assay result increases the odds of finding colorectal cancer by a factor of five. The test appears to be highly sensitive for detection of early stage colorectal cancer. Additional prospective studies are needed to validate the use of CA 11-19 as an aid in the diagnosis of colorectal cancer.

**3556 General Poster Session (Board #19), Sat, 8:00 AM-11:45 AM**

**Patterns of progression, treatment of progressive disease, and postprogression survival in the new EPOC study.** *Presenting Author: Sian Alexandra Pugh, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom*

**Background:** The New EPOC study randomised patients with operable or borderline operable colorectal liver metastasis to perioperative chemotherapy with or without cetuximab. Recruitment to the trial was halted in November 2012 because the progression free survival was significantly worse in the arm receiving cetuximab (20·5 vs. 14·1 months, HR 1·48 95%CI 1·04-2·12 p=0·03). Given this unexpected trial result acquisition of progression data was undertaken. **Methods:** There were 257 *KRAS* wild-type patients who were randomised to chemotherapy alone (arm A) or chemotherapy with cetuximab (arm B). Data regarding sites and treatment of progressive disease were obtained using case report forms for the 110 (arm A n=48, arm B n=62) *KRAS* wild-type patients with progressive disease at the cut-off date for analysis of November 2012. Post-progression survival (PPS) was calculated using the Kaplan-Meier method. **Results:** The liver was the most frequent site of progression (arm A 46% (22/48); arm B 53% (33/62)) with liver only disease accounting for the majority of those progression events (arm A 91% 20/22; arm B 79% 26/33). Overall there was no difference between the arms in respect of the distribution of progressive disease pre- or postoperatively. Further treatment for progressive disease is known for 64 patients (arm A 26/48; arm B 38/62) of whom 56 received further chemotherapy, most frequently irinotecan based. Fourteen patients received cetuximab as a further line agent (arm A n=9, arm B n=5). There was a trend towards an inferior PPS in arm B (median PPS 18·7 months arm A; 15·9 months arm B, HR 1·69 p=0·131). Of the 25 patients in whom post-progression surgery with curative intent was undertaken, 24 were still alive at a median follow-up of 11·6 months. **Conclusions:** Both the distribution of progressive disease and further treatment are as expected for such a cohort and are evenly balanced between the arms. Despite this there is a trend towards an inferior survival post progression in those receiving cetuximab for whom revisional surgery is not appropriate. Clinical trial information: 22944367.

**3557^ General Poster Session (Board #20), Sat, 8:00 AM-11:45 AM**

**Survival outcomes in the PRIME study for patients (pts) with *RAS/BRAF* wild-type (WT) metastatic colorectal cancer (mCRC), by baseline Eastern Cooperative Oncology Group (ECOG) performance status (PS).** *Presenting Author: Marc Peeters, Antwerp University Hospital and University of Antwerp, Edegem, Belgium*

**Background:** In PRIME, panitumumab (pmab) + FOLFOX4 improved overall survival (OS) for *RAS* WT mCRC pts vs FOLFOX4 alone (Douillard et al 2013). Prespecified subgroup analysis identified only ECOG PS ≥2 as a negative predictive factor for pmab efficacy; *BRAF* mutant (MT) status was a strong negative prognostic factor. Here, we further evaluate the benefit:risk profile of pmab in pts with ECOG PS 0/1 *RAS/BRAF*WT mCRC. **Methods:** PRIME was a randomized (1:1) phase 3 1st-line mCRC study comparing pmab 6.0 mg/kg Q2W + FOLFOX4 vs FOLFOX4. This exploratory analysis, conducted when ≥80% of pts had an OS event, included pts with *RAS/BRAF* WT (*KRAS/NRAS* exons 2-4 [incl. codon 59] and *BRAF* exon 15 assessed) mCRC. Median progression-free (PFS) and OS were estimated by baseline ECOG PS (stratification factor). Data were summarised descriptively and tested for significance using Cox's proportional hazards models. **Results:** Of 439 pts with *RAS/BRAF* WT mCRC, 438 had baseline ECOG PS recorded. Pts were well balanced with respect to sex, age and metastatic sites. Median PFS and OS were longer in ECOG PS 0/1 *RAS/BRAF* WT mCRC pts receiving pmab + FOLFOX4 vs FOLFOX4 (Table). Corresponding values were numerically shorter in ECOG PS 2 pts receiving pmab. Among *RAS* WT/*BRAF*MT pts, 49 were ECOG 0/1 at baseline (pmab + FOLFOX4 vs FOLFOX4 median PFS 6.7 vs 5.4 months, p=NS and OS 11.1 vs 9.1 months; p=NS); only 4 pts were ECOG 2. **Conclusions:** This post hoc analysis suggests that the PFS and OS benefits observed in pts with *RAS/BRAF* WT mCRC receiving pmab + FOLFOX4 are confined to those with a baseline ECOG PS of 0/1. Clinical trial information: NCT00364013.

**3558^ General Poster Session (Board #21), Sat, 8:00 AM-11:45 AM**

**Second-line therapies in patients with *KRAS* wild-type metastatic colorectal cancer (mCRC) after first-line therapy with FOLFIRI in combination with cetuximab or bevacizumab in the AIO KRK0306 (FIRE 3) trial.** *Presenting Author: Dominik Paul Modest, Department of Medical Oncology, Klinikum Grosshadern, University of Munich, Munich, Germany*

**Background:** AIO KRK0306 (FIRE 3) trial compared first-line therapy with FOLFIRI plus either cetuximab (arm A) or bevacizumab (arm B) in 592 patients with *KRAS* exon 2 wild-type metastatic colorectal cancer (mCRC). We investigated choice and duration of second-line therapies, as well as overall survival (OS) and OS from beginning of second-line therapy according to second-line treatment. **Methods:** The protocol recommended second-line therapy with FOLFOX plus bevacizumab vs. irinotecan plus cetuximab in arm A vs. B, but physician were free to choose any regimen. second-line treatment was defined as any new anticancer drug for mCRC following first-line therapy. Duration of second-line therapy was calculated as time from first to last application of second-line treatment. **Results:** There were 260/297 patients in arm A and 250/295 patients in arm B who were alive after first-line therapy. Of those, 78.5% of patients arm A and 76.4% in arm B received second-line therapy so far. First-line progression free survival (PFS) according to second-line antibody use was associated with 9.2 (anti-vascular endothelial growth factor [VEGF]), comparing to 9.7 (anti-epidermal growth factor receptor [EGFR]) and 11.3 months (no mAB); p=0.001. Correspondingly, OS was 25.2 (anti-VEGF) vs. 23.7 (anti-EGFR) vs. 30.8 months (no mAB), p=0.02. First-line PFS according to seconnd-line oxaliplatin (Ox) use was associated with 9.9 (Ox), comparing to 9.9 months (no Ox); p=0.56. OS according to Ox-use was 27.1 (ox) vs. 29.1 months (no Ox); p=0.10. 2nd-line therapy was administered for a median of 17.2 weeks in arm A and 14.0 weeks in arm b (p=0.08). Second-line regimens with antibody-crossover were administered for a median of 23.9 weeks in arm A and 16.1 weeks arm B (p=0.06). Updated results might be presented at the annual meeting. **Conclusions:** This retrospective analysis indicates that second-line application of antibodies was favoured in patients with shorter first-line PFS, suggesting that preplanned second-line therapy may not reflect therapeutic reality. Correspondingly, second-line treatment without antibodies compared to antibody-based regimens was associated with longer OS. A trend towards longer second-line therapy was observed in favour of patients receiving cetuximab as first-line therapy. Clinical trial information: NCT00433927.

**3559 General Poster Session (Board #22), Sat, 8:00 AM-11:45 AM**

**Cell-free DNA levels in colorectal cancer patients treated with irinotecan, healthy controls, and non-cancer patients with comorbidity.** *Presenting Author: Karen-Lise Garm Spindler, Department of Oncology, Aarhus University Hospital, Aarhus, Denmark*

**Background:** The present study investigated the clinical value of total cell free DNA (cfDNA) measurement in metastatic colorectal cancer patients treated with second-line irinotecan monotherapy. **Methods:** Patient treated with second-line irinotecan for metastatic colorectal cancer (n=100), a cohort of healthy controls with and without co-morbidity (n=70 and 100, respectively) were included. CfDNA was quantified by an in-house developed qPCR (*Spindler* et al 2012) from plasma samples drawn prior to the first cycle of chemotherapy and at time of progression. **Results:** CfDNA levels were significantly higher in cancer patients compared to controls, with a clear capability for discriminating between the groups (AUC 0.82, p<0.0001). Patients with high levels had a shorter outcome compared to those with lover levels. The cohort independent upper normal limit (UNL) divided patients into high and low risk groups. The PFS was 2.1 months (95% CI 2.0-3.4), and 6.5 (95% CI 4.2-7.2) months, (HR 2.53 (95% CI 1.57-4.06), p=<0.0001) and OS 7.4 months (95% CI 4.3-8.7) and 13.8 months (95% CI 11.9-18.9), (HR 2.52 (95% CI 1.54-4.13), p<0.0001), respectively**.** Cox regression multivariate analysis showed a PFS Hazard Ratio of 1.4 (95% CI 1.1-1.7) for each increase in cfDNA quartile, p=0.03, and 1.6 (1.3-2.0) for OS, p<0.0001, respectively. CfDNA levels measured at time of progression showed similar consistent prognostic value. **Conclusions:** CfDNA measurement contains important clinical information and could become a useful tool for prediction of outcome from chemotherapy in mCRC.

**3560 General Poster Session (Board #23), Sat, 8:00 AM-11:45 AM**

**Phase II trial of panitumumab plus FOLFOX4 or FOLFIRI in subjects with KRAS wild-type colorectal cancer and liver-limited disease: The PLANET study.** *Presenting Author: Albert Abad, University Hospital Germans Trias i Pujol-ICO, Barcelona, Spain*

**Background:** Downsizing with chemotherapy (CT) unresectable liver-limited disease (LLD) can permit resection and prolonged survival in patients (pts) with colorectal cancer (CRC). We assessed the value of adding panitumumab (P) to standard CT in this setting. **Methods:** This was a phase II, open-label, randomized, multicenter study which included pts≥18 years with wild-type (WT) *KRAS* exon 2 metastatic CRC and LLD fulfilling one of the following criteria: ≥4 metastases; at least 1 metastasis>10 cm in diameter; or technically not resectable. Pts were randomized 1:1 to receive P-FOLFOX4 or P-FOLFIRI every two weeks. The primary endpoint was the objective response rate. **Results:** There were77 pts analyzed (38 received P-FOLFOX4 and 39 P-FOLFIRI). Not confirmed response was noted in 70.1% pts (73.7% with P-FOLFOX4 and 66.7% with P-FOLFIRI). After a median of 8 P infusions in both groups, 51.9% underwent surgical resection of liver metastases (44.7% and 59.0%, respectively). The resection rate (R0+R1) was 77.5% (76.5% and 78.3%). Median progression-free survival was 12.5 months with P-FOLFOX4 and 12.6 months with P-FOLFIRI (p=0.943). Preliminary median overall survival was 32.5 and 42.4 months. Median pre-surgery relative dose-intensity (RDI) for panitumumab was 79.8% with P-FOLFOX4 and 87.5% with P-FOLFIRI, and RDI for CT was 83.0% and 88.7%. Peri-operative safety was similar between groups (22.2% and 18.5% of pts with any adverse event). Neutropenia grade 3/4 (P-FOLFOX4 39.5% vs P-FOLFIRI 10.3%; p=0.0029) and neuropathy (P-FOLFOX4 13.2% vs P-FOLFIRI 0%;p=0.025), were the only statistically significant differences in grade 3/4 adverse events. It was possible to determine the *RAS* status (exon 2,3,4 of *KRAS*/*NRAS*) in 83.1% of the pts. In the subset of pts with *RAS* WT the response rate increases to 75.5% pts (77.8% with P-FOLFOX4 and 73.1% with P-FOLFIRI). **Conclusions:** In this selected population with WT *KRAS* CRC and LLD, panitumumab plus CT offers the possibility of rapid tumour shrinkage and potentially curative hepatic resection. Similar efficacy and safety results were obtained with either P-FOLFOX4 or P-FOLFIRI schema. Clinical trial information: NCT00885885.

**3561 General Poster Session (Board #24), Sat, 8:00 AM-11:45 AM**

**Impact of delay in adjuvant oxaliplatin-based chemotherapy for stage III colon cancer.** *Presenting Author: Renata D'Alpino Peixoto, BC Cancer Agency, Vancouver, BC, Canada*

**Background:** Less than 8 weeks (w) has been recommended as the optimal time to initiate adjuvant chemotherapy (AC) based upon two meta-analyses suggesting worse OS with delayed AC. However, neither included studies with oxaliplatin-based chemotherapy and the impact of its delay remains uncertain. **Methods:** Records of pts who initiated AC with either 5-FU or capecitabine plus oxaliplatin for stage III colon cancer between 2006 and 2011 at the BC Cancer Agency were reviewed. Cox proportional hazards models were used to analyze the impact of timing of AC on RFS. Pts were categorized into initiation of AC within 8 w (G1) and after 8 w (G2) **Results:** 635 pts (52% male) with a median age of 62 yrs (range 26–80) were included. Median lymph nodes examined and involved were 15 and 3, respectively. Median time from surgery to initiation of AC was 8.3 w (SD 18.58). At a median follow-up of 57.9 months, 176 pts (27.7%) have recurred and 118 (18.6%) have died. 5y-RFS was 70.9% (95% CI 65.2-76.5) for G1 and 72.1% (95%CI 67.2-77) for G2. On multivariate analysis, T stage, N stage, obstruction and perforation were identified as poor prognostic factors for RFS. Timing for AC did not have prognostic significance (HR 1.03, p = 0.83). **Conclusions:** In our population-based study, time to oxaliplatin-based AC following stage III colon resection did not impact on RFS. Contrary to most of the existing data which is primarily based on 5FU-based AC, delay of oxaliplatin-based therapy beyond 8 w is not associated with inferior outcomes.

**Prognostic factors for RFS – univariate and multivariate analysis.**

**3562 General Poster Session (Board #25), Sat, 8:00 AM-11:45 AM**

**Comparison of ColoPrint risk classification with clinical risk in the prospective PARSC trial.** *Presenting Author: Ramon Salazar, Early Clinical Research Unit, Institut Català d'Oncologia, L´Hospitalet-Barcelona, Spain*

**Background:** The 18-gene expression profile, ColoPrint, has been developed and validated for identifying risk of recurrence in patients with early stage colon cancer (CC). In a pooled stage 2 validation study ColoPrint identified 63% of patients as Low Risk with a 3-yr recurrence free survival (RFS) of 93% while High Risk patients had a 3-yr RFS of 82% with a HR of 2.7 (p=0.001). PARSC is a prospective study for the assessment of recurrence risk in stage II CC patients using ColoPrint. ColoPrint classification is compared to NCCN risk classification. **Methods:** The study enrolled 501 patients with histologically proven stage 2 CC from 31 institutes in Europe, USA, and Asia between October 2008 and September 2013. Synchronous tumors were excluded. ColoPrint results were not disclosed to the physician and patient. Treatment was at the discretion of the physician, adhering to NCCN approved regimens or a recognized alternative. A McNemars test is performed to compare ColoPrint with NCCN risk classification. A p- value ≤ 0.05 indicates the two tests differ significantly. **Results:** ColoPrint classified 352 (70%) patients as Low Risk and 149 (30%) as High Risk. 97 patients (19%) received adjuvant chemotherapy. In the ColoPrint Low Risk group, 66 (19%) patients received adjuvant chemotherapy and 31 (21%) of ColoPrint High Risk patients received chemotherapy. According to NCCN high risk factors (T4, high grade (exclusive of MSI-H), lymphovascular/perineural invasion, perforation/obstruction, <12 nodes examined, positive margins) 274 (55%) patients were NCCN Low Risk and 227 were NCCN High Risk. 82 (30%) of the NCCN Low Risk patients are ColoPrint High Risk. 160 (70%) of the NCCN High Risk patients are ColoPrint Low Risk. MSI-status was assessed in 96 (18%) patients of which 33 were MSI high and 63 were MSS. All MSI high were classified as ColoPrint Low Risk. **Conclusions:** The PARSC study is the first prospective study to compare genomic and clinical risk assessment and we observed marked differences between NCCN risk classification and ColoPrint. The clinical validity of these methods will be based on the outcomes at 3 and 5 years. Clinical trial information: NCT00903565.

| P<0.0001 | ColoPrint low risk | ColoPrint high risk | Total |
|---|---|---|---|
| NCCN low risk | 192 | 82 | 274 |
| NCCN high risk | 160 | 67 | 227 |
| Total | 352 | 149 | 501 |

**3563 General Poster Session (Board #26), Sat, 8:00 AM-11:45 AM**

**Association outcome with genes involved in immune response and checkpoints in patients with resected colorectal liver metastases.** *Presenting Author: Stefan Stremitzer, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** In patients with colorectal liver metastases (CLM), liver resection offers the chance of cure and long-term survival. The liver is a highly immunogenic organ harboring approximately 80% of the body's tissue macrophages. Emerging data demonstrate a critical role of an immune response for cancer treatment. In this study we investigated genetic variations within genes involved in immune response and checkpoints and their association with recurrence and outcome in patients with CLM. **Methods:** Genomic DNA was extracted from formalin-fixed paraffin embedded resected bevacizumab-pretreated CLM from 149 patients [median age 62 years (range 30-80), 58.4% male, median follow-up 3.9 years (range 0.02-7.7)]. Single nucleotide polymorphisms (SNP) in nine genes associated with immune surveillance and checkpoints (CCL2, CCR2, LAG3, CD73, PDCD1, PDL1, IDO1, CTLA4, CD24) were analyzed by direct Sanger DNA sequencing and evaluated for association with response, recurrence-free survival (RFS) and overall survival (OS). **Results:** In univariate analysis, rs3739319 (IDO1) and rs8734 (CD24) showed a significant difference in three-year OS rate [(G/G or G/A 75%, A/A 49%; HR (95% CI) 2.52 (1.33, 4.80), P=0.007) and (G/G 63%, G/A or A/A 76%; HR (95% CI) 0.53 (0.28, 0.97), P=0.042), respectively]. In multivariate analysis adjusted for age, number of metastases, size of metastases and time since diagnosis of colorectal cancer, rs3739319 remained significant (HR (95% CI) 2.04 (1.03, 4.03), P=0.040). Recursive partitioning analyses revealed that rs8734 and rs3739319 were the dominant SNPs predicting histological response and OS, respectively. **Conclusions:** Our data suggest that gene variations within genes involved in immune response and checkpoints are associated with outcome in patients with resected CLM. These data might lead to improved treatment strategies modulating anti-tumor immune response by targeting novel immune checkpoints.

**3564 General Poster Session (Board #27), Sat, 8:00 AM-11:45 AM**

**Influence of genetic variations of the angiopoietin and pericyte pathways in resected colorectal liver metastases.** *Presenting Author: Stefan Stremitzer, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** Liver resection in patients with colorectal liver metastases (CLM) offers the chance of cure and long-term survival. Angiogenesis is essential for tumor growth and progression. Genes involved in angiopoietin and pericyte pathways may be escape mechanisms for anti-vascular endothelial growth factor (VEGF) therapy. Therefore, we investigated whether genes of the angiopoietin and pericyte pathways have an influence on recurrence and outcome in patients with CLM treated with bevacizumab based chemotherapy. **Methods:** Genomic DNA was extracted from resected bevacizumab-pretreated CLM (FFPE) from 149 patients [median age 62 years (range 30-80), 58.4% male, median follow-up 3.9 years (range 0.02-7.7)]. Single nucleotide polymorphisms (SNP) in nine genes (ANGPT1, ANGPT2, TIE2, PDGF-B, PDGFR-B, IGF-1, TGF-B1, RALBP1, RGS5) were analyzed by direct Sanger DNA sequencing and evaluated for association with response, recurrence-free survival (RFS) and overall survival (OS). **Results:** In univariate analysis, rs329007 (RALBP1) showed a significant difference in RFS (A/A 14.0 months, A/G or G/G 9.2 months; HR 1.60, P=0.024) and rs1800818 (PDGF-B) in three-year OS rate (A/A 78%, A/G 69%, G/G 53%; HR 1.37 and 2.12, P=0.048). In multivariate analysis adjusted for age, number of metastases, size of metastases and time since diagnosis of colorectal cancer, rs329007 remained significant (HR 1.99, P=0.002). With respect to radiological response, rs1800818 and rs329007 showed a significant difference [(G/G 71%, A/G or A/A 86%, P=0.042) and (A/A 78%, A/G or G/G 94%, P=0.018), respectively]. With respect to histological response, rs329007 showed significant different rates between the groups (A/A 36% major histological response (MjHR), 34% partial histological response (PHR), 30% no histological response (NHR); A/G or G/G 46% MjHR, 13% PHR, 41% NHR, P=0.029). Recursive partitioning analyses revealed that rs329007 and rs1800818 were the dominant SNPs predicting histological response and OS, respectively. **Conclusions:** Our data suggest that genetic variations in genes involved in the angiopoietin and pericyte pathways may be predictive and/or prognostic biomarkers in patients with resected CLM treated with bevacizumab based chemotherapy.

**3565 General Poster Session (Board #28), Sat, 8:00 AM-11:45 AM**

**Influence of genetic variants of genes potentially associated with brain metastases on overall survival in 70 colorectal cancer patients.** *Presenting Author: Matthias Preusser, Department of Medicine I and Comprehensive Cancer Center CNS Tumours Unit, Medical University of Vienna, Vienna, Austria*

**Background:** Brain metastases (BM) in colorectal cancer (CRC) are rare, developing in only 0.3-9% of the patients, and considered a late-stage manifestation of the disease. The aim of this study was to investigate whether genetic variants of genes from integrin, invasion- and adhesion-mediating, angiogenic and tumor suppressing pathways, involved in overcoming the blood-brain barrier are associated with outcome. **Methods:** Genomic DNA was extracted from formalin-fixed paraffin embedded resected BM from 70 patients with histologically proven CRC. Single nucleotide polymorphisms (SNP) in seven genes (*CXCR4*, *MMP9*, *ST6GALNAC5*, *ITGAV*, *ITGB1*, *ITGB3*, *KLF4*) were analyzed by direct Sanger DNA sequencing and evaluated for association with overall survival (OS) from resection of BM. Only SNPs with an allele frequency of ≥10% were analyzed. **Results:** In univariate analysis, rs17577 (MMP9) and rs4642 (ITGB3) showed a significant difference in OS [(G/G 7.4 months, G/A 5.1 months; HR (95% CI) 1.83 (0.95-3.53), P=0.044) and (A/A or A/G 8.0 months, G/G 4.3 months; HR (95% CI) 2.31 (1.08-4.93), P=0.014), respectively]. In multivariate analysis adjusted for baseline characteristics (primary tumor site, age at diagnosis of CRC, BM location, Karnofsky performance status), rs2236599 (KLF4), rs10171481 (ITGAV), rs1883778 (ST6GALNAC5), and rs2680880 (CXCR4) were significant in OS [(G/G 7.4 months, G/A or A/A 4.8 months; HR (95% CI) 2.12 (1.01-4.45), P=0.048), (A/A or A/G 5.3 months, G/G 15.5 months; HR (95% CI) 0.39 (0.18-0.85), P=0.018), (G/G 4.6 months, G/A or A/A 9.4 months; HR (95% CI) 0.53 (0.30-0.93), P=0.028) and (A/A 6.4 months, A/T 9.3 months, T/T 4.6 months; HR (95% CI) 0.45 (0.22-0.89) and 1.54 (0.75-3.15), P=0.005), respectively]. Recursive partitioning analyses revealed that rs4642 is the dominant SNP predicting OS. **Conclusions:** This study suggests for the first time a prognostic effect of the genetic variations within genes involved in the blood-brain barrier breach. Further analyses are needed to confirm these findings.

**3566 General Poster Session (Board #29), Sat, 8:00 AM-11:45 AM**

**Analysis of progression-free survival in the new EPOC study in an "all wild-type" population.** *Presenting Author: John A. Bridgewater, Department of Medical Oncology, University College London Cancer Institute, London, United Kingdom*

**Background:** The phase 3 new EPOC study, randomised *KRAS* wild-type (WT) patients with resectable or suboptimally resectable colorectal cancer liver metastases (CRLM) 1:1 to receive chemotherapy with or without cetuximab before and after liver resection. The primary end point was progression free survival (PFS). The trial demonstrated a detriment in PFS following the addition of cetuximab to chemotherapy from 20.5 to 14.1 months. *KRAS* was determined using pyrosequencing in codons 12, 13, and 61 (HR 1·48 95% CI 1·04-2·12 p=0.03). Subsequently, benefit from epidermal growth factor inhibition was shown to be improved following restriction to an all *RAS* WT population in patients with advanced disease (Douillard NEJM 2013). We describe a further analysis of PFS in an all WT new EPOC population. **Methods:** Samples of tumor from the primary colorectal and liver resections were obtained. Patients were further analysed using MiSeq for *KRAS* (codon 12, 13, 61, 117 and 146), *BRAF* (V600E), *NRAS* (12, 13, 61, 117 and 146), *PIK3CA* (547 and 1047). Those without any mutation were classed as "all WT". Additional qPCR was performed for MET, AREG, EREG, EGFR, HER2-4, PTEN and NT5E. Survival analyses were completed using the Kaplan-Meier method and the log-rank test. **Results:** To date 106 samples of primary tumor and 103 samples of CRLM have been analysed corresponding to 155 of the 236 *KRAS* WT patients. Further mutations were found in samples from 22 patients in the *KRAS* WT group (16 *KRAS*, 12 *NRAS*, 3 *PIK3CA,* and 6 *BRAF* mutations). Paired samples of primary tumour and CRLM were analysed for 47 patients. Three mutations were matched between the primary and corresponding CRLM, with the remaining 13 mutations (six in the primary tumor, seven in CRLM) not found in the paired sample. Analysis of PFS in the all WT population of patients previously included in the primary analysis (chemo alone arm n=48, chemo plus cetuximab arm n=54) demonstrated a similar trend in detriment in median PFS of 20.5 months to 16.4 months respectively (HR 1.34 95% CI (0.76-2.36) p = 0.32). **Conclusions:** The addition of cetuximab to chemotherapy and surgery for operable CRLM in *KRAS* wild-type patients results in an inferior PFS. More stringent selection of an all WT cohort does not significantly alter the detriment observed in the *KRAS* WT population. Clinical trial information: 22944367.

**3567 General Poster Session (Board #30), Sat, 8:00 AM-11:45 AM**

**Randomized controlled trials (RCTs) examining continuous (CS) versus intermittent strategies (IS) of delivering systemic treatment (Tx) for untreated metastatic colorectal cancer (mCRC): An updated meta-analysis from the Cancer Care Ontario program in evidence-based care.** *Presenting Author: Scott R. Berry, Sunnybrook Odette Cancer Centre, University of Toronto, Toronto, ON, Canada*

**Background:** There is varied impact on efficacy demonstrated in individual RCTs of CS vs IS of delivering systemic Tx for mCRC. Our meta-analysis of the available RCTs was updated to include results of the CAIRO3 trial. **Methods:** RCTs that compared a CS versus IS of delivering systemic Tx were identified by a systematic search and review. The results of identified trials were clinically homogeneous (Table) so the data were pooled using Review Manager software (RevMan 5.2). Overall survival (OS) hazard ratios (HRs) were extracted from the most recently reported trial results. A random effects model was used for all pooling. **Results:** 11 RCTs were identified (n= 4,809). For the 8 trials with available OS HRs, the Tx patients received after induction was: none (5 trials, n=3,036), fluoropyrimidine (1 trial, n=620), biologic (2 trials, n=852). Results of the meta-analysis are summarized in the Table (HR>1 favors CS). Sensitivity analyses demonstrated results were generally robust across induction and maintenance regimens. One sensitivity analysis of the 3 trials (CAIRO3, OPTIMOX2, COIN, n=2,389) with combination Tx induction and no maintenance Tx until progression revealed a statistically, but non-clinically significant benefit for continuous treatment (HR=1.10, 95% CI 1.00-1.20, p=0.05). QOL (data from 3 trials) was either the same in both arms (2 trials with no maintenance Tx, n=911) or improved in the IS arm (1 trial with no maintenance Tx, n=1,630). **Conclusions:** IS of delivering systemic Tx for mCRC do not result in a clinically significant reduction in OS compared to a CS of delivery whether or not maintenance therapy is included. QOL is the same or better with an IS.

**3568 General Poster Session (Board #31), Sat, 8:00 AM-11:45 AM**

**Updated analysis of *KRAS/NRAS* and *BRAF* mutations in study 20050181 of panitumumab (pmab) plus FOLFIRI for second-line treatment (tx) of metastatic colorectal cancer (mCRC).** *Presenting Author: Marc Peeters, Antwerp University Hospital and University of Antwerp, Edegem, Belgium*

**Background:** Previously, extended *RAS* analysis from this study showed a trend toward improvements in HR on OS and PFS with pmab + FOLFIRI vs FOLFIRI in WT *RAS* group vs WT *KRAS* exon 2 group. Here we report updated *RAS* data and new analysis by *BRAF* status. **Methods:** The primary objective was to assess the tx effect of pmab + FOLFIRI vs FOLFIRI on OS and PFS based on *RAS/BRAF* mutation status in the primary analysis population. Bidirectional Sanger sequencing was used to detect mutations in *KRAS* exons 3, 4 and *NRAS* exons 2, 3, 4, and *BRAF* exon 15 in patients (pts) with known WT *KRAS* exon 2 mCRC. **Results:** Overall *RAS/BRAF* ascertainment rate was 85% (n=1014/1186). 18% of WT *KRAS* exon 2 pts harbored additional *RAS* mutations (n=107/597). The incidence of *BRAF* mutations was 8.3% (45/541). Efficacy is shown (table). Tx HR for pts with WT *RAS* was 0.81 (95% CI: 0.63, 1.03; *P*=0.08) for OS and 0.70 (95% CI: 0.54, 0.91; *P*=0.007) for PFS. **Conclusions:** Improvements continued to be observed in the tx effect of pmab + FOLFIRI vs FOLFIRI on OS and PFS in WT *RAS* group vs WT *KRAS* exon 2 group in this update. Pts with MT *RAS* mCRC are unlikely to benefit by the addition of pmab to FOLFIRI, similar to pts with MT *KRAS* exon 2 mCRC. *BRAF* mutations appear to be associated with reduced OS among pts without *RAS* mutations regardless of tx arm. These findings support *RAS* testing to determine potentially appropriate pts with mCRC for pmab tx. Clinical trial information: NCT00339183.

**Multivariate prospective pharmacogenetic analysis in patients with resectable metastatic colorectal cancer (mCRC) receiving FOLFOX chemotherapy.** *Presenting Author: Marie-Christine Etienne-Grimaldi, Centre Antoine Lacassagne, Nice, France*

**Background**: To prospectively test the predictive value of gene polymorphisms related to fluorouracil (FU) and oxaliplatin (Oxa) pharmacodynamics in mCRC patients receiving FOLFOX regimens. **Methods:** 205 mCRC patients out of 284 included in the MIROX trial (GERCOR group) were enrolled (67 women, 138 men; mean age 60). All received a FOLFOX regimen (FOLFOX4 for 104 patients, FOLFOX7 for 101 patients). Maximum toxicity (NCI-CTCAE) for each toxic pattern along with best response (RECIST criteria) were recorded. Polymorphisms of genes relevant for FU, thymidylate synthase (*TYMS*, 5'UTR repeats and 3'UTR deletion), dihydropyrimidine dehydrogenase (*DPYD*, IVS14+1 G>A), 5-10methylenetetrahydrofolate reductase (*MTHFR*, 677C>T and 1298A>C), and for Oxa, glutathione S-transferase pi (*GSTP1*, 105Ile>Val), xeroderma pigmentosum (*ERCC2*, 751Lys>Gln), were determined (blood). **Results:** 62% of patients presented at least a grade 3-4 (G3-4) toxicity (29.8% neutropenia, 22% digestive toxicity (nausea/vomiting/diarrhea/mucositis)). Global toxicity, hematotoxicity and vomiting were significantly more frequent in women. Patients homozygous for the deficient *MTHFR* 1298C allele (favouring elevated methylenetetrahydrofolate concentrations) had a significantly higher risk of developing G3-4 neutropenia as compared to others (OR 3.1, 95%CI 1.1-8.6, adjusted on gender), and tended to present a greater risk of digestive toxicity (OR 2.4, 95%CI 0.9-7.0). Patients with *ERCC2* 751Lys/Gln or Gln/Gln genotype had a greater global toxicity as compared to others (OR 2.30, 95%CI 1.25-4.24, adjusted on gender), and a greater digestive toxicity (OR 2.35, 95%CI 1.1-5.1, adjusted on gender). Among the 3 patients with *DPYD* mutation (heterozygous) only 2 developed G3-4 toxicity. Response (51.8% CR+PR) was significantly lower in *MTHFR* 677TT patients relative to others (OR 0.16, 95%CI 0.05-0.52). *ERCC2* 751Lys/Gln+Gln/Gln genotype tended to be associated with longer DFS relative to Lys/Lys (RR 0.74, 95%CI 0.51-1.07). **Conclusions:** Present data confirm previous findings showing that toxicity and response to FOLFOX therapy may be driven by *MTHFR* germinal polymorphisms. Clinical trial information: NCT00268398.

**3570 General Poster Session (Board #33), Sat, 8:00 AM-11:45 AM**

**Bichemotherapy versus single-agent therapy with 5FU in elderly patients with metastatic colorectal cancer: A meta-analysis.** *Presenting Author: Gaetan Des Guetz, Oncology Department, Hôpital Avicenne, HUPSSD, UCOG 93 (APHP), Bobigny, France*

**Background**:The clinical benefit of first-line bi-chemotherapy (FOLFOX or FOLFIRI) compared to single therapy (5FU) in metastatic elderly patients (> 70 or > 75 years old) with colo-rectal cancer (CRC) is controversial. Therefore, we undertook a meta-analysis (MA) of all published phase III studies. **Methods:** We performed a PubMed search using key-words: metastatic colo-rectal cancer, phase III studies, oxaliplatin, irinotecan, survival. We also screened ASCO and the European Society for Medical Oncology (ESMO) proceedings. Few studies have been published corresponding to our inclusion criteria. The efficacy outcomes were overall survival (OS) and progression free survival (PFS). Toxicity was also examined when available. Hazard ratios (HRs) with their 95 % confidence interval (CI) were collected from the studies and pooled. By convention, HRs < 1 corresponded to a better outcome. P values < 0.05 were considered statistically significant. A fixed-effect model was used. We used Comprehensive Meta-Analysis software (Biostat, Englewood, NJ, USA). **Results:** This MA included five original studies (Mitry, and Koopman both assessing irinotecan; De Gramont, Seymour and Ducreux assessing oxaliplatin) and an already published MA of four trials comparing FOLFIRI with 5FU (Saltz, Douillard, Köhne and Seymour). Our MA included 1,225 patients (70 % men). For age, we chose a cut-off of 70 years for oxaliplatin and a cut-off of 75 years for irinotecan. The PS score was 0-1 in about 90% of patients except for the studies by Mitry and Seymour FOCUS2 which included 30% of PS2 patients. Overall, bi-therapy, compared to 5FU alone, did not improve OS (HR=1.00; CI: 0.89-1.13) but significantly improved PFS (HR=0.82; CI: 0.72-0.93). When assessed separately, FOLFIRI and FOLFOX significantly improved PFS (HR=0.83; 0.68-1.00, and HR=0.81; 0.68-0.97 respectively). The main grade 3/4 toxicities for FOLFIRI were diarrhea , nausea, vomiting, neutropenia, which occurred significantly more often than with 5FU alone. **Conclusions**: Addition of oxaliplatin or irinotecan to 5FU in metastatic CRC significantly improved PFS in elderly patients more than 70-year old, but was associated with an increased risk of toxicity for irinotecan.

**3571 General Poster Session (Board #34), Sat, 8:00 AM-11:45 AM**

**Biomarker validation study: Genes involved in ubiquitin proteasome system (UPS) dependent EGFR-degradation for prediction of efficacy in metastatic colorectal cancer patients treated with cetuximab.** *Presenting Author: Sebastian Stintzing, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** Epidermal growth factor receptor (EGFR) turnover is a highly regulated process controlling the amount of receptor proteins available for antibody binding. The ubiquitin proteasome system (UPS) is responsible for EGFR degradation. The single nucleotide polymorphism (SNP) rs895374 is located in UbcH7, an E2 ligase conducting neddylation of HECT E3 ligases involved in EGFR degradation. Neddylation activates E3 ligases and switches the balance between degradation and recycling towards degradation. We have previously reported that rs895374 correlates with progression free survival (PFS) in patients (n=108) treated with cetuximab in two phase II studies of further-line treatment. The aim of this study was to validate the predictive value of rs895374 in an independent cohort of cetuximab treated patients with a cetuximab-free chemotherapy arm serving as negative control. **Methods:** Genomic DNA was isolated from tissue samples of 455 patients (median age 64 years, male 64.2%) treated in first-line with either FOLFIRI cetuximab (n=218) or FOLFIRI bevacizumab (n=237) enrolled in the FIRE-3 trial (NCT00433927). The cetuximab arm served as validation for our previous results whereas the bevacizumab arm served as negative control arm to confirm the predictive value of this SNP. **Results:** The minor allele A was associated with shorter PFS in the FOLFIRI + cetuximab validation set, (10.5 months vs. 8.2 months; logrank p=0.005; HR 0.66 (0.47-0.89)). In the FOLFIRI plus bevacizumab arm, no difference in PFS were seen (10.3 months versus 10.5 months, logrank p=0.85; HR 1.03 (0.77-138)). rs895374 was neither associated with tumor response nor with median overall survival. **Conclusions:** The predictive value of rs895374 for cetuximab treatment could be validated and no prognostic value could be established. This is the first report proving that germline polymorphisms in the degradation process predict efficacy of cetuximab in patients with metastatic colorectal cancer. As the process of EGFR recycling is an important mechanism of cetuximab resistance, novel anti-EGFR antibodies like Sym004 may overcome resistance mechanisms by preventing EGFR recycling.

**3572 General Poster Session (Board #35), Sat, 8:00 AM-11:45 AM**

**Molecular profiling of patients (pts) with advanced colorectal cancer (CRC): Princess Margaret Cancer Center experience.** *Presenting Author: Joanne Wing-Yan Chiu, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** In routine clinical practice the prevalence of somatic mutations other than *KRAS* G12/13, *PIK3CA,* and *BRAF* in colorectal cancer (CRC) has not been well described. This study reports molecular profiling of pts with advanced CRC in clinical setting. **Methods:** Patients (pts) with advanced CRC are enrolled in an ongoing institution-wide screening program. Molecular profiling is performed on formalin-fixed and paraffin-embedded (FFPE) archival tissues using a customized Sequenom panel (23 genes, 279 mutations) or the Illumina MiSeq TruSeq Cancer Panel (48 genes, 212 amplicons, ≥500x coverage) in our Clinical Laboratory Improvement Amendments-certified laboratory. *PTEN* is determined by immunohistochemistry (IHC), with H score <1 defined as negative. Statistical analysis was performed with chi-square tests. **Results:** From March 2012 to October 2013, 190 pts were enrolled. At least one mutation was found in 55% (82/153) and 89% (33/37) of pts using Sequenom or MiSeq platforms respectively ($p<0.01$). Of all 190 pts, *KRAS* G12/13 mutation was identified in 35%, and non-G12/13 *KRAS*, *BRAF*, or *NRAS* mutations were present in 5% , 6%, and 4% respectively. Other mutations found included *PIK3CA* (13%, 24/190), *CTNNB1*, *ERBB2*, *FGFR3*, and *EGFR* (1% each). MiSeq detected additional mutations including *KRAS* A146 or L19F (4/37), *SMAD4* (4/37), *FRXW7* (3/37), *APC* (15/37), *TP53* (26/37), *ERBB4* (1/37), *PTEN* (1/37), and *IDH1* (1/37). Co-mutation with *KRAS* was found in 63% of pts with *PIK3CA* mutation and 80% of pts with *APC* mutation. Of 85 pts with known *PTEN* IHC status, 19% were negative. A higher average number of mutations was observed in right- versus left-sided CRC ($p<0.01$). Mutations with known clinical significance (*RAS* and *BRAF*) were collectively more prevalent in right colon ($p<0.01$). **Conclusions:** Targeted next-generation DNA sequencing identifies more genomic alterations than SNP genotyping. Current strategy of anti-epidermal growth factor receptor therapy in *KRAS* G12/13 wild type pts might not benefit >15% of pts due to presence of other *RAS/BRAF* mutations. Clinically relevant genomic alterations are more likely to be detected in right colon.

**3573 General Poster Session (Board #36), Sat, 8:00 AM-11:45 AM**

**FCγRIIa and FCγRIIIa polymorphisms (SNPs) and cetuximab (C) benefit in the EXPERT-C trial.** *Presenting Author: Francesco Sclafani, The Royal Marsden NHS Foundation Trust, London and Surrey, United Kingdom*

**Background:** FCγRIIa-H131R and FCγRIIIa-V158F SNPs have been reported to enhance the immune-mediated effects of monoclonal antibodies including cetuximab (C) in metastatic colorectal cancer (CRC). Although the importance of antibody-dependent cell mediated cytotoxicity could be potentially higher in the adjuvant setting, there are no data on the relationship between these SNPs and C in patients (pts) with early stage disease. We performed a pharmacogenomic analysis of EXPERT-C, a randomised phase II trial of neoadjuvant CAPOX followed by chemoradiotherapy, surgery, and adjuvant CAPOX ± C in high-risk, locally advanced rectal cancer. **Methods:** SNP analysis was performed on DNA extracted from peripheral blood samples. Kaplan-Meier method and Cox regression analysis were used to calculate survival estimates and compare treatment arms. **Results:** A blood sample was available for genotyping in 105/164 (64%) pts (CAPOX=54, CAPOX-C=51) who were representative of the study population. Baseline characteristics were evenly allocated between the two treatment arms. Twenty five (23.8%) were homozygous for FCγRIIa-131H, 52 (49.5%) heterozygous (131H/R), and 28 (26.7%) homozygous for 131R. 13 (12.4%) were homozygous for FCγRIIIa-158V, 48 (45.7%) heterozygous (158V/F), and 44 (41.9%) homozygous for 158F. No deviation from the Hardy-Weinberg equilibrium or association with tumour *RAS* status was observed. FCγRIIa-131R (HR 0.38, p=0.058) and FCγRIIIa-158F alleles (HR 0.21, p=0.007) predicted progression-free survival (PFS) in pts treated with C. In the CAPOX-C arm, carriers of both 131R and 158F alleles had a statistically significant improvement in PFS (5-yrs 78.4%, HR 0.22, p=0.002) and overall survival (OS) (5-yr 86.4%, HR 0.24, p=0.018) when compared to pts homozygous for 131H and/or 158V (5-yr PFS 35.7%, 5-yrs OS 57.1%). An interaction between C benefit and presence of 131R and 158F alleles was found for PFS (p=0.017) and remained significant after adjusting for prognostic variables (p=0.003). **Conclusions:** This is the first study investigating FCγRIIa and FCγRIIIa SNPs in early stage CRC pts treated with C. Our findings suggest an increased clinical benefit from C in this patient population in the presence of 131R and 158F alleles.

**3574 General Poster Session (Board #37), Sat, 8:00 AM-11:45 AM**

**Pharmacokinetic (PK)-guided optimization of 5-fluorouracil (5FU) exposure in colorectal cancer (CRC) patients: U.S.-based clinical practices experience.** *Presenting Author: Fadi S. Braiteh, Comprehensive Cancer Centers of Nevada, Las Vegas, NV*

**Background:** Multiple studies have demonstrated how PK-guided dosing to optimize infusional 5FU exposure improves both response rates and toxicities. With 5FU PK testing now available using a rapid, reliable immunoassay, we present US-based oncologists' experience with individualizing 5FU dosing based on PK in patients with adjuvant or metastatic CRC. **Methods:** Between June 5, 2013 and January 17, 2014, Saladax Biomedical Laboratories (a CLIA-certified lab) determined 5FU plasma levels (My5-FU assay) in 631 samples collected ~24+6Hr after the start of 5FU continuous infusion from 240 CRC patients (n=250 therapy lines). Systemic 5FU exposure (calculated as area under the curve [AUC]) and dose adjustment recommendations to achieve target range (AUC = 20 – 30 mg*hr/L) were reported to physicians. Evaluable cycle pairs were defined as two consecutive cycles with AUC results. Actual vs. target AUC, recommended vs. actual dose adjustment, and ability to adjust exposure to target range were evaluated. **Results:** Majority of AUC results (62%) were outside the target range in the first sample from each therapy line where exposure was determined, irrespective of 5FU dosing or regimen. In 288 cycle pairs, 201 (69%) were outside the target range: doses were decreased in 48% of the 40 above target range, and doses were increased in 51% of the 161 below target range. No dose change was made in 89% of the 87 within the target range. In 101 cycle pairs out of target range where a dose adjustment consistent with recommendation was made, 42% moved into the target range. **Conclusions:** 5FU exposure optimization is feasible in the US clinical setting, consistent with other reports. Body surface area based 5-FU dosing results in frequent under dosing (48%). Majority (62%) of dose adjustment recommendations were followed in subsequent cycles. PK-guided dose adjustment is a practical approach to personalize optimal 5FU exposure.

| | 5FU Dose (mg/m$^2$) in first samples received for testing | | | |
|---|---|---|---|---|
| AUC range (mg*Hr/L) | All doses (600–3,840) | < 2,400 | 2,400 | > 2,400 |
| AUC below range (<=19) | 48% | 61% | 44% | 34% |
| AUC in target range (20 – 30) | 38% | 27% | 42% | 47% |
| AUC above range (>=31) | 14% | 12% | 14% | 19% |
| # of samples | 250 | 74 (30%) | 144 (57%) | 32 (13%) |

**3575 General Poster Session (Board #38), Sat, 8:00 AM-11:45 AM**

**Panex: A pooled analysis of EXPERT and EXPERT-C, two trials of neoadjuvant chemotherapy (NACT) and chemoradiotherapy (CRT) in high-risk locally advanced rectal cancer (LARC).** *Presenting Author: Francesco Sclafani, The Royal Marsden NHS Foundation Trust, London and Surrey, United Kingdom*

**Background:** After the use of preoperative radiotherapy and TME, survival of LARC has reached a plateau. More effective therapies, predictive/prognostic factors for treatment selection and valid endpoints for clinical trials are needed. We report the results of PANEX, a pooled analysis of EXPERT and EXPERT-C, the two largest trials of neoadjuvant CAPOX followed by CRT, TME and adjuvant CAPOX ± cetuximab in MRI-defined, high-risk, LARC. **Methods:** Individual patient data were collected from the central database of each trial. Survival endpoints were analysed using Kaplan-Meier methods and multivariate Cox-regression. **Results:** 269 patients (EXPERT=105, EXPERT-C=164) were included. Baseline features: T3c/T3d (60%), T4 (22%), CRM+ (63%), distal tumour (61%), N+ (72%), EMVI (71%). Radiologic response was 62% after NACT and 80% after CRT. Surgery was performed in 91% (R0 in 87%) and T/N downstaging was achieved in 56%/55% of cases. Pathologic complete response rate was 19%. After a median follow-up of 69 mo, 5-year local progression-free survival (PFS), distant PFS, PFS and overall survival (OS) were 94%, 79%, 70% and 73%, respectively. Baseline and treatment-related factors with statistically significant independent prognostic value in multivariate analyses are shown in the Table. **Conclusions:** Short- and long-term outcomes of NACT followed by CRT in high-risk LARC compare favourably with those reported with standard CRT in risk-unselected patients. Age, T4 and EMVI may be used as baseline factors for patient stratification and treatment selection. Tumour downstaging may be a surrogate endpoint to use in future phase II trials of NACT.

| Variable | Local PFS | Distant PFS | PFS | OS |
|---|---|---|---|---|
| Baseline[1] | - | EMVI HR 2.07 p=0.03 | Age HR 1.52 p=0.04 | Age HR 1.68 p=0.02<br>T4 HR 1.75 p=0.02 |
| Treatment-related[2,3] | - | T downstaging HR 0.51 p=0.03<br>N downstaging HR 0.49 p=0.02 | T downstaging HR 0.47 p=0.002 | T downstaging HR 0.36 p<0.001 |

[1]Include: trial, treatment with cetuximab, age, sex, WHO PS, T3c/d, T4, EMVI, CRM+, distal tumour. [2]Include: T/N downstaging, R0 resection, pCR. Also, adjusted for significant baseline variables. [3]R0 vs R1/R2 resection significant for all outcome measures.

**3576 General Poster Session (Board #39), Sat, 8:00 AM-11:45 AM**

**Chemotherapy use in stage III colon cancer: A National Cancer Data Base (NCDB) analysis.** *Presenting Author: Sumit Dahal, Institute of Medicine, Tribhuvan University, Kathmandu, Nepal*

**Background:** Adjuvant chemotherapy in stage III colon cancer improves overall survival, however, prior studies have shown that it is underused. We analyzed different factors that may influence its use. **Methods:** This is a retrospective study of stage III colon cancer patients (n=207,718) diagnosed between 2000 and 2011 in the NCDB. NCDB contains ~70% of new cancer diagnosis from >1,500 American College of Surgeons-accredited cancer programs in the United States and Puerto Rico. Chi-square test was used to determine any difference in characteristics of patients who did or did not receive chemotherapy. **Results:** 35% of all stage III colon cancer patients did not receive adjuvant chemotherapy. The use of chemotherapy had increased in recent years. Its use was lower in whites, females, patients ≥60 years, patients with one or more comorbidities, non-academic centers and those with medicare insurance, lower education and income levels (all p<.0001; Table). Non-white and uninsured were more likely to be <60 years. **Conclusions:** This is the largest study to determine the use of chemotherapy in stage III colon cancer. More than one-third did not receive adjuvant chemotherapy, although its use has increased in more recent years. Age was one of the most important determinants of chemotherapy use, which may explain higher rates in non-white and uninsured. In addition to patient characteristics, race, gender and socioeconomic factors influence chemotherapy use. These findings have important implications for health care reform.

**Do patients achieving pathologic complete response (pCR) following neoadjuvant treatment for locally advanced rectal cancer (LARC) need adjuvant chemotherapy?** *Presenting Author: Anis Hamid, Alfred Health, Melbourne, Australia*

**Background:** Optimal treatment for locally advanced rectal cancer (LARC) includes neoadjuvant short-course radiotherapy (SCRT) or long-course chemoradiotherapy. One advantage of long-course treatment is potential for tumour downstaging to pathologic complete response (pCR) in 10-15%, a sub-group with an excellent long-term prognosis. Uncertainty exists regarding the need for post-operative chemotherapy in such patients. We aimed to review the treatment and outcomes of all consecutive patients achieving pCR following neoadjuvant treatment for LARC. **Methods:** All patients undergoing neoadjuvant treatment for LARC at two academic centers between 1999-2012 were identified and their resection histopathology reports reviewed to identify patients with pCR. These cases were reviewed for initial stage, pre- and post-operative treatment, local and distant recurrences as well as OS. **Results:** There were 53 (15.5%) of 342 consecutive patients undergoing curative-intent surgery achieved pCR (ypT0N0). 2/41 (4.9%) undergoing SCRT, and 51/301 (16.9%) undergoing long-course radiotherapy (LCRT) had pCR. Of 53 pCR patients, 46 were staged T3/T4 pre-operatively, all remaining were T2, node-positive except 2 patients who were T2, node-negative. Between patients who did and did not achieve pCR, there was no significant difference in age, Eastern Cooperative Oncology Group (ECOG) (0 vs 1+), the proportion undergoing SCRT versus LCRT (2/53 vs. 39/289 respectively, p=0.06) or the time from completing LCRT to surgery (p=0.32). 63% of pCR patients received adjuvant 5-FU. These patients were younger (mean age 54 vs 71 years; p<0.001), however there was no difference in ECOG. No pCR patients developed local recurrence and only 2 distant recurrences occurred. 5-year OS was 91%, and no difference in RFS or OS was seen between those who did and did not receive adjuvant 5-FU. **Conclusions:** Our findings support previous studies showing excellent outcomes (>90% 5-year DFS and OS) for patients with pCR after neoadjuvant treatment for LARC. We further demonstrate no significant difference in OS or RFS between pCR patients who did and did not receive adjuvant 5-FU. This data adds to growing evidence suggesting that there may be no advantage in administering adjuvant 5-FU to this patient population.

**3578 General Poster Session (Board #41), Sat, 8:00 AM-11:45 AM**

**Early predictors of improved long-term outcomes in first-line antiangiogenics plus chemotherapy (anti-ANG/CT) in metastatic colorectal cancer (mCRC): Analysis of individual patient (pt) data from the ARCAD database.** *Presenting Author: Everardo D. Saad, Dendrix Research, Sao Paulo, Brazil*

**Background:** Early tumor shrinkage (ETS, ≥20% decrease from baseline) is associated with improved progression-free survival (PFS) and overall survival (OS) in mCRC pts treated with epidermal growth factor receptor inhibitors. We compared the relative merits of ETS and early objective tumor response (EOTR; CR/PR by RECIST) vs. standard Best Overall Response (BOR) and Confirmed Response (ConfR) in mCRC pts treated with 1st-line anti-ANG/CT. **Methods:** Data were available from 4,776 pts enrolled on 8 randomized trials of bevacizumab (N=6), cediranib (N=1), or both (N=1). ETS, EOTR, BOR and ConfR were assessed at 6, 8/9 and 12 weeks (wks). Associations were assessed by stratified Cox models with a landmark approach. The relative prediction accuracy of distinguishing pts at high vs. low risk of progression/death was compared by C-index (c, higher values indicate better accuracy). **Results:** All response endpoints were significantly associated with PFS and OS (P≤0.001 for all hazard ratios [HRs]) (see Table). Adjusting for age, performance status, # of metastases and prior therapy, significance remained. ETS showed larger effect size than EOTR. For PFS, the prediction accuracy was similar across time points or endpoints. For OS, compared with earlier time points, ETS and EOTR at 12 wks produced larger risk reduction, with similar prediction accuracy as BOR. **Conclusions:** Early response-based endpoints are significantly associated with improved PFS and OS in mCRC pts treated with anti-ANG/CT. The prediction performance of early response based on tumor measurement is as good as for standard RECIST response. Assessment of these endpoints as surrogates for PFS/OS at the trial level is ongoing.

**Comparative effectiveness of contemporary adjuvant chemotherapy among older rectal cancer patients.** *Presenting Author: Jennifer Leigh Lund, Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background**: Guidelines for stage II and III rectal cancer in the US recommend neoadjuvant chemoradiation therapy (CRT), curative resection, and adjuvant chemotherapy. This paradigm is based on early trials without neoadjuvant CRT and extrapolations from colon cancer. Recent trials have called into question whether adjuvant chemotherapy improves overall survival (OS) among patients treated with neoadjuvant CRT. We sought to examine whether chemotherapy improves OS in patients treated with neoadjuvant CRT or radiation therapy (RT) and surgery in real world settings. **Methods:** We identified a population-based cohort of 1,431 older (65+ years) non-metastatic rectal cancer patients diagnosed from 2004-2009 using the Surveillance, Epidemiology and End Results program (SEER)-Medicare data, who underwent neoadjuvant CRT or RT and curative resection. We described patterns of adjuvant chemotherapy using binomial regression models and evaluated the comparative effectiveness of: 1) any adjuvant chemotherapy vs. no adjuvant chemotherapy and 2) adjuvant oxaliplatin+5-fluorouracil (5-FU)/capecitabine vs. 5-FU/capecitabine on OS using Cox proportional hazards regression models and propensity score (PS) matching to adjust for measured covariates. **Results:** In total, 744 patients (52%) received adjuvant chemotherapy; most received oxaliplatin (53%). Older age, lower pathologic stage, and being widowed were associated with a lower likelihood of receiving adjuvant chemotherapy. Unadjusted and PS adjusted survival was superior in patients treated with chemotherapy (adjusted hazard ratio (aHR)=0.71, 95% confidence interval (CI): 0.57, 0.89). Among patients receiving adjuvant therapy, older age, earlier year of diagnosis, lower stage, and higher census tract poverty level were associated with a lower likelihood of receiving oxaliplatin. The addition of oxaliplatin to 5-FU/capecitabine did not improve OS after PS matching (aHR=1.15, 95% CI: 0.78, 1.70). **Conclusions:** Our results suggest that older non-metastatic rectal cancer patients benefit from adjuvant chemotherapy; however, the addition of oxaliplatin to 5-FU/capecitabine may not provide any incremental benefit.

**3580 General Poster Session (Board #43), Sat, 8:00 AM-11:45 AM**

**LGR5 rs17109924 to predict chemoresistance to 5FU-based chemotherapy in adjuvant colon cancer.** *Presenting Author: Armin Gerger, Division of Clinical Oncology, Department of Internal Medicine, Medical University of Graz, Graz, Austria*

**Background:** We recently investigated 25 germline polymorphisms in a comprehensive panel of genes that have been previously associated with colon cancer stem cell genes to predict tumor recurrence in patients with stage III and high-risk stage II colon cancer treated with 5-FU based chemotherapy. We found the minor alleles of CD44 rs8193 C>T, ALCAM rs1157 G>A and LGR5 rs17109924 T>C being significantly associated with increased time to recurrence (TTR). In this study we validated these molecular biomarkers in a large and independent study cohort to clarify their predictive and/or prognostic role. **Methods:** A total of 599 consecutively collected patients with stage II and III colon cancer were included in this validation study. Genomic DNA was analyzed for CD44 rs8193, ALCAM rs1157, and LGR5 rs17109924 by TaqMan 5'-exonuclease assays. **Results:** The mean age at time of diagnosis was 64 years (std 11), with a median follow-up time of 4.2 years (range 0.1-16.6). Tumor recurrence was observed in 185 (30.9%) patients with a stage III and stage II dependent probability of three-year recurrence of 37.1% (std 2.5) and 16.5% (std 2.3), respectively. Adjuvant chemotherapy was received by 393 (65.6%) of the patients. The tested gene variants CD44 rs8193 and ALCAM rs1157 did not show a statistically significant association with TTR in the analyses. However, patients carrying at least one C allele in LGR5 rs17109924 had a significantly increased TTR compared to patients carrying the homozygous T/T (HR 0.60, 95%CI 0.37-0.98; P=0.043). Stratified by adjuvant chemotherapy, LGR5 rs17109924 was highly significant for patients receiving adjuvant chemotherapy (P=0.007) whereas no association was found for patients without adjuvant chemotherapy (P=0.633). Also after adjusting for sex, age, stage, number of resected lymph nodes, lymphovascular, vascular, and perineural invasion in the multivariate Cox analysis LGR5 rs17109924 remained significant (HR 0.38, 95%CI 0.19-0.79; P=0.009) for patients with adjuvant chemotherapy. **Conclusions:** We confirmed in a large and independent study cohort that LGR5 rs17109924 is a predictive molecular biomarker for 5-FU based adjuvant chemotherapy in patients with colon cancer.

**3581 General Poster Session (Board #44), Sat, 8:00 AM-11:45 AM**

**The prognostic and therapeutic value of EpHA2 in early colorectal cancer (CRC).** *Presenting Author: Sonali Dasgupta, CCRCB, Queen's University, Belfast, Belfast, United Kingdom*

**Background:** EpHA2 is a 130 kD transmembrane glycoprotein belonging to ephrin receptor subfamily and involved in angiogenesis/tumour neovascularisation. High EpHA2 mRNA level has recently been implicated in cetuximab resistance. Previously, we found high EpHA2 levels in a panel of invasive colorectal cancer (CRC) cells, which was associated with high levels of stem-cell marker CD44. Our aim was to investigate the prognostic value of EpHA2 and subsequently correlate expression levels to known clinico-pathological variables in early stage CRC. **Methods:** Tissue samples from 509 CRC patients were analysed. EpHA2 expression was measured using IHC. Kaplan-Meier graphs were used. Univariate and multivariate analyses employed Cox Proportional Hazards Ratio (HR) method. A backward selection method (Akaike's information criterion) was used to determine a refined multivariate model. **Results:** EpHA2 was highly expressed in CRC adenocarcinoma compared to matched normal colon tissue. In support of our preclinical invasive models, strong correlation was found between EpHA2 expression and CD44 and Lgr5 staining ($p<0.001$). In addition, high EpHA2 expression significantly correlated with vascular invasion ($p=0.03$).HR for OS for stage II/III patients with high EpHA2 expression was 1.69 (95%CI: 1.164-2.439; $p=0.003$). When stage II/III was broken down into individual stages, there was significant correlation between high EpHA2 expression and poor 5-years OS in stage II patients (HR: 2.18; 95%CI: 1.28-3.71; $p=0.005$).HR in the stage III group showed a trend to statistical significance (HR: 1.48; 95%CI=0.87-2.51; $p=0.05$). In both univariate and multivariate analyses of stage II patients, high EpHA2 expression was the only significant factor and was retained in the final multivariate model. Higher levels of EpHA2 were noted in our *RAS* and *BRAF* mutant CRC cells, and silencing EpHA2 resulted in significant decreases in migration/invasion in parental and invasive CRC sublines. Correlation between *KRAS/NRAS/BRAF*mutational status and EpHA2 expression in clinical samples is ongoing. **Conclusions:** Taken together, our study is the first to indicate that EpHA2 expression is a predictor of poor clinical outcome and a potential novel target in early stage CRC.

**3582 General Poster Session (Board #45), Sat, 8:00 AM-11:45 AM**

**Identifying an early indicator of drug efficacy in patients (pts) with metastatic colorectal cancer (mCRC): A prospective evaluation of circulating tumor cells (CTC), 18F-fluorodeoxyglucose positron-emission tomography (PET), and the RECIST criteria.** *Presenting Author: Brigette Ma, State Key Laboratory of Oncology in South China, Sir Y K Pao Centre for Cancer, Department of Clinical Oncology, Hong Kong Cancer Institute and Prince of Wales Hospital, The Chinese University of Hong Kong, Sha Tin, Hong Kong*

**Background:** The early determination of drug response is a keystone in oncology, and CTC is a promising biomarker in mCRC. This study investigated the prognostic significance of a novel dual-endpoint of 'PET and CTC response' at 4 weeks (wk), and of the conventional RECIST response at 10 wks post-1$^{st}$line chemotherapy (chemo). **Methods:** All pts had a whole-body (WB) PET-CT (contrast) and CTC analysis (7.5ml blood) at baseline, a plain PET-CT and CTC analysis at 4 wks, and a WB-CT at 10 wks after starting chemo. CTCs were isolated using the cancer cell enrichment and detection kit (Milenyi Biotech). A positive CTC is defined as having: a positive red staining, round-to-oval morphology, size = or > 2 times that of lymphocyte. Evaluable lesions must have a SUVmax = or > 2 on PET and be measurable based on RECIST (version 1.0 and 1.1). PET response is defined as = or > 30% drop in the sum of SUVmax of target lesions, and CTC response is defined as 'any level of drop', or a 'CTC < 3 cells' at 4 wks. **Results:** 70 pts have been recruited. The mean age was 63.9 yrs, 70% had oxaliplatin-based chemo. At a median follow-up of 13.6 months, 38 pts have died. At baseline, 1 pt did not have PET and CTC. At 10wks, 7 pts did not have the PET done. In a multivariate analysis, CTC level < 3 cells at 4 wks (p=0.048, odds ratio, OR = 0.106, 95% CI=0.011-0.985) was an independent predictor of OS. RECIST response (both versions, $p < 0.05$, OR = 0.021 to 0.179) predicted PFS. **Conclusions:** In this early analysis, CTC level at 4 wks and RECIST-response at 10 wks are associated with survival in pts with mCRC. The prognostic significance of dual 'PET and CTC response' at 4 wks will be reported. The optimal cut-off for a drop in SUVmax and CTC will be explored. Clinical trial information: NCT01163305.

**3583 General Poster Session (Board #46), Sat, 8:00 AM-11:45 AM**

**Hepatic oligometastases treated with stereotactic body radiation therapy: Updated 10-year analysis of the Indiana University experience.** *Presenting Author: Ben Goodman, Indiana University, Indianapolis, IN*

**Background:** Stereotactic body radiation therapy (SBRT) is a non-invasive, effective technique in the treatment of a limited number of liver metastases from solid tumors. We present the 10 year update of our single institution SBRT experience outcomes and toxicity. This is thought to be the largest single institution experience present in the literature. **Methods:** We treated 81 patients 89 different times, for a total of 106 lesions. Inclusion criteria were patients with 1-3 liver metastases without evidence of extra-hepatic progression, and at least 700 cc of liver (minus the GTV) receiving less than 1500 cGy. The majority of patients had colorectal primary cancers. Other diagnoses included: Non-colorectal GI, breast, ovarian, NSCLC, and others. Among the lesions treated the majority received prior chemotherapy. **Results:** The median overall survival was 31 months. Kaplan Meier survival estimates at 12, 24, 36, and 48 months were 85%, 61%, 34%, and 18%. The local control rate was 94% with Kaplan Meier estimates at 12, 24, 36, and 48 months being 95%, 90%, 90% and 90%. The observed toxicities noted among the 106 treatments included mostly CTC grade 1-2 toxicity with only two grade 4 and one grade 5 toxicity. There was no difference in the toxicity based on the primary site. The majority of patients had grade 1 to 2 non-hepatic GI toxicity, grade 1-2 fatigue or grade 1-2 chest wall pain. The most severe toxicity noted was 1 patient with grade 5 hepatic toxicity and 2 patients with grade 4 hepatic toxicity. In addition, two patients developed grade 1 pleural effusions thought to be secondary to treatment. Parameters affecting toxicity were evaluated based on grade 4-5 hepatic toxicity. Generalized estimating equation models were fit to test for an association between each categorical factor and grade 4-5 hepatic toxicity. Linear mixed models were used to test for an association between each continuous factor and grade 4-5 hepatic toxicity. The only patient with grade 5 toxicity was treated three different times to a total of four lesions. **Conclusions:** Stereotactic body radiation therapy is a safe and effective treatment for patients with 1-3 liver metastases with a limited toxicity profile.

**3584 General Poster Session (Board #47), Sat, 8:00 AM-11:45 AM**

**A randomized controlled trial evaluating efficacy of adjuvant oral uracil-tegafur (UFT) with leucovorin (LV) after resection of colorectal cancer liver metastases: The UFT/LV study.** *Presenting Author: Akira Kobayashi, First Department of Surgery, Shinshu University School of Medicine, Matsumoto, Japan*

**Background:** Surgical resection has been accepted as the standard therapy for colorectal cancer liver metastases (CRLM), however, high recurrence incidence even after curative resection remains an unsolved problem. There is no established adjuvant chemotherapy for CRLM, although efficacy of several adjuvant treatments for stage III colorectal cancer has been confirmed. Oral UFT/LV is one of the standard therapies in stage III colorectal cancer. We conducted this randomized, open-label, phase III trial to evaluate efficacy of adjuvant UFT/LV therapy for CRLM (stage IV). **Methods:** A patient undergoing curative resection of CRLM was randomly assigned to either UFT/LV or surgery alone (control) group. In the UFT/LV group, 5 cycles of adjuvant UFT/LV (UFT 300mg/m$^2$ and LV 75 mg/day for 28 days followed by 7 days rest in one cycle) were administered. The primary endpoint was relapse-free survival (RFS), while secondary endpoints were overall survival (OS) and safety. **Results:** Between February 2004 and December 2010, total 180 patients were enrolled to this trial, among whom 3 patients were ineligible for analysis. The baseline characteristics were well-balanced in the UFT/LV (n=88) and control (n=89) groups. Median follow-up was 4.76 years. The 3y-RFS rate in the UFT/LV group was 38.6%, which was significantly higher than the control group (32.3%). The hazard ratio for relapse in the UFT/LV relative to the control was 0.56 (95% confidence interval: 0.38-0.83, P=0.003). The 3y-OS rates were similar between the UFT/LV and control groups (82.8% vs. 81.6%, P=0.41). In the UFT/LV group without treatment-related death, the scheduled cycles was completed in 45 patients among 82 (54.9%), and the mean dose intensity ratio was 70.8%. As adverse events at any grade, hyperbilirubinemia (28.0%), liver dysfunction (23.2%), diarrhea (26.9%) and anorexia (28.0%) occurred. **Conclusions:** Adjuvant UFT/LV therapy is effective to prevent recurrence after surgical resection of CRLM. Clinical trial information: C000000013.

**3585 General Poster Session (Board #48), Sat, 8:00 AM-11:45 AM**

**Colon cancer: Characteristics and survival rates in young versus old patients.** *Presenting Author: Shams Aziz Mistry, McLaren Regional Medical Center, Flint, MI*

**Background:** Colon cancer is detected at a later stage in younger patients (YP) (< 50 years) probably due to lack of screening in this age group. There has been an increased incidence of colon cancer (1.6%) in YP, but they are underrepresented in research studies. The aim of our study is to compare characteristics of colon cancer and survival outcome in YPs (18-49 years) vs older patients (>50) using the Surveillance, Epidemiology, and End Results (SEER) database. **Methods:** Using the SEER database (1991-2010), we reviewed patients > 18 years of age with colon cancer. Multivariate Cox regression analysis was used to evaluate risk adjusted outcomes and to predict the hazard of dying. Kaplan Meier method was used to estimate the survival function. **Results:** We included 375,443 patients in our study. YPs with colon carcinoma were more likely to be African American (15.7% vs 10.6%; p<0.001), Hispanic (13.5% vs 6.7%; p<0.001) and Asian (9.2% vs 6.3%; p<0.001) as compared to the older age group. YPs were more likely to present with distant metastasis (27.7% vs 19.1%; p<0.001) and had more poorly differentiated tumors (20.3 % vs 18.0%; p< 0.001). YPs also received more cancer directed surgery (92.6 % vs 91%; p<0.001) compared to their older counterparts. Five year survival was better for younger patients in all stages{table 1}. After controlling for gender, race, marital status, grade, stage, cancer specific surgery and post-operative radiation, we found that age is an independent predictor of death, and younger patients with colon cancer had a lower risk of dying (HR 0.767; p<0.001). **Conclusions:** Previous studies of YPs with colon cancer were found to have either equivalent or better survival in stages II and IV compared to older patients. Our study shows that young patients less than 50 years of age have more advanced stages of colon cancer at diagnosis but have better stage specific survival in all stages.

**Five-year survival rate for colon cancer patient.**

| Stage of colon cancer | Young (< 50 yrs) N=29,276 | Older (≥ 50 years) N=346,167 | P-value |
|---|---|---|---|
| **Localized** | 95.6% | 91.1% | <0.001 |
| **Regional** | 76.7% | 72.8% | <0.001 |
| **Distant** | 20.3% | 16.8% | <0.001 |
| **Unstaged** | 69.3% | 50.4% | <0.001 |

**3586 General Poster Session (Board #49), Sat, 8:00 AM-11:45 AM**

**Updated results of the SOFT study: A randomized phase III trial of S-1/oxaliplatin (SOX) plus bevacizumab versus 5-FU/*l*-LV/oxaliplatin (mFOLFOX6) plus bevacizumab in patients with metastatic colorectal cancer (mCRC).** *Presenting Author: Masato Nakamura, Aizawa Hospital, Matsumoto, Japan*

**Background:** As previously reported (Yamada Y, et al. Lancet Oncol. 2013 Dec;14(13):1278-86), the SOFT study demonstrated that SOX plus bevacizumab (SOX+Bev) was non-inferior to mFOLFOX6 plus bevacizumab (mFOLFOX6+Bev) in terms of the primary endpoint of progression-free survival (PFS). We now report the final overall survival (OS) after a median follow-up of more than 3 years. **Methods:** The SOFT study was an open-label, non-inferiority, randomized phase III trial. Chemotherapy-naïve patients with mCRC, an ECOG PS of 0-1, and adequate organ functions were randomized to receive either mFOLFOX6+Bev (5 mg/kg of bevacizumab, followed by 200 mg/m$^2$ of *l*-leucovorin given simultaneously with 85 mg/m$^2$ of oxaliplatin, followed by a 400 mg/m$^2$ bolus of 5-FU on day 1 and then 2,400 mg/m$^2$ of 5-FU as an intravenous infusion over the course of 46 h, every 2 weeks) or SOX+Bev (7.5 mg/kg of bevacizumab, 130 mg/m$^2$ of oxaliplatin on day 1, and 40−60 mg of S-1 twice daily for 2 weeks, followed by a 1-week rest). The primary endpoint was PFS. Patients' data were finally updated in September 2013. **Results:** At this final analysis, the median survival time(MST) was 29.7 months (95% CI: 26.5−33.1) with mFOLFOX6+Bev and 29.6 months (95% CI: 25.8−34.7) with SOX+Bev (median follow-up, 37.7 months). The HR for OS was 1.018 (95% CI: 0.823−1.258). Median PFS was 11.7 months (95% CI: 10.9−13.3) with mFOLFOX6+Bev and 12.2 months (95% CI: 10.7−13.0) with SOX+Bev. The HR for PFS was 1.051 (95% CI: 0.876−1.262), and the p value for non-inferiority was 0.0115 (median follow-up, 31.2 months). In the subgroup analysis of PFS and OS, we recorded no clinically significant interactions between the assigned regimen and any factors. The safety profile was almost similar to primary analysis results. **Conclusions:** In this study, the MST was at least 29.5 months in both groups, indicating similar OS. Our results reconfirmed that SOX+Bev is non-inferior to mFOLFOX6+Bev in terms of PFS as first-line treatment for mCRC. SOX+Bev can thus be used instead of mFOLFOX6+Bev. Clinical trial information: JapicCTI-090699.

**3587 General Poster Session (Board #50), Sat, 8:00 AM-11:45 AM**

**Randomized controlled trial on the skin toxicity of panitumumab in third-line treatment of KRAS wild-type metastatic colorectal cancer: HGSG1001 (Japanese Skin Toxicity Evaluation Protocol with Panitumumab: J-STEPP)—Additional analysis of antitumor efficacy.** *Presenting Author: Yoshimitsu Kobayashi, Department of Gastroenterology and Hepatology, Hokkaido University Hospital, Sapporo, Japan*

**Background:** Panitumumab (Pmab) has demonstrated efficacy in patients with KRAS wild-type metastatic colorectal cancer (mCRC). Although the STEPP study (Lacouture M. E. et al. J Clin Oncol. 2010; 28: 1351-7.) showed that pre-emptive skin treatment reduced skin toxicities compared with reactive treatment among patients receiving Pmab, data for Asians has not been reported. We planned a randomized, open-label trial to verify the differences between pre-emptive and reactive treatment for skin toxicities in Japanese patients. **Methods:** Patients receiving third-line Pmab-containing regimens for mCRC were randomly assigned 1:1 to pre-emptive (skin moisturizers, sunscreen, topical steroid, and minocycline) or reactive (only skin moisturizers) skin treatment. The primary endpoint was the cumulative incidence of ≥grade 2 skin toxicities during the 6-week treatment period. Retrospectively, a dermatologist reviewed skin toxicities, in a blinded manner, using photographs. **Results:** Of 95 enrolled patients, 47 were assigned to pre-emptive, and 48 to reactive treatment. The incidence of ≥grade 2 skin toxicities during the 6-week treatment period (investigators' assessment) was 21.3% and 62.5% (risk ratio [RR], 0.34; 95% CI, 0.19 to 0.62; P < 0.001) for the pre-emptive and reactive treatment groups, respectively. A similar trend was observed in central review (18.6% and 50.0%, respectively [RR, 0.37; 95% CI, 0.19 to 0.74; P = 0.002]). There were no statistical differences in progression free survival (3.6 vs 4.0 months; hazard ratio [HR], 1.20; 95% CI, 0.78 to 1.84; P = 0.413), time to treatment failure (3.0 vs 3.5 months, [HR, 1.23; 95% CI, 0.80 to 1.89; P = 0.343]), and overall response rate (13.3% vs 18.2%; P = 0.530) between pre-emptive and reactive treatment groups. **Conclusions:** Pre-emptive skin treatment could reduce the severity of skin toxicities during Pmab treatment, and did not affect the anti-tumor efficacy of Pmab. Our data clearly validate that pre-emptive treatment can also be recommended in Japanese patients. Clinical trial information: 000004883.

**3588 General Poster Session (Board #51), Sat, 8:00 AM-11:45 AM**

**Effect of 12-week home-based exercise program on fasting insulin in stage II-III colorectal cancer survivors: A randomized controlled trial.** *Presenting Author: Mi Kyung Lee, Yonsei University, Seoul, South Korea*

**Background:** High insulin levels may be associated with an increased risk of colorectal cancer (CRC) development and recurrence. However, the effect of exercise on fasting insulin level in colorectal cancer survivors has not been fully studied. We conducted a randomized control trial to determine the effect of a 12-week home based exercise program on fasting insulin, body composition, and fitness in stage II-III CRC survivors. **Methods:** 123 stage II-III CRC survivors between 4 and 102 weeks after standard cancer therapy (surgery, chemotherapy, and/or radiation therapy) were randomly assigned to either the 12-week home-based exercise (n=62) or usual care (n=61) group. The goal of the home-based exercise was to increase the level of physical activity of the participants to 18-27 MET hours per week. The primary outcome measurement was fasting insulin and secondary outcome measurements were body composition and fitness level. **Results:** A total of 99 (80.5%) participants completed the trial. After 12 week of home-based exercise program, fasting insulin level was significantly reduced in exercise group while it did not change in control group (Ex, 6.09±3.96 vs. 4.93±3.41 μU/ml; Con, 6.74±3.40 vs. 6.73±3.01 μU/ml, between group $p$=0.045). Furthermore, percent body fat was significantly reduced (Ex, 27.53±8.59 vs. 26.83±8.41%; Con, 27.18±7.02 vs. 27.85±7.11 %, between group $p$=0.033), and 6-min walk test (Ex, 580.72±82.09 vs. 611.54±74.51 m; Con, 598.06±65.03 vs. 606.03±58.26 m, between group $p$=0.041), Chair Stand test (Ex, 19.71±6.53 vs. 23.08±5.06; Con, 23.87±6.20 vs. 23.83±4.31, between group $p$=0.004), and push up (Ex, 15.21±9.68 vs. 20.89±11.83; Con, 15.44±13.03 vs. 12.59±10.98, between group $p$ <0.000) were significantly improved in exercise group. **Conclusions:** The 12-week home based exercise intervention decreased fasting insulin and percent body fat, and improved fitness in stage II-III CRC survivors. The current study was supported by the National Research Foundation of Korea (2013K2A1A2054437) and the National R&D Program for Cancer Control, Ministry of Health & Welfare, Republic of Korea (1120230).

**3589 General Poster Session (Board #52), Sat, 8:00 AM-11:45 AM**

**Four-year survival in patients (pts) undergoing liver surgery after neoadjuvant triplet hepatic artery infusion (HAI) and intravenous cetuximab (IV-CET) for previously treated and unresectable liver metastases from kras *wt* colorectal cancer (LM-CRC) (European trial OPTILIV, NCT00852228).** *Presenting Author: Francis Levi, Medical Oncology Department, INSERM U776, Paul Brousse Hospital, Villejuif, France*

**Background:** IV chemotherapy (chemo) downsizes LM-CRC in most pts. Yet less than 15% of those with previously unresectable LM and prior chemo undergo successful complete macroscopic LM resection (R0-R1). 4-y survival is 42% in all pts with LM resection (Livermetsurvey). Purpose is to determine disease-free survival (DFS) and OS in pts with R0-R1 partial hepatectomy after neoadjuvant HAI of irinotecan, oxaliplatin, and 5-fluorouracil and IV-CET for LM-CRC in the first multicenter trial testing this strategy. **Methods:** The 9 centers accrued 64 pts with 1-3 prior chemo, bilateral LM (84% pts), a median number of 10 LM, with largest diameter of 53 mm, spread in a median of 6 segments. First intent LM surgery was deferred for high LM number (72% of the pts), large size (69%), ill location (61%), extra-hepatic disease (2%), or other cause (12%). Liver surgery was performed whenever R0-R1 became feasible at q6-9 weeks multidisciplinary review. **Results:** LM surgery occurred 2.6 to 19.4 months (mo) after inclusion (median, 5.3). Single-, two- or three-stage R0-R1 hepatectomies were performed in 15, 3 and 1 pt respectively**.** LM resection was associated with younger age (median, 52 vs 60 y, p=0.01), less liver involvement (≤25% vs >25% tumor replacement, 68% vs 38% of the pts, p=0.025; median N of segments involved, 5 vs 7, p=0.015), and 1 rather than 2-3 prior chemo (46% vs 20% of the pts, p=0.01). Resection rate did not differ according to sex, PS, primary tumor stage or grade, LM bilaterality and number, prior resections, extrahepatic disease, or objective response rate (42% vs 40%). Median DFS was 15.7 mo [95% CI, 10- 21], with LM recurring in 11 pts (58%). Median OS was 18.7 mo [13-24] with no 4-y survivor among the 45 pts without LM resection. In contrast, median OS was 35 mo [31-40] in the 19 resected patients, with 45% [10.3 - 79.7] survival at 4-y (p<0.001). **Conclusions:** The combination of IV-CET with HAI-IFO deserves upfront evaluation as a most effective neoadjuvant treatment option within a medico-surgical strategy aiming at the eradication of LM-CRC. Clinical trial information: NCT00852228.

**3590 General Poster Session (Board #53), Sat, 8:00 AM-11:45 AM**

**Benefit of EGFR-inhibition therapy for metastatic colorectal cancer patients with KRAS-mutated tumors and high plasma TIMP-1 level: Results from the NORDIC VII study.** *Presenting Author: Nils Brunner, Department of Veterinary Disease Biology, Faculty of Health and Medical Sciences, University of Copenhagen, Frederiksberg, Denmark*

**Background:** *RAS* status is the only biomarker to select patients with metastatic colorectal cancer (mCRC) for therapy with an epidermal growth factor receptor (EGFR) inhibitor. However, not all K*RAS*wild-type tumors respond to EGFR-inhibition, and some patients with mutated tumors may still benefit from therapy. To improve selection of patients for treatment with EGFR inhibitors, new biomarkers are needed. Plasma Tissue Inhibitor of Metalloproteinases-1 (TIMP-1) induces intracellular signalling activating the Akt-survival pathway, and we hypothesize that high TIMP-1 levels interact with the signalling of EGFR and thereby with the anti-tumor effects of EGFR inhibitors. The present study tests the above hypothesis in patients included in the NORDIC VII Study. **Methods:** mCRC patients were randomized to Nordic FLOX +/- cetuximab (Tveit et al., JCO, 2012). Pre-treatment plasma samples (n=426) were analysed for TIMP-1 using the MAC15 antibody kinetic ELISA. **Results:** Univariate Cox analyses including all patients showed that high pre-treatment plasma TIMP-1 was significantly associated with shorter PFS (P = .003), and OS (P < .0001). Multivariate analysis (not including treatment) demonstrated that high plasma TIMP-1 was an independent biomarker of OS (P = .016). A significant interaction between plasma TIMP-1, *KRAS* status and treatment (+/- cetuximab) was demonstrated for OS (P = .002). Patients with *KRAS* mutated tumors and high TIMP-1 level (> 3$^{rd}$quartile) had a significantly longer OS if treated with cetuximab (HR, .48; 95% CI, .25 to .93) compared to patients not treated with cetuximab. **Conclusions:** Patients with KRAS mutated tumors and a high plasma TIMP-1 level seem to benefit from EGFR-inhibition therapy. Based on these results we propose a novel hypothesis on the interaction between EGFR-1 signalling and TIMP-1.

**3591 General Poster Session (Board #54), Sat, 8:00 AM-11:45 AM**

**Coexisting KRAS and PIK3CA exon 20 mutations as a potential poor-prognosis factor in metastatic colorectal cancer (mCRC).** *Presenting Author: Maria Elena Elez Fernandez, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Molecular screening and biomarker enrichment strategies in mCRC clinical trials have demonstrated to have an impact in treatment benefit and prognosis. The data obtained from these strategies progressively incorporated in routine clinical practice, may lead to the obtention of relevant information to optimize treatment decisions. **Methods:** From 01/2011 to 12/2013, 415 patients (pts) with advanced chemorefractory mCRC underwent genetic tumor profiling as part of Vall d'Hebron University Hospital Phase I Trial Molecular Prescreening Program. Mutation (MT) profiling was performed by single-base extension chemistry followed by mass detection (MassARRAY, Sequenom) including 268 frequent hotspots in 25 oncogenes, among them, KRAS, BRAF, NRAS, and PIK3CA. **Results:** We found a KRAS MT incidence of 48% (199/415 pts), slightly above other reported studies. The PIK3CA, BRAF and NRAS MT rates were 14% (58/415), 6.5% (27/415) and 3% (12/415) respectively. Coexisting KRAS and PIK3CA MT were found in 44 out of 199 pts (22.1%). PIK3CA MT were more frequently detected in the helical domain (HD, exon 9) than in the kinase domain (KD, exon 20). Among KRAS wild type (WT) pts, HD *vs.* KD MT were detected at approximately a 2:1 ratio (8 HD, 4 KD), consistent with previous reports. Interestingly, in the KRAS MT background, the ratio of MT in HD *vs.* KD in PIK3CA was dramatically increased in our population with a 14:1 ratio (41 HD, 3 KD). Upon dissecting the KRAS MT group, we found G13D MT to show a very low coexistence with PIK3CA MT (3/36 pts, 8%) in contrast to other series in less heavily pretreated populations. **Conclusions:** This study represents a thorough profiling of frequent oncogene MT in mCRC. Our analysis shows that certain profiles such as coexisting KRAS and PIK3CA-KD MT or KRAS G13D and PIK3CA MT seem to be underrepresented in our heavily pretreated population. Therefore, these findings suggest that both groups would be of particular poor prognosis. Nevertheless, this observation must be confirmed in larger and prospective series representing overall mCRC population.

**3592^ General Poster Session (Board #55), Sat, 8:00 AM-11:45 AM**

**AIO KRK0306, FIRE3 trial: CEA and CA19-9 influence outcome of patients with KRAS exon wild-type metastatic colorectal cancer (mCRC) receiving first-line therapy with FOLFIRI plus cetuximab or bevacizumab.** *Presenting Author: Marlies Michl, Department of Hematology and Oncology, Klinikum Großhadern and Comprehensive Cancer Center, LMU Munich, Munich, Germany*

**Background:** To examine the impact of tumor marker response of carcinoembryonic antigen (CEA) and carbohydrate-antigen 19-9 (CA19-9) on overall survival (OS) and progression free survival (PFS) in patients with KRAS wild-type mCRC receiving first line chemotherapy in the FIRE3-trial comparing FOLFIRI + cetuximab (cet) vs. FOLFIRI + bevacizumab (bev). **Methods:** Baseline tumor marker levels, the time to nadir (in days; d) and the percentage of tumor marker decrease observed at the nadir compared with baseline were analyzed. The percentage was 0 for no change and negative if the tumor marker increased. Comparisons relied on Mann-Whitney U tests for independent groups and Wilcoxon signed-rank tests for dependent ones. ROC analysis resulted in a cut-off value using the maximum of sensitivity and specificity for best response. **Results:** For analysis of CEA, 472/592 pts (cet arm: 230 pts; bev arm: 242 pts) were eligible and for CA19-9, 439/592 pts (cet arm: 209 pts; bev arm: 230 pts). Baseline CEA (log) and CA19-9 (log) levels both significantly correlated with OS ($p=0.008$ and $p<0.0001$, respectively), but not with PFS ($p=0.26$ and $p=0.15$, respectively). For CEA and CA19-9 median time to nadir was comparable for both study arms, however in all patients CA19-9 nadir occurred earlier than CEA nadir ($p<0.0001$). Extent of CEA nadir significantly differed between treatment arms (cet arm: median: 83.0%; IQR: 40.9%-94.7%; bev arm: median: 72.3%; IQR: 26.3%-91.0%; $p=0.003$). A similiar trend was observed for CA19-9 nadir (cet arm: median: 64.3%; IQR: 13.4%-90.7%; bev arm: 47.0%; IQR: 1.7%-86.4%; $p=0.085$). In univariate analysis, a CEA decrease of more than 75% correlated with longer OS (33.2 vs. 22.9 mo; $p<0.0001$; HR 0.63; 95%CI: 0.50–0.80) and PFS (11.7 vs. 9.0 mo; $p=0.007$; HR 0.67; 95%CI: 0.62–0.93). **Conclusions:** In this analysis, we demonstrate that a greater decrease of CEA during therapy correlates with longer survival and the depth of CEA decrease is significantly greater in the cetuximab-arm compared to the bevacizumab-arm. Clinical trial information: NCT00433927.

**3593 General Poster Session (Board #56), Sat, 8:00 AM-11:45 AM**

**Constitutive single nucleotide polymorphisms (SNP) assessment for predicting tolerability and efficacy of triplet hepatic artery infusion (HAI) and intravenous cetuximab (IV-CET) in patients (pts) with liver metastases from colorectal cancer (LM-CRC) (European trial OPTILIV, NCT00852228).** *Presenting Author: Francis Levi, Medical Oncology Department, INSERM U776, Paul Brousse Hospital, Villejuif, France*

**Background:** The combination of IV-CET and HAI of irinotecan , oxaliplatin and 5-fluorouracil displayed high activity as 2-4$^{th}$chemotherapy line for initially unresectable wt KRAS LM-CRC, yielding a macroscopic complete resection rate (R0+R1) of 29.7% and an overall survival of 25.7 months (Ducreux, ASCO 2013). The purpose is to identify the pts whose constitutive SNPs predict for best outcomes on this neoadjuvant protocol. **Methods:** 192 constitutive SNPs from 36 pharmacogenetically-relevant genes were analysed in pt blood cells using the ADME PGx panel with the MassArray platform (Sequenom, USA). Relations between polymorphic genes with minor SNPs and grade distribution for main toxicities per pt over 6 courses, best tumor response, and R0+R1, were explored using Mann Whitney or Fisher Exact test. **Results:** Gene polymorphisms were assessed in 52/64 registered pts with unresectable LM-CRC (16F; 36M), aged 33-76 years with good PS (0-1: 98%) receiving IV-CET + IFO-HAI as 2$^{nd}$ line for 21 pts (40%) and 3$^{rd}$-4$^{th}$line for 31 pts (60%). Main grade 3-4 toxicities were neutropenia (40%), abdominal pain (29%), fatigue (21%), and diarrhea (17%). Objective response was achieved in 20 pts (39%). Secondary R0-R1 LM resection was performed in 14/52 pts (27%). None of the minor SNPs in the 36 genes studied was a potential predictor of LM resection, nor displayed any significant relation with pt characteristics except for Cyp2C19 and sex ($p<0.05$). Best objective response was associated with minor SNPs in SLC22A2 ($p=0.049$) and UGT2B15 ($p=0.011$). Neutropenia, fatigue and diarrhea were associated with minor SNPs in Cyp2C19 ($p<0.05$). Neutropenia was further related to minor SNPs in Cyp1A2 ($p = 0.017$) and SLC22A1 ($p=0.027$), while diarrhea was predicted by minor SNPs in Cyp2D6A ($p<0.05$). **Conclusions:** This selected pharmacogenetics analysis revealed six genes involved in drug metabolism and transport whose minor SNPs predicted safety and efficacy outcomes and could warrant treatment adjustment for pts on neoadjuvant triplet HAI and IV-CET for LM-CRC. Clinical trial information: NCT00852228.

**3594 General Poster Session (Board #57), Sat, 8:00 AM-11:45 AM**

**The role of JAK1/2-STAT3 as acute resistance mechanism to MEK inhibition in BRAF-mutant colorectal cancer cell lines.** *Presenting Author: Basak Celtikci, Queen's University, CCRCB, Belfast, United Kingdom*

**Background:** Oncogenic mutations in *BRAF* occur in 8% of patients with advanced colorectal cancer (CRC) and have been shown to correlate with poor prognosis. In contrast to *BRAF* mutant (MT) melanoma, where the BRAF inhibitor Vemurafenib (PLX4032) has shown significant increases in response rates and overall survival, only minor responses to Vemurafenib treatment have been reported in *BRAF*MT CRC. Clear understanding of the vulnerabilities of *BRAF*MT CRC is important, and identification of druggable targets uniquely required by *BRAF*MT CRC tumours has the potential to fill a gap in the therapeutic armamentarium of advanced CRC. The aim of this study was to identify novel resistance mechanisms to MEK inhibition in *BRAF*MT CRC. **Methods:** Paired *BRAF*MT/WT RKO and VACO432 CRC cells and non-isogenic *BRAF*MT LIM2405, WiDR, HT-29 and COLO205 CRC cells were used. Changes in protein expression/activity were assessed by Western Blotting. Interactions between MEK1/2 and JAK1/2 or c-MET inhibition were assessed using the MTT cell viability assays and Flow Cytometry. Apoptosis was measured using Western Blotting for PARP, cleaved caspase 3, 8 and 9, and caspase 3/7 and 8 activity assays. **Results:** Treatment with MEK1/2 inhibitors AZD6244, trametinib, UO126 and PD98059 resulted in acute increases in STAT3 activity in the *BRAF*MT RKO and VACO432 cells but not in their *BRAF*WT clones and this was associated with increases in JAK2 activity. Inhibition of JAK/STAT3 activation using gene specific siRNA or small molecule inhibitors TG101348 or AZD1480, abrogated this survival response and resulted in synergy and significant increases in cell death when combined with MEK1/2 inhibitors AZD6244 or trametinib in *BRAF*MT CRC cells. The RTK c-MET is activated upstream of STAT3 following MEK1/2 inhibition. Inhibition of c-MET and MEK1/2, using pharmacological inhibitors (crizotinib and AZD6244), results in synergy and increased cell death in *BRAF*MT CRC cells. **Conclusions:** We have identified JAK/STAT3 activation as an important escape mechanism for *BRAF*MT CRC following MEK1/2 inhibition in vitro. Combinations of JAK/MEKi or MET/MEKi can be a potential novel treatment strategy for poor prognostic *BRAF*MT advanced CRC patients.

**3595 General Poster Session (Board #58), Sat, 8:00 AM-11:45 AM**

**Clinical course of patients with oxaliplatin-associated neuropathy: N08CB (Alliance).** *Presenting Author: Deirdre R. Pachman, Mayo Clinic, Rochester, MN*

**Background:** Oxaliplatin is commonly associated with acute neuropathy, as well as a more troublesome chronic neurotoxicity. Details regarding the clinical course of these toxicities are not well defined. **Methods:** Acute and chronic oxaliplatin-induced peripheral neuropathy were evaluated in patients with colon cancer receiving adjuvant FOLFOX (fluorouracil, leucovorin, oxaliplatin) in a previously reported calcium/magnesium neuropathy prevention trial (Loprinzi JCO 2013). Acute neuropathy was assessed using daily questionnaires for 6 days starting with each cycle of FOLFOX. Chronic neurotoxicity was assessed using the EORTC QLQ-CIPN20 tool before each dose of oxaliplatin and at 1, 3, 6, 12, and 18 months after chemotherapy. **Results:** 89% of patients (308/346) had at least one acute neuropathy symptom (Sx) with the first cycle of FOLFOX: sensitivity to touching cold items (71%), sensitivity to swallowing cold items (71%), throat discomfort (63%), or muscle cramps (42%). Acute neuropathy Sx occurred within a day after oxaliplatin, peaked at day 3, then improved. These Sxs, however, did not resolve completely between treatments and were about twice as severe in cycles 2-12, than in cycle 1. Cycle 1 acute neuropathy Sx severity predicted acute Sx severity in subsequent cycles. Regarding the chronic neurotoxicity, tingling was the most severe Sx (1.91 out of 1-4), followed by numbness (1.72), and then pain (1.28). During chemotherapy, hand Sxs (1.70) were more prominent than feet Sxs (1.57). Following chemotherapy completion, sensory Sxs initially continued to worsen, on average, with improvement beginning approximately 3 months post-chemotherapy. By 18 months, residual numbness/tingling was more severe in feet than in hands. Patients with more severe acute neuropathy during the first cycle of therapy had more chronic sensory neurotoxicity ($P<0.0001$). **Conclusions:** Acute oxaliplatin-associated neuropathy Sxs do not completely resolve between treatment cycles and are only half as severe on the first cycle compared with subsequent cycles. There is a correlation between the severity of acute and chronic neuropathy. Hand Sxs are more severe during therapy, while feet symptoms become more prominent during follow up. Clinical trial information: NCT01099449.

**3596 General Poster Session (Board #59), Sat, 8:00 AM-11:45 AM**

**Modified FOLFOXIRI plus cetuximab (cet) as induction treatment in unresectable metastatic colorectal cancer (mCRC) patients (pts): Preliminary results of the phase II randomized Macbeth trial by GONO group.** *Presenting Author: Chiara Cremolini, U.O. Oncologia Medica 2, Azienda Ospedaliero-Universitaria Pisana, Istituto Toscano Tumori, Pisa, Italy*

**Background:** Phase II trials investigated the combination of a triple chemotherapy regimen with anti-EGFR monoclonal antibodies reporting promising activity but some concerns about the safety profile. The optimal maintenance regimen to be adopted following chemotherapy + an anti-EGFR is also not well established. The aims of MACBETH trial are to evaluate the activity and safety of 1st-line mFOLFOXIRI plus cet and to explore the role of maintenance with cet or bev in unresectable and molecularly selected mCRC pts. The study initially enrolled *KRAS* exon 2 wt pts, but after amendment only *RAS* and *BRAF*wt pts were eligible. **Methods:** Pts are randomized to receive an induction treatment of up to 8 cycles of mFOLFOXIRI + cet (cet 500 mg/sqm, irinotecan 130 mg/sqm, oxaliplatin 85 mg/sqm, 5 l-LV 200 mg/sqm, 5FU infusion 2400 mg/sqm over 48h q2w), followed by cet until disease progression (PD) or the same regimen followed by bev until PD. Primary endpoint is 10 months-Progression Free Rate (10m-PFR). Target accrual is 136 pts. **Results:** Between November 2011 and January 2014, 212 pts were screened and 94 pts were randomized in 18 Italian centers. At the data cut-off of Dec 2013, 72 pts completed the induction phase. Pts' characteristics were: median age 59 yrs, ECOG PS 0 92%, synchronous metastases 79%, multiple sites of disease 60%, *NRAS* mutated 4.2%, *BRAF* mutated 2.8%. The median number of administered cycles was 8. Main grade 3-4 toxicities were neutropenia (34.7%), febrile neutropenia (2.7%), diarrhoea (21.3%), skin rash (14.7%), stomatitis (6.7%), neurotoxicity (2.7%). One (1.4%) and 50 (69.4%) pts achieved CR and PR, respectively (RR in the intention to treat population: 70.8%). Ten (13.9%) pts reported SD (DCR: 84.7%) and 4 (5.6%) progressed. Seven (9.7%) pts did not undergo response assessment. Out of 65 pts evaluable for RECIST response, RR and DCR were 78.5% and 93.8%, respectively. **Conclusions:** A short "induction" treatment with mFOLFOXIRI + cet, according to the present schedule, shows a feasible safety profile with encouraging activity. The trial is still ongoing and updated results will be presented. Clinical trial information: 2011-000840-70.

**3597 General Poster Session (Board #60), Sat, 8:00 AM-11:45 AM**

**Molecular profiling of EGFR pathway according to location of colorectal cancer (CRC): Analysis of 1,001 patients in single institute.** *Presenting Author: Eiji Shinozaki, Department of Gastroenterology, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan*

**Background:** Location of colon cancer (right-sided versus left-sided) was reported as a predictor of benefit from cetuximab in the subanalysis of NCIC CTG CO.17 trial. On the other hand, retrospective analyses have identified *KRAS* including codon61, codon146, *BRAF*, *NRAS*, or *PIK3CA* mutations as potentially negative predictive factors for anti EGFR treatments. This analysis aimed to reveal the prevalence of these mutations in the EGFR pathway according to location of CRC in a large cohort. **Methods:** Consecutive patients of 1,001 CRC from January 2012 to October 2013 were analyzed in this study. Multiplex genotyping of EGFR pathway was performed on archival samples using Luminex Assay (MABGEN and GENOSEARCH Mu-PACK, MBL) for *KRAS* including codons 61 and 146, *BRAF*, *NRAS*, and *PIK3CA*. We examined the correlation among mutation profile, clinical data and location of CRC. Statistical analysis was conducted by chi-square test. **Results:** The incidence of mutations; *KRAS* codon12 and 13, codon61 and 146, *BRAF*, *NRAS* and *PIK3CA* were 38%, 4.6%, 5.1%, 3.5% and 9.1%, respectively. So called all *RAS* mutations accounted for 47% in this cohort. The difference of prevalence according to the location of CRC was confirmed in *KRAS* codon 12 and 13, *BRAF*. The respective proportion of mutations were 55.9%, 14% for right sided(R), 30.6%, 5.5% for left sided(L), 37.2%, 1% for rectal(RC) CRC (*KRAS*: R vs L, RC $P<0.01$, *BRAF*: R vs L vs RC $P<0.01$). **Conclusions:** According to the location of CRC the incidence of *KRAS* codon 12 and 13, *BRAF* mutation were different. Increased *BRAF* mutation in R ,which was strong negative prognostic factor could affect unfavorable outcome of anti EGFR treatment.

**3598 General Poster Session (Board #61), Sat, 8:00 AM-11:45 AM**

**Compliance and safety of neoadjuvant intensity modulated radiotherapy (IMRT) with concurrent capecitabine for locally advanced rectal cancer: Updated results from a phase II trial (ChiCTR-TNC-10001094).** *Presenting Author: Yongheng Li, Peking University Cancer Hospital, Beijing, China*

**Background:** We have prospectively studied the neoadjuvant IMRT with concurrent capecitabine followed by TME for locally advanced rectal cancer to assess efficacy, compliance and toxicity in a phase II trial. Here, we report updated results. **Methods:** A total of 260 patients with clinical stage II-III mid-low rectal cancer received IMRT and surgery from December 2008 to May 2013. Patients received IMRT with gross targeting volume (GTV)/ clinical targeting volume (CTV) of 50.6/41.8 Gy in 22 fractions plus concurrent capecitabine (825 mg/m$^2$twice daily) in 30 days. The interval from IMRT to surgery is 6 to12 weeks. The short-term results were analyzed. **Results:** The compliance rate is 99.6%, one patient discontinued treatment following 17 fractions of radiation for diarrhea. There was no Grade 4 toxicity recorded. The incidence of Grade 3 toxicities is 5.8%, including: diarrhea (4.2%), neutropenia (1.5%) and radiation dermatitis (0.4%). The toxicity was listed in the Table. Pathological complete response occurred in 18.5% (48/260) of patients. Anastomotic leakage rate was 2.6% (4/152) in patients with sphincter preservation. Perineal wound infection (20.8%, 20/96) or skin dehiscence (8.3%, 8/96) were main complications in patients who received abdominoperineal excision. Surgical re-interventions were needed in three patients and no mortality was recorded. **Conclusions:** Neoadjuvant IMRT plus concurrent capecitabine for rectal cancer achieved high rate of pCR, excellent compliance and minor acute toxicity. This high intensity regimen might be considered as a component for intensified treatment with induction or consolidation chemotherapy to maximize the effect to achieve clinical complete response in future trials. Clinical trial information: 10001094.

**Toxicities during the neoadjuvant treatment.**

| Toxicity | Total (%) | G1 | G2 | G3 | G4 |
|---|---|---|---|---|---|
| Neutropenia | 116 (44.6%) | 90 (34.6%) | 22 (8.5%) | 4 (1.5%) | |
| Thrombocytopenia | 12 (4.6%) | 8 (3.1%) | 4 (1.5%) | | |
| Diarrhea | 231(88.8%) | 170 (65.4%) | 50 (19.2%) | 11 (4.2%) | |
| Radiation dermatitis | 235 (90.4%) | 210 (80.8%) | 24 (9.2%) | 1 (0.4%) | |
| Fatigue | 71 (27.3%) | 67 (25.8%) | 4 (1.5%) | | |
| Vomiting | 40 (15.4%) | 37 (14.2%) | 3 (1.2%) | | |

**3599 General Poster Session (Board #62), Sat, 8:00 AM-11:45 AM**

**Validation of the NSABP neoadjuvant rectal score (NAR) in a prospective phase II study evaluating an experimental regimen and a standard chemoradiation cohort with molecular genotyping.** *Presenting Author: Theodore S. Hong, Massachusetts General Hospital, Boston, MA*

**Background:** NSABP recently proposed replacing pCR with a new neoadjuvant rectal score (NAR) based on clinical downstaging from pre to post-treatment, pathologic (yp) stage. The NAR formula yields values from 0-100; higher scores indicate poor prognosis. In NSABP R04 (n=1479), the mean NAR = 15.61 with SD of 14.37, and OS hazard ratio/unit (HR) = 1.04 ($p<0.0001$). NAR showed a stronger association with OS than pCR, and was proposed as a new endpoint for phase II trials. We sought to evaluate the prognostic significance of NAR in two previously published datasets. **Methods:** Patient (pt) data from 2 IRB approved, previously published studies were used. Study 1 was a phase I/II study evaluating bevacizumab (bev) and erlotinib (erl) with neoadjuvant chemoradiation (CRT) (Ann Oncol 2014;25:121-6). Study 2 was a retrospective review of pts receiving 5-FU/RT (J Gastrointest Canc epub 2013, PMID24006244), with mutational analysis. All pts had pretreatment M0 and T3/4 or node + disease by MRI. Study 1 had 32 pts, with a pCR rate of 33%. Study 2 had 79 pts, with a pCR rate of 21.5%. NAR = [ 5pN- 3(cT-pT) + 12]$^2$/ 9.61 where pN = yp nodal stage (0,1,2), cT = clinical T-stage (1,2,3,4), and pT= yp T stage (0,1,2,3,4). The NAR score's association with DFS was tested as a pseudocontinuous variable in a Cox model, and is reported as a HR/unit. **Results:** In study 1, the mean NAR = 12.67 (SD =12.20): DFS HR 1.12 (1.04, 1.21, p=0.004). In study 2, mean NAR = 16.85 (SD = 16.17), DFS HR = 1.07 (1.03, 1.12, p=0.001). Mutational frequency in study 2 was KRAS 43%, APC 17%, BRAF 4%, NRAS 4%, PIK3CA 4%, TP53 11%. For study 2 pts with any mutation, mean NAR = 18.90 (SD =15.66): DFS HR 1.07 (1.01, 1.14, p=0.025). For study 2 pts with NO mutation, mean NAR = 13.85 (SD =16.69): DFS HR 1.07 (1.01, 1.13, p=0.004). **Conclusions:** Higher NAR was associated with worse DFS in a standard CRT cohort and an experimental phase II cohort, confirming the findings in NSABP R04. The mean NAR of 12.67 in the bev/erl study compares favorably to both NSABP R04 (15.61) and the retrospective CRT cohort (16.85). In study 2, pts with no mutation had a lower NAR than those with a mutation (13.85 vs 18.90), suggesting more favorable prognosis.

**3600 General Poster Session (Board #63), Sat, 8:00 AM-11:45 AM**

**Gender and tumor location as predictors for efficacy: Influence on endpoints in first-line treatment with FOLFIRI in combination with cetuximab or bevacizumab in the AIO KRK 0306 (FIRE3) trial.** *Presenting Author: Volker Heinemann, Department of Medical Oncology, Klinikum Grosshadern, University of Munich, Munich, Germany*

**Background:** FIRE-3 compared first-line therapy with FOLFIRI plus either cetuximab or bevacizumab in 592 KRAS exon 2 wild-type mCRC patients. We analyzed the efficacy dependent on gender and primary tumor location within the RAS wild-type population (n=342). **Methods:** Primary tumor location was defined as follows: right sided CRC (RCRC): coecum to hepatic flexure; left sided CRC (LCRC): splenic flexure to rectum. Colon transversum tumors (n=9) were excluded. Differences in response (ORR) and survival (PFS/OS) within both treatment arms were calculated using two-sided Fisher´s exact and logrank test, respectively. **Results:** In location wise comparison LCRC shows better efficacy results (ORR, PFS and OS) when compared with RCRC especially in the cetuximab arm (Table). Female gender has a trend towards lower tumor response rates, shorter PFS and OS when compared to male patients. **Conclusions:** MCRC is a heterogeneous disease. Treatment efficacy depends on primary tumor location and patients' gender. Effects were more prominent in patients receiving FOLFIRI plus cetuximab where male patients with LCRC tumors are favored.

**Survival following stage II/III colon cancer (CC): Accent-based comparison versus matched general population (MGP).** *Presenting Author: Lindsay A. Renfro, Mayo Clinic, Rochester, MN*

**Background:** The post-treatment survival experience of CC patients (pts) is well described in the literature, which states that cure is a probable outcome for some pts; formal survival comparisons vs. MGP are limited. **Methods:** Data from 32,745 pts enrolled to 25 randomized adjuvant trials conducted from 1977-2012 in 41 countries were pooled and 8 years of follow-up considered. The observed long-term survival experience of ACCENT pts was compared to the expected survival from a sex, age, country, and year MGP, overall and by stage (II, III), sex, treatment (surgery, 5FU, 5FU+oxaliplatin), age (< 70, 70+), year (pre/post 1990), and recurrence (Y/N). Comparisons were made at randomization (rand) and repeated conditional on survival to 1, 3, 5 years. CC/MGP equivalence was tested and observed Kaplan-Meier rates compared with expected MGP rates 3 years out from each landmark. **Results:** Within each ACCENT cohort, long-term survival of CC pts remained statistically worse than the MGP, though it improved over time given survival to certain landmarks. Among those surviving 5 years, stage II, oxaliplatin-treated, elderly, and recurrence-free pts achieved subsequent 3 year survival rates within 5% of the MGP; pts without recurrence had subsequent 3 yr. survival within 0.5% of MGP. **Conclusions:** Among CC pts on clinical trials who survive up to 5 years, subsequent long-term survival remains poorer than a MGP, but notably stage II, age 70+, received oxal, and recurrence-free pts achieve similar rates. These findings emphasize the need for access to quality care and the continued need for improved treatment/follow-up strategies.

**% Diff (MGP - CC) survival 3 yrs post baseline time point.**

**3602 General Poster Session (Board #65), Sat, 8:00 AM-11:45 AM**

**Genetic variants of TCF7L2 and AXIN2 predict gender and tumor location-dependent clinical outcome in FIRE-3 trial: A validation study.** *Presenting Author: Yan Ning, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** Wnt signaling pathway genes TCF7L2 and AXIN2 complex control the proliferation and differentiation of intestinal epithelial cells. Our previous study showed that TCF7L2 and AXIN2 polymorphisms(SNPs) were associated with clinical outcome of mCRC patients(pts) treated with first line FOLFIRI/BEV from TRIBE (arm A) and PROVETTA trials (n=455) (ASCO 2013#3566). Our data demonstrated that the association of TCF7L2rs7903146 and AXIN2 rs2240308 snps with PFS and OS is depended on gender and location. The goal of the current study was to prospectively validate our previous findings in mCRC pts enrolled in FIRE-3 clinical trial, which treated with either first line FOLFIRI/BEV or FOLFIRI/cetuximab. **Methods:** Genomic DNA was isolated from tissue samples of 592 pts (patient characteristics gender, median age median follow up) treated with first-line FOLFIRI/ bevacizumab (n=295) or FOLFIRI cetuximab (n=297) from the FIRE-3 trial (NCT00433927). All pts were KRAS exon 2 wild-type. The bevacizumab arm served as validation arm whereas the cetuximab arm served as control arm. **Results:** Our data validated that TCF7L2rs7903146 and AXIN2 rs2240308 snps could predict clinical outcome when adjusted by pts gender and tumor location. 1) In right-sided tumors, Female pts with any T allele of TCF7L2rs7903146 were associated with significantly longer PFS(median=13 mos) (HR: 0.38; 95% CI: 0.15, 0.97) in comparison to those carrying C/C genetype(median=5.7 mos, P = 0.04), which is consistent with our previous data. 2) In left-sided tumors, Female pts with AXIN2 rs2240308 any A allele had shorter OS(median=24.8 mos)(HR: 2.87; 95% CI: 1.07,7.76; P = 0.026) compared to those with G/G variants(median=44.3 mos), which validated our previous data. No significant difference in control arm. **Conclusions:** In this study, we prospectively validated the predictive value of TCF7L2 rs7903146 and AXIN2 rs2240308 snps in mCRC pts treated with first-line FOLFIRI/BEV. More importantly, This is first time confirmed that this predictive value is dependent on gender and tumor location in over 900 mCRC pts, suggesting Wnt signaling may play different role in female vs male and in right vs left side tumors.

**3603 General Poster Session (Board #66), Sat, 8:00 AM-11:45 AM**

**Final results from NSABP protocol R-04: Neoadjuvant chemoradiation (RT) comparing continuous infusion (CIV) 5-FU with capecitabine (Cape) with or without oxaliplatin (Ox) in patients with stage II and III rectal cancer.** *Presenting Author: Carmen Joseph Allegra, National Surgical Adjuvant Breast and Bowel Project, University of Florida, Gainesville, FL*

**Background:** The two primary aims of NSABP R-04 were 1) Can the oral fluoropyrimidine, Cape be substituted for the standard of care in the curative setting of Stage II & III rectal cancer namely, CIV 5-FU, during neoadjuvant RT; and 2) Can the addition of Ox enhance the activity of fluoropyrimidine sensitized RT? **Methods:** Pts with clinical stage II or III rectal cancer undergoing preoperative RT (4,500cGy in 25 fractions over 5 wks + boost of 540cGy-1080cGy in 3-6 daily fractions) were randomly assigned to one of four chemotherapy regimens in a 2x2 design: CVI 5-FU (225mg/m$^2$ 5 days/wk), with or without intravenous Ox (50mg/m$^2$ /wk x 5) or oral Cape (825 mg/m$^2$ BID 5 days/wk), with or without Ox (50mg/m$^2$/wk x 5). The primary endpoint was local-regional (L-R) tumor control that included L-R tumor recurrence, less than a complete surgical resection, and no surgery for any reason. **Results:** From July 2004 to August 2010, 1,608 patients were randomly assigned and 99.2% were eligible for analysis. There were no significant differences in 3 year L-R tumor event rates (11.2 vs 11.8%), 5 year DFS (66.4 vs 67.7%), or 5 year OS (79.9 vs 80.8%) between regimens using 5-FU vs Cape; and, 11.2 vs 12.1%, 69.2 vs 64.2%, and 81.3 vs 79.0% for Ox vs no Ox for the three endpoints of L-R events, DFS, and OS. The addition of Ox was associated with significantly more overall and grade 3-4 diarrhea (p<0.0001). Three-year rates of L-R recurrence among all pts who underwent R0 resection ranged from 2.9 – 4.6%. An unplanned subset analysis did not show significant differences for the use of Ox regardless of T-stage or ypCR status. **Conclusions:** CVI 5-FU or oral Cape combined with RT produced similar outcomes for L-R control, DFS and OS, and establishes Cape as a standard of care in the pre-op rectal setting. Ox did not improve L-R failure rate, DFS, or OS for any patient risk group but did add significant toxicity. Molecular studies using this fully annotated tissue bank are on-going. Support: U10-CA-12027, U10-CA-37377, U10-CA-69651, U-10-CA-69974; Sanofi; Roche. Clinical trial information: NCT00058474.

**3604 General Poster Session (Board #67), Sat, 8:00 AM-11:45 AM**

**Circulating DNA as a strong multimarker prognostic tool in metastatic colorectal cancer patients.** *Presenting Author: Safia El Messaoudi, IRCM INSERM, Montpellier, France*

**Background:** The aim of our study was to evaluate the prognostic role of various circulating cell-free DNA (cfDNA) parameters in metastatic colorectal cancer (mCRC) patients. **Methods:** We used a novel method, termed Intplex, which determines simultaneously from plasma, total cfDNA concentration, cfDNA fragmentation level, *KRAS/BRAF* mutational status, and cfDNA mutation load (% of mutant cfDNA). These parameters were tested in a mCRC patient cohort (n=98), which enabled validation of plasma DNA as a liquid biopsy to detect *KRAS/BRAF* mutations using the STARD criteria . **Results:** Median overall survival (OS) of the patients of the full cohort was 22 months (IC 95% [16.9-28.1]). Data confirmed *BRAF* mutational status as an excellent factor of poor prognosis (median OS, 22.9 vs. 3.4 months; relative risk (RR)=8.9, (IC95% [3.1-25.4], P<0.001) compared to *KRAS* mutational status (RR=1.1, IC 95% [0.7-1.9], P=0.66). OS was statistically different in patient groups with lower total cfDNA concentrations (median=28.1 months) compared with those with higher total cfDNA concentrations (median=17.8 months) than the median (RR=1.94, IC 95% [1.2-3.2], P=0.009). By using the multivariate Cox model, total cfDNA conc. proved statistically to be a strong, independent prognostic factor (P=0.035). Median OS was 31.1 and 11.1 months (P=0.121; RR=1.8, IC 95% [0.9-3.8]) in patients with lower and higher mutation loads than the median (10.3%). This difference was confirmed statistically when considering the mutant cfDNA conc. median (i.e. 3.1 ng/ml, RR=2.4, P=0.015). The fragmentation level did not appear to discriminate patients with regards to survival. CEA level at the conventional threshold conc. (5 ng/ml) was as a moderate prognostic factor (OS, 27.1 vs. 21.8 months; RR=1.24, 95% IC [0.7-2.2], P=0.48). **Conclusions:** Our study demonstrates for the time in a large cohort of mCRC patients that in addition to providing an advantageous alternative to tumor-tissue analysis for point mutation detection, other cfDNA parameters, such as total conc. and mutation load, are strong prognostic factors. Thus, prospective studies are needed to confirm multi-marker cfDNA analysis as a simple tool to help define the best care management options.

**3605 General Poster Session (Board #68), Sat, 8:00 AM-11:45 AM**

**CpG island methylator phenotype (CIMP) and outcome differences for African Americans (AA) and Caucasians (C) treated with FOLFOX4 or the combination with bevacizumab (B) in patients (pts) with metastatic colorectal cancer (MCRC): Results from the Eastern Cooperative Oncology Group study E3200.** *Presenting Author: Edith P. Mitchell, Kimmel Cancer Center of Thomas Jefferson University, Philadelphia, PA*

**Background:** The relationship between race and poorer clinical outcomes with systemic chemotherapy in patients with metastatic colorectal cancer is uncertain. CIMP High has been associated with a lack of survival benefit from 5-fluorouracil (5FU)-based chemotherapy while conflicting results for chemotherapy combinations have been reported. We analyzed outcomes for AA and C patients enrolled in E3200 and evaluated for CIMP in pts with adequate tissue samples. **Methods:** A total of 820 pts enrolled in E3200 were randomized to one of three treatments: FOLFOX4, bevacizumab, or the combination. Overall survival (OS), progression free survival (PFS) and response rates (RR) and CIMP were analyzed according to race. Demographic information was collected by data management personnel at study sites and reported at registration. CIMP was analyzed in 281 pts with adequate tissue specimens; 261 were C and 20 AA. **Results:** There were no differences for AA and C in regards to number of metastatic sites, performance status, gender, prior therapy and age distribution. Prediction of tumor response did not differ according to treatment arm based on CIMP. AA had worse OS (p=0.03), PFS (p=0.08) and RR (p=0.02) than C pts. CIMP showed significant interaction with differences between AA and C pts. There was improved OS and PFS for C pts with CIMP values less than the median than those above while AA showed better survival with values greater than the median. **Conclusions:** These results suggest outcome differences based on race in the treatment of MCRC in pts may be associated with molecular features. Additional studies are required to elucidate the cause for the observed variation. [caption[Cox proportional hazards analyses comparing CIMP high versus CIMP low[/caption] Clinical trial information: NCT00897819.

**3606 General Poster Session (Board #69), Sat, 8:00 AM-11:45 AM**

**Impact of PI3K aberrations on efficacy of perifosine (P), x-PECT: A phase III randomized study of P plus capecitabine (PC) versus placebo plus capecitabine (C) in refractory metastatic colorectal cancer (mCRC) patients.** *Presenting Author: Cathy Eng, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** P is an oral, synthetic alkylphospholipid that affects several signaling pathways, including PI3K/Akt. The X-PECT trial randomized 468 patients (pts) to PC (50 mg po QD) or C (1000 mg/m$^2$BID, D1-14 q21D). We hypothesized pts having PI3K aberrations (PIK3CA and PTEN loss) would derive greater benefit from P for response rate, progression-free survival (PFS) and/or overall survival (OS). X-PECT did not meet its primary endpoint of OS (p = 0.32). Here we present the final tissue correlatives. **Methods:** Archival formalin-fixed paraffin-embedded (*FFPE)*tissues were requested on all pts. Sequenom MassARRAY (MALDI-TOF MS) was utilized for detection of *PIK3CA, PI3KR1, Akt, Ras,* and *Raf* mutations (MT). *PTEN* expression was assessed by IHC. Reverse phase protein array (RPPA) was evaluated in fresh frozen specimens, paired pre- and post-one cycle from pts at MD Anderson. Kaplan-Meier method was used to estimate median OS and PFS; Cox proportional hazard regression analysis and log rank test were applied to evaluate OS and PFS with patient demographics and markers. Wilcoxon rank sum test and Fisher's exact test were performed for continuous or categorical variables. **Results:** 272 pts had FFPE tissue samples. 57% of pts were male. 45% of all pts had a *KRAS* MT; *NRAS* (1%); *BRAF* (3%); *PIK3CA* (9%); *Akt* (<1%), and loss of PTEN by IHC (16%). Loss of PTEN or *PIK3CA* MT were noted in 25% of pts. *Ras* WT was noted in 50% of all pts. Univariate analysis noted no difference for PFS for loss of PTEN/*PIK3CA* MT [p=0.32; HR= 0.81, (95% CI: 0.54-1.23)] or for *Ras*MT (p=0.11; HR=1.34, (95% CI: .93-1.92)]. RPPA data of 9 pts was available; only 6 pts (5 placebo pts) with paired pre- and on-treatment samples were evaluable. C alone was associated with reduction in p-Akt T308 (p=0.05), downstream target p-PRAS40 T246 (p=0.03), as well as proliferation marker PCNA (p<0.01). **Conclusions:** The presence of a *PIK3CA* MT or loss of PTEN occurred in 25% of refractory mCRC pts but did not improve the efficacy of perifosine. Capecitabine alone appeared to inhibit *Akt* signaling and proliferation. Additional studies are needed for validation. Clinical trial information: NCT01097018.

**3607 General Poster Session (Board #70), Sat, 8:00 AM-11:45 AM**

**Rechallenge with anti-EGFR–based therapy in metastatic colorectal cancer: Impact of intervening time interval and prior anti-EGFR response.** *Presenting Author: Xiaochun Liu, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** This retrospective study aims to investigate the activity of retreatment with anti-EGFR-based therapy in order to explore the concept of clonal evolution by evaluating the impact of prior activity and intervening time interval. **Methods:** One hundred and four *KRAS*-wild-type metastatic colorectal patients (pts) were re-treated on phase I or I/II clinical trials containing anti-EGFR therapy after progressing on prior cetuximab or panitumumab. Physician-recorded response (CR, PR, SD >=6 months) were used for prior treatment evaluation, and the best response per RECIST criteria were used for the re-treatment evaluation. The multivariate analysis was constructed with response on prior treatment, interval time between the two treatments, age, race, gender, Royal Marsden Hospital prognostic score, and performance status. **Results:** Pt characteristics were: 72% Caucasian, 66% < 60 years of age, 51% female gender, median PS 1, 84% normal albumin, and 76% elevated LDH levels. Re-treatment anti-EGFR agents were cetuximab (n=89) or cetuximab plus erlotinib (n=15). The median interval time between prior and re-treatment was 4.55 months (range: 0.46-58.7). Pts who responded to the prior cetuximab or panitumumab were more likely to respond to the re-treatment compared to the non-responders in both univariate ($p$ = 0.005) and multivariate analyses (OR: 3.45, 95% CI: 1.35, 8.85, $p$ = 0.01). The response rate in re-treatment also correlated with interval time between the two anti-EGFR based therapies ($p$ = 0.044). Moreover, median PFS on re-treatment was marginally increased in prior responders (4.37 months, 95% CI: 2.92, 5.82) compared to prior non-responders (2.37 months, 95% CI, 1.52, 3.22) in univariate ($p$ = 0.056) and multivariate analysis (HR: 0.67, 95% CI: 0.42-1.08, $p$ = 0.101). **Conclusions:** Our data supports the concept of clonal evolution though the impact appears less robust than previously reported (Santini et al. 2012). Further work to validate which pts benefit from re-challenge treatment post progression is needed.

**3608 General Poster Session (Board #71), Sat, 8:00 AM-11:45 AM**

**S-1 plus oxaliplatin versus capecitabine plus oxaliplatin for first-line treatment of patients with metastatic colorectal cancer: Updated results from a phase 3 trial.** *Presenting Author: Young Suk Park, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** We report updated progression free survival (PFS) and overall survival (OS) data from the trial which compared capecitabine plus oxaliplatin (COX) vs S-1 plus oxaliplatin (SOX) for first line treatment with metastatic colorectal cancer. **Methods:** This trial was a randomised, two arm, non-inferiority phase 3 comparison of COX (capecitabine 1000 mg/m2 twice daily on days 1-14 and oxaliplatin 130 mg/m2 on day 1) vs SOX (S-1 40mg/m2 twice daily on days 1-14 and oxaliplatin 130 mg/m2 on day 1). The primary end point was to show non-inferiority of SOX relative to COX in terms of PFS. A follow-up exploratory analysis of PFS and OS was performed. **Results:** The intent to treat (ITT) population comprised 340 patients (SOX arm: 168 and COX arm: 172). Updated median PFS was 7.1 months (95% CI 6.4-8.0) in the SOX group and 6.3 months (4.9-6.7) in the COX group (hazard ratio[HR], 0.83 [0.66-1.04]; p=0.10). The median OS was 19.0 months (15.3-23.0) in the SOX group and 18.4 months (14.1-20.7) in the COX group (HR, 0.86 [0.68-1.08]; p=0.19). Subgroup analyses according to principal demographic factors such as sex. age, ECOG performance status, primary tumour location, measurability, previous adjuvant therapy and number of metastatic organs and liver metastasis showed no interaction between treatment and any characteristic. **Conclusions:** Updated survival analysis shows that SOX is similar to COX, confirming the primary analysis for PFS. The SOX regimen could be an alternative first line doublet chemotherapy strategy for patients with metastatic colorectal cancer. Clinical trial information: NCT00677443.

**3609 General Poster Session (Board #72), Sat, 8:00 AM-11:45 AM**

**Single nucleotide polymorphisms (SNPs) in vascular endothelial growth factor (*VEGF*) family genes as predictive or prognostic biomarkers in patients (pts) with metastatic colorectal cancer (mCRC): Analysis of the phase III MAX study.** *Presenting Author: Fiona J.M. Chionh, Ludwig Institute for Cancer Research, Melbourne, Australia*

**Background:** Adding bevacizumab (B) to chemotherapy (CT) improves survival outcomes in pts with mCRC. Pt subgroups benefiting most from B need to be identified. SNPs in genes for VEGF-A and its receptors VEGF-R1/–R2 can affect their expression/production. We hypothesised these may be prognostic and/or predictive biomarkers for response and survival outcomes in pts treated with CT and B for mCRC. **Methods:** We analysed tissue from 325 of 471 pts (69%) randomised to capecitabine (C), or C + B, or C + B + mitomycin for mCRC. We performed Taqman SNP genotyping assays on available (in order of preference) normal (51%), adenoma (2%), or malignant (47%) FFPE tissue. 16 candidate SNPs in *VEGF-A* ($n$ = 6), *-R1* ($n$ = 4), and *-R2* ($n$ = 6), all in Hardy-Weinberg equilibrium with minor allele frequency ≥ 10%, were analysed for associations between genotype and response rate (RR), progression-free survival (PFS) and overall survival (OS). We assessed if SNP genotypes were predictive of B efficacy using tests for B treatment - SNP genotype interactions. **Results:** Of the SNPs analysed, *VEGF-A* rs25648 major allele C was significantly associated with improved PFS and OS, including when adjusted for B treatment (Table), but not associated with RR ($p$= 0.30). Other than B treatment, no clinico-pathologic variables were associated with survival outcomes. There were no significant interactions between B treatment and any SNP genotypes. **Conclusions:** *VEGF-A* rs25648 was an independent prognostic biomarker for PFS and OS in pts with mCRC, with allele C conferring improved prognosis, but was not predictive of B efficacy. This finding is biologically plausible as rs25648 is in the *VEGF-A* 5'UTR/promoter region, and in previous studies the CC genotype has been associated with lower VEGF-A levels/expression.

| rs25648 genotype | Reference | HR (95% CI), median (months PFS | HR (95% CI), median (months OS | HR (95% CI) adjusted for B treatment PFS | HR (95% CI) adjusted for B treatment OS |

**3610 General Poster Session (Board #73), Sat, 8:00 AM-11:45 AM**

**Perturbations in PI3K pathway and cyclin dependent kinase (CDK) pathway to predict complete responders in CRC patients treated with ADAPT therapy.** *Presenting Author: Edward H. Lin, Seattle Cancer Care Alliance, Seattle, WA*

**Background:** Aspirin or selective COX-2 inhibitor may improve overall survival (OS) in colorectal cancer (CRC) patients with PIK3CA mutations. However, routine use of anti-inflammatory agents in metastatic CRC patients remains controversial. We showed that 3-year maintenance celecoxib, also a stemness inhibitor coupled with capecitabine in a two-step ADAPT (activating dormant tumor cells and potentiate targeting) therapy led to 40% complete responders (CR) whose median survival reached 92.7 months in patients with unresectable stage IV CRC (Lin et al. AACR LBA254). We sought to determine genetic aberrations and related pathways as predictor of CR to ADAPT therapy. **Methods:** We retrospectively reviewed 50 consecutive stage IV CRC patients who had achieved CR with ADAPT therapy alone or in conjunction with metastectomy between 2006-2012 at University of Washington. All patients were tested for a panel of 199 cancer-related genes (UW Oncoplex) with Illumina deep sequencing platform **Results:** We select first 25 patients as training set to derive classifier for CR versus none CR that were at first blind to biostaticians. We found that genes involved in the PI3K pathway were significantly mutated in the CR group whereas CDK pathways were altered in the none CR group ($p < 0.0001$, sensitivity 91.7%, specificity 76.9%). CR events were independent of other worst prognostic factors including K-ras, B-raf, and p53. In vitro treatment of CRC cell lines with ADAPT drugs confirms strongest PI3K pathway inhibition effects ($p = 0$) and cell cycle pathway ($p < 0.05$). Validation set analysis will be reported at the meeting. **Conclusions:** Altered PI3Kand CDK pathways predict CR from ADAPT therapy in advanced unresectable CRC patients. Ongoing retrospective and prospective phase II ADAPT studies intend to validate these above findings. Funded by Gateway for Cancer Research and Lyon Foundation.

**3611 General Poster Session (Board #74), Sat, 8:00 AM-11:45 AM**

**Functional genomic screens and identification of signaling pathways in oxaliplatin-resistance in colorectal cancer.** *Presenting Author: Niharika B. Mettu, Duke University Medical Center, Durham, NC*

**Background:** In colorectal cancer, many patients develop resistance to oxaliplatin, which is a challenge given the limited number of therapeutic options in the treatment of this disease. While many mechanisms have been purported to explain the etiology of resistance to oxaliplatin in colorectal cancer, the role of intracellular signaling pathways that may be implicated in this phenomenon is not well-understood. **Methods:** We performed a functional genomic screen using a lentiviral overexpression system, in order to identify pathways that conferred a survival advantage to 2 patient-derived colorectal cancer cell lines treated with oxaliplatin in vitro. We classified 20 patient-derived colorectal cancer xenografts as either sensitive or resistant to oxaliplatin based upon tumor growth inhibition, and performed affymetrix microarray analysis on a representative mouse for each xenograft. This gene expression data was used to perform gene set enrichment analysis (GSEA, Gene Pattern) to identify pathways associated with resistance in vivo. We validated the importance of the pathway we identified in vitro using GI50 curves and in vivo by pharmacologically inhibiting the pathway and measuring effect on tumor volume in the absence and presence of oxaliplatin. **Results:** From our functional genomic screen, we found upregulation of the Wnt pathway in oxaliplatin-resistant, patient-derived colorectal cancer cell lines. GSEA identified Wnt pathway upregulation in oxaliplatin-resistant tumors treated with oxaliplatin. Activation of the Wnt pathway conferred oxaliplatin-resistance to patient-derived colorectal cancer cell lines in vitro. And finally, treatment of a patient-derived colorectal cancer xenograft with the Wnt inhibitor niclosamide was able to resensitize the tumor to oxaliplatin in vivo. **Conclusions:** Our study shows that functional genomic screening approaches can be utilized to identify novel targets that can be used to overcome resistance to therapy, and suggests that Wnt pathway inhibition may be able to resensitize colorectal cancer to oxaliplatin.

**3612 General Poster Session (Board #75), Sat, 8:00 AM-11:45 AM**

**Surveillance for asymptomatic recurrence in resected stage III colon cancer (CC): Does it result in a more favorable outcome?** *Presenting Author: Martin Smoragiewicz, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** Evidence supports a modest survival benefit for intensive post-treatment surveillance following potentially curative resection of CC. However, no studies so far included only patients with stage III CC, who have the highest risk of recurrence. **Methods:** Medical records of patients who initiated adjuvant chemotherapy (AC) with either 5-FU or capecitabine plus oxaliplatin for stage III CC between 2007 and 2011 at the BC Cancer Agency were reviewed. Kaplan-Meier and log rank test were generated to investigate whether diagnosis of recurrence based on symptoms was associated with worse OS. OS1 was considered from date of recurrence to date of death or last FU. OS2 was considered time from surgery (sg) to date of death or last follow-up (FU). **Results:** Of635 pts who received oxaliplatin-based AC for stage III colon cancer, 176 patients (27.7%) have recurred and 118 (18.6%) have died at a median FU of 57.9 months. Recurrence was detected based on CEA elevation (G1) in 72 (41.1%) pts, abnormal imaging (G1) in 77 (44%) and symptoms (G2) in 26 (14.9%). Median time from sg to recurrence was shorter in G1 as compared to G2 (18.5 vs 25.7 months, p=0.003, HR 0.501). Median OS1 was significantly prolonged in G1 as compared to G2 (26.7 vs 6.5 months, p<0.001, HR 0.393). However, median OS2 was not statistically different between G1 and G2 (49.8 vs 40.1, p=0.327, HR 0.776). Patients with surveillance detected recurrence underwent significantly more potentially curative metastasectomy than patients with recurrence detected due to symptoms (33% vs 8%, p= 0.014). **Conclusions:** In our population-based study, patients who were symptomatic at the time of recurrence were diagnosed later than those detected by abnormal CEA or imaging and had shorter OS1. However, OS2 was similar in both groups adjusting for the effect of lead time bias. Surveillance for asymptomatic recurrence may still provide an opportunity for curative metastasectomy but the overall survival impact is unclear.

**3613 General Poster Session (Board #76), Sat, 8:00 AM-11:45 AM**

**Association between body mass index and all-cause mortality in colorectal cancer patients: A meta-analysis of prospective cohort studies.** *Presenting Author: Junga Lee, Yonsei University, Seoul, South Korea*

**Background:** Studies have reported conflicting results on association between body mass index (BMI) and colorectal cancer-specific mortality and all-cause mortality in colorectal cancer patients. **Methods:** We performed a meta-analysis of 13 prospective cohort studies to identify the association between BMI (pre-diagnosis BMI or post-diagnosis BMI) and mortality outcome measures. Random-effects meta-analyses were performed to determine the risk ratio (RR) and 95% confidence interval (CIs). The analysis included 52,278 patients followed up over a period ranging from 4.9 to 20 years (median: 9.9 years). **Results:** We found that pre-diagnosis underweight was associated with increased all-cause mortality (RR: 1.62, 95% CI: 1.18-2.23, $p<0.01$) and obesity (BMI $\geq$ 30 kg/m$^2$) was associated with increased colorectal cancer-specific mortality (RR: 1.20, 95% CI: 1.07-1.36, $p<0.01$) and all-cause mortality (RR: 1.24, 95% CI: 1.12-1.38, $p<0.01$). On the other hand, post-diagnosis underweight (RR: 1.33, 95% CI: 1.19-1.47, $p<0.01$) and class II/III obesity (BMI $\geq$ 35 kg/m$^2$; RR: 1.13, 95%CI: 1.03-1.14, $p<0.01$) were associated with significantly increased all-cause mortality. When subgroup analysis according to gender was conducted, post-diagnosis obesity was associated with increased all-cause mortality (RR: 1.131, 95% CI: 1.054-1.213, $p<0.01$) in women only. **Conclusions:** Being obese prior to diagnosis of CRC was associated with CRC specific mortality and all-cause mortality, while being underweight and obesity after diagnosis was associated with increased all-cause mortality. Maintaining a normal body weight should be recommended to all individuals including colorectal cancer patients. This study was supported by National Research Foundation of Korea (2013 K2A1A2054437).

**3614 General Poster Session (Board #77), Sat, 8:00 AM-11:45 AM**

**Timing of adjuvant therapy in stage II-III colorectal cancer.** *Presenting Author: Lucas Vieira dos Santos, Instituto de Ensino e Pesquisa São Lucas, São Paulo, Brazil*

**Background:** Delay in commencing adjuvant therapy for colorectal cancer seems to impair survival in some retrospective studies. This is a large, bi-institutional retrospective study evaluating the impact of chemotherapy delay in survival. **Methods:** The interval between the primary surgery and the start of adjuvant chemotherapy was calculated. Survival was estimated using Kaplan-Meier method and the impact of multiple prognostic factors on survival by Cox Regression. **Results:** By the end of 2012, 2143 colorectal patients treated by surgery were identified from a retrospective database in two Brazilian institutions. Only stage II and III colorectal patients were selected, comprising 1963 patients, and 1318 patients received adjuvant chemotherapy (46% of patients started adjuvant chemotherapy within 6 weeks of surgery). The median follow up were 36 months. Patients starting chemotherapy within 6 weeks of surgery (vs. after 6 weeks) had longer overall survival (median not reached, HR 0.742, 95%CI 0.59-0.93, p=0.011). In the multivariate analysis, age, place of origin, stage, histological grade, emergency surgery, pre-operative therapy and radiotherapy were independent prognostic factors, but the interval between surgery and start of adjuvant therapy was not (HR 0.909, 95%CI 0.717-1.154, p=0.435). Sensitivity analysis using showed similar results. **Conclusions:** In this large retrospective study, the classic prognostic factors impacted on survival, and the timing of adjuvant therapy did not. Patients with delayed chemotherapy may harbor worst prognostic factors. Further investigation is warranted.

**3615 General Poster Session (Board #78), Sat, 8:00 AM-11:45 AM**

**IMPACT trial: Predictive factors for maintenance therapy with MGN1703 in patients with metastatic colorectal carcinoma.** *Presenting Author: Jorge Riera-Knorrenschild, Universitätsklinikum Giessen und Marburg, Marburg, Germany*

**Background:** The immunomodulator MGN1703, a TLR-9 agonist, has shown good safety profile in patients with metastatic solid tumors. The IMPACT trial was conducted to assess clinical efficacy, safety, and immunological effects of MGN1703 as maintenance therapy twice weekly. **Methods:** The international randomized (2:1) double-blind placebo-controlled phase 2 IMPACT trial in mCRC patients with disease control after 1st-line chemotherapy by FOLFOX/XELOX or FOLFIRI +/- bevacizumab. After randomization of 59 out of 129 planned patients (43 MGN1703, 16 placebo) the trial was prematurely closed due to slow recruitment. **Results:** A superior effect of MGN1703 compared to placebo was shown: HR for the primary endpoint PFS on maintenance was 0.55 (p=0.041) by local and 0.56 (p=0.070) by independent assessment. For PFS from start of induction therapy the HR was 0.50 (p=0.022) and 0.49 (p=0.030), respectively. Notably, at time of study closure 4 MGN1703 patients were still free of PD and continued in compassionate use. A possible predictive effect was identified by Cox regression analyses: HR of 0.07 (p<0.0001) for patients with normal CEA and 0.39 (p=0.005) for patients with an objective response. Evaluation of biological activity via cell populations and chemokine serum levels confirmed immune system activation in MGN1703 patients. Cox regression and ROC analyses identified of activated NKT-cells ($CD3^+/CD56^+/CD69^+$) at baseline as potentially predictive for a benefit from MGN1703 treatment (HR: 0.27, p=0.007). Study treatment was well tolerated: 32.6% vs. 18.8% of patients (MGN1703 vs. placebo) had drug-related AE and in only 1 patient per arm it was of grade 3 (MGN1703: sensory polyneuropathy, placebo: papular exanthema). Seven SAEs were reported of which only 1 was possible drug-related (moderate atypical pneumonia). **Conclusions:** Following induction chemotherapy, MGN1703 maintenance in mCRC patients is associated with improved PFS and an activation of the innate and adaptive immune system. Treatment was safe and well tolerated. There is preliminary evidence that CEA levels, tumor response, and activated NKT cells before start of MGN1703 therapy allow for identification of benefitting patients. Clinical trial information: NCT01208194.

**3616 General Poster Session (Board #79), Sat, 8:00 AM-11:45 AM**

**Improved disease-free survival with intraportal chemotherapy plus adjuvant chemotherapy (mFOLFOX6) as adjuvant treatment in colon cancer.** *Presenting Author: Wenju Chang, Fudan University, Shanghai, China*

**Background:** The optimal time from surgery to the start of chemotherapy in colon cancer is unknown. We evaluated the impact on survival of intraportal chemotherapy (IPC) administrated during surgery plus adjuvant chemotherapy (AC) as treatment for stage II and III colon cancer. **Methods:** Patients with stage II or stage III colon cancer were randomly assigned to receive IPC plus mFOLFOX6 (OCTREE) or mFOLFOX6 alone. The primary end point was disease-free survival (DFS). Secondary endpoints included metastasis-free survival (MFS), overall survival (OS) and safety. **Results:** The intent-to-treat population comprised 237 patients. After a median follow-up of 44 months, The 3-year DFS rate was 85.2% (95% CI 81.9 to 88.4) with OCTREE and 75.6% (95% CI 71.7 to 79.4) with mFOLFOX6 alone ($P = .030$). The hazard ratio (OCTREE versus mFOLFOX6) was 0.66 (95% CI, 0.43 to 0.90, $P = .016$). The 3-year MFS rates were 87.6% versus 78.0%, when compared OCTREE with mFOLFOX6, the hazard ratio was 0.59 (95% CI, 0.38 to 0.92, $P = .023$). Patients in OCTREE arm had decreased distant metastases events (12.7% versus 22.7%; $P = .044$) compared with those in mFOLFOX6 arm. Grade 3 hepatic toxicity was observed in 1.7% of patients receiving OCTREE within two weeks after surgery, and could be cured with medicine. Only one patient died as a result of any cause within 6 months of receiving chemotherapy, with no significant difference between regimens. **Conclusions:** Intraoperative intraportal chemotherapy combined with mFOLFOX6, reduced the occurrence of distant metastasis, and therefore improved DFS in patients with stage II and stage III colon cancer. Clinical trial information: NCT01972503.

**3617 General Poster Session (Board #80), Sat, 8:00 AM-11:45 AM**

**Randomized phase III trial of FOLFOX versus XELOX as adjuvant chemotherapy in patients with early-stage colorectal adenocarcinoma.** *Presenting Author: Dimitrios G. Pectasides, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece*

**Background:** The aim of the trial was to compare two active adjuvant chemotherapy regimens in patients with early stage colorectal cancer (CRC). **Methods:** Patients were assigned to oxaliplatin 85 mg/m$^2$ as a 2-h iv infusion (d1), given concurrently with leucovorin 200 mg/m$^2$, followed by 5-FU 400 mg/m$^2$ as an iv bolus (d1) and 5-FU 2400 mg/m$^2$ as a 46-h iv infusion (d1 & d2) every 14 d for 12 cycles (group A, FOLFOX6) or oxaliplatin 130 mg/m$^2$ as a 2-h iv infusion (d1) and capecitabine 1000 mg/m$^2$ per os (d1-14) every 21 d for 8 cycles (group B, XELOX). Primary endpoint was disease-free survival (DFS). Tumors were classified as MMR proficient (pMMR) or MMR deficient (dMMR) according to MLH1, PMS2, MSH2 and MSH6 protein expression. *KRAS* exon2 and *BRAF*V600E mutational status was also assessed. **Results:** Between 2005 and 2008, 439 patients were enrolled with 414 being eligible. Of the latter, 201 were randomized to FOLFOX and 213 to XELOX. Most common grade 3-4 toxicities were neutropenia (13.8% with FOLFOX vs 4.4% with XELOX, $p<0.0001$) and sensory neuropathy (3.2% with FOLFOX vs 2.1% with XELOX, $p=0.25$). Vomiting was more frequent in the XELOX group (1.6% vs 0%, $p=0.017$). After a median follow-up of 74.7 months, 3-year DFS was 79.8% (95% CI 76.5-83.4) in the FOLFOX group and 79.5% (95% CI 75.9-83.1) in the XELOX group ($p=0.78$). Three-year OS was 87.2% (95% CI 84.1-91.1) in the FOLFOX and 86.9% (95% CI 83.4-89.9) in the XELOX group ($p=0.84$). Overall, 34 of the 308 available tumors (11.0%) were dMMR, 104 of 306 (34.0%) *KRAS* mutant and 15 of 306 (4.9%) *BRAF* mutant. Multivariate analysis showed that primary site in the left colon, earlier TNM stage and the presence of anemia at diagnosis were associated with better DFS and overall survival (OS), while grade 1-2 tumors were associated with better OS. Finally, in the left colon only, dMMR tumors were associated with shorter OS ($N=208$, $p=0.016$ for interaction) and *KRAS*mutated tumors were associated with shorter DFS ($N=209$, $p=0.123$ for interaction). **Conclusions:** The FOLFOX and XELOX regimens did not differ significantly in their efficacy as adjuvant treatment in high-risk CRC patients. A significant interaction was found between primary site location and MMR status with respect to OS. Clinical trial information: ACTRN12610000509066.

**3618 General Poster Session (Board #81), Sat, 8:00 AM-11:45 AM**

**Molecular subtyping of colorectal cancer for identification of patients with a mesenchymal tumor type who might benefit from TGF-beta inhibition.** *Presenting Author: Ramon Salazar, Early Clinical Research Unit, Institut Català d'Oncologia, L´Hospitalet-Barcelona, Spain*

**Background:** Currently, most colorectal cancer (CRC) patients receive chemotherapy treatment, even though many patients do not benefit. Therefore, a better understanding of the biology is required to identify those patients who will benefit from chemotherapy and to find a more tailored therapy plan for all other patients. **Methods:** A molecular subtype classification (A-, B-, C-type) was developed using expression data of 188 stage I-IV CRC patients and validated in 543 stage II and III patients. Subtypes were correlated to clinical factors, prognosis and treatment benefit (stage III). To determine whether TGF-$\beta$ signaling is elevated, 78 patient biopsies were analyzed for TGF-beta (receptor) and phospho-SMAD2/3 expression. To analyze the effect of TGF-$\beta$ activation, we studied the effects of C-type-like cell lines under treatment with Cisplatin, Oxaliplatin or 5-FU. We analyzed the presence of subtypes in all stages (TCGA data, $n=218$), and investigate the stability of classification in multiple biopsies from the same tumor and in matching primary and liver metastases samples. **Results:** We developed a diagnostic test that allows the classification of colorectal cancer tumors into different intrinsic molecular subtypes. The heterogeneity of these subtypes is largely based on 3 biological hallmarks of the tumor. Especially C-type CRC is of clinical interest, as C-type patients have the worst outcome, a mesenchymal phenotype and show no benefit from chemotherapy treatment. The C-type subgroup has elevated TGF-$\beta$ signaling (*TGFB1*, $p=0.0012$; *TGFBR1*, $p=0.0005$) and increased p-SMAD2/3 staining in the tumor cells (1.9-fold, $p=0.0002$). In cell line experiments, up-regulation of TGF-$\beta$ signaling resulted in resistance against chemotherapy. We confirmed the presence of C-type tumors in stage IV CRC (16%) and currently investigate the stability of the subtype phenotype in 33 pairs of matching primary tumor and metastases. **Conclusions:** The molecular subtypes differ largely in prognosis and response to chemotherapy. A treatment strategy combining standard drugs with agents suppressing TGF-$\beta$ signaling might benefit C-type patients.

**3619 General Poster Session (Board #82), Sat, 8:00 AM-11:45 AM**

**Efficiency of biomarker screening for enriched metastatic colorectal cancer trials: The ATTACC program experience.** *Presenting Author: Van Karlyle Morris, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Incorporation of multiple enrichment biomarkers into prospective clinical trials for metastatic colorectal cancer (mCRC) has been proposed or initiated by NSABP, EORTC, NCI Colon Task Force, and UK MRC. The feasibility of large scale screening efforts in mCRC has not been previously assessed. **Methods:** Patients (pts) with 5-FU refractory mCRC at MD Anderson Cancer Center were offered screening in the Assessment of Targeted Therapies Against Colorectal Cancer (ATTACC) program to identify eligibility for companion phase I or II clinical trials with a therapy targeted to an aberration detected in the patient, based on FFPE testing by immunohistochemistry (IHC), 50-gene sequencing, and CpG island methylation phenotype (CIMP) assays. Ten unstained slides were required. **Results:** Between 8/2010 and 1/2014, 506 pts were enrolled. Median time from consent to results was 28 days (interquartile range 22-37 days). Outside tissue was obtained after a median of 6 days (4-10 days). IHC, sequencing, and CIMP results required a median of 10, 13, and 20 days, respectively (Table), with 95% yield. During this 40 month period, between 20 and 40% of pts were eligible on the basis of screened tumor biomarkers for at least one of the 18 companion studies. Given trial-specific eligibility, study logistics, and intermittent study openings, only 14% of pts enrolled on an enriched companion trial, representing an approximate 50% efficiency of enrolling eligible patients. 66% received alternate treatments off protocol, 16% enrolled on unenriched studies, and 4% received no further therapy due to a declining performance status. **Conclusions:** Even though dedicated screening infrastructures such as ATTACC represent an efficient strategy for enrichment studies, a majority of patients did not ultimately participate on a companion trial due to dropout of biomarker-eligible patients and a cumulative lack of trials targeting a majority of screened patients. Both of these hurdles need to be addressed to improve success of this strategy.

**3620 General Poster Session (Board #83), Sat, 8:00 AM-11:45 AM**

**Immune checkpoints expression in MSI versus MSS colorectal cancers and their potential therapeutic implications.** *Presenting Author: Nicolas Jose Llosa, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Colorectal cancer (CRC) is divided into 2 groups based on genomic differences: chromosomal instability (80%), and microsatellite instability (MSI) (20%). MSI CRC is associated with a favorable prognosis independent of classic clinical prognostic factors. MSI CRC has been characterized by an intense immune infiltration which was assumed to be related to a high density of mutations creating numerous neoantigens. We compared the nature of inflammation in MSS and MSI CRC specimens to identify biomarkers which could guide therapeutic interventions. **Methods:** Pairs of CRC and normal tissues were enzymatically dissociated to isolate leukocytes by density gradient and their phenotypic characterization was done via multi-parameter flow cytometry (MFC). Immune infiltration was scored using immunohistochemistry (IHC) and *in situ* molecular analysis was performed via laser capture microdissection (LCM) and TaqMan quantitative RT-PCR. **Results:** IHC analysis of immune infiltrates in 15 CRC specimens delineated 3 distinct areas denominated intraepithelial lymphocytes (TIL), tumor stroma (TS) and invasive margin (IM). Scoring of $CD3^+$, $CD4^+$ and $CD8^+$ cells demonstrated that MSI specimens (n=8) were characterized by a higher infiltration of all three populations compared to MSS samples (n=7). Molecular analysis of the TIL (3 MSI versus 3 MSS) indicated that the tumor microenvironment of MSI CRC was characterized by a high expression of IFNg and genes associated with cytotoxic T cells (CTL) including *CD8A*, *TBX21*, *PERF*, *GZM*. Strikingly, MSI samples had a greater expression of IFN-g-driven immune checkpoints such as PD-1, PD-L1, IDO-1 and INOS suggesting that the high density of infiltrating CTL and IFNg stimulate mechanisms of adaptive immune resistance in MSI tumors. MFC analysis of TIL performed on fresh tumors confirmed the higher presence of IFNg-producing $PD1^{hi}$ $CD8^+$CTL in MSI samples (n=8). **Conclusions:** The genetic origin of CRC dictates the nature and intensity of inflammation. A strong IFNg -driven inflammatory response in MSI CRC patients triggered the expression of PD-L1 and IDO-1 which could be targeted to enhance clinical benefit and be predictive of response to immune checkpoint inhibitors.

**3621 General Poster Session (Board #84), Sat, 8:00 AM-11:45 AM**

**A marker-driven phase II trial of neoadjuvant chemotherapy in locally advanced colon cancer.** *Presenting Author: Anders Kristian Moeller Jakobsen, Department of Oncology, Vejle Hospital, Vejle, Denmark*

**Background:** The treatment of locally advanced colon cancer faces many challenges and new approaches are needed. Neoadjuvant chemotherapy has proven valuable in several tumors, but it has not been elucidated in colon cancer. One major reason has been the lack of validated methods for selection, but recent improvement in CT scanning has allowed for identification of high-risk patients in need of adjuvant chemotherapy. **Methods:** Patients with resectable colon cancer fulfilling the following criteria were offered inclusion; Histopathological verification of adenocarcinoma, T3 tumor on CT scan with extramural tumor invasion $>$ 5 mm or T4 tumor, age $\geq$ 18 years, PS $\leq$ 2, adequate hematology, and informed consent. Patients with KRAS, BRAF, or PIK3CA mutation or unknown mutational status received 3 cycles of capecitabine 2000 $mg/m^2$days 1-14 q3w and oxaliplatin 130 mg iv day 1 q3w. Wildtype patients received the same chemotherapy supplemented with panitumumab 9 mg/kg iv q3w. After the operation, patients fulfilling the international criteria for adjuvant chemotherapy received 5 cycles of the same chemotherapy without panitumumab. Patients not fulfilling the criteria (converted patients) were offered follow-up only. The primary endpoint was the fraction of converted patients. Secondary endpoints were 2-year disease free survival (DFS) and toxicity. The study was approved by the Regional Scientific Ethical Committee (S-20100014) and registered at ClinicalTrials.gov (NCT01918527). **Results:** The study included 77 patients. The conversion rate was 42% in the wildtype group compared to 51% in patients with a mutation. The objective response rate by CT scan was 45%. Three patients had complete pathological remission. The cumulative recurrence rate in converted vs. non-converted patients was 3% vs. 27% (p=0.003) translating into a 2-year DFS of 96% vs. 54% (p=0.004). Toxicity was manageable and 90% received $\geq$ two cycles of the three planned cycles of neoadjuvant chemotherapy. **Conclusions:** Neoadjuvant chemotherapy in colon cancer is feasible and the results suggest that a major part of the patients can be spared adjuvant chemotherapy. A randomized trial is warranted. Clinical trial information: NCT01918527.

**3622 General Poster Session (Board #85), Sat, 8:00 AM-11:45 AM**

**A new method to analyze adverse events longitudinally in oncology clinical trials.** *Presenting Author: Gita Thanarajasingam, Mayo Clinic, Rochester, MN*

**Background:** There are significant limitations to the current method for displaying treatment-related adverse events (AE) in clinical trials. Tables displaying grade 3 and 4 AEs do not capture toxicity profiles that evolve over time and do not provide clinically relevant information on when a given AE could arise, its probable duration and its severity at a given point in therapy. We developed a novel method of analysis to better capture and represent longitudinal AE data. **Methods:** Graphical and analytical routines were developed to analyze adverse events longitudinally. Mean symptom and toxicity values are plotted over time on a single axis for direct comparison. Butterfly plots compare adverse events by treatment arms longitudinally. Multiple longitudinal techniques (repeated measures modeling, profile analysis, area under the curve analysis, change from baseline, and time to event) are included. Heat maps, event charts and stream plots are produced for individual patient results over time. **Results:** The methodology was validated in two completed clinical trials in colorectal cancer treatment (N9741) and cancer control (979254). In N9741, a higher incidence and severity of diarrhea, nausea and vomiting in patients on IROX (irinotecan/oxaliplatin) versus FOLFOX (fluorouracil/oxaliplatin) was most pronounced in the first treatment cycle and declined sharply by cycle 2. An increased incidence of alopecia in this cohort was also most apparent upfront, from the first to the second cycle, as compared to a lower overall incidence of alopecia with a gradual rise from cycles 1 through 5 in patients on FOLFOX. In study 979254, a higher incidence of dry mouth in patients using venlafaxine 150 mg/d as compared with placebo was most prominent only later in therapy, at weeks 4 and 5 (incidence of 22% for placebo and 13% for venlafaxine 150 mg/d at week 1, p=0.25, versus, 2.2% and 49%, respectively, at week 5, p=0.0001). **Conclusions:** A new method of analyzing AEs in clinical trials that incorporates the dimension of time offers a more complete depiction of chemotherapy toxicity than current methods. Longitudinal analyses of toxicity over time can provide enhanced patient education and guide clinical management on a given chemotherapy strategy.

**3623 General Poster Session (Board #86), Sat, 8:00 AM-11:45 AM**

**Response rates to hepatic arterial infusion (HAI) pump therapy in patients with metastatic colorectal cancer liver metastases (mCRC LM) after progression on all standard chemotherapies.** *Presenting Author: Andrea Cercek, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** To evaluate the overall response rate of HAI with floxuridine (FUDR) in the refractory setting in patients with mCRC LM. **Methods:** After obtaining an IRB waiver a computerized search was performed for patients with mCRC treated with 5FU, oxaliplatin and irinotecan +/- EGFR and VEGF inhibitor from 2003-2012 . Charts were reviewed to ensure patients (pts); had received all standard therapies prior to HAI pump placement, all pts received HAI FUDR and that no new systemic targeted or cytotoxic therapies were used with HAI pump. Imaging was re-reviewed for confirmation of progression prior to HAI pump placement and for best response using RECIST 1.1 criteria. **Results:** 75 pts were identified; of these 23 had radiographic disease progression on all standard chemotherapies (5FU, irinotecan and oxaliplatin) prior to having a pump placed. Of the 23 evaluable pts, the median age was 53 (range 37-75). Six pts had low volume extrahepatic metastases at the time of pump placement. The overall response rate (ORR) was 8/23 (35%); 10/23 (43%) pts had stable disease (SD). The median duration of SD was 4 months (range 1-10). Median follow up, measured from the date of HAI initiation, was 24 months and median overall survival (OS) was 22 months (95% CI 13-16). The median hepatic progression free survival (hPFS) was 4.5 months [CI: 3.8-6.7]. Thirteen pts developed extrahepatic disease progression (including 5 pts with preexisting extrahepatic disease). The median overall PFS was 3.9 months [95% CI 2.24-5.33]. Median number of HAI treatments was 4 cycles (range 1-13). Six out of 23 (26%) pts required a 50-75% dose reduction by the second cycle due to elevated liver function tests and 18/23 (78%) required a dose reduction after the $3^{rd}$ cycle. No pts required stents or developed long term liver or biliary toxicity. **Conclusions:** In a cohort of 23 patients with mCRC LM, refractory to all standard agents, treatment with HAI FUDR resulted in an ORR by RECIST 1.1 of 35% and median OS of 22 months. Further studies focusing on locoregional therapy in patients with liver predominant disease are warranted. Studies to molecularly characterize these tumors are ongoing.

**3624 General Poster Session (Board #87), Sat, 8:00 AM-11:45 AM**

**Molecular evaluation of primary tumor (PT) and synchronous liver metastasis in colorectal cancer (srLmCRC) patients after cetuximab-based chemotherapy.** *Presenting Author: Daniela Adua, Medical Oncology Unit, S. Orsola-Malpighi Hospital, Bologna, Italy*

**Background:** Molecular heterogeneity among PT and LmCRC is not yet defined. Next Generation Sequencing (NGS) in clinical practice could increase the change of identifying multiple molecular driver alterations calling for therapy. This study evaluates mutations in PT and sLmCRC exon2 KRAS wt patients who underwent chemotherapy (CT) containing cetuximab. **Methods:** Genomic analysis was conducted in 7 sLmCRC pts: before CT on a PT biopsy, after CT on a PT surgical specimen and all srLmCRC. A total of 54 lesions were examined. DNA libraries were generated using the Ion AmpliSeq Colon and Lung Cancer Panel including 22 mutated genes (KRAS, EGFR, BRAF, PIK3CA, AKT1, ERBB2, PTEN, NRAS, STK11, MAP2K1, ALK, DDR2, CTNNB1, MET, TP53, SMAD4, FBXW7, FGFR3, NOTCH1, ERBB4 , FGFR1, FGFR2) and sequenced on a Ion PGM system **Results:** A partial response was achieved in all pts, with a median PFS of 11 months (4-15). Molecular analysis of genes correlated with target therapy is shown in the following table (K=KRAS; N=NRAS; P=PIK3AC; M=MET; m= -; wt= + ). Pt 1 showed heterogeneity in PT before and after CT with KRASm clonal selection and related expression of the mucinous pattern; in srLmCRC: 5/9 KRASm exon2, 1/9 PIK3CAm exon20, 2/9 KRASm exon2 and PIK3CA exon20. In pt 7 NRASm exon2 was identified in PT before and after CT; differences in srLmCRC: 3/5 no mutation, 1/5 NRASm exon2, 1/5 PIK3CAm exon20. The other cases showed rare mutations: SMAD4 (pt 2), TP53 (pts 2,5,6,7), FBXW7 (pt1). **Conclusions:** Our preliminary data suggest a potential role for NGS in the evaluation of biological drug resistance affecting future sequential treatments strategy

**3625 General Poster Session (Board #88), Sat, 8:00 AM-11:45 AM**

**Programmed death 1 (PD-1) lymphocytes and ligand (PD-L1) in colorectal cancer and their relationship to microsatellite instability status.** *Presenting Author: Zoran Gatalica, Caris Life Sciences, Phoenix, AZ*

**Background:** PD-1 activation by its ligands (PD-L1 and PD-L2) inhibits T-cell activation and plays a role in cancer progression. PD-L1 is widely expressed in many cell types in tumor microenvironment. In contrast, expression of PD-1 is restricted to a small subset of T-lymphocytes. Inhibition of PD-1/PD-L1 interaction showed no benefit in a small number of colorectal cancers (CRC) studied in clinical trials. We investigated tumor infiltrating PD-1+ lymphocytes and PD-L1 expressing cells in CRC to gain insight in their role as biomarkers. **Methods:** 77 CRC cases (53 sporadic and 24 hereditary, including 23 Lynch syndrome and 1 FAP) were profiled (Caris Life Sciences) for the presence of PD-1 and PD-L1 expressing cells, mismatch repair proteins, DNA microsatellite instability (MSI) and select cancer genes sequences (NGS). Only intraepithelial PD-1+ lymphocytes (IEL) and aberrantly expressed PD-L1 on carcinoma cells were considered specific. **Results:** PD-1+ IEL were detected in 47% of sporadic CRC. Microsatellite stable (MSS) cancers were frequently (61%) negative for PD-1. Microsatellite instability-high (MSI-H, both Lynch syndrome and sporadic) were significantly ($p<0.03$) more frequently infiltrated with PD-1+ IEL than MSS (72% MSI-H vs. 39% MSS). Similarly, PD-L1+ cancer cells were more common in MSI-H (56%) than in MSS (21%, $p=0.007$), but the expression was patchy in all cases. Concurrent PD1+ IEL and PD-L1 cancer cells were seen in 30% of MSI-H and 5% of MSS cancers ($p=0.008$). **Conclusions:** Consideration of immune checkpoint therapies for colorectal cancer needs to consider the presence of PD-1 lymphocytes and cancer cell specific PD-L1 expression. PD-1+ IEL and PD-L1+ cancer cells are more frequent in MSI-H than in MSS colorectal cancers, which are rare in general CRC population.

**3626 General Poster Session (Board #89), Sat, 8:00 AM-11:45 AM**

**Prognostic impact of reduced lymph node yield in lymph-node negative rectal cancer specimens following neoadjuvant treatment.** *Presenting Author: Benjamin Garlipp, Otto von Guericke University Medical School, Magdeburg, Germany*

**Background:** Pathologic examination of at least 12 lymph nodes (LN) is required as per NCCN and ESMO guidelines to accurately identify pN0 rectal cancer. However, this may not apply to patients undergoing surgery following neoadjuvant treatment because LN may be rendered unrecognizable by preoperative chemoradiation. The prognostic impact of reduced LN yield in rectal cancer specimens following neoadjuvant treatment is unknown. **Methods:** Data from the prospective German multicenter Quality Assurance in Rectal Cancer observational trial were retrospectively analyzed. Patients undergoing radical surgery for rectal cancer between 01/01/2007 and 12/31/2009 who were staged to have pN0 disease were included. Propensity Score Analysis using factors potentially influencing the decision for or against neoadjuvant treatment was performed to compensate for bias inflicted by factors that affect both the decision on neoadjuvant treatment and survival. Cox regression including age, complicated surgery, pT stage, propensity score for neoadjuvant treatment, LN yield, and interaction between the latter two was then performed to identify factors independently influencing survival. **Results:** The full data set included 4,154 patients of whom 1,914 (46.1%) underwent neoadjuvant treatment. Significantly fewer LN were retrieved in neoadjuvantly treated patients (median, 13 vs. 15; $p<0.001$). Complete data were available for 1,394 patients. Only age ($p<0.001$), advanced pT stage ($p=0.001$ and $p<0.001$ for pT3 and pT4, respectively), and complicated surgery ($p<0.001$) were independently associated with survival. Neither number of LN, propensity for neoadjuvant treatment, nor interaction between these two were identified as factors independently affecting survival. Only when interaction between propensity for neoadjuvant treatment and LN number was removed from the model, number of LN retrieved was found to be an independent prognostic factor ($p=0.027$). **Conclusions:** Although neoadjuvant treatment reduces the number of LN retrieved in rectal cancer specimens, our data suggest that this has no influence on the prognostic impact of the number of LN examined in patients with pN0 rectal cancer.

**3627 General Poster Session (Board #90), Sat, 8:00 AM-11:45 AM**

**Comparative effectiveness of laparoscopy versus open colectomy among nonmetastatic colon cancer patients: An analysis using the National Cancer Data Base.** *Presenting Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

**Background:** Laparoscopy (LAC) has gained wide acceptance as a curative treatment for non-metastatic colon cancer after the publications of several major clinical trials in the last decade. However, there is limited data regarding the comparative effectiveness of LAC vs. open colectomy (OC) in routine clinical practice. The objective of the study is to compare short-term surgical outcomes between LAC and OC using a national hospital-based cancer registry dataset. **Methods:** The National Cancer Data Base was used to identify stage I-III colon cancer patients aged 18-84 between 2010 and 2011. An intent-to-treat analysis was conducted where converted cases were included in the LAC group. A propensity score matching (PS) method was used to create comparable LAC and OC groups. Patients were clustered at the hospital-level for multilevel regression analysis to investigate the associations between various clinical, demographic, and contextual variables (i.e. surgeon/hospital volume measurements, insurance types, and facility types) and short-term surgical outcomes (i.e. 30-day mortality, 30-day readmission, and length of hospital stay). Sensitivity analyses were conducted to examine the robustness of our findings by excluding converted colectomies (LAC completed only vs. OC), and including patients aged 85 and above at the time of diagnoses. **Results:** A total of 45,876 patients undergoing colectomy were included, 18,717 (41%) LAC and 27,159 (59%) OC. After PS, all variables were balanced and there were 18,189 patients in each of LAC and OC groups. Compared to OC, LAC showed consistent benefits in the 30-day mortality rate (OR = 0.51, 95%CI: 0.43---0.60, $p < 0.001$) and length of hospital stay (IRR = 0.82, 95%CI: 0.80---0.83, $p < 0.001$), but not the 30-day readmission rate (OR =0.93, 95%CI: 0.84---1.03, $p = 0.136$). These findings were not affected by either exclusion of converted cases nor inclusion of patients aged 85 and above. **Conclusions:** Compared to open colectomy, laparoscopic colectomy has lower 30 day mortality and shorter length of hospital stay in routine clinical practice.

**3628 General Poster Session (Board #91), Sat, 8:00 AM-11:45 AM**

**Association of adjuvant chemotherapy with clinical outcomes in patients treated with neoadjuvant chemoradiation for locally advanced rectal cancer.** *Presenting Author: Michael M. Vickers, Tom Baker Cancer Centre, Calgary, AB, Canada*

**Background:** Clinical trial data does not support the routine use of adjuvant chemotherapy (ACT) following neoadjuvant chemoradiation (nCRT) and surgery (Sx) in rectal cancer (Ca). Few studies have included oxaliplatin-based ACT or assessed the benefit in specific pathologic stage (Pstage) subgroups. **Methods:** Data from patients (pts) with locally advanced rectal Ca who received nCRT and had curative intent Sx from 2005 to 2012 were collected from Tom Baker Cancer Center, Cross Cancer Institute, BC Cancer Agency, Ottawa Hospital Cancer Centre and Dr. H. Bliss Murphy Cancer Centre. The effect of ACT on Time Free of Recurrence (TFR – death without recurrence censored), Disease Free Survival (DFS) and Overall Survival (OS) was assessed using cox proportional hazards model, controlling for age, sex, performance status (PS), circumferential resection margin (CRM), location of tumor, RT dose, Clinical stage (Cstage), Pstage. **Results:** 1172 pts were included, with a mean age of 61.6 (± 0.33) and a mean follow-up time of 3.8 years (± 0.05). 303 (25.9%) pts received oxaliplatin-based ACT, while 328 (28%) did not receive any ACT and these pts were more likely to be older (65.8 v 65 yrs, $p<0.0001$), have worse PS ($p=0.009$), receive lower doses of RT ($p=0.0003$) and have earlier Cstage ($p=0.004$) on univariate analysis compared with ACT pts. Univariate analyses for Pstage 0-II were non-significant (NS) for effect of ACT on TFR and DFS. See Table for all pts and Pstage III outcomes controlling for covariates above. Assessment of ACT in high risk v low risk stage II (as in colon Ca) was NS for TFR ($p=0.47$), DFS ($p=0.7$) and OS ($p=0.7$) adjusting for age, PS and CRM. **Conclusions:** ACT improved clinical outcomes in our retrospective database, however the benefits may be limited to those with Pstage III. Studies are needed to clarify if factors used to stratify stage II colon Ca into high vs. low risk may be applied to estimate recurrence risk in Pstage II rectal Ca.

| Population | TFR (95% CIs) | p-value | DFS (95% CIs) | p-value | OS (95% CIs) | p-value |

**3629 General Poster Session (Board #92), Sat, 8:00 AM-11:45 AM**

**Extended *RAS* analysis and subsequent anti-EGFR and anti-VEGF treatment (tx) in PEAK: A first-line phase 2 study of FOLFOX6 + panitumumab (pmab) or bevacizumab (bev) in metastatic colorectal cancer (mCRC).** *Presenting Author: Fernando Rivera, Hospital Universitario Marqués de Valdecilla, Santander, Spain*

**Background:** In PEAK, progression-free survival (PFS) was similar and overall survival (OS) was improved with pmab + FOLFOX6 relative to bev + FOLFOX6 in patients (pts) with WT *KRAS* exon 2 mCRC. In an extended *RAS* analysis (exons 2, 3, and 4 of *KRAS/NRAS*), this improvement was enhanced in pts with WT *RAS*. This analysis evaluates pts who received subsequent biologic therapy in PEAK. **Methods:** Kaplan-Meier medians for OS were estimated for pts receiving pmab/subsequent anti-VEGF tx and pts receiving bev/subsequent anti-EGFR tx. Analyses were performed on pts with WT *KRAS* exon 2 and WT *RAS* from an exploratory, updated analysis (03Jan2013). Results are from the time of randomization. **Results:** Demographic and baseline characteristics were generally similar with differences of < 20% between arms. Results are shown (Table). Prespecified analyses suggest that individual *RAS* exons that are WT favor the pmab arm and will be presented. **Conclusions:** In this exploratory analysis, the time and % of pts to biologic subsequent tx were similar between the arms. Median OS was observed to be longer for pts receiving pmab/subsequent anti-VEGF tx relative to pts receiving bev/subsequent anti-EGFR tx and the improvements were similar to that in the total populations of the WT *KRAS* exon 2 and WT *RAS* groups. Clinical trial information: NCT00819780.

**Comparison of quantitative methods of assessing the hepatic burden of disease as predictors of overall survival at the initial diagnosis of stage IV colorectal cancer.** *Presenting Author: Michael Hayden Rosenthal, Dana-Farber Cancer Institute, Department of Imaging, Boston, MA*

**Background:** The metastatic tumor burden in the liver may be related to prognosis in patients with stage 4 colorectal cancer, but it is unclear if standard measurement techniques such as those used in the Response Evaluation Criteria for Solid Tumors (RECIST) will capture that prognostic information. Counting all liver lesions >= 1cm in size could offer a feasible alternative for whole-liver disease assessment. **Methods:** In this IRB-approved, HIPAA-compliant retrospective study, two board-certified radiologists independently reviewed the baseline imaging studies of 60 subjects with treatment-naïve stage 4 colorectal cancer. The hepatic tumor burden was assessed in two ways: by measuring the longest dimensions of the five largest measurable liver lesions, and by counting the number of lesions measuring at least 1 cm in size. Overall survival was assessed from diagnosis to death or censoring via the electronic medical record, which also references the social security death master file. No subject was lost to follow-up over a median of 1233 days. The sum of the longest dimensions of the five largest liver lesions (SLD5, in cm; RECIST 1.0 standard), the sum of the longest dimensions of the two largest liver lesions (SLD2, in cm; RECIST 1.1 standard), and the count of lesions measuring at least 1 cm in size were assessed as continuous predictors of overall survival using both univariate and multivariate Cox proportional hazards models. **Results:** Univariate analyses showed hazard rate ratios of 1.02 (CI 0.99-1.05), 1.01 (0.95-1.07), and 1.02 (CI 1.01 – 1.04) per unit change for the SLD5, SLD2, and count metrics, respectively ($p=0.33$, $p=0.77$, and $p=<0.001$). The multivariate model showed that only the count of liver lesions remained an independent predictor of survival with a hazard rate ratio of 1.02 per unit change (CI 1.01 – 1.04, $p<0.001$). **Conclusions:** In this cohort, the whole-liver count of lesions larger than 1 cm is superior to the RECIST 1.0 and 1.1 baseline assessments of sums of longest dimensions as a predictor of overall survival at the initial diagnosis of stage 4 colorectal cancer. Further research is necessary to validate this result in a larger cohort.

**3631 General Poster Session (Board #94), Sat, 8:00 AM-11:45 AM**

**Impact of preoperative treatments on the immune microenvironnement of colorectal liver metastases.** *Presenting Author: Frederic Bibeau, Pathology Department, Institut du Cancer de Montpelier, Montpellier, France*

**Background:** An adaptive $CD8^+/CD45^+$ immune response, is considered as a favorable prognostic factor in primary colorectal cancer (CRC). $FoxP3^+$regulatory T lymphocytes (Ly) inhibit this response. Such data are lacking in CRC liver metastases (LM), notably after preoperative treatments. We aim to analyze this subject. **Methods:** 105 CRC LM were selected as follows: chemotherapy alone (CT, n= 29), CT + anti-VEGF (bevacizumab) (n= 27), CT + anti-EGFR (cetuximab) (n= 20), surgery alone (control group, n= 29). LM were treated in first-line. Histologic response was assessed according to the Tumor Regression Grade (major response: MR, partial response: PR, no response: NR). Immune microenvironnement was evaluated as follows: intratumoral (IT), peritumoral (PT) , classified as minor or major and assessed by immunohistochemistry to characterize: i)T Ly: $CD8^+$ (cytotoxic) , CD $45^+$ (memory), $Tbet^+$ (T helper 1), $FoxP3^+$ (regulators) ii) macrophages: $CD68^+$, $CD163^+$. **Results:** A major immune infiltrate was more frequently associated with LM showing MR vs PR vs NR, with the following markers and locations: $CD8^+$ (IT; $p = 0.003$), $CD45^+$ (IT; $p = 0.011$), $Tbet^+$ (PT; $p= 0.015$), CD 68(IT; $p= 0.050$), CD163 (PT, IT; $p = 0.002$, $p = 0.023$). Conversely, a major $FoxP3^+$ IT infiltrate was more frequently associated with LM displaying NR vs PR vs MR ($p = 0.033$). Moreover, a major immune infiltrate was more frequently associated with treated LM than with untreated LM as folows: $CD8^+$ (IT; $p = 0.012$), $TBet^+$ (PT, IT; $p = 0.015$ $p= 0.023$), CD 68 (IT; $p = 0.048$), CD163 (IT; $p = 0.012$). Among treated LM, a major PT CD45 infiltrate was more frequently associated with CT+anti-EGFR than other treatments ($p = 0.036$), and a major IT CD45 infiltrate was more frequently associated with CT+anti-EGFR and chemotherapy alone than CT+anti-VEGF ( $p = 0.022$). **Conclusions:** Pre-operative treatments have an impact on CRC LM immune microenvironnement. Treated CRC LM with histologic response harbor a $CD8^+/CD45^+$ adaptive immune response, a stimulated T helper 1 pathway and a down regulation of Treg lymphocytes. The use of therapies targeting the immune microenvironnement can be suggested as an option in LM CRC. The prognostic impact of these results will be determined and presented.

**3632 General Poster Session (Board #95), Sat, 8:00 AM-11:45 AM**

**High-throughput exome array for identification of novel polymorphisms associated with clinical outcome in mCRC patients treated with first-line FOLFOXIRI/BEV versus FOLFIRI/BEV (TRIBE trial; NCT00719797).** *Presenting Author: Wu Zhang, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** TRIBE is a phase III randomized trial comparing FOLFOXIRI/Bev vs FOLFIRI/Bev as first-line treatment for metastatic colorectal cancer. In this post genomic area, whole exome sequence is emerging as an useful tool to identify novel snps to associated with clinical outcome. Here we tested the hypothesis that whole exome sequence may identifies snps to predict clinical outcome in mCRC patients enrolled in TRIBE study. **Methods:** Genomic DNA was extracted from peripheral blood of 503 pts. Arm A(FOLFIRI/BEV)(n=253); Arm B (FOLFOXIRI/BEV)(n=250), median age 60 years(29-75), Females(n=202) and males(n=301);Median follow up is 32.3 months. The Illumina HumanExome array with custom content was genotyped on 432 pts on Illumina HiSeq plateform. After applying genotyping quality control filters, 385 individuals and 241,812 single nucleotide polymorphisms (SNPs) remained in the analysis. Arm A included 163 pts with a mean age of 59.9 years (SD=9.14) and mean OS of 22.9 months while Arm B included 222 pts with mean age of 59.9 years and mean OS of 23.3 months. A Cox proportional hazard regression analysis was implemented to assess SNP associations with RR,PFS and OS after adjusting for sex, treatment arm, age at trial entry, number of metastases, ECOG, and mutation status for KRAS and BRAF. GenABEL was used for the statistical analysis. **Results:** Although our main effect analysis did not identify a genome-wide association ($P<5x10^{-8}$), our preliminary analysis did observe several promising associations between SNPs and OS. Our top association, rs10008360 on chromosome 4(VEGFR-2), with hazard ratio (HR) of 6.49 ($P=2.84x10^{-6}$). We observed four additional markers associated with OS ($P<1.0x10^{-4}$). Rare burden testing and pathway analyses are underway to determine additional biological candidates. Updated detailed analysis including response and PFS results will be presented at meeting. **Conclusions:** This is the first study identifies novel snps may predict which patient could benefit from bevacizumab-based therapy. These preliminary data warrants further validation clinical trials.

**3633 General Poster Session (Board #96), Sat, 8:00 AM-11:45 AM**

**Association of CpG island methylator phenotype (CIMP) with inferior progression-free survival with anti-EGFR monoclonal antibody therapy in metastatic colorectal cancer.** *Presenting Author: Michael Sangmin Lee, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Deranged epigenetic regulation is thought to play an important role in pathogenesis and behavior of metastatic colorectal cancer (mCRC). The CpG island methylator phenotype (CIMP) is associated with distinct tumor biology, which may have differential sensitivity to targeted drug therapy. We hypothesized that methylation status affects susceptibility to anti-epidermal growth factor receptor (EGFR) monoclonal antibodies (mAbs). **Methods:** 195 mCRC patients initially tested as KRAS wild-type had tumor tissue successfully tested for CIMP status via bisulfite pyrosequencing and PCR amplification of MINT1, MINT2, and MINT31 loci and promoter sequences of p14, p16, and hMLH1. Next generation sequencing for KRAS, BRAF, and NRAS mutations was done. The duration of the first anti-EGFR mAb treatment and reason for cessation was retrospectively determined, and log-rank test was used for comparisons of progression-free survival (PFS). Cox regression analysis was performed. **Results:** 162 patients received therapy that included an anti-EGFR mAb: 24% CIMP-high (≥40% of tested sequences methylated), 40% CIMP-low, and 25% CIMP-none. Median PFS was 2.8 mo, 6.5 mo, and 6.5 mo respectively (p=0.0005 by log-rank test). On Cox regression analysis, CIMP-high was significantly associated with decreased PFS (HR 2.4, p=0.0002 on univariate analysis). CIMP-high status was associated with inferior PFS in the subgroup of patients known to be BRAF wild-type (p=0.03), and in the subgroup of known BRAF wild-type/NRAS wild-type patients (p=0.03). After excluding the 11 patients who received anti-EGFR mAb therapy first-line, CIMP-high status remained significantly associated with inferior PFS in the known BRAF wild-type and the known BRAF wild-type/NRAS wild-type subpopulations. **Conclusions:** CIMP-high methylation status is associated with shorter PFS on treatment with anti-EGFR mAb therapies, even among patients with BRAF and NRAS wild-type tumors.

**3634 General Poster Session (Board #97), Sat, 8:00 AM-11:45 AM**

**The safety and tolerability of veliparib (V) plus capecitabine (C) and radiation (RT) in subjects with locally advanced rectal cancer (LARC): Results of a phase 1b study.** *Presenting Author: Brian G. Czito, Duke University Medical Center, Durham, NC*

**Background:** Patients (pts) with LARC treated with neoadjuvant RT/C and then surgery have significant relapse rates with low rates of complete response. V is a potent, orally bioavailable PARP inhibitor that has been shown to enhance the efficacy of chemotherapy and RT in preclinical models. This study sought to establish the recommended phase 2 dose (RPTD) as well as to assess safety, pharmacokinetics (PK), and preliminary activity of V + RT/C in pts with LARC. **Methods:** Pts with stage II-III rectal cancer received RT (50.4Gy/1.8Gy/fraction) with C (825 mg/m$^2$BID) five days per week (W) for 5.5W. Dosing of V (BID, 20mg-400mg) continued from W1D2 to 2 days past RT. Pts underwent surgery 5-10W following RT. Assessments include identification of RPTD with the Exposure Adjusted Continual Reassessment Method, adverse events (AEs), PK, and pathological response: no disease present on pathologic review (ypCR), microscopic disease only (yCR), and tumor downstaging. **Results:** As of Dec 8, 2013, 18 pts have been enrolled, 12/6 male/female, median age 55 yrs; 1 pt discontinued due to an AE. The most common treatment-emergent AEs (>20% pts, n ≥ 4) were diarrhea (39%), nausea (39%), fatigue (33%), radiation skin injury (33%), dysuria (22%), and constipation (22%). One Grade 3/4 event of diarrhea and one post-operative event of anastomosis dehiscence were deemed at least possibly related to V. One dose limiting toxicity (DLT) occurred at 70mg BID V (radiation skin injury requiring dose interruption); 1 pt at 400 mg BID described ongoing intolerable nausea not meeting the criteria of a DLT. The RPTD is 400 mg V in combination with RT/C. PK results from 16 pts suggest that V PK was approximately dose proportional when administered with RT/C and that V had no effect on the PK of C. To date, 11/15 (73%) pts have been downstaged post-surgery; with 4/16 (25%) ypCR and 4/16 (25%) yCR. **Conclusions:** V at 400 mg in combination with RT/C has an acceptable safety profile, and the combination will move forward in an expanded cohort to better define toxicity and efficacy. Escalations of V resulted in approximately dose proportional increases in the V PK with no clear effect on C PK. Clinical trial information: NCT01589419.

**3635 General Poster Session (Board #98), Sat, 8:00 AM-11:45 AM**

**Extended follow-up following aggressive resection of locally recurrent rectal cancer.** *Presenting Author: Francis SW Zih, University of Toronto, Toronto, ON, Canada*

**Background:** The literature on resection of locally recurrent rectal cancer (LRRC) consists largely of case series based on retrospective data collection with median follow-up of less than 36 months. The goal of the present study was to determine outcomes after 5 to 10 yrs of follow-up in a group of patients managed with a consistent approach. **Methods:** We identified patients who underwent resection of LRRC between 06/1997 and 05/2005 from the prospective colorectal cancer databases in two cancer centers at the University of Toronto, Canada. Median follow-up time for the entire cohort (n=52) was 44 months; median follow-up in surviving patients (n=25) was 91 months. **Results:** All 52 patients (median age=60, 31 male) underwent grossly complete resection of their locoregional recurrence; 6 had synchronous distant metastases at the time of LRRC resection. The most common operative procedure for LRRC was a pelvic exenteration with sacrectomy (n=22). 24 patients had received adjuvant XRT for their primary tumor and 26 radionaïve patients received XRT prior to resection for recurrence. At last follow-up, 16 patients were alive with no evidence of disease; 9 alive with disease; 26 had died of disease; and 1 died of other causes. For the entire cohort (n=52), 5-yr and 8-yr Overall Survival (OS) were 49% and 46%, respectively; median OS was 60 months. M1 disease at the time of LRRC resection was associated with inferior OS (p=0.04). Predictors of improved OS included node negative primary cancer (p=0.02); receipt of systemic chemotherapy prior to LRRC resection (p=0.02); and R0 margin of resection on LRRC (p<0.0001). Sacrectomy (n=30) was not a prognostic factor. In patients with no distant metastases at the time of LRRC resection (M0, n=46), 5-yr and 8-yr re-recurrence-free survival were 35% and 31%, respectively. Patients who were clinically M0 at time of LRRC resection in whom R0 resection was achieved (n=36) had 5-yr and 8-yr OS of 65% and 61%, respectively; in that group, re-recurrence-free survival at 5 and 8 yrs were 45% and 39%, respectively. **Conclusions:** Margin negative resection of LRRC can result in extended survival beyond 5 yrs. Use of preoperative systemic chemotherapy and sacrectomy may be associated with improved results.

**3636^ General Poster Session (Board #99), Sat, 8:00 AM-11:45 AM**

**Phase I study of preoperative continuous 5-FU and sorafenib with external radiation therapy in locally advanced rectal adenocarcinoma.** *Presenting Author: Gopi Kesaria Prithviraj, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Preoperative treatment with fluoropyrimidine-based chemoradiotherapy is the standard of care in locally advanced rectal cancer (T3, T4 or N1). Sorafenib inhibits of ras/raf, PDFGR and VEGFR with synergistic activity with radiation (RT). This phase I study evaluated the safety and efficacy of sorafenib with infusional 5-FU and RT in patients with locally advanced rectal cancer. **Methods:** Patients with stage II or III rectal cancer, confirmed by endoscopic ultrasound (EUS) and CT scan, were recruited in 4 cohorts of 3 patients per dose level (DL), with an expansion cohort at the MTD. A 3+3 dose escalation design was used. RT was given in 25 fractions at 1.8Gy (45Gy) day 1-5 at all dose levels. Patients underwent surgery 6-10 weeks following neoadjuvant therapy. **Results:** 14 patients were enrolled at Moffitt Cancer Center, including 8 females and 6 males with a median age of 55 years (range: 40-72). After observing toxicity in the first cohort (2 patients with G2 and G3 skin toxicity and 1 patient with G2 mucositis) requiring dose interruptions, an amendment was made to change the schedule of chemotherapy and sorafenib to days 1-5 instead of daily. Following this, hypertension was the only G3 toxicity seen. 2 patients had G3 hypertension at 200mg adjusted dose(day1-5); 1 patient had G3 hypertension at the 400 mg PO BID dose level, and no grade IV toxicities were observed. No perioperative complications were seen. One patient is awaiting surgery. Due to patient refusal, 2 patients did not undergo surgery. *KRAS* status was available for 10 patients. The pCR rate was 36% and downstaging was observed in 81.8% of patients. The pCR was 50% in those with *KRAS* mutant tumors (2/4 pts). **Conclusions:** After changing the dosing schedule, this regimen was very well tolerated. The pCR and downstaging rate of the tumor is encouraging. Accrual to the expansion cohort is ongoing. Clinical trial information: NCT01376453.

**3637 General Poster Session (Board #100), Sat, 8:00 AM-11:45 AM**

**Molecular profiling of 6,892 colorectal cancer patients to identify potential treatment options.** *Presenting Author: Wafik S. El-Deiry, Penn State Hershey Cancer Institute, Hershey, PA*

**Background:** Colorectal cancer (CRC) especially with KRAS/BRAF mutation (MT) is aggressive and has limited treatment options when metastatic. We used a multiplatform molecular profiling (MP) approach to identify potential treatments not typically considered for CRC in order to improve the management of this disease. **Methods:** We evaluated6,892 CRCs referred to Caris Life Sciences by MP including sequencing (Sanger/NGS), protein expression (IHC) and gene amplification (CISH/FISH). **Results:** CRC metastases (mets) to liver, brain, ovary or lung (n=1507) showed expression of actionable markers including high TOPO1 (52%), low RRM1 (57%), TS (71%) and MGMT (39%), suggesting benefit from irinotecan, gemcitabine, 5FU/capecitabine and temozolomide. Brain mets had higher TOP2A (100% vs. 81%), while ovarian mets had lower TUBB3 (16% vs. 43%) than the other mets ($p<0.05$). Brain and lung mets had higher KRAS mutations (65% and 59%) than other mets (47%, $p=0.07$, $<0.01$), suggesting poor response to EGFR inhibitors (EGFRi). Additional analysis at other metastatic sites will be presented. BRAF-mutated CRC (n=455) showed coincident high IHC of RRM1 (56%), TS (53%) and low PDGFR (22%) compared with wild type, suggesting decreased response to gemcitabine, 5FU/capecitabine, or antiangiogenics. Mutation in other genes (APC, PTEN, HNF1A, ABL1, and RB1) may also suggest targeted therapies for these patients. KRAS-mutated CRC had higher cMET (47% vs. 36%) and lower MGMT (56% vs. 63%), suggesting cMETi and temozolomide. KRAS-mutated CRC also had high TUBB3 (42% vs. 33%) and low HER2 by IHC (0.5%) and FISH (3%), indicating less benefit from taxanes or HER2i ($p<0.05$). MP of CRC of ascending, descending colon or rectum showed KRAS mutations in 43%, 23%, 43%; PIK3CA in 29%, 25%, and 10% or BRAF in 27%, 18% and 3.3%, respectively. **Conclusions:** MP of 6,892 CRCs identified significant differences among tumors with BRAF/KRAS-MT and metastases, prompting unexpected treatment options. Agents uncommonly used in CRC metastases such as temozolomide are suggested, and etoposide or taxanes are suggested for brain or ovarian mets, respectively. Targeted therapies could be considered for KRAS or BRAF mutated tumors based on actionable targets revealed by MP.

**3638 General Poster Session (Board #101), Sat, 8:00 AM-11:45 AM**

**Axitinib in refractory colorectal metastatic cancer: A phase II study of increasing doses with dynamic contrast-enhanced ultrasonography monitory of the response.** *Presenting Author: Michel Ducreux, Paris Sud University, Le Kremlin Bicetre, France*

**Background:** Anti-angiogenic therapy plays a role in the treatment of colorectal cancer (CRC). We used monotherapy axitinib every other week given in refractory patients to evaluate the efficacy of this drug given at increasing doses and the role of Dynamic Contrast enhanced ultrasonography (DCE-US) to predict and measure its efficacy. **Methods:** Patients (pts) should have refractory metastatic CRC with at least one measurable lesion into the liver with DCE-US. They were given axitinib 5mg bid for one week followed by one week rest (Cycle 1) and then in case of good tolerance 7 mg bid for one week followed by one week rest (Cycle 2) and then 10 mg bid for one week followed by one week rest (Cycle 3). After 6 weeks of treatment a new CT-scan was performed to evaluate the efficacy of the treatment following RECIST criteria. If at least a stable disease was observed axitinib alone was continued at the same dose, if not addition of chemotherapy (CT) (Folfiri regimen) was allowed. DCE-US was performed on one liver metastasis at baseline D2, 7, 15, 21, 29, 35, 43. AUC, corresponding to the blood volume was calculated at each time point. **Results:** 25 pts (W: 10, M: 15; median age 60) are evaluable. Kras status: mutant 11, wild-type 9, unknown 5. 84% of the pts received more than 2 lines of CT before entry in the study. ECOG PS was 0 in 24% of the pts, 1 in 60%, 2 in 12% and 3 in 4%. Cycles received: 25 pts cycle 1, 24 pts cycle 2, 21 pts cycle 3. The only grade 3 toxicity frequently observed was hypertension (28%, 25%, 15% in cycle 1, 2, 3, respectively). No objective response was observed, stable disease was seen in 32% of the cases. Median overall survival was 5.8 months [IC 95%: 5.1 – 9.9], median overall progression free-survival was 1.5 months [IC 95%: 1.3 – 3.0]. A total of 169 DCE-US were analyzed. The median of AUC decreases by 55% from baseline to D43. AUC decreases by 53%, 1 % and 10 % after the first, second and third cycle, respectively. **Conclusions:** This study has shown that heavily pretreated patients patients who received axitinib monotherapy given every other week had a median overall survival of 5.8 months. DCE-US monitoring could help to detect the patients who get the greater benefit of the treatment. Clinical trial information: NCT01486251.

**3639 General Poster Session (Board #102), Sat, 8:00 AM-11:45 AM**

**The consistency of effect of ziv-aflibercept (Z) in the bevacizumab (B) pre-treated subgroup of patients (pts) in the velour trial stratified by first-line progression ≥ 9 months (mos) versus < 9 mos.** *Presenting Author: Paulo Marcelo Hoff, Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil*

**Background:** The addition of B to an oxaliplatin-based regimen in 1st line metastatic colorectal cancer (mCRC) pts has shown a median progression free survival (PFS) of 9.4 mos as seen in NO16966. In the ML18147 study, the benefit of B added to chemotherapy (CT) in 2nd line mCRC following 1st line CT + B combinations, was evaluated in pts pre-stratified by 1st line PFS ≤9 mos and >9 mos. We evaluated the consistency of the treatment effect of Z+FOLFIRI (F) vs placebo (P)+F according to the timing of progression from 1st line therapy (<9 mos *vs.* ≥9 mos) in the subgroup of pts treated with an oxaliplatin containing regimen and B in 1stline from VELOUR (NCT00561470). **Methods:** In VELOUR, 186 pts in the Z+F and 187 in the P+F groups were stratified to prior B. There were 17 pts (9 in Z+F and 8 in P+F arm) who experienced recurrence during or within 6 mos of completing adjuvant oxaliplatin-based therapy – (a population excluded from ML18147), who were excluded from this analysis. The prior B treated subgroup was analyzed by the timeframe of 1stline progression ([PFS] ≥9 vs <9 mos) in this post-hoc analysis. Hazard Ratio (HR) was adjusted on the baseline value of: Performance Status, prior B, age, hypertension, and number of metastatic organs. **Results:** Z+F had an overall survival (OS) benefit in B pre-treated pts both with 1st line PFS ≥9 mos and in pts with 1stline PFS < 9 mos, as shown by the median difference (MD) in OS (Table). A similar benefit was observed with PFS. **Conclusions:** In this post hoc analysis, pts benefited from Z+F therapy regardless of the timing of their 1st line progression <9 months *or* ≥9 months on a 1st line oxaliplatin + B containing regimen. Clinical trial information: NCT00561470.

| Prior B Subgroup | P+F [95% CI] N = 168 | Z+F [95% CI] N=161 | Median difference (mo) HR [95% CI] |
|---|---|---|---|
| **1st line PFS ≥9 mos** | | | |
| **Pts, n** | 92 | 86 | |
| **Median OS, mos** | 14.23 [11.6; 18.9] | 17.94 [14.5; 21.5] | 3.71 |
| **aHR** | | | 0.772 [0.52; 1.15] |
| **Median PFS, mos** | 4.24 [3.9; 5.5] | 7.26 [6.5; 8.7] | 3.02 |
| **aHR** | | | 0.588 [0.391; 0.89] |

**3640 General Poster Session (Board #103), Sat, 8:00 AM-11:45 AM**

**mRNA expression levels of candidate genes and clinical outcome in mCRC patients treated with FOLFOXIRI plus bevacizumab (bev) or FOLFIRI plus bev in the TRIBE study.** *Presenting Author: Dongyun Yang, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background**: Phase III TRIBE trial demonstrated that first-line FOLFOXIRI plus bev improved PFS and RECIST response and, at adjusted analyses, OS as compared to FOLFIRI plus bev. Previous data suggested that higher *ERCC1* expression levels could be responsible for resistance to oxaliplatin-containing chemotherapy. Limited data are available up today for the predictive effect of the expression levels of major genes involved in tumoral angiogenesis. **Methods**: mRNA expression levels of *ERCC1*, *VEGF-A, -B, -C, VEGFR1, VEGFR2, ACVRL1, EGFL7* and *EPHB4* were measured using RT-PCR. Biomarker-adaptive threshold design by Jiang, Freilin and Simon (JNCI 2007) was used to identify which mRNA levels may predict subsets of patients who were more likely to benefit FOLFOXIRI + bev than FOLFIRI + bev. **Results**: Tissue samples adequate for expression analyses were available for 228 out of 503 randomized pts (45%). Pts with the tissue available had similar baseline characteristics as the whole cohort. Pts with high intratumoral *ERCC1* (>0.62) or high *VEGF C* (>0.211) were more likely to have longer PFS in FOLFOXIRI + bev (median=12.0 mths) than in FOLFIRI + bev (median=9.7 mths) (HR=0.46 and 0.24 for high *ERCC1* and *VEGF-C* expression level vs. HR=1.55 and 1.20 for low *ERCC1* and *VEGF-C* expression level; unadjusted *P* for interaction=0.0035 and 0.0037 for *ERCC1* and *VEGF-C*, respectively). *ERCC1* and *VEGF-C* expression levels also predicted similar differences in response and OS between two therapies. Applying recursive partitioning identified distinct signatures of genes predicting response (ranging from 20 to 76%, PFS (6-18 mths) and OS (18-49 mths). **Conclusions:** the findings suggested predictive roles for *ERCC1* and *VEGF-C* levels in patients receiving first-line FOLFOXIRI + bev vs in FOLFIRI + bev. Gene expression signature specific for response, PFS and OS may be important new biomarkers which warrant further validation.

**3641 General Poster Session (Board #104), Sat, 8:00 AM-11:45 AM**

**Comparison of survival and nodal staging in rectal cancer patients undergoing sentinel lymph node mapping versus conventional surgery.** *Presenting Author: Sukamal Saha, McLaren Regional Medical Center, Michigan State University, Flint, MI*

**Background:** Nodal metastasis (mets) is one of the most important prognostic factors in rectal cancer (RCa). Sentinel lymph node (SLN) mapping (M) identifies more nodal mets compared to conventional surgery (ConvSx). This identification may lead to upstaging and change in adjuvant treatment, thereby impacting survival. A retrospective study was undertaken comparing RCa patients (pts) undergoing total mesorectal excision (TME) with SLNM (Group A) vs. ConvSx without SLNM (Group B) for survival and nodal staging. **Methods:** SLNM was performed by using a blue dye injected subserosally for tumors above the peritoneal reflection, and trans-anally for tumors below the reflection, prior to TME. Data was collected for pts demographics, neoadjuvant and adjuvant therapy, TNM staging, SLN status, and 5 year overall survival. **Results:** Group A had 99 pts with an average (avg) age of 66 yrs (M:F = 57:42). Group B had 183 pts with an avg age of 63 yrs (M:F = 125:60). Avg number of LNs for Group A vs. Group B was 12 vs. 12.5. SLNM was successful in 87% of pts with an avg number of SLN per patient being 2.1. Overall nodal positivity was 24% vs. 33% for Group A vs. Group B, probably due to much higher use of neoadjuvant chemo-radiation in Group A (79%) vs. Group B (28%). For Group A pts the SLN was the only positive node in 33%. Overall 5 year survival for Group A vs. Group B was 57% vs. 40%. For both node -ve and node + pts, 5 year survival for all pts receiving neoadjuvant therapy for Group A was 50% vs. 22% for Group B, and not receiving neoadjuvant therapy was 71% vs. 48%, respectively. (See Table.) **Conclusions:** SLNM in RCa pts is highly feasible with better overall survival for both node positive and node negative patients when compared to pts who underwent ConvSx, irrespective of whether or not neoadjuvant therapy was received. SLNM may be performed during surgery for RCa pts.

**Comparison of five year survival: Group A vs. Group B.**

| | Node positive | | Node negative | |
|---|---|---|---|---|
| | Group A | Group B | Group A | Group B |
| T1 | N/A | 75.0% | 68.0% | 56.0% |
| T2 | 20% | 36% | 71.0% | 48.0% |
| T3 | 47% | 27% | 50.0% | 45.0% |
| T4 | 67% | 40% | 50% | 13.0% |

| | Group A | Group B |
|---|---|---|
| Neoadjuvant therapy | 50% | 22% |
| No neoadjuvant therapy | 71% | 48% |

**3642 General Poster Session (Board #105), Sat, 8:00 AM-11:45 AM**

**Effect of chemotherapy on the progress in colorectal cancer survival in the past two decades.** *Presenting Author: Irfan Jawed, Lawrence Memorial Hospital Oncology Center, Lawrence, KS*

**Background:** The past two decades have seen steady gains in the overall survival (OS) of colorectal cancer (CRC) patients. **Methods:** We reviewed 106 phase III and large phase II trials in CRC evaluating first and subsequent lines of therapy. Outcomes examined in the experimental (EA) and control arms (CA) included progression free survival (PFS), overall response rate (ORR), stable disease (SD), OS, and post protocol survival (PPS = OS - PFS). **Results:** The wealth of data provided significant correlations. The OS of EA has improved 0.76 mos/yr. Importantly OS of CA improved 0.55 mos/yr reflecting use of experimental therapies in CA in subsequent studies. A high correlation between gains in PFS and gains in OS in individual trials ($p<0.001$; slope=1.08) suggests within one trial PFS gains account for most OS gains. However, because PFS improved only 0.27 and 0.22 mos/yr, in EA and CA respectively, factors other than experimental and salvage therapies are needed to explain observed gains in OS over time. The discordance of OS/PFS gains over time point to important contributions from improved care and lead time bias suggested by: PPS gains of 0.43 and 0.32 mos/yr, in EA and CA respectively, accounting for large portion of OS gains despite OS improvement of only 0.11-0.13 mos/yr in 18 trials in second and subsequent lines insufficient to account for higher OS gains. As expected PFS correlates highly with OS, but importantly ORR had very high correlations with both PFS and OS. SD emerged as an adverse outcome, OS decreasing as SD rates increase. Examination of the effect on OS of the principal drugs showed oxaliplatin, irinotecan and bevacizumab contributed significantly while capecitabine and cetuximab/panitumumab did not. Capecitabine outcome not surprising for an oral substitute of an effective drug; while cetuximab/panitumumab results likely reflect the lack of efficacy/harm in patients harboring MT KRAS tumors. **Conclusions:** The OS of CRC patients enrolled in trials has improved gradually over the past two decades, with contributing factors including chemotherapy but importantly also likely lead time bias and better supportive care. Meaningful progress will require novel paradigms and much better salvage therapies.

**3643 General Poster Session (Board #106), Sat, 8:00 AM-11:45 AM**

**Surgical resection and intraoperative radiation therapy for locally recurrent rectal carcinoma.** *Presenting Author: David Furfaro, Harvard Medical School, Boston, MA*

**Background:** Surgical resection with intraoperative radiation therapy (IORT) has been used to treat locally recurrent rectosigmoid adenocarcinoma (LRRSA). We present the experience at Massachusetts General Hospital (MGH) with resection and IORT for LRRSA. **Methods:** We retrospectively evaluated patients with LRRSA referred for IORT. Charts were evaluated for TNM staging, treatment regimen, IORT, resection margins, complications, recurrences, and current status. For the purpose of this study, R0 resection was defined as margins > 1mm from tumor. We evaluated the prognostic impact of treatment and resection margins on local control (LC), 5-year overall survival (OS) and disease-free survival (DFS). **Results:** Between 1995 and 2010, 51 patients with LRRSA were referred for IORT. Pre-operative radiation therapy was delivered to 88.2% of patients—for 5.9% this was re-irradiation—and 27.5% received post-resection radiation. IORT was delivered to 42 patients. Neoadjuvant chemotherapy was given to 96.1% of patients, and 76.5% had adjuvant chemotherapy. The resection margins achieved, measured as R0, clear margins with tumor within 1 mm (R<1mm), R1 and R2, were 49.0%, 7.8%, 25.5%, and 17.6%, respectively. The overall 5-year LC, OS and DFS were 52.3%, 60.9% and 36.4% respectively. The patients who received resection and IORT vs resection alone did not have improved DFS (HR 1.07, $p=0.896$), LC (HR 1.40, $p=0.590$) or OS (HR 0.52, $p=0.247$). R0 resection predicted favorable LC (HR 0.34, $p=0.017$), DFS (HR 0.22, $p<0.001$) and OS (HR 0.32, $p=0.043$). Patients with R0 margins vs R<1mm had improved LC (HR 0.20, $p=0.024$) and DFS (HR 0.12, $p=0.004$). On multivariate regression, margins of R0 or R<1mm (vs. R1 or R2) improved OS (HR 0.31, $p=0.028$), patients with worse resection margin status had worse DFS (HR 5.19, $p<0.001$), and R0 resections improved LC (HR 0.34, $p=0.017$). **Conclusions:** For patients with LRRSA optimal 5-year DFS, LC and OS were achieved with a margin negative surgical resection. Patients with R<1mm resections had the same OS as patients with R0 resections, but had worse DFS and LC. IORT in addition to surgical resection did not improve DFS, LC, or OS; however, the results are limited due to small sample size and patient selection bias.

**3644 General Poster Session (Board #107), Sat, 8:00 AM-11:45 AM**

**Incidence of diabetes among patients with colorectal cancer.** *Presenting Author: Simron Singh, Odette Cancer Centre, Sunnybrook Health Sciences Centre; University of Toronto, Toronto, ON, Canada*

**Background:** Emerging data show an increasingly recognized risk of colorectal cancer (CRC) in patients with type 2 diabetes (DM) likely due to common biologic pathways. Few data are available on DM incidence among patients with CRC. Our objective was to determine whether patients with CRC have a higher incidence of DM compared to those without CRC. **Methods:** We conducted a population-based retrospective cohort study in Ontario, Canada, using administrative databases comparing the incidence of DM among all CRC patients identified in the Ontario Cancer registry from Jan 1, 2002 to Dec 31, 2011 with an age-matched control population without CRC. We used Cox proportional hazard to study the association. We modeled the effect of CRC on the cause-specific hazard of developing DM and censored subjects at the time of a competing event. Subgroup analysis was performed on patients receiving chemotherapy vs. not, metastatic disease vs. not and colon vs. rectal cancer. **Results:** We identified 39,707 persons with CRC and 198,535 controls. The mean age was 68 and 48.6% were female. We found an overall DM incidence of 8.7% over a mean follow up time of 4.8 years. On multivariable analysis, the effect of CRC on the instantaneous hazard of the DM incidence varied over time, and thus we estimated instantaneous hazard ratios (IHR) for years 1-5 of follow up. The risk of DM among CRC patients was significantly higher than controls for at least five years post CRC diagnosis. The overall DM incidence was higher in patients with no metastasis (10.6% vs 8.6%, $p<0.01$), and lower in patients who received chemotherapy (8.0% vs 9.0%, $p<0.01$). **Conclusions:** This is among the first study to report an increased DM incidence among CRC survivors. This association may be due to common risk factors rather than a treatment effect, as the risk remains elevated for at least five years post diagnosis. The hazard may be underestimated, as patients with advanced cancer may not be formally diagnosed with DM. These results strengthen our understanding of the common biologic pathway of both diseases and have major implications for survivorship care in patients with CRC.

| Years since CRC diagnosis | IHR (95% CI) of DM (CRC vs. no CRC) |
|---|---|
| 1 | 1.42 (1.37, 1.47) |
| 2 | 1.36 (1.32, 1.41) |
| 3 | 1.31 (1.26, 1.36) |
| 4 | 1.26 (1.21, 1.31) |
| 5 | 1.21 (1.16, 1.26) |

**3645 General Poster Session (Board #108), Sat, 8:00 AM-11:45 AM**

**Monitoring changes in circulating tumor DNA in gastrointestinal malignancies using a novel next-generation sequencing method.** *Presenting Author: Edward Samuel James, Yale School of Medicine, New Haven, CT*

**Background:** Circulating tumor DNA (ctDNA) is showing promise as a highly-specific cancer biomarker. We have developed an ultrasensitive ctDNA assay that can evaluate recurrent cancer-associated point mutations and insertions/deletions simultaneously in multiple genes without prior knowledge of the tumor's mutation profile. Here we report on use of this assay for non-invasively assessing tumor mutation status and for monitoring treatment response or disease progression in patients with gastrointestinal malignancies. **Methods:** Plasma samples were collected at multiple time points in a cohort of patients (pts) with colorectal, pancreatic, or bile duct malignancies in the locally advanced, metastatic and adjuvant settings. Mutation-prone regions of genes known to be commonly mutated in GI tumors were amplified by multiplexed PCR, and the resultant amplicons were subjected to next-generation ultra-deep sequencing. Application of novel techniques to suppress sequencer and PCR errors allowed mutations to be identified and quantified with a sensitivity of approximately 1 variant in 5,000 molecules. **Results:** 75 plasma samples from 17 pts were analyzed for the presence of tumor-derived mutations. We found plasma DNA mutations in the following genes: KRAS (7 pts), TP-53 (2 pts), and PIK3CA (1 pt). Among the 8 pts whose tumors were profiled by an independent clinical lab, our plasma results showed perfect concordance of mutation status and type. Testing of serial samples revealed that ctDNA levels changed appropriately with therapy or with disease progression. Examples include one case that showed a dramatic decrease in ctDNA after initiation of first-line chemotherapy, a second case that had rising levels upon development of liver metastases, and a third case that showed reversal of a rising trend upon switching to a different chemotherapeutic regimen. **Conclusions:** We present here a novel NGS-based method for identifying and measuring mutant ctDNA. Results from this cohort of patients with GI malignancies indicate that this approach may find clinical utility for non-invasive assessment of tumor mutation status and for monitoring of recurrence, progression, or therapeutic response.

**3646 General Poster Session (Board #109), Sat, 8:00 AM-11:45 AM**

**A phase II study of 5-FU/l-LV/oxaliplatin (mFOLFOX6) in patients with metastatic or unresectable small bowel adenocarcinoma.** *Presenting Author: Norisuke Nakayama, Kanagawa Cancer Center, Yokohama, Japan*

**Background:** Several prospective and retrospective studies have suggested that chemotherapy prolongs survival in patients with metastatic or recurrent small bowel adenocarcinoma (SBA). However, there is no standard chemotherapyregimen for this disease. The aim of this study was to evaluate the efficacy and safety of mFOLFOX6 as a first-line therapy in patients with SBA. **Methods:** This study was designed as a multi-center, single-arm, open-label phase II study. Eligibility criteria included a histologically proved diagnosis of adenocarcinoma, age 20–80 years, and an Eastern Cooperative Oncology Group performance status (PS) of 0–2. The mFOLFOX6 treatment comprised oxaliplatin (85 mg/m$^2$) and l-leucovorin (200 mg/m$^2$) administered intravenously over a two hour period on day one, followed by a bolus of 5-FU bolus (400 mg/m$^2$) and a 46 hour infusion of 5-FU (2400 mg/m$^2$) every two weeks. The primary endpoint was one year progression-free survival (PFS). The secondary endpoints included overall response rate (ORR), overall survival (OS), PFS, and safety. **Results:** Between April 2010 and November 2012, 24 patients were enrolled from 12 institutions. Median age: 63 years (range, 31–79); male/female ratio: 18/6; PS 0: 17 (71%); PS 1: 7 (29%); locally advanced/metastatic disease: 2/22; primary tumor site: duodenum (58%) and jejunum (42%). The median follow-up time was 14.7 months (3.7-40.3). The one-year PFS was 23.3%. The ORR was 45% (9/20). The median PFS and OS were 5.9 months (95% CI, 3.0–10.2) and 17.3 months (95% CI, 11.7–19.0), respectively. The common grade 3 or 4 toxicities were neutropenia (38%), anemia/peripheral neuropathy (25%), stricture (17%), fatigue/anorexia/bilirubin increase (8%), and diarrhea (4%). There were no treatment-related deaths. **Conclusions:** This phase II study showed a good efficacy with an acceptable safety profile. The mFOLFOX6 regimen is moderately active and well tolerated as a first-line treatment for SBA. Clinical trial information: UMIN000002797.

**3647 General Poster Session (Board #110), Sat, 8:00 AM-11:45 AM**

**Molecular profiling of small-bowel adenocarcinomas.** *Presenting Author: Rebecca Anne Feldman-Moreno, Caris Life Sciences, Phoenix, AZ*

**Background:** Small-bowel adenocarcinoma (SBA) is a rare malignancy with limited knowledge of the molecular mechanisms, or clinical evidence-based guidelines for therapy. We conducted a comprehensive analysis of biomarkers with therapeutic relevance for SBA. **Methods:** We examined the biomarker profiles of 266 SBA cases. Multiplatform biomarker panel included a combination of sequencing (Sanger, NGS), protein expression (IHC) and gene amplification (CISH /FISH). **Results:** Several biomarkers have been identified by IHC evaluation in ~250 patients: high TOP2A (74%) and low TUBB3 (81%), low ERCC1 (71%), low RRM1 (69%) and low TS (63%)- favorable for chemotherapy drugs such as doxorubicin, taxanes, oxaliplatin, gemcitabine and capecitabine, respectively. A minority of cases were found to express other favorable chemotherapy response biomarkers: low MGMT (alkylating agents, 30%), high SPARC (nab-paclitaxel, 36%) and high TOPO1 (irinotecan, 39%). SBA demonstrated a high prevalence of multidrug resistance gene expression: MRP1 and BCRP (83%) and PGP (51%). Unexpectedly, a number of cases showed genomic alterations associated with activated oncogenic signaling: EGFR (13% or 12/96), TOP2A (12% or 4/33), HER2 (7% or 9/130) and cMET (1.4% or 1/71). Two patients demonstrated co-amplification of TOP2A and HER2, suggesting these patients may benefit from anthracyclines. Evaluation of mutational hotspots demonstrated a high incidence of oncogenic/tumor suppressor mutations in 60% (47/78) of patients. We discovered that mutations in TP53 (51%) and KRAS (46%) were most common. Other genes with notable alterations included: APC (22%), SMAD4 (20%), BRAF (9%), CTNNB1 (7%) and PTEN (5%). Recent data suggest favorable responses to cetuximab in SBA; these results and high frequency of KRAS mutations in our series indicate that KRAS testing may be recommended in SBA. **Conclusions:** Our data demonstrate the potential utility of a wide range of traditional chemotherapies for SBA, targeted therapies utilized for other cancer types as well as therapies under clinical investigation. SBA exhibits biologically similar tumorigenesis as large-bowel adenocarcinoma, therefore similar treatment guidelines and biomarker testing strategies should be considered.

**TPS3648^ General Poster Session (Board #111A), Sat, 8:00 AM-11:45 AM**

**Strategic 1-multi-line therapy trial in unresectable wild-type RAS metastatic colorectal cancer: A gercor randomized open-label phase III study.** *Presenting Author: Benoist Chibaudel, Hôpital Saint-Antoine, Paris, France*

**Background:** Several strategies using chemotherapy and molecular targeted drugs are available for the treatment of unresectable metastatic colorectal cancer. Recent and ongoing randomized trials evaluate chemotherapy with bevacizumab or epidermal growth factor receptor (EGFR) inhibitors, but the prior and/or subsequent lines are not fixed and the imbalanced cross-overs will not allow to interpret overall survival. This STRATEGIC-1 trial is a study designed to determine the best sequence of therapy and to define subset populations that will benefit most from one sequence. **Methods:** This is an ongoing randomized, two-arm, phase III study comparing two multi-line therapeutic strategies in patients wild-type RAS unresectable metastatic colorectal adenocarcinoma, ECOG PS 0-2 and age $\geq$ 18years. Randomization is stratified by center, GERCOR prognostic score (using PS and LDH level), prior use of oxaliplatin in adjuvant setting and the extent of metastatic disease. Patients (n=474) are randomized (1:1) to either (arm A) FOLFIRI/cetuximab, followed by an oxaliplatin-based chemotherapy with bevacizumab or (arm B) OPTIMOX/bevacizumab, followed by an irinotecan-based chemotherapy with bevacizumab, followed by anti-EGFR mab (cetuximab or panitumumab) with or without irinotecan. The primary endpoint is Duration of Disease Control (DDC). The sample size was planned for testing the primary variable DDC with a two-sided 5% $\alpha$ type one error and a 10% $\beta$ type two error (Software: EAST 5.3) and a planned interim analysis. A 33% reduction in the risk of event (HR 0.67) was assumed under $H_1$ in the arm B. Secondary endpoints include OS, HR-QoL, TFS, ORR and PFS per sequence, salvage surgery rate, safety and correlations between biomarkers and clinical outcome. CRC tissue (primary or met.) and blood collection are mandatory for biomarker analyses. Enrolment began in October 2013. Clinical trial information: NCT01910610.

**TPS3649 General Poster Session (Board #111B), Sat, 8:00 AM-11:45 AM**

**A randomized phase II study (B2151005) of the intravenous phosphatidylinositol 3-kinase (PI3K)/mammalian target of rapamycin (mTOR) inhibitor PF-05212384 plus irinotecan versus cetuximab plus irinotecan in patients with wild-type *KRAS* metastatic colorectal cancer (mCRC).** *Presenting Author: Josep Tabernero, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** The combination of cetuximab plus irinotecan is considered a standard of care regimen for third-line treatment of patients with wild-type *KRAS* metastatic colorectal cancer (mCRC). However, the combination of cetuximab plus irinotecan provides limited tumor control and is associated with skin rash, diarrhea, and neutropenia. Thus, the need for more efficacious and better tolerated regimens remains high. Signaling through the phosphatidylinositol 3-kinase (PI3K) pathway is associated with resistance to a variety of antitumor agents. This association has been described in pre-clinical studies for cytotoxic chemotherapeutic agents with different mechanisms of action, including taxanes and DNA-damaging agents. In the clinic, activation of the PI3K pathway in tumors has been correlated with decreased response to therapy and worse clinical outcomes. Preliminary data from the phase I study B1271002 indicate that the combination of the intravenous PI3K/mammalian target of rapamycin (mTOR) inhibitor PF-05212384 and irinotecan is well tolerated and shows promising antitumor activity in patients with mCRC, suggesting the need to further explore this regimen. **Methods:** This trial was designed to investigate whether the combination of PF-05212384 plus irinotecan is superior to the combination of cetuximab plus irinotecan in prolonging progression-free survival in patients with wild-type *KRAS* mCRC. Additionally, the study includes a lead-in cohort to determine the safety of this combination in Japanese patients. The study is being conducted in men and women with wild-type *KRAS* mCRC whose disease has progressed following treatment with irinotecan, oxaliplatin and fluoropyrimidine therapy in the metastatic setting. Eligible patients will be randomly assigned to either treatment arm. This global trial is open to enrollment and has recruited its first patients. Clinical trial information: NCT01925274.

**TPS3650 General Poster Session (Board #112A), Sat, 8:00 AM-11:45 AM**

**A phase II trial of maintenance ADAPT therapy targeting colon cancer stem cells in patients with metastatic colorectal cancer.** *Presenting Author: Edward H. Lin, Seattle Cancer Care Alliance, Seattle, WA*

**Background:** Presence of cancer stem cells (CSC) appears to be the chief cause of drug resistance to cytotoxic or targeted chemotherapy. Experimental models suggest that these resistant cancer cells undergo dormancy transition that is best targeted with a stemness modulator in its activation window through a strategy that we call ADAPT: Activating (CSC) from Dormancy And Potentiate for Targeting. In vitro and in vivo data suggest that 5FU activates while celecoxib inhibits and depletes these putative colorectal CSC. We retrospectively administer three year ADAPT therapy in unresectable metastatic colorectal cancer (MCRC) patients using capecitabine and celecoxib +/- radiation following maximal responses (complete (CR) and partial response (PR) and stable disease (SD)) to first-line combination chemotherapy. ADAPT therapy led to 30% CR and additional 10% surgical CR whose median survival reached 92.7 months in patients with unresectable MCRC. (Lin et al AACR 2010 LB-254). **Methods:** Fred Hutch Cancer Research Center institutional review board (IRB) approved this prospective phase II ADAPT study funded by Gateway for Cancer Cure in October 2013. The primary endpoint is to determine the rate of CR at three years. The secondary objectives are to determine progression free survival, overall survival, and relapse free survival (if CR) based on intent to treat analysis. Forty-three unresectable MCRC patients except those with brain or bone metastases or severe bowel obstruction will be enrolled and patients must have achieved maximal response (CR, PR, or SD) to first-line chemotherapy before prior to three-year ADAPT protocol +/-radiation. Patient must not be allergic to NSAIDs or sulfonamide and aspirin is not allowed. Eight patients have been enrolled to date and trial will be terminated if less than one complete response (including surgical CR) in the first 20 MCRC patients. Translational "omics" endpoints using UW Oncoplex assay and RareCyte technology are being explored. Clinical trial information: NCT01729923.

**TPS3651 General Poster Session (Board #112B), Sat, 8:00 AM-11:45 AM**

**Regorafenib as a single agent for first-line treatment of frail and/or unfit for polychemotherapy patients with metastatic colorectal cancer (mCRC): A study of the Spanish Cooperative Group for digestive tumor therapy (TTD).** *Presenting Author: Enrique Grande, Hospital Universitario Ramon y Cajal, Medical Oncology Department, Madrid, Spain*

**Background:** More than half of the mCRC are diagnosed in patients over 70 years. Around 15-20% of patients diagnosed of mCRC do not qualify to receive polychemotherapy as first-line systemic therapy due to age and/or comorbidities. The optimal treatment strategy for this group of patients has not been adequately defined. Regorafenib is a multikinase inhibitor that has shown benefit in overall and progression free survival (PFS) over placebo in patients with mCRC who have failed to all approved standard therapies (*Grothey et al. 2013*). This trial will assess the efficacy and safety of regorafenib as a single agent in the first-line setting of frail and/or unfit mCRC patients who are ineligible to receive polychemotherapy. **Methods:** This is a phase II, single-arm, open-label study conducted in patients with mCRC who are considered frail and/or unfit to receive polychemotherapy. Patients should meet at least one of the following criteria: Dependence in activities of daily living owing to the presence of comorbidities other than those resulting from the deterioration caused by the neoplastic disease and/or presence of three or more of the following entities: congestive heart failure, other chronic cardiovascular diseases, chronic obstructive pulmonary disease, cerebrovascular disease, peripheral neuropathy, chronic kidney failure, hypertension, diabetes mellitus, systemic vasculitis, or severe arthritis; presence of geriatric syndromes such as age $>$ 85 years, fecal or urinary incontinence, spontaneous bone fractures, mild and moderate dementia, or patients who fall repeatedly. Patients will receive regorafenib 160 mg PO, three weeks on/one week off in a four-week cycle. The primary endpoint is PFS rate at six months. There are 46 patients who needed to demonstrate that the treatment is effective if PFS rate at six months is higher than 55% and to reject the null hypothesis (PFS rate at six months $<$ 35%), considering an alpha error of 0.05 and a power of 80%. Elderly and unfit for chemotherapy mCRC remains a clinical unmet need in the daily clinical practice. Regorafenib is an active and promising agent that could fill up this gap. Clinical trial information: NCT01875380.

**TPS3652 General Poster Session (Board #113A), Sat, 8:00 AM-11:45 AM**

**STEAM: A randomized, open-label, phase 2 trial of sequential and concurrent FOLFOXIRI-bevacizumab (BEV) versus FOLFOX-BEV for the first-line (1L) treatment (tx) of patients (pts) with metastatic colorectal cancer (mCRC).** *Presenting Author: Johanna C. Bendell, The Sarah Cannon Research Institute, Nashville, TN*

**Background:** Recent randomized trials investigating 5-fluorouracil [5-FU]/leucovorin [LV]/oxaliplatin/irinotecan (FOLFOXIRI) with bevacizumab (BEV) for the first-line (1L) treatment (tx) of metastatic colorectal cancer (mCRC) patients (pts) showed improved progression-free survival (PFS) and overall response rate (ORR) vs. 5-FU/LV/irinotecan (FOLFIRI) with BEV (Falcone et al, ASCO 2013) and improved PFS, ORR, and resection rate of metastases vs. 5-FU/LV/oxaliplatin (FOLFOX) with BEV (Bridgewater et al, ESMO 2013). Toxicity may be a limitation of the regimen; alternating tx with FOLFOX and FOLFIRI (sequential FOLFOXIRI) may improve the tolerability of treating 1L pts with all three agents. The efficacy and safety of FOLFOXIRI-BEV have yet to be investigated in the US, and the impact of maintenance and of BEV tx beyond disease progression (PD) following FOLFOXIRI-BEV is unknown. **Methods:** The STEAM study (NCT01765582) is a randomized, open-label, US-based, phase 2 trial investigating sequential or concurrent FOLFOXIRI-BEV vs. FOLFOX-BEV and maintenance tx in pts with previously untreated mCRC. Key eligibility criteria include unresectable mCRC and age 18–75 years. Pts are randomized 1:1:1 to concurrent FOLFOXIRI-BEV, sequential FOLFOXIRI-BEV (alternating FOLFOX and FOLFIRI q4w), or FOLFOX-BEV q2w during a four to six month induction phase (BEV 5 mg/kg in each arm). After induction, pts receive 5-FU/LV + BEV (5 mg/kg) q2w or capecitabine + BEV (7.5 mg/kg) q3w as maintenance tx until PD. After PD, pts receive second-line (2L) 5-FU–based chemotherapy (physician's choice) with BEV (dose equivalent of 2.5 mg/kg/week) until 2L PD. Pts are stratified by extent of metastatic disease (liver-limited vs non–liver-limited), primary tumor location (right- vs left-sided), and study center. Primary objectives are to evaluate 1L ORR (concurrent FOLFOXIRI-BEV vs FOLFOX-BEV), 1L PFS (concurrent and sequential FOLFOXIRI-BEV vs FOLFOX-BEV), and safety. Secondary objectives include resection rate, rate of conversion to resectable disease, time to 2L PFS, and overall survival (concurrent and sequential FOLFOXIRI-BEV vs FOLFOX-BEV). The study has enrolled 109 of a planned 280 pts to date. Clinical trial information: NCT01765582.

**TPS3653 General Poster Session (Board #113B), Sat, 8:00 AM-11:45 AM**

**Bevacizumab and combination chemotherapy in rectal cancer until surgery (BACCHUS): A phase II, multicenter, open-label, randomized study of neoadjuvant chemotherapy alone without radiation in patients with MRI-defined high-risk cancer of the rectum not threatening the circumferential margin.** *Presenting Author: Mark Harrison, Mount Vernon Hospital, Northwood, United Kingdom*

**Background:** In locally advanced rectal cancer (LARC), local recurrence is uncommon with good quality total mesorectal excision (TME) allowing preoperative chemo-radiotherapy (PCRT) to be omitted. The risk of developing metastases can be partly predicted using magnetic resonance imaging (MRI). PCRT does not benefit all patients with LARC, and is associated with long-term morbidity. Chemotherapy (Cty) may reduce the chance of local recurrence, but compliance to postoperative adjuvant Cty is poor, and its efficacy following CRT has been questioned. Neoadjuvant Cty is being examined in primary colon and rectal cancer (FOXTROT). BACCHUS will examine the efficacy and safety of intensified systemic Cty for LARC prior to TME. **Methods:** This is a multi-centre, randomized phase II trial. Eligible pts must have histologically confirmed LARC, distal part of the tumour 4-12 cm from anal verge, no metastases, poor prognostic features on pelvic MRI, WHO performance status 0-1. Pts receive folinic acid + fluorouracil + oxaliplatin (FOLFOX) + bevacizumab or FOLFOX + irinotecan (FOLFOXIRI) + bevacizumab, given in two weekly cycles for up to six cycles prior to TME. MRI and positron emission tomography–computed tomography (PET/CT) are repeated prior to cycle four. Pts stop treatment if they fail to respond (defined as $\geq$30% decrease in Standardised Uptake Value compared to baseline PET/CT). The primary endpoint is pathological complete response (pCR) rate. Secondary endpoints are response rate (RECIST v1.1), circumferential resection margin-negative resection rate, T and N stage downstaging, progression-free, disease-free and overall survival, local control, one-year colostomy rate, acute toxicity, compliance to chemotherapy, tumour regression grade, and tumour cell density. Thirty pts in each arm are required to detect an improvement from 5-20% pCR rate for each regimen compared to RT alone (80% power, $\alpha$=0.05, assuming 10% non-evaluable rate). A regimen will be considered successful if at least 4/27 pCRs are observed. Clinical trial information: NCT01650428.

**TPS3654 General Poster Session (Board #114A), Sat, 8:00 AM-11:45 AM**

**Randomized phase II study of panitumumab (Pmab) plus irinotecan (CPT-11) versus cetuximab (Cmab) plus CPT-11 in patients with KRAS wild-type (WT) metastatic colorectal cancer (mCRC) following treatment with fluoropyrimidine, CPT-11, and oxaliplatin (L-OHP) chemotherapy: WJOG6510G.** *Presenting Author: Daisuke Sakai, Osaka University Graduate School of Medicine, Osaka, Japan*

**Background:** Pmab and Cmab are known to be effective in KRAS WT mCRC. Recent study showed that Pmab and Cmab monotherapy were comparable in patients with KRAS WT mCRC previously treated with fluoropyrimidine-, L-OHP-, and CPT-11- based regimens. However, it is not clear whether their combination therapy with CPT-11 confers similar benefit. **Methods:** This randomized phase II study of Pmab + CPT-11 or Cmab + CPT-11 recruits patients with mCRC with KRAS WT from 45 sites in Japan. Primary objective is progression free survival (PFS), with a non-inferiority margin of 1.3 (80% CI). Median PFS with both arms is assumed to be 6.0 months. Secondary objectives are overall survival, response rate, disease control rate, and safety. Eligibility: Patients with proven colorectal adenocarcinoma with KRAS (exon 2) WT; unresectable metastatic disease; failed prior regimens containing CPT-11 and L-OHP and fluoropyrimidine; age>=20years; ECOG performance status 0-2; evaluable disease, as defined by the RECIST criteria v1.1; adequate hematologic, renal, hepatic and metabolic function; expected survival>=90 days; written informed consent obtained from the patient. Patients are randomized after stratification by site; PS; refractory or intolerance for L-OHP; previous use of bevacizumab to receive either arm A) Cmab (400 mg/m2 followed by 250 mg/m2 weekly) + CPT-11 (150mg/m2 every 2 weeks) or arm B) Pmab (6 mg/kg every 2 weeks) + CPT-11 (same dose as arm A). Status: Opened to accrual December 2011, at 31 Jan 2014 93/120 patients have been enrolled. Clinical trial information: UMIN000006643.

**TPS3655 General Poster Session (Board #114B), Sat, 8:00 AM-11:45 AM**

**Two phase III studies comparing 6 months of either mFOLFOX6 or XELOX with 3 months of the same regimen as adjuvant chemotherapy in patients with completely resected stage III colon cancer (ACHIEVE) or high-risk stage II colon cancer (ACHIEVE-2).** *Presenting Author: Takayuki Yoshino, National Cancer Center Hospital East, Chiba, Japan*

**Background:** The International Duration Evaluation of Adjuvant Chemotherapy (IDEA) collaboration was established to prospectively combine/analyze data from several randomized trials conducted around the world to test whether three months of oxaliplatin-based adjuvant therapy (FOLFOX4/ mFOLFOX6 or XELOX) is non-inferior for disease-free survival (DFS) to six months of the same therapy in patients with stage III or high-risk stage II colon cancer. ACHIEVE (JFMC47-1202-C3) and ACHIEVE-2 (JFMC48-1301-C4) are in progress as part of the IDEA project. **Methods:** The ACHIEVE and ACHIEVE-2 trials, conducted by the Japanese Foundation for Multidisciplinary Treatment of Cancer (JFMC), are open-label, randomized, phase III, multicenter studies in Japanese patients with completely resected stage III or high-risk stage II colon cancer, respectively. Main eligibility criteria are adenocarcinoma of the colon; ECOG performance status of 0-1; age 20 years or older; registration within eight weeks of curative resection; starting oxaliplatin-based chemotherapy within two weeks after registration; and adequate organ function. Allocation is done centrally with a 1:1 ratio using randomization stratified by the primary site, number of lymph nodes involved, regimen, age, and participating center for stage III, or by depth of invasion, number of lymph nodes examined, regimen, age, and participating center for high-risk stage II. The primary endpoint is to evaluate whether treatment for three months is not inferior to six months in terms of relapse-free survival (RFS), which is defined as time to colon cancer recurrence or death from any cause. Main secondary endpoints include DFS, overall survival (OS) and adverse events. The target sample size is 1,200 patients for stage III and 500 patients for high-risk stage II. As of February 2014, 992 patients have been randomized for stage III. Enrollment for high-risk stage II starts in February 2014. Study ID: UMIN 000008543 for ACHIEVE and UMIN 000013036 for ACHIEVE-2. Clinical trial information: UMIN 000008543 and UMIN 000013036.

**TPS3656 General Poster Session (Board #115A), Sat, 8:00 AM-11:45 AM**

**Biopsy-driven study to identify biomarkers predictive of clinical response to second-line regorafenib in patients with metastatic colorectal cancer.** *Presenting Author: Petr Kavan, Department of Oncology, McGill University and the Segal Cancer Center, Sir Mortimer B. Davis, Jewish General Hospital, Montreal, QC, Canada*

**Background**: Biopsy-driven trials offer unique opportunities for discovery and validation of molecular signatures. We began a Phase II investigator-initiated study (IIS) to identify biomarkers (BMs) predictive of response to regorafenib in patients with metastatic colorectal cancer (mCRC) (QCROC-06; NCT01949194). Regorafenib is an oral multikinase inhibitor that targets angiogenic, stromal and oncogenic kinases. Results from the CORRECT trial suggest that some patients benefit more than others from single-agent regorafenib, but the trial was not designed to study these differences (Grothey et al. The Lancet 381: 303-312, 2012). **Methods**: Patients with mCRC and at least one liver metastasis available for biopsy, who have failed first-line treatment, are eligible for this study of second-line treatment with single-agent regorafenib. The primary objective is to identify BMs in blood or tissue. Secondary objectives include progression free survival, response rate and safety. Patients are accrued at four Canadian centers to collect 42 evaluable pre-treatment biopsies. Two patients have been enrolled so far. The trial is part of a portfolio of sequential biopsy-driven IIS. Patients are primarily recruited after participating in QCROC-01, a prospective study to identify BMs of resistance to first-line therapy. A biopsy taken at resistance to first-line treatment serves as the entry biopsy for QCROC-06. Another biopsy at disease progression is optional. Genomic material is isolated from all biopsies, and blood is collected regularly for analysis of VEGF polymorphism and circulating tumor DNA. BMs will be identified using targeted and global profiling approaches. We assume a maximum of 10 BMs, and an overall type 1 error of 5%, and that a disease control rate of 74% will be achieved. With 80% power, this sample size allows us to detect BM(s) if the proportion of patients with the BM(s) is $\leq$ 26% in non-responders and $\geq$ 84% in responders. Bioinformatics analysis will correlate findings with response to regorafenib. The trial is supported by Bayer HealthCare. Clinical trial information: NCT01949194.

**TPS3657 General Poster Session (Board #115B), Sat, 8:00 AM-11:45 AM**

**Randomized phase Ib/II study of PF-05212384 plus 5-fluorouracil-leucovorin-irinotecan (FOLFIRI) versus bevacizumab plus FOLFIRI in metastatic colorectal cancer (B2151007; NCT01937715).** *Presenting Author: Zev A. Wainberg, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA*

**Background:** Despite recent advances in cytotoxic chemotherapies and targeted agents, metastatic colorectal cancer (mCRC) continues to be an area of great unmet medical need. Patients with mCRC are typically treated with a fluoropyrimidine plus oxaliplatin or irinotecan, with or without an anti-angiogenic agent or monoclonal antibody to epidermal growth factor receptor. Although these regimens are considered standard of care, they are only moderately effective, and more-active regimens are needed. Signaling through the phosphatidylinositol 3-kinase (PI3K) pathway is associated with resistance to chemotherapies with different mechanisms of action, including taxanes and DNA-damaging agents, in nonclinical models. In the clinic, PI3K pathway activation in tumors has been correlated with decreased response to therapy and worse clinical outcomes. The combination of PF-05212384 (intravenous PI3K/mammalian target of rapamycin inhibitor) and irinotecan was additive in preclinical mCRC models and showed preliminary antitumor activity with acceptable tolerability in a phase I study (B1271002; NCT01347866) in patients with cancer, including mCRC, warranting further exploration of irinotecan-based combination regimens. **Methods:** This global study includes a dose escalation, phase Ib portion to evaluate dose limiting toxicities (primary endpoint) and determine the recommended phase II dose of PF-05212384 combined with FOLFIRI. A separate lead-in cohort to confirm the safety of the PF-05212384/FOLFIRI combination will be conducted at clinical sites in Japan. Then, a randomized phase II portion will investigate whether PF-05212384 plus FOLFIRI is superior to bevacizumab plus FOLFIRI in prolonging progression-free survival (primary endpoint) in patients with mutated or wild-type *KRAS* mCRC and disease progression on a first-line oxaliplatin-containing regimen or with progression within six months of an oxaliplatin-containing regimen in the adjuvant setting. Secondary endpoints include safety, overall survival, and biomarker correlations associated with the PI3K pathway. This trial is now recruiting. Clinical trial information: NCT01937715.

**TPS3658 General Poster Session (Board #116A), Sat, 8:00 AM-11:45 AM**

**A randomized, double-blind, placebo-controlled, multicenter, binational, phase II trial of immunotherapy with L-BLP25 (tecemotide) in patients with colorectal carcinoma following R0/R1 hepatic metastasectomy.** *Presenting Author: Stefan Kasper, Department of Medical Oncology, West German Cancer Center, University Hospital Essen, Essen, Germany*

**Background:** Surgical resection is the only potentially curative treatment for colorectal cancer (CRC) metastases. The five-year survival rate following R0 resection of liver mets is 28-39% and recurrence occurs in approximately 70%. Adjuvant chemotherapy does not significantly improve clinical outcomes. The primary endpoint of the L-BLP25 In Colorectal Cancer trial (LICC) is to test if tecemotide, an active MUC1-specific cancer immunotherapy, increases recurrence-free survival (RFS) time over placebo in CRC patients (pts) after R0/R1 resection of hepatic mets. **Methods:** This is a binational, phase II, multicenter, randomized, double-blind, placebo controlled trial with a sample size of 159 pts from 23 centers in pts with stage IV CRC limited to liver mets. Pts must have had a complete resection of the primary tumor with curative intent and a R0/R1 resection of all syn/metachronous mets. Eligible pts are randomized 2:1 to receive either tecemotide or placebo. Pts in the tecemotide arm receive a single dose of 300 mg/m$^2$ cyclophosphamide (CPA) three days before the first tecemotide dose, then primary treatment with tecemotide 930 $\mu$g weekly for eight weeks, followed by maintenance doses at six-week (year one and two) and 12-week (year three) intervals or until recurrence. In the control arm CPA is replaced by saline solution and tecemotide by placebo. Primary objective of the trial is RFS time. Secondary objectives include overall survival (OS), safety, tolerance, and RFS/OS in MUC1-positive cancers. Exploratory immune response analyses are independently run in a project supported by the German Ministry of Education and Research. The study started in Q3 2011. Recruitment is estimated to be completed by Q3 2014 and follow-up by Q3 2018. Interim analyses have not been planned and endpoint assessment is estimated for Q3 2017. Independent medical and radiological review will guarantee data quality. By Jan 24, 2014, 23 centers have been initiated and 81 pts recruited. Two SUSARS have been reported by Jan 2014. No practical issues have been identified during setup and early conduct of the study. Updated recruitment figures will be presented at the meeting. Clinical trial information: NCT01462513.

**TPS3659 General Poster Session (Board #116B), Sat, 8:00 AM-11:45 AM**

**Regorafenib assessment guided by metabolic imaging in refractory advanced colorectal cancer (aCRC): REGARD-C study.** *Presenting Author: Alain Hendlisz, Institut Jules Bordet, Brussells, Belgium*

**Background:** Regorafenib, an oral multi-tyrosine kinase inhibitor that shares with sorafenib several targets on tumor angiogenesis, oncogenesis, and tumor microenvironment, was recently approved for patients (pts) with pretreated advanced colorectal cancer (aCRC). The drug improves the pts' outcome, but with significant toxicities, underscoring the need to identify those who will not benefit. A previous study (SoMore trial) showed that early FDGPET-based metabolic response assessment (MRA) may adequately discriminate pts with chemorefractory aCRC unlikely to benefit from a sorafenib-capecitabine combination. RegARd-C aims to explore early MRA in pts treated with regorafenib as a clinical tool to spare pts from needless toxicity from a drug that gives them little or no benefit and as a translational tool to guide comprehensive genomic and epigenetic research on the determinants of drug resistance. **Methods:** RegARd-C's (EUDRACT 2012-005655-16) is a multi-centric prospective study. Its primary objective is to identify in a population of pts with pretreated aCRC, those who will not benefit from regorafenib given at 160 mg/day, three weeks/4. Baseline PET is repeated at D14 of the first treatment course. MRA results are blinded for the investigators. Tumor tissues, optionally obtained from a PET-measurable lesion, and blood samples (at baseline; after the first chemotherapy course; and every two months) are collected. Overall survival (OS) is the primary endpoint and will be correlated with metabolic parameters, and genetic, epigenetic and molecular aberrations assessed from tumor biopsies and blood samples using gene expression and methylation profiling, RNA and exome sequencing. As the study is exploratory, no formal hypothesis was formulated. We arbitrarily decided to have a sample size of 105 evaluable pts with 70 pts as a derivation set and 35 pts as a validation set. Taking into account an expected 20-25% drop-out rate, between 124 and 140 pts will be accrued.This sample size is, however, sufficient to validate the hypothesis generated by the SoMore study, which found a prognostic impact of homogeneous metabolic response on OS, with an estimated HR of 0.59. RegARd-C has accrued 76 pts since August 2013. Clinical trial information: NCT01929616.

**TPS3660 General Poster Session (Board #117A), Sat, 8:00 AM-11:45 AM**

**The NCIC CTG and AGITG CO.23 trial: A phase III randomized study of BBI608 plus best supportive care (BSC) versus placebo (PBO) plus BSC in patients (Pts) with pretreated advanced colorectal carcinoma (CRC).** *Presenting Author: Derek J. Jonker, The Ottawa Hospital Research Institute, Ottawa, ON, Canada*

**Background:** BBI608 is an orally-administered first-in-class cancer stemness inhibitor which blocks cancer stem cell (CSC) self-renewal and induces cell death in CSCs as well as non-stem cancer cells by inhibition of the Stat3, $\beta$-catenin and Nanog pathways. Encouraging signs of anticancer activity, particularly in colorectal carcinoma (CRC), were observed in a phase I dose escalation study: disease control in 8/12 (67%) evaluable patients (pts); median progression free survival (PFS) equals 14 weeks; median overall survival (OS) equals 47 weeks (Langleben *et al. J Clin Oncol* 2013; 31 suppl; abstr 2542). Similar activity in CRC pts was observed in a subsequent phase I/II extension study. On the basis of these data, a phase III trial was designed and is being conducted by the National Cancer Institute of Canada (NCIC) Clinical Trials Group and the Australasian Gastrointestinal Trials Group under special protocol assessment with the FDA. **Methods:** This randomized, double-blind, placebo (PBO)-controlled study (ClinicalTrials.gov NCT01830621) will assess the efficacy and safety of BBI608+best supportive care (BSC) versus PBO+BSC in pts with metastatic or advanced, unresectable, refractory CRC (target n=650). Pts have no remaining approved therapies available, having failed standard chemotherapy based regimens containing a fluoropyrimidine, irinotecan and oxaliplatin (and an EGFR inhibitor, if *KRAS* wild type). Pts are randomized in a 1:1 ratio to receive BBI608 480 mg or matching PBO twice daily continuously. Treatment will continue until disease progression, death, intolerable toxicity, or patient/investigator decision to stop. Primary endpoint is OS; secondary endpoints include disease control rate, PFS, safety, and quality of life. Analysis will be according to randomized group stratified by Eastern Cooperative Oncology Group performance status (0 vs. 1), *KRAS* status (wild type vs. mutant), prior anti-vascular endothelial growth factor therapy (yes vs .no), and time from diagnosis of metastatic disease to randomization ($<$18 vs. $\geq$18 months). In addition blood, plasma, and archival tissue will be assessed for pharmacokinetic and biomarker analyses and health utility will be measured. As of February 2014, 130 pts were randomized and recruitment is ongoing in Canada, Australia, New Zealand and Japan. Clinical trial information: NCT01830621.

**TPS3661 General Poster Session (Board #117B), Sat, 8:00 AM-11:45 AM**

**ONC-2012-001: A single-arm phase II study of tivantinib (ARQ 197) plus cetuximab in EGFR inhibitor-resistant *MET* high patients (pts) with locally advanced or metastatic colorectal cancer (CRC) with wild-type *KRAS*.** *Presenting Author: Lorenza Rimassa, Humanitas Cancer Center, Humanitas Clinical and Research Hospital, Rozzano, Italy*

**Background:** *MET* overexpression has been identified in 30-70% colorectal cancer (CRC) and activation of this pathway can be associated to resistance to cetuximab (Krumbach R et al, *Eur J Cancer* 41:1231-43, 2011). Tivantinib (ARQ 197) is a non-adenosine triphosphate (ATP)-competitive, oral inhibitor of the *MET* receptor tyrosine kinase. The ARQ 197-A-U252 phase I/II trial in wild-type *KRAS* metastatic CRC (mCRC) demonstrated that tivantinib in combination with irinotecan and cetuximab is well tolerated and showed encouraging antitumor activity, particularly in *MET*-high patients (pts) (Eng C et al, *J Clin Oncol* 31, 2013; suppl, abstr 3508). Additionally in the last years, the potential role of epidermal growth factor receptor inhibitors beyond progression in mCRC has been evaluated. Adding tivantinib to cetuximab is based on a strong rationale to improve outcome in cetuximab resistant *MET*-high mCRC pts. **Methods:** Enrollment in this single-arm, Simon 2-stage, phase II study (ONC-2012-001) has begun. Eligible pts have: MET-high (at immunohistochemistry), surgically unresectable, locally advanced or metastatic CRC; received $>$1 prior systemic therapy for advanced or metastatic disease; progressed on or after a cetuximab or panitumumab containing regimen after a best response of at least stable disease and within three months before enrollment; Eastern Cooperative Oncology Group performance score $<$ 2; adequate bone marrow, liver and kidney functions. Pts receive tivantinib 240 mg p.o. twice daily plus cetuximab 500 mg i.v. every two weeks and are evaluated by CT or MRI scan at eight-week intervals. The primary endpoint is objective response rate. Secondary endpoints include progression-free survival, overall survival and safety. Treatment continues until disease progression or unacceptable toxicity. Pts discontinued from study treatment will be followed for survival. As of January 28, 2014, four of the planned first-stage 21 pts have been enrolled. This trial is expected to complete enrollment by the end of 2014. Clinical trial information: NCT01892527.

**TPS3662 General Poster Session (Board #118A), Sat, 8:00 AM-11:45 AM**

**Randomized phase II study of regorafenib followed by cetuximab versus reverse sequence for wild-type *KRAS* metastatic colorectal cancer previously treated with fluoropyrimidine, oxaliplatin, and irinotecan (REVERCE).** *Presenting Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** Regorafenib (RE) and cetuximab (CE) are both effective treatments for patients (pts) with metastatic colorectal cancer (mCRC) with the current standard sequence as CE followed by RE. For optimal continuum of care for mCRC pts, it is important to compare efficacy and safety of different sequential treatments. Furthermore, several possible biomarkers including oncogenic mutations and serum protein have been identified for both RE and CE treatment so far. The objective of this study is to evaluate the efficacy and safety of sequential treatment of RE followed by CE as compared with CE followed by RE. Exploratory objective is to investigate several biomarkers with an aim of producing findings that may be useful in elucidating the mechanism of resistance to each agent and contribute to future individualized therapy. **Methods:** This multicenter randomized phase II trial will enroll pts with *KRAS* wild-type mCRC after failure of chemotherapy including fluoropyrimidine, oxaliplatin, and irinotecan (UMIN000011294). Pts will be randomized (1:1; stratified by prior use of bevacizumab and intent to use irinotecan in combination with CE) to receive sequential treatment with RE followed by CE $\pm$ irinotecan or reverse sequence (CE $\pm$ irinotecan followed by RE). Primary endpoint is overall survival (OS). Secondary endpoints include time to sequential treatment failure (TTF), progression-free survival (PFS) of sequential treatment, anti-tumor effects (response rate, disease control rate) of RE or CE, safety, and patients reported outcome of quality of life (QOL). Exploratory endpoint is to investigate possible biomarkers including oncogenic mutations from circulating cell free DNA by liquid biopsy with serial measurement and multiple serum proteins related to epidermal growth factor receptor or vascular endothelial growth factor pathway change over time at several point of sequential treatment. To evaluate the similarity of OS between both arms (HR between 0.8 and 1.25), the sample size was planned as 180 subjects in total to observe 132 deaths with 1.5-year enrollment and subsequent 1.5-year follow-up periods. As of 21 Jan 2014, eight pts have been enrolled. Clinical trial information: UMIN000011294.

**TPS3663 General Poster Session (Board #118B), Sat, 8:00 AM-11:45 AM**

**A phase III study of the impact of a physical activity program on disease-free survival in patients with high-risk stage II or stage III colon cancer: A randomized controlled trial (NCIC CTG CO.21).** *Presenting Author: Christopher M. Booth, Division of Cancer Care & Epidemiology, Cancer Research Institute, Queen's University, Kingston, ON, Canada*

**Background:** Observational studies indicate that physical activity (PA) is associated with colon-cancer specific survival. The National Cancer Institute of Canada Clinical Trial Group CO.21 (CHALLENGE) trial is designed to determine the effects of a structured physical activity (PA) intervention on disease-free survival in high-risk stage II or III colon cancer survivors who have completed adjuvant chemotherapy within the previous 2-6 months. **Methods:** Phase III randomized controlled trial. Target sample size of 962 patients is powered to detect a Hazard Ratio of 0.75 for disease-free survival (DFS). Trial participants are stratified by centre, disease stage, body mass index, and performance prior to randomization to a structured PA intervention or general health education materials. The PA intervention consists of a behavioural support program and supervised PA sessions delivered over a three-year period, beginning with regular face-to-face sessions and tapering to less frequent face-to-face or telephone sessions. The goal of the PA program is to increase weekly PA by 10 METhours/week. The PA program is delivered by physical activity consultants trained in exercise physiology and behavior change. Outcomes:The primary endpoint is DFS. Important secondary endpoints include multiple patient-reported outcomes (including those that address fatigue), objective physical functioning, biologic correlative markers (including assessment of the insulin pathway), and an economic analysis. Data is also being collected on motivational outcomes and behavior change that will inform program delivery. Current Enrollment:The study is open at 20 centers in Canada and 26 centers in Australia and will open in other countries in 2014. Accrual as of February 3, 2014 includes 311 registered and 262 randomized patients. Summary: Cancer survivors and cancer care professionals are interested in the potential role of PA to improve disease-free survival and quality of life. A randomized controlled trial is needed to provide compelling evidence to justify changes in health care policies and practice. Clinical trial information: NCT00819208.

**TPS3664 General Poster Session (Board #119A), Sat, 8:00 AM-11:45 AM**

**Phase II randomized study of induction FOLFOXIRI plus bevacizumab (bev) followed by maintenance with bev alone or bev plus metronomic chemotherapy (metroCT) in metastatic colorectal cancer (mCRC): The MOMA trial.** *Presenting Author: Lisa Salvatore, U.O. Oncologia Medica 2, Azienda Ospedaliero-Universitaria Pisana, Istituto Toscano Tumori, Pisa, Italy*

**Background:** FOLFOXIRI plus bevacizumab (bev) followed by 5-FU plus bev is an efficacious option for first line tx of metastatic colorectal cancer (mCRC) patients (pts) (TRIBE study). CAIRO-3 trial demonstrated that maintenance with standard doses of capecitabine plus bev provides a significant second progression (PFS2) advantage, as compared to observation alone, although at the cost of some toxicities that limited the rate of reintroduction of CAPOX. Metronomic chemotherapy (metroCT) may represent an alternative and better tolerated strategy for targeting tumor angiogenesis and preclinical evidences show that it may synergize with bev in order to maximize the antiangiogenic effect. On the basis of such premises we are conducting the MOMA study to explore maintenance tx with bev alone or bev plus metroCT following a four-months induction phase with FOLFOXIRI plus bev. **Methods:** This is a multi-center, phase II randomized study. Pts with unresectable mCRC, untreated for the metastatic disease, are randomized to receive 8 cycles of induction FOLFOXIRI plus bv, followed by bev (7.5 mg/Kg every three weeks) until the evidence of disease progression (PD), or the same induction regimen followed by bev in combination with metronomic capecitabine and oral cyclophosphamide (Cape: 500 mg/tid, CTX: 50 mg/die) continuously, until PD. The primary end-point is first-line PFS. FOLFOXIRI plus bev is reintroduced in pts undergoing PD during maintenance. Secondary end-points are response rate, resection rate, duration of response, time to strategy failure, time to second PD, overall survival, safety profile and the evaluation of potential surrogate markers of bev and metroCT efficacy (including pharmacodynamic, pharmacokinetic, and pharmacogenetic parameters). According to Rubinstein and Korn's design, estimating a first-line PFS with CT plus bev of 11 months, to detect a hazard ratio of 0.75 in favour of the experimental arm, with a power of 80% and a type-I error of 15%, 173 events are required. From May 2012 to Jan 2014, 117 pts have been so far enrolled in 13 Italian centers and the study is still recruiting. Supported by ARCO Foundation. Clinical trial information: 2011-006332-23.

**TPS3665 General Poster Session (Board #119B), Sat, 8:00 AM-11:45 AM**

**E7208: A randomized phase II trial of irinotecan and cetuximab (IC) versus IC plus ramucirumab (ICR) in second-line therapy of KRAS wild-type colorectal cancer (CRC).** *Presenting Author: Howard S. Hochster, Department of Medical Oncology, Yale University School of Medicine, New Haven, CT*

**Background:** Anti-angiogenic therapy for CRC has been accepted as standard therapy with approval of bevacizumab (bev) in both first-line and second-line settings. At the time this study was started, the benefit of continuing an anti-angiogenic in second line therapy was unproven. Ramucirumab (RAM, IMC 1121b) is a humanized antibody directed against the VEGF-R2 receptor, which may prove to have different activity compared to anti-VEGF antibody (bev). Additionally, while combining the anti-EGFR antibody, cetuximab (CMAB), with bev in first-line unselected patients was not effective, it is unknown whether the same may be true with RAM plus CMAB in a second-line setting for KRAS-selected patients. **Methods:** The study was designed as a randomized phase II trial with 147 patients assigned to IC = Irinotecan (I) 180 mg/m2 IV plus CMAB 500 mg/m2 IV q2w versus ICR = IC plus RAM 8 mg/kg IV q2w. Eligibility included prior treatment on one prior oxaliplatin and bev-containing regimen and progression within 42 days of last bev, PS 0-1, KRAS codon 12,13 wild-type and standard other chemo and bev criteria. Doses were modified for neutropenia, diarrhea, mucositis, rash and grade 3 other toxicities. The study was activated 10/8/10. After the first 35 patients were enrolled, accrual was held 6/24/12 for toxicity analysis per protocol. More grade 3 events of mucositis, diarrhea, neutropenia and perforation events (including peri-rectal abscesses) were seen in the ICR arm. The study has been modified to reflect the actual doses received, and will reopen with modified ICR (mICR) = I 150 mg/m2, CMAB 400 mg/m2 and RAM 6 mg/kg IV q2w. An additional 100 pts will be accrued to the revised study, giving 85% power to detect improved median PFS from 4.5 to 7.65 months. New eligibility criteria include any progression from 1$^{st}$ line chemo (on or off), normal albumin, no bowel perforation or obstruction in last 6 months. The revision was approved by CTEP in December 2013 and will re-open to accrual in March 2014, with SWOG participation. Clinical trial information: NCT01079780.

**TPS3666 General Poster Session (Board #120A), Sat, 8:00 AM-11:45 AM**

**UCGI 25: A multicentric randomized phase II trial evaluating dual targeting of the epidermal growth factor (EGFR) using the combination of cetuximab and afatinib versus cetuximab alone in patients (pts) wih chemotherapy refractory wtRAS metastatic colorectal cancer (mCRC).** *Presenting Author: Hélène Senellart, Institut de Cancerologie de l'Ouest-site René Gauducheau, Nantes, France*

**Background:** A previous study assessing erlotinib-cetuximab combo in chemo- refractory wt KRAS mCRC (Weickhardt AJ, et al J Clin Oncol 201;30:1505-12) has shown encouraging data (ORR=41 %, PFS=5.6 months). Afatinib is an Erb-B family blocker that irreversibly blocks signaling from all relevant Erb-B family homo and heterodimers. **Methods:** We conduct a randomized phase II study to determine the benefit of afatinib plus cetuximab versus cetuximab alone in patients with wtRAS metastatic CRC after oxaliplatin and irinotecan failure.Key eligibility criteria: pts with mCRC expressing wt KRAS/NRAS status; ECOG status 0 or 1; no disease progression with previous anti-EGFR targeted therapy; failure with a prior regimen containing irinotecan or oxaliplatin for metastatic disease; pts must have previously received a thymidylate inhibitor at any point for treatment of CRC; Pts are randomized 2:1 to receive oral afatinib (40 mg/qd) in combo with i.v. cetuximab (500mg/m$^2$ q 2 weeks) or cetuximab alone (500mg/m$^2$ q2 weeks). Dose adjustments are permitted according to the occurrence of drug related Adverse Events (AE). Pts receive treatment until PD or unacceptable AE. Pts randomized in the cetuximab arm have the opportunity to crossover to the combo arm after disease progression. The primary endpoint is the 6-month PFS rate. Secondary endpoints include ORR, median PFS, OS, safety and tolerability. Target enrolment is 75 pts. Completion of pt recruitment and data analyses are awaited. this study is promoted by UNICANCER GI. Clinical trial information: NCT01919879.

**TPS3667 General Poster Session (Board #120B), Sat, 8:00 AM-11:45 AM**

**A phase IB/II study of neoadjuvant chemoradiotherapy with CRLX101 and capecitabine for locally advanced rectal cancer.** *Presenting Author: Michael Joseph Eblan, Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Neoadjuvant chemoradiotherapy followed by surgical resection is the standard of care for locally advanced rectal cancer. There is strong interest in the development of novel agents and strategies to further improve the therapeutic ratio of chemoradiotherapy. One innovative approach is to incorporate nanoparticle (NP) therapeutics, which are known to preferentially accumulate in tumors. CRLX101 is a NP formulation of camptothecin (CPT), a potent nanotherapeutic shown to be safe in phase I clinical evaluation. In addition to inhibiting Topo-1, CRLX101 demonstrates durable suppression of HIF-1$\alpha$, a regulator of the tumor survival pathway that was previously considered un-druggable. It has also been implicated in resistance to radiotherapy. Preclinically, CRLX101 has been shown to be a potent radiosensitizer. The purpose of this study is to evaluate whether the addition of CRLX101 to capecitabine and radiotherapy can improve pathologic complete response (pCR) and clinical outcomes for rectal cancer. **Methods:** This ongoing open label, single-arm multicenter Phase Ib/II study is designed to identify the maximum tolerated dose (MTD) using a 3+3 dose escalation design. The MTD will be assigned as the recommended Phase II dose (RP2D). In Phase II, we will evaluate the efficacy of RP2D and further characterize the safety of CRLX101 when combined with CRT prior to surgery in patients with locally advanced rectal carcinoma (stage cT3-4N0 or cT1-4N+). Patients in the Phase Ib study with resectable disease and treated at the RP2D will be included in the Phase II study population. Target accrual is 53 evaluable patients in the Phase II trial, using a Simon two-stage design, with a primary endpoint of pCR. Secondary objectives include evaluation of pathologic response, disease free survival (DFS) and overall survival (OS). We hypothesize that our proposed regimen is safe, and will improve the rate of pCR as compared to 15-25% pCR rate of historical controls. If the results are consistent with a pCR rate of at least 35%, the treatment regimen will be considered worthy of further investigation. The study was initiated in December, 2013. Clinical trial information: NCT02010567.

**4000 Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

**A randomized double-blind phase 2 study of ruxolitinib (RUX) or placebo (PBO) with capecitabine (CAPE) as second-line therapy in patients (pts) with metastatic pancreatic cancer (mPC).** *Presenting Author: Herbert Hurwitz, Duke University Medical Center, Durham, NC*

**Background:** Local and systemic inflammation (INFL) are hallmarks of cancer, including PC, that adversely impact prognosis. Given the role of JAK-STAT signaling in cancer INFL, the efficacy and safety of RUX, a JAK1/JAK2 inhibitor, given with CAPE in pts with mPC refractory to initial therapy was explored. **Methods:** Pts with adequate performance status and organ function who progressed after gemcitabine treatment were included. RUX + CAPE was well tolerated in a 9 pt safety run-in. Subsequently, 127 pts were randomized to CAPE 1000 mg/m$^2$ BID days 1–14 with either RUX 15 mg BID or PBO on days 1–21 of a 21-day cycle. The primary endpoint was OS; secondary endpoints included PFS and ORR. To detect a HR $\leq$0.6 with 2-sided $\alpha$=0.2 and $\beta$<0.2, final analysis was planned to occur after 97 deaths. Subgroup analyses were prespecified to explore treatment heterogeneity and a hypothesis that RUX would preferentially benefit pts with evidence of INFL. **Results:** In the randomized population, OS and PFS favored RUX (Table). Confirmed ORR was 7.8% for RUX and 0% for PBO. In a prespecified subgroup of pts with INFL, as measured by serum C-reactive protein (CRP > group median of 13 mg/L), OS significantly favored RUX over PBO (Table). In this subgroup, 3 and 6 month survival was 48% and 42% with RUX vs 29% and 11% with PBO, respectively. In pts with CRP $\leq$13 mg/L, significant benefits in OS or PFS were not observed (HR = 0.89 and 0.82, respectively). OS benefit was also seen in pts classified by modified Glasgow Prognostic Score (mGPS), a measure of INFL in cancer (HRs 0.91, 0.71, 0.49 for mGPS 0, 1, 2, respectively). The combination of RUX and CAPE was generally well tolerated. Grade 3 or 4 (G3/4) adverse events occurred in 75% and 82% of RUX and PBO pts, respectively. G3/4 neutropenia and thrombocytopenia were uncommon in RUX pts (1.7% and 0%, respectively). G3/4 anemia occurred more frequently on RUX (15.3%) than PBO (1.7%). **Conclusions:** RUX may improve OS and PFS in mPC pts with INFL characterized by elevated CRP or mGPS of 1 or 2. Clinical trial information: NCT01423604.

| HR (95% CI) | RUX | PBO |
|---|---|---|
| Randomized, n | 64 | 63 |
| OS | 0.79 (0.53–1.18) p=0.25 | |
| PFS | 0.75 (0.52–1.10) p=0.28 | |
| CRP >13 mg/L, n | 31 | 29 |
| OS | 0.47 (0.26–0.85) p=0.01 | |
| PFS | 0.62 (0.35–1.1) p=0.20 | |

**4001^ Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

**Impact of chemoradiotherapy (CRT) on local control and time without treatment in patients with locally advanced pancreatic cancer (LAPC) included in the international phase III LAP 07 study.** *Presenting Author: Florence Huguet, Hopital Tenon, Paris, France*

**Background:** In the LAP07 multicenter randomized study, administration of CRT in patients with LAPC controlled with induction chemotherapy (CT) was not superior to continuing CT alone in terms of overall survival. However, whether CRT should have an impact on locoregional tumor control remains unknown. **Methods:** LAPC patients were first randomized to gemcitabine or gemcitabine plus erlotinib. Patients with controlled disease after 4 months of CT were then randomized to two additional months of CT or CRT 54 Gy and concurrent capecitabine. A quality control for radiotherapy was done using validation by a dummy run and assessment of treated patients. Primary objective was overall survival (OS) in patients who acceded to the second randomization. Survivals were estimated using the Kaplan-Meier method and compared using the log-rank test. **Results:** Among the 442 included patients, 269 patients had tumor control after 4 months of induction CT and were randomized to either the CRT arm (n=133) or the CT arm (n=136). The OS was not significantly different between the two arms (15.2 vs 16.5 months, p=0.8). At the time of analysis, 238 patients had a tumor progression, which was locoregional in 96 patients (50.5%) and metastatic in 97 patients (49.5%). In the CRT arm, patients had significantly less local tumor progression compared to the CT arm (34% vs 65%, p<0.0001). Median time without treatment (i.e. reintroduction of chemotherapy) was longer in the CRT arm compared to the CT arm (159 vs 96 days, respectively, p=0.05). **Conclusions:** Even though the OS was not improved in the CRT arm, patients with non-progressive LAPC after 4 months of induction CT had a longer time without treatment in the CRT arm with significantly less local tumor progression which could translate into a better quality of life. Clinical trial information: NCT00634725.

**4002 Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

**ABC-03: A randomized phase II trial of cediranib (AZD2171) or placebo in combination with cisplatin/gemcitabine (CisGem) chemotherapy for patients (pts) with advanced biliary tract cancer (ABC).** *Presenting Author: Juan W. Valle, University of Manchester, Manchester Academic Health Science Centre; Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, United Kingdom*

**Background:** ABCs exhibit increased VEGF expression, correlating with metastatic disease. Combining cediranib (which inhibits VEGFR1, 2 and 3 tyrosine kinase and VEGF-induced signaling in endothelial cells) with CisGem may improve outcome. **Methods:** Pts with histo-/cytologically confirmed ABC, aged $\geq$18 yrs, ECOG PS 0-1 and adequate bone marrow, liver and renal function were randomized to receive Cis (25mg/m$^2$) followed by Gem (1000mg/m$^2$) on days 1 and 8 of a 21-day cycle (up to 8 cycles), plus either cediranib (20mg once daily [OD]) or placebo (OD), until disease progression (PD). Tumor assessment was performed 12-weekly until PD. The target hazard ratio (HR) for progression-free survival (PFS, primary endpoint) was 0.64, requiring 136 pts (for 92 PFS events, 80% power, alpha=0.2, two-sided, ITT analysis). **Results:** 124 pts were enrolled (62 per arm, Apr-11 to Sep-12, study closed early due to cessation of cediranib development). Pt characteristics (cediranib vs. placebo): median age 68.0 vs. 64.5 years; 45% vs. 55% female; 19% locally advanced and 81% metastatic vs. 13% and 87%; bile duct, gall bladder, ampulla (%): 61, 32, 6 vs. 63, 31, 6; prior adjuvant chemotherapy: 3% vs. 2%; ECOG PS 0, 1: 44, 56 vs. 45, 55%. The most common grade 3-4 non-haematological adverse events (AEs) were hypertension, diarrhea and fatigue; 50% and 45% of cediranib and placebo pts experienced grade 3-4 haematological AEs, predominantly neutropenia (40 vs. 39%). Response rate (RECIST, in evaluable pts): cediranib (23/55 [43%] vs. placebo 10/53 [19%], p=0.01. With a median follow-up of 11.9 mo, PFS was not different (median (95%-CI)): 7.7 (6.3 – 9.3) vs. 7.4 (5.7 – 8.6) mo, HR (80% CI) 0.99 (0.78 – 1.26), p=0.95; with a trend for longer OS in the cediranib arm, median (95% CI): 14.1 (10.2 – 16.0) vs. 11.9 (9.2 – 13.4) mo, HR (95% CI) 0.76 (0.50 – 1.14), p=0.19. ELISA was performed for 15 potential plasma biomarkers of which Angiopoietin-2 (HR 0.65 (0.44 to 0.97) p=0.006) and Fibroblast Growth Factor-b (HR 0.83 (0.68 to 1.00) p=0.009) were the most significant. **Conclusions:** Cediranib appears to improve response rate but not PFS; effect on OS may warrant further studies. Clinical trial information: NCT00939848.

**4003 Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

**Phase III study of apatinib in advanced gastric cancer: A randomized, double-blind, placebo-controlled trial.** *Presenting Author: Shukui Qin, PLA Cancer Center of Nanjing Bayi Hospital, Nanjing, China*

**Background:** Molecular targeted therapy has made great progress in the treatment of gastric cancer. This paper reports the outcome of a phase III clinical study of apatinib, as an oral small molecular of VEGFR-2 tyrosine kinase inhibitor, in the treatment of patients with advanced gastric cancer who prior failure to second-line chemotherapy. This study may provide a new treatment options and leading a new hope for these patients. **Methods:** This is a multicenter, randomized, double-blind, placebo-controlled phase 3 trial. Apatinib or matching placebo, 850 mg, po, qd, 28 days as one cycle. Primary outcomes were overall survival. Study randomization was centralized and stratified according to the number of metastatic sites ($\leq$2 or >2). Planned to enroll 270 cases: 180 of apatinib and 90 of placebo. This trial was registered with ClinicalTrials.gov, number NCT01512745. **Results:** The patient baseline characteristics were similar in two arms in regards to age, historical of the disease, gender, ECOG scores, number of metastatic sites, pathological grading, clinical stage and therapy history(P>0.05). As the efficacy, median overall survival (mOS) was significantly prolonger in the apatinib group compare with in the placebo group (195 days versus 140 days ; HR= 0.71; 95% CI (0.54~0.94); p< 0.016). Median progression-free survival (mPFS) was also prolonged in the apatinib group compared with the placebo group (78 days versus 53 days, HR= 0.44, 95%CI (0.33~0.61), *P*<0.0001). The objective response rates (ORR) of apatinib group and placebo group were 2.84% and 0.00% respectively. As the safety, Treatment of apatinib group was generally well tolerated. Most of the adverse reaction could be managed by dose interruptions or reductions. Grade 3/4 adverse reactions that occurred in more than 2% of patients were hypertension, hand-and-foot syndrome, proteinuria, fatigue, anorexia, elevated aminotransferase. **Conclusions:** This study further confirmed the efficacy and safety of apatinib in the patients with advanced gastric cancer. 850 mg, qd is the recommended dose for clinical use. Clinical trial information: NCT01512745.

**4004 Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

**Ramucirumab (RAM) plus FOLFOX as front-line therapy (Rx) for advanced gastric or esophageal adenocarcinoma (GE-AC): Randomized, double-blind, multicenter phase 2 trial.** *Presenting Author: Harry H. Yoon, Mayo Clinic, Rochester, MN*

**Background:** RAM, an anti-VEGFR2 monoclonal antibody, improved overall survival (OS) in 2 phase 3 trials in patients (pts) with previously treated gastric/gastroesophageal junction (GEJ) AC. We report the first assessment of RAM as 1st-line Rx for GE-AC. **Methods:** Pts with untreated metastatic or locally advanced unresectable GE-AC (PS ≤1) were randomized 1:1 to mFOLFOX6 plus RAM (8 mg/kg IV) v placebo (PL), q14d. Primary endpoint was progression-free survival (PFS), with 80% power to detect HR 0.71 ($\alpha$ =.3). Secondary endpoints included OS, response rate (RR), disease control rate (DCR), and safety. **Results:** 168 pts (RAM 84 v PL 84) enrolled at 47 US sites, 04/11 – 08/12. Pt characteristics: age (65 v 60); male (75% v 73%); gastric (23% v 24%), GEJ (31% v 27%), esophageal (46% v 49%); metastatic (95% v 94%). Median PFS 6.4 v 6.7 m (HR 0.98 [95% CI 0.69 – 1.37]; p =.89) and OS 11.7 v 11.5 m (HR 1.08 [0.73-1.58]). Subgroup analyses by primary tumor location: for esophageal, median PFS was 5.6 v 6.1 m (HR 1.30); for gastric/GEJ, PFS was 8.7 v 7.1 m (HR 0.77 [0.48 – 1.24]; p =.28) and OS 14.6 v 12.5 m. PFS rate at 3 m was higher in RAM v PL (89% v 75%, p =.020), but not at 6, 9, or 12 m. RR (CR, PR) 45% v 46%. DCR (SD, CR, PR) 85% v 67% (p =.008). Most common grade ≥3 adverse events (AEs): neutropenia (27% v 36%), fatigue (18% v 15%), neuropathy (9% v 11%). Grade ≥3 AEs of special interest were uncommon, except hypertension. Median cycles of OX were similar among arms (8.5 v 9.5), but cycles of 5FU or RAM/PL (both 9 v 11) were lower in RAM arm. Rx discontinuation for non-progressive disease (PD) was more common in RAM: pt/physician decision (27% v 10%), AEs (21% v 6%). In exploratory analyses that censored PFS at Rx discontinuation for non-PD, HR for PFS favored RAM arm (HR 0.76; p =.194), mainly in gastric/GEJ pts (PFS 9.3 v 7.6 m; HR 0.53 [0.29 – 0.97]; p =.036). **Conclusions:** Addition of RAM to FOLFOX did not improve median PFS but showed PFS difference at 3 m and improved DCR. Longer PFS in RAM v PL was observed in gastric/GEJ cancer pts. A higher non-PD discontinuation rate and lower drug exposure in RAM arm may have impacted PFS assessment. These data are critical for clinical development of RAM in gastric cancer. Clinical trial information: NCT01246960.

**4005 Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

**RAINBOW: A global, phase III, randomized, double-blind study of ramucirumab (RAM) plus paclitaxel (PTX) versus placebo (PL) plus PTX in the treatment of metastatic gastroesophageal junction and gastric adenocarcinoma (mGC) following disease progression on first-line platinum- and fluoropyrimidine-containing combination therapy—Efficacy analysis in Japanese and Western patients.** *Presenting Author: Shuichi Hironaka, Clinical Trial Promotion Department, Chiba Cancer Center, Chiba, Japan*

**Background:** RAINBOW, a global phase III trial, demonstrated significant improvements in overall survival (OS), progression-free survival (PFS), and objective response rate (ORR) in patients (pts) with mGC receiving RAM, a human IgG1 VEGF-receptor-2 targeted antibody, plus PTX compared with PL plus PTX. In global trials for mGC, regional differences in survival outcomes have been reported. Here, we analyzed clinical outcomes of Japanese (JP) pts and Western (Europe, US, Australia) pts. **Methods:** Eligibility included Eastern Cooperative Oncology Group performance status ≤1, adequate organ function, and disease progression during or within 4 months of the last dose of first-line therapy. OS and PFS were compared using a stratified log-rank test. ORR was analyzed using a Cochran-Mantel-Haenszel test. **Results:** Of 665 patients randomized worldwide, 140 were JP pts and 398 were Western pts. Efficacy results are shown in the Table. **Conclusions:** Benefit was seen in PFS, ORR, and the 6-mos OS rate in the JP population, which was consistent with the Western population. Prolonged post-progression survival in JP pts may be due to higher use of post-discontinuation treatment (PDT) and may have masked the potential OS benefit. Clinical trial information: NCT01170663.

**STORM: A phase III randomized, double-blind, placebo-controlled trial of adjuvant sorafenib after resection or ablation to prevent recurrence of hepatocellular carcinoma (HCC)** *Presenting Author: Jordi Bruix, BCLC Group, Liver Unit, Hospital Clinic, University of Barcelona, Barcelona, Spain*

**Background:** Sorafenib is a multikinase inhibitor with proven efficacy in unresectable HCC. We evaluated the efficacy and safety of adjuvant sorafenib for HCC. **Methods:** Patients who had undergone surgical resection or local ablation with curative intent and had an intermediate or high recurrence risk were eligible. Main inclusion criteria were Child-Pugh score 5–7, ECOG PS 0, and no residual disease confirmed by CT or MRI. Exclusion criteria included recurrent HCC, ascites, extrahepatic spread, macrovascular invasion, and prior systemic therapy for HCC. Patients were stratified by curative treatment, geographic region, recurrence risk, and Child-Pugh status and randomized 1:1 to treatment with sorafenib 400 mg orally twice a day or placebo for a maximum of 4 yrs. The primary endpoint was recurrence-free survival (RFS) by independent review. Secondary endpoints included time to recurrence (TTR) and overall survival (OS). **Results:** A total of 1114 patients were randomized (n=556 sorafenib; n=558 placebo). Baseline characteristics were balanced between groups. Median age was 59 yrs, 62% were Asian, 81% had resection, 97% were Child-Pugh A, and 46% had high recurrence risk. The analysis was based on a total of 464 RFS events. No differences in RFS, TTR, and OS were observed (Table). The sorafenib group had a shorter median treatment duration (12.5 vs 22.2 mos) and lower mean daily dose (578 vs 778 mg). Discontinuation rates with sorafenib were higher due to treatment-emergent adverse events (TEAE) (24% vs 7%) and consent withdrawal (17% vs 6%). Most common grade (Gr) 3–4 sorafenib TEAEs occurring more frequently vs placebo were hand-foot skin reaction (28%), hypertension (7%), and diarrhea (6%). **Conclusions:**The primary endpoint of the trial was not met. Adverse events are consistent with the known sorafenib safety profile and no new safety findings were observed. Clinical trial information: NCT00692770.

**RTOG 0436: A phase III trial evaluating the addition of cetuximab to paclitaxel, cisplatin, and radiation for patients with esophageal cancer treated without surgery.** *Presenting Author: David H. Ilson, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** RTOG 0436 is a randomized Ph III trial evaluating cetuximab added to concurrent chemoradiation for patients (pts) undergoing non-operative management of esophageal carcinoma (EC). **Methods:** Pts with biopsy proven squamous cell or adenocarcinoma of the esophagus (T1N1M0; T2-4 AnyN M0; Any T/N M1a) were randomized to weekly concurrent cisplatin (50 mg/m2), paclitaxel (25 mg/m2) for 6 weeks and daily radiation 50.4 Gy/1.8 Gy fractions ± weekly cetuximab (400 mg/m2 day 1 then weekly 250 mg/m2) for 6 weeks. Pts were stratified by histology, tumor size (< 5 cm vs > 5cm) and the status of celiac lymph nodal involvement. Overall survival (OS) was the primary endpoint, with a planned accrual of 420 pts to detect an increase in 2-year OS from 41% to 53%; 80% power and 1-sided 0.025 alpha. An interim analysis of cCR was planned for the first 150 of each histology. **Results:** The study accrued 344 pts from 2008-2013 and 328 were eligible. Based on interim analyses, the study stopped accruing adeno pts in 5/2012 and SCC pts in 1/2013. Pts were well matched for pretreatment characteristics: 80% T3/4 disease, 66% N1, and 19% celiac nodes. Grade 3/4/5 treatment (tx) related AEs were 45%, 22%, 4% in Arm 1 (cetuximab) and 49%, 17%, 1% in Arm 2 (no cetuximab). A cCR rate of 56% was observed in Arm 1 vs 59% in Arm 2 [p=0.72]. No differences were seen in cCR between tx arms for either histology. The 12 and 24 mo OS rates for cCR pts were 79% and 58% vs 53% and 30% for those with residual disease [p<0.0001]. Median follow-up for all pts is 15.4 mos. The 12 and 24 mo OS (95% CI) for Arm 1 is 64% (56%, 71%) and 44% (36%, 52%) vs 65% (57%, 72%) and 42% (34%, 50%) for Arm 2 [p=0.70]. Adeno pts (n=203) had a 12 and 24 mo OS of 65% and 43% for Arm 1 vs 64% and 41% for Arm 2 [p=0.37]. The 12 and 24 mo OS for the 125 SCC pts was 62% and 46% for Arm 1 vs 67% and 43% for Arm 2 [p=0.97]. **Conclusions:** Cetuximab added to chemoradiation did not improve OS. There were no differences in cCR rates by tx arm. These results add to the growing body of literature indicating no benefit for current EGFR targeted agents in the tx of unselected patients with EC. Supported by RTOG CA21661 and CCOP CA3742 NCI grants and Bristol Myers Squibb. Clinical trial information: NCT00655876.

**4008 Oral Abstract Session, Mon, 1:15 PM-4:15 PM**

**Phase III trial to compare capecitabine/cisplatin (XP) versus XP plus concurrent capecitabine-radiotherapy in gastric cancer (GC): The final report on the ARTIST trial.** *Presenting Author: Jeeyun Lee, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** The adjuvant chemoradiation therapy in stomach cancer (ARTIST) trial is the first study to investigate the efficacy of postoperative chemoradiation therapy as adjuvant treatment in gastric cancer patients with curative resection and extended D2 lymph node dissection. In this study, we report on the final analysis of the disease free survival (DFS) and survival (OS). **Methods:** XP arm received six cycles of XP (capecitabine 2000 mg/m$^2$ per day on days 1 to 14 and cisplatin 60 mg/m$^2$ on day 1, repeated every 3 weeks) chemotherapy. XP/XRT/XP arm received two cycles of XP followed by 45 Gy radiotherapy (capecitabine 1650 mg/m$^2$/d for 5 weeks) and two cycles of XP. Preplanned subgroup analyses on Lauren classification and lymph node status were performed. EGFR, HER2 and MET overexpression were studied in this patient cohort and correaltive analyses with DFS and OS were performed. **Results:** Of 458 patients, 228 patients were randomized to the XP arm and 230 patients were randomized to the XP/XRT/XP arm. At final analysis, the addition of radiotherapy to XP chemotherapy did not significantly prolong DFS (HR 1.352, 95% CI 0.952 - 1.922; P=0.0922). In the intestinal subtype, however, DFS on the XP/XRT/XP arm was significantly prolonged when compared with XP alone (HR 2.883, 95% CI, 1.36 - 6.111, P=0.0057). In contrast, the addition of RT to XP in diffuse type GC did not considerably prolong DFS (HR 1.161, 95% CI, 0.753-1.791; P=0.4985). In accordance with the results from the first report, the DFS was superior in XP/XRT/XP then XP alone in LN(+) group. Currently, biomarker analyses including HER1, HER2, MET are being carried out. The correlative analyses between these markers and DFS/OS will be presented. **Conclusions:** Overall, the ARTIST trial was a negative trial with no significant difference in DFS between XP alone and XP/XRT/XP. However, XP/XRT/XP significantly prolonged DFS in intestinal type by Lauren classification when compared to XP alone. After a longer follow up duration, XP/XRT/XP seemed to benefit LN(+) GC patients. Hence, a subsequent ARTIST-II (TS-1 alone, TS-1/oxaliplatin, TS-1/oxaliplatin/RT) is enrolling patients with pathologic LN(+) GC. Clinical trial information: 00323830.

**4009 Poster Highlights Session (Board #27), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A randomized phase III study in advanced esophageal cancer (OC) to compare the quality of life (QoL) and palliation of dysphagia in patients treated with radiotherapy (RT) or chemoradiotherapy (CRT) TROG 03.01 NCIC CTG ES.2.** *Presenting Author: Michael Gordon Penniment, Royal Adelaide Hospital, Adelaide, Australia*

**Background:** RT is known to relieve dysphagia of advanced oesophageal cancer, there is no data from randomised phase III trials determining response, toxicity, or role of palliative CRT. Aims 1) to establish effective and least toxic treatment for symptom relief of advanced OC 2) determine effects of common cancer treatments on QoL and end of life care 3) establish an evidence base for patient decision making regarding the optimal management for incurable OC. **Methods:** 220 patients were randomised to receive a course of palliative RT [35 Gy in 15 fractions, (n=115) or 30 Gy in 10 fractions (n=105) in Canada and UK], or concomitant CRT with Cisplatin and 5FU (D1-4) (n=111). Dysphagia was measured using the Mellow score, toxicity using CTCAE v2, and QoL using EORTC QLQ30 and oesophagus module (OES-18). The primary end point was the proportion of patients with improved dysphagia as measured at week 9 and maintained until week 13. **Results:** The patients receiving radiotherapy alone showed a dysphagia response (at any point) of 67.89% compared to chemotherapy response in 73.87%, this was not a significant difference (p=0.343). There was increased toxicity in patients receiving CRT, with worse bowel conditions (nausea (p=0.0019) and vomiting (p=0.0072)). The median survival was 210 days for CRT and 203 days for RT alone. The baseline parameters of both groups were well matched at randomisation and although the results of the trial showed equally poor survival prognosis in both arms, there were some patients (n=21) still alive at 2 years post treatment. **Conclusions:** Although the CRT group had slightly better dysphagia response and median survival, the bowel toxicity was worse. Further analysis of QoL, toxicity and durable palliative response will be published. This multicentre trial, conducted in the UK, Canada, Australia and New Zealand reflects practice in several countries RT alone remains an excellent tool for palliation of patients with advanced OC and should remain the standard of care. Clinical trial information: NCT00193882.

**4010 Poster Highlights Session (Board #28), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Can induction chemotherapy improve dysphagia in locally advanced esophageal/GEJ cancer?** *Presenting Author: Elizabeth Won, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** Dysphagia is one of the most common presenting symptoms in esophageal cancer (EC) and can lead to significant nutritional decline, which is associated with increased toxicity and poor outcomes. Invasive feeding tubes (FT) or endoscopic stents are frequently used to improve nutrition in this setting. We evaluated the role of induction chemotherapy prior to concurrent chemoradiation as presurgical treatment in improving dysphagia. **Methods:** Retrospective analysis of 4 prospective studies conducted at MSKCC with induction chemotherapy followed by concurrent chemoRT and surgery in locally advanced esophageal/GEJ cancer. Regimens included cisplatin/paclitaxel, cisplatin/irinotecan, and cisplatin/irinotecan/bevacizumab. Dysphagia was graded prospectively using a validated dysphagia scale. Response of dysphagia and nutritional status to induction chemotherapy was evaluated. **Results:** Of 161 patients (pts) undergoing induction chemotherapy, [median age 59(21-76), KPS 90 (70-100), 77% adenocarcinoma], 121 (76%) had dysphagia, with 59(37%) with grade 2 dysphagia or higher (20% Stage II, 80% Stage III). 6(4%) required EGD dilatation/stent and none required FT placement prior to treatment. 22% pts had>10% body weight loss prior to treatment and average weight loss in all pts was 4.3kg. After induction chemotherapy, 103 (65%) had improvement in dysphagia. This was associated with a weight gain in 42% of pts. Only 7(4%) had worsening dysphagia after induction chemotherapy: 4/7 required FT (2% of all pts), 2/7 EGD intervention (1% of all pts). 6/7 of these pts with worsening dysphagia had poor short term outcomes: 2/7 progressive disease, 3/7 unresectable, 1/7 post-operative death. **Conclusions:** Induction chemotherapy prior to concurrent chemoradiation for locally advanced esophageal cancer can effectively improve swallowing and nutritional status, while mitigating need for feeding tubes or stents in patients with significant dysphagia. Post-induction dysphagia may be prognostic and merits further investigation. Research supported by Foundation 14.

**4011 Poster Highlights Session (Board #29), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Impact of external-beam radiation therapy on outcomes among patients with resected gastric cancer: A multi-institutional analysis.** *Presenting Author: Aslam Ejaz, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Use of perioperative chemotherapy (CTx) alone versus chemoradiation therapy (cXRT) in the treatment of resectable gastric cancer remains varied. We sought to define the utilization and effect of CTx alone versus cXRT on patients having undergone curative-intent resection for gastric cancer. **Methods:** Using the multi-institutional U.S. Gastric Cancer Collaborative database, we identified 505 patients between 2000 and 2012 with gastric cancer who received perioperative therapy in addition to curative-intent resection. The impact of perioperative therapy on survival was analyzed by the use of propensity-score matching of clinicopathologic factors among patients who received CTx alone versus cXRT. **Results:** Median patient age was 62 years and the majority of patients were male (58%). Surgical resection involved either partial gastrectomy (54%) or total gastrectomy (46%). On pathology, median tumor size was 5.0 cm; most patients had a T3 (37%) or T4 (36%) lesion and lymph node metastasis (74%). Margin status was R0 in most patients (89%). 211 (42%) patients received perioperative CTx alone whereas the remaining 294 (58%) patients received 5-FU based cXRT. Factors associated with receipt of cXRT were younger age (OR 0.98), T3 tumors (OR 1.52), and lymph node metastasis (OR 2.03) (all P < .05). Recurrence occurred in 214 (39%) patients. At a median follow-up of 28 months, median overall survival (OS) was 33.4 months and 5-year survival was 36.7%. Factors associated with worse OS included tumor size (HR 1.1), T-stage (HR 1.5), and lymph node metastasis (HR 1.58) (all P<0.05). In contrast, receipt of cXRT was associated with improved long-term OS (CTx alone: 21 months vs. cXRT 45 months; p<0.001). In the propensity-matched multivariate model that adjusted for tumor size, T-stage, and nodal status, cXRT remained associated with an improved long-term disease-free (HR 0.43) and overall (HR 0.41) survival (both P<0.001). **Conclusions:** XRT was utilized in 58% of patients undergoing curative-intent resection for gastric cancer. Using propensity-matched analysis, cXRT was an independent factor associated with improved recurrence-free and overall survival.

**4012 Poster Highlights Session (Board #30), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Lymph node yield and survival in gastric carcinoma.** *Presenting Author: Jennifer E. Samples, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Although the extent of lymph node (LN) dissection in gastric cancer remains controversial, it is recommended that at least15 LN be examined for accurate staging. Existing data suggest that many gastrectomies performed in the US do not achieve this benchmark. This study examines trends in LN yield over time in patients undergoing curative surgery for gastric cancer and the relationship between LN yield and survival. **Methods:** Under IRB waiver, all National Cancer Database patients who underwent total, distal or proximal gastrectomy for gastric cancer from 1998-2011 were examined. Patients with metastatic disease or for whom treatment was indicated to be palliative were excluded from this study. Wilcoxan rank-sum test was used to compare LN yield. Cox proportional hazards models were used to compare overall survival. **Results:** 73,674 patients met inclusion criteria. 7,938 (10.8%) had neoadjuvant therapy. Patients who received neoadjuvant therapy had higher median LN yield than patients who did not (12 vs. 9, $p<0.001$). Median LN yield improved over time (8 in 1998 vs. 11 in 2011, $p<0.001$), as did the proportion of patients with LN yield >15 (21% in 1998 vs. 36% in 2011, $p<0.001$). Median overall survival (OS) was positively associated with LN yield in node-positive and node-negative patients. See Table. These survival differences persisted after adjustment for patient demographics and comorbidity. **Conclusions:** Slow improvement in LN yield has been seen on a population level over the past two decades, although nearly two thirds of all patients undergoing curative resection still have fewer than 15 LN examined. Higher LN yield is associated with better OS in patients with resectable gastric carcinoma. Based on these results, continued effort is needed to improve surgical quality in patients undergoing curative resection for gastric cancer.

**Toxicity, surgical complications, and short-term mortality in a randomized trial of neoadjuvant cisplatin/5FU versus epirubicin/cisplatin and capecitabine prior to resection of lower esophageal/gastroesophageal junction (GOJ) adenocarcinoma (MRC OEO5, ISRCTN01852072, CRUK 02/010).** *Presenting Author: David Cunningham, Royal Marsden Hospital, Sutton, United Kingdom*

**Background:** Randomized trials have shown that neoadjuvant approaches improve survival following esophagectomy. Data on toxicities from the different approaches are often not reported in detail. **Methods:** OEO5 is a Cancer Research UK funded multi-centre, phase III randomized clinical trial for resectable (T1/2 N1 M0 to T3/4 N0/1 M0) adenocarcinoma of the lower esophagus and Type I/II GOJ. Patients were randomly allocated (1:1) to 2 cycles of cisplatin/5FU (CF) or 4 cycles of epirubicin/cisplatin and capecitabine (ECX) pre-operatively followed by esophagectomy with 2-field lymphadenectomy. The Independent Data Monitoring Committee and Trial Steering Committee agreed to release data on treatment related toxicities and deaths up to 90 days post-surgery. Overall survival is the primary outcome measure but is not yet mature; events having accrued more slowly than expected. **Results:** Between 2005 and 2011, 897 patients (median age 62 years (range 27-81), 90% male, 63% T3 N1, WHO PS 0-1) were randomly allocated to CF (451) or ECX (446). CF: 96% received 2 cycles, ECX: 81% received 4 cycles. Any grade 3/4 toxicity (CF 30%, ECX 47%, $p<0.001$), (CF v ECX: neutropenia 16% v 23%, diarrhoea 1% v 8% and plantar palmar erythema 0% v 9%). Median time (days) from randomisation (day 1 of last chemo cycle) to surgery (CF 72 (45), ECX 128(58)). Surgical data were available on 878 (CF 446, ECX 432) patients, with 84% reported as having resection and reconstruction. Post-operative complications reported in CF 54% and ECX 59% (life threatening complications CF 7% vs ECX 9%). No differences were seen in anastomotic leak rates (clinical 11%, radiologic only 5%), thromboembolic complications (4%) or deaths within 30 days of operation (2% both arms), or within 90 days (CF 4%, ECX 5%). **Conclusions:** Four cycles of ECX compared to 2 cycles of CF increased chemotherapy related toxicity, but did not affect resection rates, surgical complications or 90 day mortality. Clinical trial information: ISRCTN01852072.

**4015 Poster Highlights Session (Board #33), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Association of a DNA damage response deficiency (DDRD) assay and prognosis in early-stage esophageal adenocarcinoma.** *Presenting Author: Richard C. Turkington, Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom*

**Background:** The incidence of esophageal adenocarcinoma (EAC) has increased 6-fold in the last 30 years and in early stage EAC 5-year survival remains poor at 25-35%. Neoadjuvant therapy confers a significant improvement in outcomes but the optimal approach for individual patients remains unclear. We assessed a 44 gene DNA Damage Response Deficient (DDRD) assay, previously developed to detect loss of the Fanconi Anaemia (FA)/BRCA pathway in breast cancer, as a predictor of prognosis following DNA damaging chemotherapy in EAC. **Methods:** This study was conducted using 63 formalin fixed paraffin embedded (FFPE) pre-treatment endoscopic biopsy specimens from early stage EAC patients treated with cisplatin-based neoadjuvant chemotherapy followed by surgical resection between 2004 and 2010 at the NI Cancer Centre. EAC biopsies were profiled using the Xcel array, a cDNA microarray-based technology optimized for archival FFPE tissue (Almac/Affymetrix), and scored for the DDRD assay. The association between the DDRD score and prognosis was assessed by Kaplan-Meier analysis and Cox Proportional Hazards regression. **Results:** Sufficient quality RNA for analysis was obtained for 62 out of 63 samples (98.4%). A total of 13 samples (21%) were characterised as DDRD positive with the remaining 49 samples (79%) DDRD negative. With a median follow up of 65 months, DDRD assay positivity demonstrated a statistically significant association with disease-free (HR 0.33; 95% CI 0.13-0.87; $p=0.024$) and overall survival (HR 0.32; 95% CI 0.12-0.82; $p=0.017$; median DDRD+ve 94.3 months vs DDRD-ve 32.2 months). The assay was not predictive of survival in patients who did not receive chemotherapy. **Conclusions:** The DDRD assay is the first array-based biomarker using pre-treatment FFPE biopsies to be validated as predictive of prognosis following DNA damaging chemotherapy in early stage EAC.

**Epidermal growth factor receptor copy number gain (EGFR CNG) and response to gefitinib in esophageal cancer (EC): Results of a biomarker analysis of a phase III trial of gefitinib versus placebo (TRANS-COG).** *Presenting Author: Russell D. Petty, University of Aberdeen, Aberdeen, Scotland*

**Background:** The Cancer Oesophagus Gefitinib (COG) trial randomised (1:1) 450 patients(pts) with advanced EC who had progressed after 1-2 lines of chemotherapy to gefitinib (G) or placebo (P). Improved disease control rates- DCR= RECIST CR+PR+SD at 8 weeks (P 15.6%, G 24.1%, $p = 0.016$), improved patient reported outcomes, and progression free survival (HR = 0.80, 95%CI 0.66, 0.96, $p = 0.020$) were seen with G-indicative of rapid and durable responses that were observed in a subset. We hypothesised that EGFR CNG in ECs would identify a subgroup responsive to G. **Methods:** EGFR CNG was determined by FISH on FFPE tumour specimens(all subject to central pathology review) and performed blind to treatment allocation and outcome. Disomy, low and high trisomy and low polysomy were classified as negative (No CNG) and high polysomy and amplification as positive(CNG). Primary endpoint was OS for G versus P in EGFR CNG and no CNG groups. Secondary endpoints were PFS, DCR and HRQL and outcomes in EGFR amplified patients only. **Results:** EGFR FISH results were available for 295 patients. Clinical features were not different from the COG trial . EGFR CNG was found in 46/295 (15.6%). There was no significant correlation with EGFR CNG and any clinical features which were also balanced in G and P groups. In EGFR CNG Pts OS was improved with G compared to P (HR=0.53 95%CI 0.28, 0.98 $p=0.042$), with survival for G vs P 71 vs 64% ,38 vs 14% , 25 vs 5% and 13 vs 0% at 3 ,6, 9, and 12 months respectively. There was no difference in OS for G vs P in EGFR No CNG pts (HR=0.892 95%CI 0.69, 1.16 $p=0.395$). For PFS EGFR CNG pts, HR=0.58, 95%CI 0.30, 1.07 $p=0.080$ for G vs P and HR=0.83 95% CI 0.64, 1.07,$p=0.144$ for EGFR No CNG pts. DCR was improved for G in EGFR CNG pts(42 vs 13%, $p=0.035$), and less so for EGFR No CNG (24 vs 14 %, $p=0.053$). EGFR amplification(6%) pts gained greatest benefit from G ( OS, HR=0.19 95%CI 0.05, 0.65 $p=0.007$). **Conclusions:** EGFR CNG identified a subgroup of EC who benefit from Gefitinib as a second line treatment and is a useful predictive biomarker for the first stratified treatment approach in this setting and also a subgroup that may be responsive to other anti-EGFR therapies. Clinical trial information: ISRCTN32435732.

**4017 Poster Highlights Session (Board #35), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Tumor profiling of 1,306 gastric and esophageal carcinomas and different treatment options.** *Presenting Author: John Thomas Miura, Medical College of Wisconsin, Milwaukee, WI*

**Background:** NCCN guidelines state that chemotherapies for esophageal and gastric carcinomas may be used interchangeably. We interrogated biomarkers from a large cohort of gastroesophageal cancer patients to identify similar and different alterations with therapeutic implications for gastric and esophageal cancers. **Methods:** 666 gastric adenocarcinoma (GA) and 640 esophageal (553 adenocarcinoma, or EA, and 87 others) cases were evaluated by a combination of sequencing (Sanger, NGS), protein expression (IHC) and gene amplification (CISH/FISH). **Results:** In the complete cohort of 1306 patients, 30 of 45 (66%) genes tested had mutations, with the highest rates seen in TP53 (54%), APC (10%), SMAD4 (5.9%), KRAS (5.9%) and PIK3CA (5.1%). Elevated IHC of TOP2A was seen in 76% of cases, TOPO1 in 51% and SPARC in 25%; decreased IHC of ERCC1 was seen in 65%, RRM1 in 62%, TS in 61% and MGMT in 45%, indicating benefit from epirubicin, irinotecan, nab-paclitaxel, platinums, gemcitabine, 5FU/capecitabine and temozolomide, respectively. In the HER2-positive cases, additional alterations were seen including low TS (50%), ERCC1 (63%), RRM1 (55%) and high TOPO1 (53%), indicating potential benefit from combining trastuzumab with 5FU/capecitabine, cisplatin, gemcitabine and irinotecan, respectively. When comparing EA to GA, select biomarkers showed a differential pattern between cancer types (Table), suggesting potential variability in efficacy of available therapeutic agents. **Conclusions:** A multiplatform biomarker analysis identified common actionable targets in gastric and esophageal cancer as well as significant biomarker differences in EA and GA. This indicates the potential clinical impact of molecular profiling and highlights the need for separation of the two cancer entities for therapeutics.

**Biomarker comparison of gastric (GA) and esophageal adenocarcinoma (EA).**

| Target biomarker | Associated therapeutic agent | EA (%) | GA (%) | p-value |

*Lack of benefit.

**4018 Poster Highlights Session (Board #36), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Genetic variants in tumor immune checkpoints as prognostic markers in patients (pts) with localized advanced gastric cancer (AGC).** *Presenting Author: Yu Sunakawa, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** Multiple tumor immune checkpoint receptors and ligands, some of which are selectively upregulated in various types of tumors, play a role as an antitumor immune suppressor. The potential use of immune-based therapy in gastrointestinal cancers is just being realized. We examined the prognostic impact of single nucleotide polymorphisms (SNPs) in genes encoding for immune checkpoints on clinical outcome in pts with localized AGC from U.S. and Japan (JPN). **Methods:** Genomic DNA was extracted from blood or tissues of 161 Japanese pts (median age 68; median follow-up 4 yrs) for evaluation set and 105 U.S. pts (median age 59; median follow-up 3.3 yrs) for validation set, with localized AGC treated with surgery alone or plus adjuvant therapy (stage Ib-IV; AJCC-6$^{th}$). Thirty-six functional SNPs in genes of immune checkpoints (*PDCD1, CD274, CD73, IDO1, CTLA4, LAG3, ADORA2A,* and *FOXP3*) were analyzed by PCR-based direct sequencing for association with disease-free survival (DFS) / time to recurrence (TTR) and overall survival (OS). **Results:** The univariate analysis showed 4 SNPs were significantly associated with DFS and OS in JPN cohort. *IDO1* rs9657182 remained significant upon multivariate analysis. Any C allele of *PDCD1* rs10204525 in U.S. cohort was associated with worse TTR and OS compared to T/T genotype (2.1 vs 7.0 y; HR 2.01; p=0.03, 4.1 vs 7.3 y; HR 2.46; p=0.02, respectively) as well as worse DFS and OS in JPN cohort (HR 1.61; p=0.03, HR 1.79; p=0.01, respectively) in univariate analysis. Interestingly, pts with any T allele of *CD73* rs6922 in U.S. cohort had shorter OS compared to those with G/G genotype (HR 2.48; p=0.03) but longer OS in JPN cohort (HR 0.58; p=0.04) in uni- and multivariate analyses, there was no association with TTR/DFS in both cohorts. This different impact on OS reached statistical significance (p=0.002). **Conclusions:** Our results showed for the first time that tumor immune checkpoint SNPs may serve as a prognostic marker in pts with localized AGC and that there may be an ethnic difference in the impact on clinical outcome by genetic variants in immune checkpoints. Our data suggest that clinical trials using drugs targeting immune checkpoints should be stratified by ethnicity.

**4019 Poster Highlights Session (Board #37), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Apatinib in Chinese patients with advanced hepatocellular carcinoma: A phase II randomized, open-label trial.** *Presenting Author: Shukui Qin, Nanjing Bayi Hospital, Nanjing, China*

**Background:** Advanced hepatocellular carcinoma (HCC) is the third most common cause of cancer death in worldwide. Apatinib is a novel oral multi-kinase inhibitor of the vascular endothelial growth factor receptor-2 . Here report the results of phase II clinical study of apatinib as first- line treatment in chinese patients with advanced HCC. **Methods:** This was a multicenter, randomized, open-label, dose-finding, phase II trial. Treatment naive Patients with advanced HCC had Child-Pugh liver function class A were randomized to receive apatinib 850 mg/qd or 750 mg/qd. The efficacy was assessed at the end of each 8 weeks period. Primary endpoint was time to progression (TTP). Secondary endpoint included overall survival (OS), objective response rate (ORR), disease control rate (DCR), the level of $\alpha$-fetoprotein (AFP) and safety. According to oncology clinical trial Simon two-stage design, thirty-six patients were enrolled into stage 1 and 85 patients were enrolled into stage 2 (extension phase) of the trial. The trial was registered with ClinicalTrial.gov, NO. NCT01192971. **Results:** From 2010.07-2012.03 Total 121 patients were enrolled. The patient baseline characteristics of two treatment groups were similar with regards to disease status, ECOG scores, number of metastatic sites, pathological grading and prior therapy (P>0.05). For efficacy, median time to progression of the 850 mg group and the 750 mg group was 4.2 months and 3.3 months respectively. The median overall survival of the two groups was 9.7 months and 9.8 months respectively. The DCR was 48.57% for 850 mg qd group and 37.25% for 750 mg qd, respectively. Apatinib has been well tolerable in patients, most of the adverse event could be managed by dose interruptions or reductions. There was no significant favorable safety profile between two groups, above 2% of patients were elevated aminotransferase, thrombocytopenia, elevated bilirubin, hypertension, leukocytopenia, hand-and-foot syndrome, fatigue. **Conclusions:** Results of this uncontrolled phase II study indicated that apatinib has potential survival benefit in patients with advance HCC. 850 mg/qd or 750 mg/qd was recommended dose for further clinical study. Clinical trial information: NCT01192971.

**4020 Poster Highlights Session (Board #38), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**E2208: Randomized phase II study of paclitaxel with or without the anti-IGF-IR antibody cixutumumab (IMC-A12) as second-line treatment for patients with metastatic esophageal or GE junction cancer.** *Presenting Author: Steven J. Cohen, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Paclitaxel has activity in previously treated metastatic esophagus/GE junction cancer. Given activation of IGFR signaling in these patients (pts), we performed a randomized phase II study of paclitaxel ± cixutumumab (anti-IGF1R). **Methods:** Pts with metastatic measurable adenocarcinoma or squamous cell carcinoma of esophagus/GE junction who had progressed on one line of systemic therapy (recurrence within 6 months of adjuvant permitted) were randomized 1:1 to receive paclitaxel, 80 mg/m2 IV days 1,8,15 Q28 alone (Arm A) or with cixutumumab, 10 mg/kg days 1,15 Q28 (Arm B). CT imaging Q2 cycles. Key eligibility: ECOG PS 0-2, no prior taxane, fasting glucose ≤ 160 mg/dL, HgbA1C ≤ 7%. Primary endpoint PFS. Secondary endpoints OS, RR, toxicity. 90 pts would provide 90% power to detect a PFS difference of 3.5 m in experimental arm vs. 2m in control. **Results:** 94 pts were enrolled between 9/2010 and 10/2012 and 87 were evaluable for efficacy (43 Arm A, 44 Arm B). Pt characteristics were balanced between arms: median age 62 (range 40-89), 78% male, 94% Caucasian, 82% adenoca, 16% squamous ca, 54% GE junction, 18% lower esophageal, PS 0/1=39%/56%. Median number of cycles=2 on both arms. Most common grade 3/4 non-heme tox (%) Arm A(fatigue=8, hyperglycemia=5,hypophosphatemia=5), Arm B (hyperglycemia=11, muscle weakness=5, mucositis=5). Grade 3/4 heme tox (%ArmA/B):anemia 10/9, neutropenia 8/18, plts 0/2. 2 deaths in Arm A and 1 in Arm B were judged possibly related to therapy. Median PFS for all patients was 2.6 (90% CL [2.0-3.5]) months. Median PFS for Arms A and B were 2.6 (90% CL [1.8-4.1]) and 2.3 (90% CL [2.0-3.6]) months, respectively (p=0.72). Median OS for all patients was 6.4 (90% CL, 5.0-7.9) months. Median OS for Arms A and B were 6.5 (90% CL, 4.6-9.5) and 6.4 (90% CL, 4.9-8.0) months, respectively (p=0.92). The RR (CR+PR) for Arm A and B were 12% [90% CI: 5%, 23%] and 14% [90% CI: 6%, 25%], respectively. **Conclusions:** The addition of cixutumumab to paclitaxel in second-line therapy of metastatic esophageal/GE junction cancer was well tolerated but did not improve clinical outcome. Clinical trial information: NCT01142388.

**4021 Poster Highlights Session (Board #40), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase II randomized, placebo controlled study to evaluate the efficacy of the combination of gemcitabine, erlotinib, and metformin in patients with locally advanced or metastatic pancreatic cancer.** *Presenting Author: Johanna Wilmink, Academic Medical Center, Amsterdam, Netherlands*

**Background:** In addition to clinical data from retrospective observational studies, there is a strong preclinical rationale for a beneficial effect of metformin in cancer treatment. Therefore we conducted a randomized phase II, placebo controlled study to assess the clinical effects of metformin in pancreatic cancer. **Methods:** Patients with locally advanced or metastatic pancreatic cancer were randomly assigned to gemcitabine at 1000 mg/m$^2$ on day 1, 8 and 15 q 4 weeks plus erlotinib 100 mg once daily in combination with metformin or placebo. Metformin was administered at a dose of 500 mg twice daily during the first week. If tolerated well, the dose was increased to 1000 mg twice daily. Patients were stratified according to stage of disease and the presence of diabetes. The primary endpoint was survival at 6 months. Secondary endpoints were overall survival (OS), progression free survival (PFS), objective response rate-(ORR), toxicity profile, pharmacodynamics, and biomarker research. Results: A total of 121 patients were included. Baseline characteristics were well balanced. Median follow-up is 23.6 months (95%CI: 17.5-29.6). Survival at 6 months was 55% (95% CI: 42-68) for the metformin arm versus 66% (95% CI: 54-78) for the placebo arm (p=0.23). Median OS and PFS were 6.8 (95%CI: 5.3-8.3)and 4.4 (95%CI: 2.0-6.7) months for the metformin arm versus 7.6 (95%CI: 6.3-9.0) and 5.4 (95%CI: 4.7-6.1) months for the placebo arm (p=0. 62 and p=0.45), respectively. The objective response rate was 9% in both groups. The addition of metformin was well tolerated with no significant differences in grade ≥3 toxicity between treatment arms. Baseline insulin and glucose levels were not predictive for outcome. Conclusion: The addition of metformin to gemcitabine and erlotinib does not improve the outcome of patients with locally advanced or metastatic pancreatic cancer. Additional data on predictive biomarkers, including IGF1 and IGF binding protein-3 and pharmacodynamics will be presented at the meeting. Clinical trial information: NCT01210911.

**4022 Poster Highlights Session (Board #41), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**PANCREOX: A randomized phase 3 study of 5FU/LV with or without oxaliplatin for second-line advanced pancreatic cancer (APC) in patients (pts) who have received gemcitabine (GEM)-based chemotherapy (CT).** *Presenting Author: Sharlene Gill, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background**: There is no current standard of care for APC after 1st line GEM. The CONKO3 study (ASCO 2008) reported a survival benefit with 2nd line oxaliplatin-5FU (OFF), but has not yet been validated. PANCREOX was initiated to evaluate the benefit of mFOLFOX6 vs infusional 5FU/LV in this setting. **Methods**: Pts with APC previously treated with GEM and ECOG PS <=2 were eligible. 108 pts were randomized. PFS was the primary endpoint in this Canadian, multicentre, open-label study. Secondary outcomes included OS and quality of life. Pts received mFOLFOX6 or infusional 5FU/LV until progression. **Results**: Pt characteristics, efficacy and quality of life results are shown in the Table. Duration of 1st line GEM was similar. More pts withdrew due to adverse events (AEs) in the mFOLFOX6 arm (20.4% vs 1.9%) and due to progression in the 5FU/LV arm (74.1% vs 50.0%). No difference was observed in PFS (median 3.1 vs 2.9 mos, p=0.99). OS was inferior in pts assigned to mFOLFOX6 (median 6.1 vs 9.9 mos, p=0.02). Use of post-progression therapy was significantly higher in the 5FU/LV arm (25% vs 6.8%, p<0.05). Increased toxicity was observed with the addition of oxaliplatin in 2nd line APC with grade 3/4 possibly-related AEs occurring in 63% of mFOLFOX6 pts and 11% of 5FU/LV pts. No treatment related deaths. **Conclusions**: No benefit was observed with the addition of oxaliplatin to infusional 5FU/LV in GEM-treated 2nd line APC. PFS was similar and OS was inferior with mFOLFOX6. Given the proven benefit of FOLFIRINOX in untreated APC (ACCORD 11), these results suggest that the opportunity for use of oxaliplatin-based CT would be primarily in the 1st-line setting. Funding: Sanofi Canada. Clinical trial information: NCT01121848.

**Phase IB trial of cisplatin (C), gemcitabine (G), and veliparib (V) in patients with known or potential BRCA or PALB2-mutated pancreas adenocarcinoma (PC).** *Presenting Author: Eileen Mary O'Reilly, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** 5% to 8% PC have *BRCA 1,2* mutations; higher in Ashkenazi Jewish with PC (10-15%). Pre-clinical data demonstrates that DNA-damaging drugs (C) and poly-ADP ribose polymerase inhibitors (PARPi) have significant activity in BRCA mut PC models. This trial evaluates the optimal dose of V with fixed doses of C and G in PC. **Methods:** Primary endpoints: Determination of dose-limiting toxicity (DLT) and Recommended Phase II Dose (RP2D), safety (NCI CTCAE 4.0). Secondary endpoints: RECIST 1.1 response rate (RR), duration of response, progression-free survival, overall survival and correlatives involving tumor biopsies to evaluate mechanisms of sensitivity, resistance to platinum and PARPi. Eligibility: Untreated BRCA, PALB2 mut PC or strong personal/family history of pancreas or BRCA-related malignancy; measurable stage III/IV PC; ECOG 0-1. Treatment Plan: C 25mg/m$^2$ IV, G 600mg/m$^2$ IV, both d3, 10, q 3 weeks and V PO BID day 1- X. **Results:** Between 02/12– 10/13, N= 33 screened, 17 enrolled. Male = 10, Female = 7. Median age = 60 years (range 42- 72). BRCA = 9. Non-BRCA = 8. Four dose levels of V evaluated; 2 DLT's at V 80 mg PO BID continuous dosing (Table). Grade 3-4 toxicities: Anemia, neutropenia, thrombocytopenia, fatigue. 1 fatal bowel perforation tumor/diverticulitis*. For N= 9 BRCA patients: 5 (56%) partial responses (PR), 4 (44%) stable disease. For N= 8 non-BRCA: 5 stable, 2 progression. N= 5 BRCA patients continue on study and 7 of 9 BRCA patients are alive. Tissue analyses on BRCA subset will be presented. **Conclusions:** The RP2D of veliparib is 80 mg PO BID day 1-12 q 3 weeks with fixed dose C + G. Main grade 3-4 toxicities are hematologic, fatigue. The combination of C, G + V shows high activity in BRCA mut PC. A randomized phase II trial evaluating C, G +/- V is underway in BRCA/PALB2 mut PC (NCT01585805). Funding and acknowledgements: National Cancer Institute CTEP, Lustgarten Foundation, AbbVie. Clinical trial information: NCT01585805.

**Prognosis model for overall survival in locally advanced pancreatic cancer (LAPC): An ancillary study of the LAP 07 trial.** *Presenting Author: Dewi Vernerey, Methodological and Quality of Life in Oncology Unit, EA 3181, University Hospital of Besancon, France, BESANCON, France*

**Background:** The management of LAPC patients remains controversial. Better discrimination for Overall Survival (OS) is needed to improve therapeutic decisions. We aimed to address this issue on the largest phase III cohort of LAPC by establishing the first prognosis model for OS with the full spectrum of parameters currently available at diagnosis. **Methods:** We enrolled the 442 LAPC patients recruited in LAP07, an international multicenter randomized phase III trial (NCT00634725). Thirty-five baseline variables among demographic, cancer history, clinical, biological and radiological parameters were evaluated in univariate and multivariate analyses as prognostic factors for OS. The predictive value of the final model was evaluated with Harrell's C-index. This analysis was repeated 1000 times with the use of bootstrap sample to derive 95%CI for the C. A prognostic score was then developed based on the identified prognostic factors in the final model. **Results:** Independent prognostic factors identified in multivariate analysis (n=370) for OS were: age (HR= 1.01; 95%CI 1.00 - 1.03; p=0.0418), pain (HR= 1.36 ; 95%CI 1.08 - 1.71; p=0.0094), albumin (HR= 0.96; 95%CI 0.94 - 0.98; p=0.0001) and tumor size (HR= 1.01; 95%CI 1.00 - 1.02; p=0.0033). Harrell's C-statistic for the final model was 0.60 (95%CI 0.56 - 0.63). A prognostic score between 0 and 4 was then calculated for each patient, based on the previous model. Three risk groups for death could be identified: "lower risk" (score∈[0,1]; n=17; median OS = 18.8 months; HR=1), "intermediate risk" (score∈(1,2]; n=166 ;median OS = 13.4 months; HR=1.7), "higher risk" (score∈(2,4]; n=187 ; median OS = 11.8 months; HR=2.1), p = 0.0101 by the global log rank test. **Conclusions:** Our results highlighted four OS's independent pronostic factors among a broad spectrum of parameters at time of diagnosis.We have identified three groups with clearcut different prognostic profiles. The determination of this simple prognostic score should allow risk stratification that may help guiding clinical management of patients with LAPC and to design for future clinical trials. An external validation with a cohort issued from ARCAD meta-analysis is pending.

**4025 Poster Highlights Session (Board #44), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II study of refametinib (BAY 86-9766), an allosteric dual MEK 1/2 inhibitor, and gemcitabine in patients with unresectable, locally advanced, or metastatic pancreatic cancer.** *Presenting Author: Jean-Luc Van Laethem, Erasme University Hospital, Brussels, Belgium*

**Background:** Refametinib is a potent oral allosteric MEK 1/2 inhibitor with single-agent and synergistic activities in combination with gemcitabine in preclinical pancreatic cancer (PC) models. We report the results of a single-arm, open-label, phase 2a study combining refametinib and gemcitabine in advanced PC. **Methods:** Eligibility criteria included: ECOG PS $\leq 2$; locally advanced, unresectable or metastatic pancreatic adenocarcinoma; and no prior systemic therapy. Refametinib was administered 50 mg bid po in combination with gemcitabine (1000 mg/m2 IV weekly for 7 of 8 weeks in C1; 3 of 4 weeks in subsequent cycles). The primary objective was overall response rate (ORR); secondary objectives were duration of response (DOR), disease control rate (DCR), time to progression (TTP), progression-free survival (PFS), overall survival (OS) and safety. All responses were confirmed by central independent radiological review. Genetic biomarker analysis was conducted on circulating tumor DNA from plasma samples (BEAMing). **Results:** Sixty patients were treated: median age 63 yrs, 53% male, 40% PS 0. KRAS mutations were detected in 39 patients (65%). Best overall response was PR in 35% [median DOR 3.8 mo (117 days; 95% CI: 83-265)]; SD in 38%, PD in 10%, and not evaluable in 17% The DCR was 73%. Median TTP was 7.4 mo (224 days; 95% CI: 188, UL ND); median PFS 6.2 mo (190 days; 95% CI: 112-225); OS 8.9 mo (270 days; 95% CI: 200-355). In the KRAS subgroups (mut/WT respectively) the ORR, mPFS and OS were 28%/48% (p=0.136), 4.6/9.0 mo (HR 0.26) and 6.6/18.2 mo (HR 0.27). Full biomarker analysis is being reported separately (Riess et al, this meeting). The most common grade 3-4 TEAEs were neutropenia (43%), thrombocytopenia (22%) anemia (12%), elevations of AST (12%) or ALT (13%), DVT (10%), hypertension (12%), fatigue (15%) and rash acneiform (10%). **Conclusions:** The combination of refametinib and gemcitabine in advanced PC is active, with an acceptable safety profile. The reported high prevalence of KRAS mutations in PC patients was confirmed by BEAMing. A trend towards improved outcomes (ORR, PFS and OS) in patients with KRAS wild type PC was observed. Clinical trial information: NCT01251640.

**Feasibility and results of a randomized phase Ib study of fractionated $^{90}$Y-clivatuzumab tetraxetan in patients with metastatic pancreatic cancer having two or more prior therapies.** *Presenting Author: Vincent J. Picozzi, Virginia Mason Medical Center, Seattle, WA*

**Background:** Radioimmunotherapy (RAIT) is an option to avoid side effects of further chemotherapy for advanced metastatic pancreatic ductal cancer (mPC). This multicenter, phase Ib study aimed at determining the contribution of low radiosensitizing doses of gemcitabine (GEM) to fractionated doses of $^{90}$Y-clivatuzumab tetraxetanin pts with mPC after $\geq$ 2prior GEM- or 5FU-containing regimens. **Methods:** Pts were randomized to Arm A (4-week cycles: 200 mg/m$^2$ GEM, weekly, combined with 6.5 mCi/m$^2$ $^{90}$Y-clivatuzumab tetraxetan, once-weekly the last 3 weeks) or Arm B (3-week cycles: 6.5 mCi/m$^2$ $^{90}$Y-clivatuzumab tetraxetan alone, once-weekly), repeating cycles after 4-week delays until unacceptable toxicity or pt deterioration. Safety and efficacy were evaluated. **Results:** Fifty-eight pts (33M/25F; median age 63.5) were treated on arm A (N=29) or B (N=29), 1.6 median years from diagnosis with a median of 3 (2-7) prior treatments. The main toxicity was transient myelosuppression, as expected, with dose reductions for cytopenias (cycle 1, 14%; cycle $\geq$ 2, 70%) limiting the number of Grade 3-4 events per cycle (thrombocytopenia, 13%; neutropenia, anemia, <7%). Serious events (thromboembolism, coagulopathy, infection) in 6 pts were felt to be consistent with known risks in mPC. A total of 53/58 pts (27 Arm A, 26 Arm B, 91% overall) completed $\geq$1 full treatment cycle and thus were evaluable. Pts terminated further treatment due to disease progression, with 23 pts (12 Arm A, 11 Arm B; 40%) receiving multiple cycles, including 7 pts (6 Arm A, 1 Arm B; 12%) with 3-7 cycles. Two pts in Arm A had PRs by RECIST. Kaplan-Meier median overall survival (OS) was 119 days (30-508) in Arm A *v* 84 days (27-287) in Arm B (hazard ratio 0.54, 95% CI: 0.27-0.87; *P*=0.020, log-rank). The median OS for Arm A *v* Arm B increased to 240 *v* 103 days with multiple cycles (*P*= 0.004) and 3 pts in Arm A still being observed (11 – 17 mos). **Conclusions:** This is the first randomized trial completed in mPC pts having $\geq$ 2 prior therapies. Fractionated RAIT with $^{90}$Y-clivatuzumab tetraxetan and low-dose gemcitabineappears promising in this population, supporting Phase 3 studies of this combination now being initiated. Clinical trial information: NCT01510561.

**4027^ Poster Highlights Session (Board #46), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Analyses of updated overall survival (OS) and prognostic effect of neutrophil-to-lymphocyte ratio (NLR) and CA 19-9 from the phase III MPACT study of *nab*-paclitaxel (*nab*-P) plus gemcitabine (Gem) versus Gem for patients (pts) with metastatic pancreatic cancer (PC).** *Presenting Author: David Goldstein, Prince of Wales Hospital, Sydney, Australia*

**Background:** In the phase III MPACT trial, *nab*-P + Gem demonstrated superior OS vs Gem (primary endpoint; median 8.5 vs 6.7 months; HR 0.72; *P*< 0.001) with manageable toxicity in pts with metastatic PC. The primary analyses were based on a cutoff of Sep 17, 2012, at which time 80% of pts had died. Here, we report an updated OS analysis (post hoc) and an assessment of pts with elevated NLR or elevated CA 19-9 at baseline, 2 accepted markers of poor prognosis. **Methods:** 861 pts with metastatic PC and a Karnofsky performance status $\geq$ 70 were randomized at 151 community and academic centers 1:1 to receive *nab*-P 125 mg/m$^2$ + Gem 1,000 mg/m$^2$ on days 1, 8, and 15 of each 28-day cycle or Gem 1,000 mg/m$^2$weekly for 7 wks followed by 1 wk of rest (cycle 1) and then days 1, 8, and 15 of each 28-day cycle (cycle $\geq$ 2). The data for the OS analysis were collected through May 9, 2013. Baseline NLR and CA19-9 were measured in blood samples collected before treatment. **Results:** As of the updated data cutoff, 380 of 431 pts (88%) in the *nab*-P + Gem arm and 394 of 430 pts (92%) in the Gem-alone arm had died. OS was superior for *nab*-P + Gem in the intent-to-treat (ITT) population, and longer follow-up identified > 3-yr survivors in the *nab*-P + Gem arm (Table). In a pooled–treatment-arm analysis, a NLR $\leq$ 5 was associated with longer OS vs a NLR > 5 (median 9.1 vs 5.0 months; HR 1.839; *P* < 0.001). Median OS was longer with *nab*-P + Gem vs Gem for pts with a NLR > 5 and pts with CA 19-9 > 59 × upper limit of normal (ULN; Table). **Conclusions:** Updated data confirmed the treatment effect favoring *nab*-P + Gem for OS. Additional follow-up has identified long-term survivors in the *nab*-P + Gem arm. The improved OS for pts treated with *nab*-P + Gem who have a NLR > 5 or an elevated CA 19-9 supports the relative benefit of the combination, even for pts with markers of poor prognosis. Clinical trial information: NCT00844649.

**Biomarker analyses and association with clinical outcomes in patients with advanced hepatocellular carcinoma (HCC) treated with sorafenib with or without erlotinib in the phase III SEARCH trial.** *Presenting Author: Andrew X. Zhu, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background:** Sorafenib (S) is the current standard therapy for advanced HCC but validated biomarkers predicting its clinical outcome are lacking. The present study aimed to identify biomarkers predicting prognosis and/or response to S ± erlotinib (E) in HCC patients from the randomized phase III SEARCH trial. **Methods:** A total of 720 patients were randomized to receive oral S 400 mg bid plus either E 150 mg qd or placebo (P). VEGF-A, VEGF-C, PDGF-BB, KIT (extracellular domain), HGF, bFGF, IGF-2, amphiregulin, betacellulin, EGF, epigen, epiregulin, heregulin, hbEGF, and TGF-a were measured in baseline plasma samples. Mutations in 19 oncogenes were analyzed in archival biopsies (Sequenom OncoCarta). **Results:** Baseline plasma biomarker data were available for 494 (69%) patients; n=243 S/E and 251 S/P. Treatment-independent analyses (combining both treatment arms) indicated that elevated HGF was associated with poor overall survival (OS; HR=0.598 [low vs high expression], multiplicity adjusted (adj) p=0.0007). Elevated plasma VEGF-A levels and low levels of KIT showed a similar trend towards poor survival (VEGF-A: HR=0.722 [low vs high expression], p=0.03, adj-p=0.39; KIT: HR=0.713 [high vs low expression], p=0.05, adj-p=0.60). High levels of plasma VEGF-C correlated with longer time to tumor progression (HR=0.626 [high vs low expression], adj-p=0.0042). Finally, in 67% of evaluable patients (339/494), a multi-marker composite signature consisting of HGF, VEGF-A, KIT, epigen, and VEGF-C correlated with improved OS: median OS 349 vs 184 days, HR=0.505, p=0.00002. None of the 15 baseline plasma biomarkers predicted efficacy from E in biomarker-treatment interaction analyses. Oncogenic mutations were detected in only 2 patient samples. **Conclusions:** HGF, VEGF-A, KIT, and VEGF-C baseline plasma levels were associated with clinical outcomes in HCC patients treated with S ± E, and these biomarkers plus epigen constituted a multi-marker composite signature for improved OS. Because S was used in both arms, whether these biomarkers are prognostic or also predictive of benefit from S alone in this population remains to be determined. Clinical trial information: NCT0901901.

**4029 Poster Highlights Session (Board #48), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Final analysis: Randomized, blinded, placebo-controlled phase II trial of sorafenib with and without mapatumumab in patients with advanced hepatocellular carcinoma (HCC).** *Presenting Author: Tudor-Eliade Ciuleanu, Prof. Dr. I. Chiricuta Institute of Oncology, Cluj County, Romania*

**Background:** TRAIL is a member of the tumor necrosis factor ligand super family that induces programmed cell death primarily in tumor cells (including liver tumors) through TRAIL death receptors. Mapatumumab (M) is an agonistic monoclonal antibody that targets one of the TRAIL death receptors, TRAIL-R1, and may promote apoptosis of cancer cells. **Methods:** Patients (Pts) with chemotherapy-naive advanced HCC were randomized 1:1 to sorafenib 400 mg BID continuously + IV Placebo (SP) or sorafenib 400 mg BID continuously + mapatumumab 30 mg/kg (SM) on day 1 every 21 days. Stratification variables were BCLC C vs B, and ECOG PS 0 vs 1, 2. Eligibility: bilirubin < 3 mg/dL, AST and ALT ≥ 5 x ULN, and INR ≥ 1.5. Radiologic progression was determined by blinded independent central review. The primary endpoint was time to progression (TTP). The sample size of 100 was sufficient to estimate median TTP with a precision of -1.9 to +2.6 months (mo). **Results:** 101 pts were in the ITT population: 51 SP and 50 SM. Treatment arms were balanced for the stratification variables. Demographics (SP vs SM): mean AFP 3177.7 vs 1534 mg/L, Male 76.5% vs 52%, Age 60.8 vs 60 years. Median (med) duration of M dosing was 3.3 mo and 84% pts received ≥ 90% of planned dose. Med cumulative sorafenib (S) dose (SP vs SM) was 73600 vs 75200 mg; 52.9% (SP) and 54% (SM) received ≥ 90% of the planned S dose. **Conclusions:** The addition of mapatumumab to sorafenib did not improve TTP (primary endpoint) or other efficacy endpoints. The combination did not substantially change the toxicity profile of sorafenib. Clinical trial information: NCT01258608.

**SWOG S0809: A phase II trial of adjuvant capecitabine (cap)/gemcitabine (gem) followed by concurrent capecitabine and radiotherapy in extrahepatic cholangiocarcinoma (EHCC) and gallbladder carcinoma (GBCA).** *Presenting Author: Edgar Ben-Josef, University of Pennsylvania, Philadelphia, PA*

**Background:** The role of adjuvant therapy after resection of EHCC or GBCA is unknown. S0809 was designed to estimate the stratum-specific (R0 and R1) and overall 2-year survival (OS), overall disease-free survival (DFS), local relapse (LR), and toxicity in patients (pts) treated with this adjuvant regimen. **Methods:** Eligibility included tissue diagnosis of EHCC or GBCA s/p radical resection, pT2-4, N+ or R1, M0, and PS 0-1. Pts received 4 cycles of gem (1 g/m2 IV, d1, d8) and cap (1500 mg/m2/d, days 1-14) q 21 days followed by concurrent cap (1330 mg/m2/d) and radiation (45 Gy to regional lymphatics and 54-59.4 Gy to the tumor bed). A total of 80 evaluable pts were needed; results would be considered promising if the 95% confidence interval (CI) for 2-year OS excluded a rate <45% and if the stratum specific point estimates were ≥65% for R0 and ≥45% for R1. Central pathology and radiation therapy reviews were performed. **Results:** 79 evaluable pts (54 R0, 25 R1) were registered; median age 62 yrs, 52% women, 62% EHCC and 38% GBCA. 86% of pts completed planned therapy; 3 pts discontinued therapy due to adverse effects (AEs). Grade 3 and 4 AEs were observed in 53% and 11% of pts. Most common grade 3/4 AEs included neutropenia (44%), hand-foot syndrome (13%), diarrhea (8%), lymphopenia (8%), and leukopenia (6%). There was one death from GI hemorrhage. Median OS was 33 months (33/30 for R0/R1). 12 pts developed LR, of whom 9 had a concurrent distant relapse. 24 patients developed distant-only relapse. **Conclusions:** This trial establishes the feasibility of adjuvant treatment in EHCC and GBCA and provides critically needed prospective data acquired in a multi-institutional setting. Both efficacy data and completion rate are promising and warrant further investigation in a phase 3 trial. Clinical trial information: NCT00789958.

**A comparison between 5-fluorouracil/mitomycin (FM) and capecitabine/mitomycin (CM) in combination with radiation (RT) for squamous cell carcinoma (SCC) of the anal canal.** *Presenting Author: Dante D.C. Wan, BC Cancer Agency, Vancouver Centre, Vancouver, BC, Canada*

**Background:** There are no randomized phase III trials comparing 5FU versus capecitabine in combination with mitomycin and RT for locally advanced anal cancer. Capecitabine has been increasingly adopted in substitution for infusional 5FU, based on data from other disease sites as well as the easier administration. In this retrospective cohort analysis, we aim to evaluate the outcomes of patients treated with both regimens. **Methods:** Patients with new histologic diagnosis of SCC of the anal canal who initiated curative-intent RT (50-54 Gy) with CM or FM between 1998 and 2013 at one of 6 provincial cancer centers in British Columbia were included. Their characteristics and outcomes were retrospectively analyzed. Differences in proportions were analyzed using the Chi-square test. Disease free survival was estimated using the Kaplan Meier method with log rank test for comparison. **Results:** A total of 300 patients (195 females) were reviewed. Median age was 58.5 (range 18-85). 34% of the patients were T3 or above and 29% were N2 or above. Median tumor size was 4 cm. Only 4.3% were HIV positive. 194 pts (64.6%) were treated with FM and 106 (35.3%) with CM. The groups were balanced for age, gender, histology, HIV status, T and N status. Median follow-up was 61.7 months (75.2 for FM and 15.8 for CM). Median DFS was not reached in both groups (p 0.24, HR 0.774). The remainder of response and outcomes are included in the Table. **Conclusions:** There is no difference between the two cohorts in this retrospective study. Additionally, there is a trend towards lower recurrence rates favoring capecitabine that may be explored in larger phase III studies. Capecitabine can be considered an alternative to 5FU in the chemoradiation treatment of SCC of the anus.

| Total (n=300) | Capecitabine (n=106) | 5-FU (n=194) | p value |
|---|---|---|---|

**Patient and tumor characteristics impacting on lymph node metastases rate (LNMR) in squamous cell carcinoma of the anal canal and margin (SCCA) using data from the NCRI randomized phase III ACT II trial: Implications for radiotherapy target volume.** *Presenting Author: Robert Glynne-Jones, Mount Vernon Centre for Cancer Treatment, Middlesex, United Kingdom*

**Background:** The prognosis of SCCA is linked to lymph node involvement. TNM Staging of SCCA is clinically based using physical examination, proctoscopy, and imaging. We aimed to determine tumour- and patient-related clinical LNMR in SCCA. **Methods:** The ACT II trial results are reported. We investigated the LNMR as determined by clinical examination and CT (cN+) from patient-related (age, sex, baseline WBC, platelets and Hb) and tumour-related factors (site, differentiation, histological type, cT stage and size of tumour (≥/<5cm). Magnetic resonance imaging (MRI) was commonly used from 2005. **Results:** We examined 892 evaluable patients (of 940 recruited). Median age 58 years (IQR 51-65 years); tumour site – canal (750/892 - 84%), margin (125/892 - 14%); stage cT1-T2 (467/892 - 52%), cT3-T4 (406/892 - 46%). Overall cN+ (305/940 - 32%), cN0 (587/940 – 62%, cNX (48/940 - 5%). Estimates of LNMR for anal canal only were 15% (113/750), 14% (102/750) and 8% (60/750) for N1 N2 and N3 respectively. There is evidence of an association between nodal status and cT-stage (p<0.0001)- stage cT1: (19/88 -22%) cT2:(85/379 -22%), cT3:(122/276-44%), cT4:(74/130-57%), cTX:(5/19-26%). In multivariate analysis only tumour site (canal vs margin HR=0.51, p=0.008), WBC (≥11 109/l HR=1.55, p=0.026) and T-stage (T2 vs T1 HR=1.00, T3 vs T1 HR=2.42, T4 vs T1 HR=3.79, p<0.0001) remained significant. 99 of 355 patients (28%) randomised pre-2005 were cN+ compared with 206 of 537 patients (38%) randomised post-2005 (p-value=0.0013). **Conclusions:** In the ACT II trial for stages cT1 and cT2, the baseline risk of clinical nodal involvement is 22% and in stages cT3 or cT4 is 48%.Radiotherapy field sizes should continue to be determined by N stage in second phase. The introduction of MRI after 2005 may have influenced the baseline nodal staging, and its utility in determining clinical target volume within intensity-modulated radiotherapy plans needs evaluation. Clinical trial information: NCT00025090.

**4033 Poster Highlights Session (Board #52), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Nomograms to predict prognosis in pseudomyxoma peritonei: A Peritoneal Surface Oncology Group International (PSOGI) multicenter study.** *Presenting Author: Shigeki Kusamura, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** We built nomograms for predicting overall (OS) and progression-free survivals (PFS) in patients with pseudomyxoma peritonei (PMP) treated with cytoreductive surgery (CRS)+/-intraperitoneal chemotherapy (IPCT). **Methods:** Data from 1,715 PMP patients in 31 centers from 1993 to 2012 constituted the developing set. The covariates were previous systemic chemotherapy (sCT), histologic subtype (Ronnett's criteria), peritoneal cancer index (PCI), completeness of cytoreduction (CC), IPCT (Hyperthermic intraperitoneal chemotherapy [HIPEC], early postoperative chemotherapy [EPIC], or both), lymph node status (LN), G3-5 morbidity (NCI CTCAE v3), and surgical proficiency. Centers with >100 procedures for PMP were considered proficient. Continuous variables were transformed using restricted cubic splines. We handled missing data using multiple imputation with chained equations (MICE) approach. We fitted a Cox model in each of the different completed developing datasets generated by MICE. Pooled estimates of regression coefficients, variances, and models' discriminations (bootstrap corrected Harrell C indexes) were obtained using Rubin's rule. The nomograms were externally validated on 733 PMP patients from two high-volume referral centers in USA (validating set). **Results:** In the developing set the median follow-up was 39 months. Five-year OS and PFS rates were 74.1% (95%CI: 71.3-76.8) and 52.3% (95%CI: 49.4-55.2), respectively. The means of adjusted Harrell C indexes for OS and PFS were 0.80 and 0.74 in the developing set and 0.74 and 0.72 in the validating set. In the developing set significant predictors of OS were sCT, PCI, CC, IPCT, histological subtype, LN, and G3-5 morbidity while those of PFS were surgical proficiency, sCT, histological subtype, PCI, CC, and IPCT. **Conclusions:** These nomograms may allow predicting OS and PFS providing individualized outcome prognostication. They would support therapeutic decision-making and stratification of future clinical trials.

**4034 General Poster Session (Board #121), Sat, 8:00 AM-11:45 AM**

**Phase II trial of panitumumab (P) plus mytomicin C (M), 5-fluorouracil (5-FU), and radiation (RT) in patients with squamous cell carcinoma of the anal canal (SCAC): Safety and efficacy profile—VITAL study, GEMCAD 09-02 clinical trial.** *Presenting Author: Jaime Feliu, Medical Oncology Department. La Paz University Hospital, Madrid, Spain*

**Background:** Standard of care for SCAC has remained unchanged over the past 4 decades. More than 80% of these tumors overexpress the EGFR receptor and <5% present KRAS mutations (Van Damme, BMC 2010). We therefore initiated a multicenter phase II study (NCT01285778) to assess the efficacy and tolerability of adding the EGFR inhibitor panitumumab to the standard M/5FU/RT regimen in patients with non-metastatic SCAC. **Methods:** Patients received P (6 mg/kg on day 1, every 2 weeks for 8 weeks), M (10mg/m2 q28 days x2) and 5-FU (1000mg/m2/day IV infusion days 1-4 q 28 days x 2) concurrently with RT 45 Gy (1,8 Gy per fraction) to the primary tumor, mesorectal, iliac and inguinal nodes, followed by a boost of 10-15 Gy to the primary tumor and affected lymph nodes. The trial was designed to include 58 pts with stage >T2N0 to have 80% power to detect an increment of 3y-DFS rate from 50% (Ajani, JAMA 2008) to 70%. **Results:** Between 1/2011 and 11/2013, 58 pts were accrued. To date, results of 36 patients are available (56% female, median age 54 years, VIH positive 6%, ECOG PS: 0 (44%)/1 (53%)/2 (3%), stage I (3%)/II (25%)/IIIA (19%)/IIIB (50%). Thirty-three (92%) patients developed G3/4 adverse events (Table 1). There were no toxic deaths. At 8 weeks, 56% pts experienced CR; 36% persistent but not progressive disease and 8% disease progression. At 24 weeks 55% had CR, 6% persistent but not progressive disease; 19% disease progression, and 20% had not been evaluated. **Conclusions:** The addition of P to M/5-FU/RT is a tolerable regimen with a good compliance and an acceptable safety profile. Full data of toxicity and post-treatment CR rate will be reported at ASCO Meeting. Clinical trial information: NCT01285778.

**Tumor HPV status and invasive squamous cell carcinoma of the anus: Outcomes from a single institution.** *Presenting Author: Bhargavi Yalamarti, University of Massachusetts Medical School, Worcester, MA*

**Background:** Squamous cell carcinomas (SCC) of the anus are associated with infection with Human Papilloma Virus (HPV) genotypes 16 and 18 in 80% of cases. Chemoradiotherapy (CRT) confers 70% 3-year relapse-free survival. Clinical outcomes of anal SCC in relation to common tumor HPV genotypes 16 and 18, has not been reported in patients from the USA. **Methods:** 81 patients with anal SCC were treated between January 1998 and December 2013 at our institution. Complete data on clinical outcomes and archived specimens for genotyping were available for 62 patients. Tumor HPV status was determined by HPV DNA testing from paraffin-embedded tumor tissues. **Results:** All 62 patients received radiation therapy > or = 50Gy and 87% received concurrent chemotherapy with 5-FU plus Mitomycin in 90.4% and 5-FU plus Cisplatin in 9.6%. 52 patients (83%) had HPV positive (+) tumors and 46 patients had genotype 16, 3 patients (3/52) had both genotype 16 and 18, 1 had genotype 18. 10 (17%) patients had HPV negative (-) tumors. The mean age at diagnosis for the HPV+ group was 55.06 years, compared to 64.8 years in the HPV- group (p=0.017). The percentage of males in the HPV+ group is 36.5% (19/52) and 60% (6/10) in the HPV- group (p=0.291). In the HPV+ group, 41 patients (78.8%) were T stage 1 to 2, 36 patients (69.2%) had no lymph node (LN) involvement. In the HPV- group, 5 patients (50%) were with T stage 1 to 2 and 5 patients (50%) had no LN involvement. After a median follow up of 7 years, 16/62(25.8%) patients had recurrence of anal cancer and 12 of them were HPV+ with genotype 16. The HPV+ group had longer time to relapse (HR=0.571, [95% CI=0.144 to 2.265], p=0.425) after adjustment for the size of the tumor and nodal status. 4/62(6.4%) patients died, two in the HPV+ and 2 in the HPV- group. 93.5% (58/62) of patients are alive at 5 yrs. In the HPV+ group, 96.1%(50/52) are alive as compared to 80% (8/10) alive in the HPV- group at the end of 5 yrs. The HPV+ group had longer time to death (HR=0.736, [95% CI=0.141 to3.854], p=0.717) after adjustment for tumor size and nodal status **Conclusions:** In our cohort, HPV+ anal SCC is more commonly diagnosed at a younger age and in women. There was a trend towards longer time to loco-regional relapse and death in HPV+ group than in the HPV- group.

**4036 General Poster Session (Board #123), Sat, 8:00 AM-11:45 AM**

**Prognostic significance and therapeutic implications of c-MET in esophageal squamous cell cancer.** *Presenting Author: Ching Tzao, Division of Thoracic Surgery, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan*

**Background:** c-MET is a receptor tyrosine kinase (RTK) that has been shown to be overexpressed and may serve as a potential therapeutic target in a variety of human cancers. We aimed to study if c-MET expression correlates with patients' outcome with therapeutic implications in esophageal squamous cell cancer (ESCC). **Methods:** Expression of c-MET was analyzed by immunohistochemistry in tumors from 97 resected ESCC with correlative analysis with clinicopathologic variables. Cytotoxicity (MTT), cell migration, and assays for cell cycle and apoptosis were conducted in KYSE-510 and KYSE-170 ESCC cell lines in response to two c-Met inhibitors, SU11274 and PHA665752. Expression of cell cycle regulators, cyclin A and B1, tumor suppressors including Rb, p53 p21 and p27, and intrinsic apoptotic factors were determined by immunoblotting. Mice inoculated with KYSE 170 ESCC cell line were used to test effects of c-MET inhibitors in vivo. **Results:** Expression of c-Met within resected ESCC correlated positively with T status ($P = 0.008$), N status ($P < 0.001$), M status ($P = 0.048$) and stage ($P < 0.001$). Patients with low expression of c-Met showed better survival compared to those with high expression ($P = 0.0001$). SU11274 and PHA665752 significantly inhibited viability and migration of KYSE-170 and 510-ESCC cells with decreased expression of phosphorylated c-MET (p-c-MET). When treated with c-MET inhibitors, p27and p53 was upregulated with a concomitant decrease in cyclin-dependent kinase 6 (Cdk6) in KYSE-170 cells, whereas cyclin A and B1 in was decreased in KYSE-170 cells with an induction of G1 or G2 cell cycle arrest. Apoptosis was induced by c-Met inhibitors with upregulation of pro-apoptic factors, Bcl-2-associated X protein (BAX) and BCL2-interacting killer (BIK) in KYSE-170 cells. Growth was significantly suppressed in murine tumors of KYSE-170 when treated with c-MET inhibitors with decreased expression in p-c-MET. **Conclusions:** c-MET expression may serve as a predictor for poor prognosis in resected ESCC. c-MET inhibitors, SU11274 and PHA665752 had significant anticancer effects in ESCC cell lines in vitro and in vivo, suggesting that c-MET may serve as a potential therapeutic target for ESCC.

**4037 General Poster Session (Board #124), Sat, 8:00 AM-11:45 AM**

**Perioperative versus preoperative chemotherapy with surgery in patients with resectable squamous-cell carcinoma of esophagus: A phase III randomized trial.** *Presenting Author: Yang Zhao, Second Affiliated Hospital to Xi'an Jiaotong University, Xi'an, China*

**Background:** We assessed whether a regimen of perioperative PCF (paclitaxel, cisplatin, and fluorouracil) to surgery improves outcomes among patients with potentially curable squamous-cell carcinoma of esophagus comparing with preoperative chemotherapy and surgery. **Methods:** We randomly assigned patients with resectable squamous-cell carcinoma of esophagus to receive either perioperative chemotherapy (175, Arm A) or preoperative chemotherapy (171, Arm B) with surgery.Chemotherapy consisted of two preoperative with or without two postoperative cycles of intravenous paclitaxel (200 mg per square meter of body-surface area) and cisplatin (60 mg per square meter) on day 1, and a continuous intravenous infusion of fluorouracil (700 mg per square meter per day) for 5 days. Primary end point was progression-free survival (PFS), secondary end point was overall survival (OS). **Results:** PCF-related adverse effects were similar to the previously reported among patients with the squamous-cell carcinoma of esophagus. The postoperative morbidities were similar between the perioperative-chemotherapy-surgery group and the preoperative-chemotherapy-surgery group, as were the numbers of deaths within 30 days after surgery. There were no significant differences in resectability and postoperative pathological stage. With a median follow-up of 50 months of all patients, 104 patients in the perioperative-chemotherapy-surgery group and 114 in the preoperarive-chemotherapy-group had died. As compared with the preoperative-chemotherapy-surgery group, the perioperative-chemotherapy-surgery group had a greater likelihood of progression-free survival (hazard ratio for progression, 0.62; 95 percent confidence interval, 0.49 to 0.73; $P < 0.001$) and of overall survival (hazard ratio for death, 0.79; 95 percent confidence interval, 0.59 to 0.95; $P < 0.001$; five-year survival rate, 38 percent vs. 24 percent). **Conclusions:** In patients with operable esophageal squamous-cell carcinoma, a perioperative regimen of PCF can significantly improved 5-year progression-free and overall survival comparing to preoperative chemotherapy. NCT01225523 Clinical trial information: NCT01225523.

**4038 General Poster Session (Board #125), Sat, 8:00 AM-11:45 AM**

**The revised AJCC staging (7th edition) and prognostic stratification in esophagogastric adenocarcinoma.** *Presenting Author: Haris Zahoor, Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA*

**Background:** AJCC esophageal staging assigns prognostic groups based on tumor, node, and metastasis classifications. In 2010, AJCC 7th ed. separated adenocarcinoma from squamous cell histology and added tumor grade and number of involved regional nodes. Our study aim was to compare survival prognostication for esophagogastric adenocarcinoma between AJCC 7 and AJCC 6th ed. stage groupings. **Methods:** We abstracted pathology and survival for surgically resected esophagogastric adenocarcinoma patients (n=836; 1997 to 2011); 256 received induction therapy. AJCC stage was assigned; overall survival in months (esophagectomy to death or most recent alive contact) was analyzed. Discriminatory ability and homogeneity, by stage, was assessed with Kaplan-Meier (KM) curves. Monotonicity comparisons were evaluated with linear trend chi-squared tests. Overall survival was compared using Cox regression and Akaike Information Criterion (AIC) was used to assess model fit. **Results:** Compared to AJCC 6, AJCC 7 restaged 165 patients (Table). KM log-rank statistic indicated stronger differentiation in AJCC 7 curves compared to AJCC 6 (166.128 vs 185.523 overall). Cox likelihood ratio (162.957 vs. 173.951 overall) and AIC (4831.011 vs 4820.016 overall) indicate better model fit to the survival data for AJCC 7 versus AJCC 6, overall and for induction subgroups (data not shown). As stage group increases, stronger linear trends for survival were observed at 24, 36, and 60 months using AJCC7 stage groupings, overall and for induction subgroups, compared to AJCC 6. **Conclusions:** AJCC 7 stage groupings demonstrate superior homogeneity, discriminatory ability, and monotonicity compared to AJCC 6. Incorporating the extent of nodal disease, and tumor grade into the revised AJCC 7 stage classification improves prognostic stratification of surgically resected esophagogastric adenocarcinoma patients, including patients who received induction therapy.

**Patients upstaged or downstaged comparing AJCC 6 to AJCC 7.**

| Upstaged | Number of patients |
|---|---|
| IIa to IIb | 77 |
| IIb to IIIa | 29 |
| IIb to IIIc | 10 |
| **Downstaged** | **Number of patients** |
| IIa to Ib | 32 |
| IVa to IIb | 1 |
| IVa to IIIa | 3 |
| IVa to IIIb | 3 |
| IVa to IIIc | 10 |

**4039 General Poster Session (Board #126), Sat, 8:00 AM-11:45 AM**

**Candidate drug therapies for molecularly defined subgroups of esophageal cancer identified from high-throughput drug screening.** *Presenting Author: Irene Yu-Shing Chong, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

**Background:** There is a pressing clinical requirement to identify novel treatment strategies for oesophageal cancers, especially considering the rising incidence and poor patient prognosis. The use of high-throughput small molecule drug screens has the potential to identify therapies not previously acknowledged to be efficacious for individual cancer types. **Methods:** To identify effective drug therapies for molecularly defined subgroups of patients with oesophageal cancer, high-throughput drug screening was undertaken in 17 oesophageal cancer cell line models using a small molecule library incorporating 78 drugs. Genomic profiles regarding gene mutation and copy number variation for each of the oesophageal cell line models used in the drug screen were obtained from publically available data repositories (Cancer Cell Line Encyclopedia and COSMIC cell line project). **Results:** Broad spectrum sensitivity across the oesophageal cell line models was observed for targeted agents including PF03758309 (PAK4 inhibitor) and BI2536 (PLK-1 inhibitor). A differential sensitivity between the oesophageal cancer cell lines was observed for other targeted agents including BEZ235 (PIK3CA/mTOR inhibitor). The oesophageal cell lines most sensitive to BEZ235 harboured COSM760 PIK3CA p.E542K, a missense mutation located in the helicase domain. Sensitivity to small molecule tankyrase inhibitors which inhibit the Wnt pathway was most pronounced in OE19, which harbours biallelic methylation of the APC promotor 1A. Single agent in vivo efficacy of a novel tankyrase inhibitor was also demonstrated, with significant differences in tumour weight and volume between the drug and vehicle groups (P=0.0024 and P=0.0048, respectively). **Conclusions:** High-throughput drug screening of oesophageal cancer cell lines has identified novel sensitivities to drugs including small molecule tankyrase inhibitors. It is possible that promotor hypermethylation of APC contributes towards the activation of Wnt signalIng, and may serve as a candidate predictive biomarker for tankyrase inhibitor sensitivity.

**4040 General Poster Session (Board #127), Sat, 8:00 AM-11:45 AM**

**The effect of FGFR4 Gly388Arg polymorphism on treatment outcomes after chemoradiotherapy in esophageal cancer patients.** *Presenting Author: Sanghee Cho, Department of Hematology-Oncology, Chonnam National Univeristy Hwasun Hospital, Gwangju, South Korea*

**Background:** Fibroblast growth factor receptor 4 (FGFR4) has been associated with increased risk, staging, and metastasis in several type of cancer. The purpose of this study was to evaluate the prognostic role of FGFR4 Gly388Arg polymorphism in esophageal cancer after chemoradiotherapy. **Methods:** Peripheral blood samples from 250 patients who were treated with chemoradiotherapy were used for this study. Patients were diagnosed as a stage of I in 12 (5%), II in 54 (21%), III in 115 (46%) and IV in 69 (28) patients. All of the patients were received chemotherapy using cisplatin and fluorouracil or cisplatin and docetaxel. **Results:** The overall response was 85%, with 21% complete response and 64% partial response. The overall survival (stage II, 34 months; stage III, 23.3 months; stage IV, 19.3 months, p=0.005) and progression survival (stage II, 23.8 months; stage III, 12.8 months; stage IV, 9 months, p=0.001) was significantly improved according to stage. In FGFR4 genotypic analysis, 96 patients (38.6%) were homozygous for Gly388 allele, with 113 heterozygous (45.4%) and 40 (16.0) homozygous for Arg388 allele. There was no significant association between FGFR4 genotype and stage. However, Gly388 allele patients show better overall response rate (90.6%) than Arg388 carriers (82.4%, p=0.050). In early stage (stage I and II, n=66), Gly388 allele patients tended to have a better OS or PFS (not available until this analysis) than Arg388 carriers (PFS: 38 months, 95% CI 7.7-68.1; OS: 49 months, 95% CI 24.8-73.5). However, in advanced stage (III, IV), the survival outcomes was similar between genotypes. **Conclusions:** Present study shows that FGFR4 Gly388 allele has a prognostic role in response after chemoradiotherapy in esophageal cancer. Especially in early stage of esophageal cancer, FGFR4 might have an important role in disease progression and survival outcomes. It suggests that the possibility of new therapeutic target for esophageal cancer treatment.

**4041 General Poster Session (Board #128), Sat, 8:00 AM-11:45 AM**

**A phase II study of MK-2206, an allosteric inhibitor of AKT as second-line therapy for advanced gastric and gastroesophageal junction (GEJ) cancer: A SWOG Cooperative Group trial (S1005).** *Presenting Author: Ramesh K. Ramanathan, TGen-Virginia G. Piper Cancer Center at Scottsdale Healthcare, Scottsdale, AZ*

**Background:** The PI3K/AKT/MTOR pathway is frequently activated in gastric/GEJ cancers. This study evaluated the activity of single agent MK-2206 at the dose of 60 mg every other day in this tumor type. **Methods:** Eligible patients (pts) had gastric /GEJ adenocarcinoma with measurable disease, who had had progression after first-line treatment, or recurrence within six months after adjuvant therapy. Other pertinent eligibility criteria included a Zubrod performance status of 0-1, a fasting serum glucose ≤150 mg/dL, and < Grade 2 malabsorption or chronic diarrhea. Adequate hematologic, renal, hepatic, and cardiac function were required. Prior treatment with a PI3, AKT, or mTOR inhibitor was not allowed. MK-2206 (60 mg every other day) was given until progression or intolerable toxicity. Primary endpoint was overall survival (OS), secondary endpoints were safety, progression free survival (PFS) and response rate (RR). The study required 60 evaluable pts and a median OS of 6.5 months (mo) (power of 89%, significance level 0.07) to be considered encouraging for further investigation. **Results:** Seventy-five pts were enrolled between 1/1/11 to 5/1/13. Eight pts were ineligible and one pt withdrew; 66 pts were included in the analyses. Median age is 60.7 yrs (range 30.4-86.7), Males 70%, White 89% and Asian 6%. There were 2 deaths possibly related to study drug (cardiac arrest and respiratory failure). Gr 4 adverse events (AEs) were hyperglycemia, anemia and lung infection (1 each). Gr 3 AEs were infrequent and < 5% except for fatigue (6%). Other all Gr AEs included anemia 15%, anorexia 27%, diarrhea 24%, fatigue 48%, hyperglycemia 29%, nausea 40%, vomiting 20%, maculopapular rash 30%, and acneiform rash 8%. The RR is 2%, median PFS is 1.8 mo. (95% CI of 1.7- 1.8) and median OS is 5 mo (95% CI 4 - 10 mo). **Conclusions:** MK-2206 as 2nd line therapy in an unselected group of gastric/GEJ cancers was well tolerated with some evidence of activity (RR 2%, OS 5.0 mo) and in the range of other second line agents (irinotecan, docetaxel, ramucirumab). The primary study endpoint of 6.5 mo was not met. (Support: NIH/NCI cooperative group grants CA32102 and CA38926). Clinical trial information: NCT01260701.

**4042 General Poster Session (Board #129), Sat, 8:00 AM-11:45 AM**

**Effect of metastasis associated in colon cancer-1 on lymphangiogenesis in human gastric cancer.** *Presenting Author: Li Sun, Department of Oncology, Nanfang Hospital, Southern Medical University, Guangzhou, China*

**Background:** Metastasis-associated in colon cancer-1 (MACC1), a new oncogene predominantly expressed in several solid tumors including gastric cancer (GC), is associated with cancer lymph node positivity. Nodal dissemination of GC critically determines clinical outcome of affected patients. Therefore, we conducted the study to investigate whether MACC1 influences GC lymphatic metastasis and to explore the potential underlying mechanism. **Methods:** Immunohistochemistry analysis was performed in 190 GC tissues with MACC1, LVYE-1 to find out the relationship between MACC1 and lymph node metastasis as well as lymphangiogenensis. MTT, Transwell migration and 3D-culture assay were conducted to evaluate the effects of MACC1 on the proliferation, migration and capillary-like structure capacity of human lymphatic endothelial cells (HLECs) after co-cultured with MACC1 supernatant. Besides, vascular endothelial growth factor-C (VEGF-C)/VEGF-D expression in GC cells were detected by qRT-PCR, Western blot and ELISA. **Results:** Presence of MACC1 was correlated with lymph node metastasis ($p<0.01$) and lymphangiogenesis ($p<0.001$); meanwhile, absence of MACC1 expression contributed to a better prognosis for GC patients ($p<0.001$). Additionally, in vitro studies demonstrated that MACC1 upregulated HLECs' capacity of tube-like formation through enhancing cell proliferation and migration. MACC1 also promoted both lymphangiogenesis and lymphatic invasion in nude mice transplantation assay. Moreover, MACC1 significantly increased the expression of VEGF-C/VEGF-D in GC cells and transplanted tumors both in protein and gene level, which was subsequently suppressed by inhibitor of hepatocyte growth factor (HGF)/c-Met signaling axis. **Conclusions:** All these data suggested a critical role for MACC1 in lymphatic dissemination of gastric cancer, providing evidence that MACC1 upregulated VEGF-C/VEGF-D expression to promote lymphangiogensis partially via HGF/c-Met pathway.

**4043 General Poster Session (Board #130), Sat, 8:00 AM-11:45 AM**

**The R0 resection rate after neoadjuvant bevacizumab (Bev) plus DOF versus DOF in local advanced gastric carcinoma (LAGC) and its association with circulating tumor cell (CTC).** *Presenting Author: Nan Du, Department of Oncology, First Affiliated Hospital, Chinese PLA General Hospital, Beijing, China*

**Background:** Local advanced gastric carcinoma (LAGC) is suggested to be potentially cured by R0 resection, and neoadjuvant chemotherapy can increase the R0 resection rate but not enough. Bevacizumab (Bev), an anti-tumor angiogenesis monoclonal antibody, combined with chemotherapy has been shown effective in advanced GC. In addition, CTC has been suggested as an indicator of the anti-tumor drugs' efficacy. Therefore, in this study, we plan to evaluate the efficacy and safety of neoadjuvant Bev plus docetaxel/oxaliplatin/5-FU/CF (DOF) versus DOF in mainly gastric antrum LAGC, and to investigate whether CTC is an effectiveness indicator. **Methods:** 80 patients diagnosed as IIIb-IIIc GC have been enrolled and randomly assigned (1:1) to receive neoadjuvant Bev (5 mg/kg, d1) plus DOF (docetaxel, 75 mg/m$^2$, iv, d1; oxaliplatin, 85 mg/m$^2$, iv, d1; 5-FU, iv infusion 600 mg/m$^2$ and iv injection 400mg/m$^2$, d1-2; CF, 200 mg/m$^2$, d1 and d2) or DOF each 3-week, up to 2-4 cycles preoperation, and another 2-4 cycles postoperation up to total 6 cycles. The primary endpoint is R0 resection rate. CTC was detected every 8 weeks. All patients signed the informed consent. **Results:** For ORR and R0 resection rate, there were significant differences between the Bev plus DOF and DOF groups (65.0% vs. 42.5% and 77.5% vs. 52.5%; $P<0.05$). Compared to DOF group, Bev plus DOF group had dramatically more CTC number declined ($P<0.05$), and had 21 of 24 (87.5%) patients achieving R0 resection [10 of 15 (66.7%) patients with DOF]. The medium survival was 17.6 months (95% CI: 14.153-21.047) with Bev plus DOF versus 16.4 months (95% CI: 12.949-19.851) with DOF; OS of the two groups had no significant statistical difference ($p=0.776$). Furthermore, both single-variant and multi-variants Cox regression analysis found that neoadjuvant regimen,R0 resection rate and CTC were independent survival prognostic predictors in LAGC ($P<0.05$). **Conclusions:** Neoadjuvant Bev plus DOF can reduce TN staging and improve ORR and R0 resection rate in LAGC with controllable adverse effects. CTC number declined may act as an effectiveness and survival predictor in LAGC.

**4044 General Poster Session (Board #131), Sat, 8:00 AM-11:45 AM**

**Reduction of heart volume during neoadjuvant chemoradiation in patients with resectable esophageal cancer.** *Presenting Author: Nadia Haj Mohammad, Academisch Medisch Centrum, Amsterdam, Netherlands*

**Background:** Neoadjuvant chemoradiation (nCRT) followed by surgery based on the Dutch CROSS scheme is considered curative intent treatment for patients with resectable esophageal cancer. Ideally the high dose region of the radiotherapy treatment would only include the esophagus as target organ. However, inevitably the heart will receive a part of the chemoradiation dose. Recently, decreases in heart volume have been reported during nCRT. This change in heart volume can be of great importance because it could result in inaccurate dose delivery to the tumor and organs at risk. The aim of the study was to establish hemodynamic aspects and predictors of changes in heart volume during nCRT. **Methods:** A prospective pilot study was conducted in patients who were treated with 5 weeks nCRT consisting of carboplatin AUC 2 and paclitaxel 50 mg/m2 concomitant with radiotherapy (41.4 Gy/1.8 Gy per fraction) followed by resection. Physical parameters, cardiac volume on CT, cardiac blood markers (troponin, NT-proBNP, CK, CK-MB) and cardiac ultrasound including 2D strain analysis were obtained at baseline and at the end of treatment. **Results:** 23 patients were included. A significant mean decrease of 55.3 ml (6.1%) in heart volume was detected (95% CI 36.7-73.8 ml p=0.000). Blood pressure (BP) significantly decreased (systolic BP mean decrease of 18 mmHg (95% CI 11-26 mmHg p=0.000) and diastolic BP mean decrease of 8 mmHg (95% CI 2-14 mmHg p=0.008) and heart rate during cardiac ultrasound significantly increased with 6 beats/min (95% CI 1-11 beats/min p=0.021). An evident trend of an increased vena cava inferior collaps index of 5.1 % (95 % CI -0.8-11 % p=0.086) was observed, all suggesting dehydration in the course of treatment. Left ventricle ejection fraction, 2D strain and cardiac blood markers showed no significant changes. Independent predictors for reduced heart volume were low baseline creatinin (p=0.001) and low left ventricle endsystolic volume (p= 0.012). **Conclusions:** The heart volume is significantly reduced after 5 weeks of nCRT and is not accompanied by overt cardiac dysfunction. Patients with low baseline creatinin and low left ventricle endsystolic volume are more at risk for heart volume reduction. Clinical trial information: NL42999.018.12.

**4045 General Poster Session (Board #132), Sat, 8:00 AM-11:45 AM**

**Prognostic factors for patients with advanced thoracic esophageal squamous cell carcinoma receiving preoperative cisplatin plus 5-fluorouracil (JCOG9907).** *Presenting Author: Tomoya Yokota, Divison of Gastrointestinal Oncology, Shizuoka Cancer Center, Sunto-gun, Japan*

**Background:** Preoperative chemotherapy with cisplatin plus 5-fluorouracil followed by esophagectomy with 2-3 field lymph node dissection is one of the standard treatments for patients with clinical stage II/III squamous cell carcinoma (SCC) of the esophagus. This study investigated the prognostic factors for patients who received preoperative chemotherapy. **Methods:** Of 164 patients assigned to receive preoperative chemotherapy in JCOG9907 study, multivariate analyses were performed in 159 patients for evaluating preoperative prognostic factors and in 154 patients for postoperative prognostic factors. **Results:** Multivariate analyses using preoperative factors showed that clinical T3 (vs.cT1-2) (HR 3.602, p=0.0007) and serum albumin (Alb)<4.0g/dl (vs.>=4.0g/dl) (HR 2.293, p=0.0005) were associated with a poor prognosis. A prognostic index using these preoperative factors was constructed dividing patients into good (cT1-2 and Alb>=4.0: 3yOS 92.3%), moderate (cT1-2 and Alb<4.0 or cT3 and Alb>=4.0: 66.3%), and poor (cT3 and Alb<4.0: 37.2%) risk groups. Three independent prognostic factors were identified by multivariate analysis using postoperative factors: pathological curability pB [either R1, R0 with stage IV, or the nodal dissection area smaller than the extent of nodal metastasis] or pC [R2] (vs. pA [R0]) (HR 2.199, p=0.0027), pathological N1-4 (vs. pN0) (HR 3.397, p=0.0012) and histological therapeutic effect (Grade>=2) (HR 0.301, p=0.0104). A prognostic index using postoperative factors was constructed dividing patients into good (no or one risk factor), moderate (two risk factors) or poor (three risk factors) risk groups. 3yOS for good, moderate and poor risk groups were 87.7%, 56.0%, and 31.6%, respectively. **Conclusions:** cT, Alb and postoperative pathological findings are independent prognostic factors for advanced thoracic esophageal SCC patients who received preoperative chemotherapy. Information from this analysis can be used to aid clinical decision-making and help individual patient risk stratification.

**4046 General Poster Session (Board #133), Sat, 8:00 AM-11:45 AM**

**Molecular profiling of resected esophageal cancer and its correlation with clinical outcome.** *Presenting Author: Tomoya Yokota, Divison of Gastrointestinal Oncology, Shizuoka Cancer Center, Sunto-gun, Japan*

**Background:** The tumor related gene profiling in esophageal cancer remains unknown and requires further investigation in order to promote efficient and rapid development of molecular-target agents. The aim of this study was to evaluate the expression level and mutations of tumor related genes in resected esophageal cancer and to assess correlation of the profiling with clinical outcome. **Methods:** 135 consecutive patients with esophageal cancer who underwent esophagectomy at Shizuoka Cancer Center and Toyama University between October 2002 and November 2011 were analyzed. Protein expression of MET, EGFR, ALK and HGF was determined by Automated QUantification Analysis. Copy number of EGFR, PIK3CA, MET and FGFR1/2 was analyzed by real time PCR. The translocation of ALK gene and mutations of tumor related genes were evaluated by fluorescence in situ hybridisation and TruSeq Amplicon Cancer Panel, respectively. Prognostic factors associated with survival were identified by multivariate analyses using the Cox proportional hazards model. **Results:** Overall, heavy smoking was significantly associated with high HGF expression (p=0.03938), but was not an independent prognostic factor. After adjustment for clinical features by multivariate Cox regression analysis, high expression of ALK was associated with poor OS in patients without neoadjuvant therapy (HR 4.589, p=0.0102). The translocation of ALK gene was present only in 1 patient. High expression of MET was associated with poor OS in patients with neoadjuvant therapy (HR 5.68, p=0.043). Mutations in p53 and PIK3CA were present in 73% and 13%, respectively. The frequency of mutations in APC, BRAF, ERBB4, VHL, KRAS and EGFR was less than 10%. PIK3CA amplification was observed in 2%. **Conclusions:** High expression of ALK and MET may be prognostic factors for resected esophageal cancer. Esophageal cancers with high expression level of ALK and MET might be possible candidates for ALK and MET targeting therapies.

**4047 General Poster Session (Board #134), Sat, 8:00 AM-11:45 AM**

**Phase I study of epigenetic priming using azacitidine prior to neoadjuvant chemotherapy in patients with resectable esophageal and gastric adenocarcinoma.** *Presenting Author: Bryan J. Schneider, Weill Cornell Medical College, New York, NY*

**Background:** Epigenetic silencing of tumor suppressor genes (TSGs) is an acquired abnormality observed in cancer and is prototypically linked to DNA methylation. 5-Azacitidine (V) is a cytosine analog and a DNA hypomethylating agent (DHA). Reactivated expression of TSGs is commonly implicated in the clinical activity of DHAs since TSGs often regulate apoptosis, DNA repair, and checkpoint control. We postulated that pretreatment (priming) with V would increase the efficacy of neoadjuvant chemotherapy by reactivating TSGs during administration of cytotoxics. The study was conducted to identify a tolerable dose of V prior to epirubicin (E), oxaliplatin (O), capecitabine (X), (EOX) neoadjuvant chemotherapy. **Methods:** Eligible patients (pts) had locally-advanced, resectable esophageal/gastric adenocarcinoma, no prior therapy, ECOG 0-2 and adequate organ function. V (75mg/m$^2$) was given subcutaneously for 3 (Dose Level, DL 1) or 5 (DL 2) days with EOX (E 50 mg/m$^2$, O 130 mg/m$^2$, X 625 mg/m$^2$ bid x 21 d) beginning on the last day of V. Cycles were repeated every 21 days. Residual tumor was resected after cycle 3. Standard 3+3 methodology guided V dose escalation. DNA methylation at control and biomarker regions was measured by digital droplet, bisulfite qPCR in tumor samples prior to therapy and at resection. **Results:** 10 pts were mostly male (9M:1F), median age 54 yrs (40-84) and esophageal (3), gastric (5), or GEJ (2) tumors. 9 pts completed the planned 3 cycles; 3 on DL1, 7 on DL2. A MTD was not identified. One DLT was identified (DL2) during cycle 2: Grade 4 dehydration and hypokalemia. Other toxicities included grade 4 neutropenia (n = 4), pulmonary embolus (n = 1) and grade 3 nausea (n = 3). Overall response rate was 60% (CR/PR: 2/4) by PERCIST and included 2 pathologic CR and a third with only a microscopic tumor focus found at resection. Responding pts with informative DNA methylation abnormalities at baseline demonstrated significant DNA hypomethylation at CDKN2A, HPP1, ESR1 and TIMP3 in the resected specimen. **Conclusions:** Neoadjuvant V-EOX was well tolerated with significant clinical and epigenetic responses. Research was partially, supported by a grant from Celgene, Inc. Clinical trial information: NCT01386346.

**4048 General Poster Session (Board #135), Sat, 8:00 AM-11:45 AM**

**Prevalence of MET and HER2 biomarkers in stage IV gastric cancer.** *Presenting Author: Robert D. Loberg, Molecular Sciences & Computational Biology, Amgen, Inc., Thousand Oaks, CA*

**Background:** Estimates of the frequency of genomic alterations in *MET* and *HER2* in gastric cancer vary widely, but alterations in *MET* are generally less common than alterations in *HER2*. We examined a large set of stage IV gastric cancer samples for variation in *MET* and *HER2*gene copy number. We also assessed HER2 protein expression in these samples. **Methods:** Formalin-fixed, paraffin-embedded (FFPE) stage IV gastric cancer tumor samples (N = 309) were collected in Russia (n = 195), China (n = 99), and other countries (n = 15). Samples were analyzed by fluorescence in situ hybridization (FISH) for *MET* gene amplification (Dako *MET* IQFISH pharmDx) and *HER2* gene amplification (Dako *HER2* IQFISH pharmDx) and by immunohistochemistry (IHC) for HER2 protein expression (Dako HercepTest). All assays were performed according to the manufacturer's instructions. This is the first published use of the Dako *MET* IQFISH pharmDx assay. Cohen's kappa coefficient, a statistical measure that takes into account agreement that occurs by chance, was used to assess agreement between measurements. **Results:** We found *MET* gene copy number variation ($\geq$ 5 copies) in 17 of 305 samples (6%), and *MET* gene amplification (*MET/CEN-7* $\geq$ 2.0) in 12 of 305 samples (4%). The proportion of samples that were *MET* gene amplified was similar in the Chinese and Russian samples. We found *HER2* gene copy number variation ($\geq$ 5 copies) in 54 of 280 samples (19%), and *HER2* gene amplification (*HER2/CEN-17* $\geq$ 2.0) in 43 of 280 samples (15%). Of the 201 evaluable HER2 IHC samples, 22 (11%) were positive for HER2 protein expression. *HER2* FISH and HER2 IHC results showed that *HER2* gene amplification and protein expression commonly occur in the same tumors (kappa = 0.71 to 0.76). *HER2* and *MET* FISH results showed that *MET* and *HER2*gene amplification rarely occur in the same tumors (kappa $<$ 0.05); only one sample was amplified for both genes. **Conclusions:** *MET* gene amplification was observed in 4% of this large set of stage IV gastric cancer samples. Prevalence of *HER2* gene amplification and expression was in the same range as found in previously published studies. Our results indicate that *MET* gene amplification and *HER2* gene amplification may occur in different subpopulations of stage IV gastric cancers.

**4049 General Poster Session (Board #136), Sat, 8:00 AM-11:45 AM**

**Survival benefit of metastasectomy plus chemotherapy versus chemotherapy alone for Krukenberg tumors from advanced stomach cancer.** *Presenting Author: Jang Ho Cho, Department of Medical Oncology, Gangnam Severance Hospital, Seoul, South Korea*

**Background:** Although systemic chemotherapy is the optimal treatment strategy for metastatic stomach cancer, several local treatments have been investigated to improve overall survival (OS) in patients with oligometastasis or limited metastasis. Because the survival benefit of metastasectomy has not been clearly validated for krukenberg tumors, we evaluated the survival benefit of ovarian metastasectomy in krukenberg tumor from stomach cancer and identified prognostic factors for survival. **Methods:** Of 27,103 patients who were diagnosed with stomach cancer between March 2004 and February 2013 at Yonsei University Medical Center, 244 female patients with krukenberg tumor detected by abdominal-pelvis computed tomography or gynecologic ultrasonography were included in the study and reviewed retrospectively Patients were divided into two arms according to treatment modality: arm A, metastasectomy plus chemotherapy and arm B, chemotherapy alone. **Results:** OS was increased by 9 and 11 months in arm A compared with arm B for patients initially diagnosed with stage IV stomach cancer (21.0 vs. 12.0 months; $p < 0.001$) and those with recurrent krukenberg tumors (19.0 vs. 8 months; $p = 0.002$), respectively. Metastasectomy (hazard ratio [HR] = 0.517 [95% confidence interval {CI}, 0.330–0.809]; $p = 0.004$), signet-ring cell pathology (HR = 1.753 [95% CI, 1.187–2.588]; $p = 0.005$), peritoneal carcinomatosis (HR = 1.564 [95% CI, 1.041–2.350]; $p = 0.031$), and an elevated serum CA125 level (>35 U/mL) (HR = 1.786 [95% CI, 1.148–2.780]; $p = 0.010$) were significant prognostic factors for survival. **Conclusions:** OS was prolonged with chemotherapy plus metastasectomy than with chemotherapy alone in patients with krukenberg tumors from stomach cancer. This survival benefit was observed both in patients initially diagnosed with stage IV stomach cancer and in those diagnosed with recurrent krukenberg tumor. Metastasectomy, signet-ring cell pathology, peritoneal carcinomatosis, and an elevated serum CA125 level were prognostic factors for survival. Future prospective randomized trials are needed to confirm the optimal treatment strategy for krukenberg tumors from stomach cancer.

**4050 General Poster Session (Board #137), Sat, 8:00 AM-11:45 AM**

**Clinical impact of induction chemotherapy followed by surgery for gastric cancer with positive peritoneal cytology.** *Presenting Author: Masaki Aizawa, Niigata Cancer Center Hospital, Niigata, Niigata, Japan*

**Background:** The gastric cancer patients with peritoneal metastasis have poor survival. Nevertheless, the survival rate in patients who accompany with positive peritoneal cytology as only the evidence of distant metastasis has been superior to that in patients with overt peritoneal dissemination. In such patients, the combination of preoperative chemotherapy and surgery may enable to perform potentially R0 resection. The aim of this study was to verify the clinical significance of R0 resection following the clearance of free cancer in the peritoneal cavity. **Methods:** The retrospective study was conducted using a prospectively maintained database. A total of 53 gastric cancer patients with free cancer cells in the peritoneal cavity, as evaluated by staging laparoscopy between January 2001 and December 2010, but no other evidence of distant metastasis, which underwent induction chemotherapy (mostly S-1+cisplatin regimen) followed by surgery were identified. Then, the correlation between clinicopathological features and the prognosis was assessed by COX proportional hazards analysis. **Results:** The MST and 5-year OS rate of the 53 study participants were 19.7 months and 25.6%, respectively. In 28 patients, the peritoneal cytology converted from positive to negative after the induction chemotherapy, and microscopically margin negative gastrectomy was performed subsequently. The MST of 31.4 months and 5-year OS rate of 36.1% of these patients were significantly more favorable than the corresponding values of 12.7 months and 15.0% in the patients who failed to diminish the free cancer cell in the peritoneal cavity ($P< 0.001$). Multivariate survival analysis identified the residual tumor (HR: 3.419, 95%CI: 1.695-6.895, $p=0.001$) as well as macroscopic Type 4 tumor (HR: 2.636, 95%CI: 1.022-6.798, $p=0.04$) as an independent prognostic factor. **Conclusions:** The conversion of positive peritoneal cytology by induction chemotherapy might improve the prognosis. The results suggested an adequate impact to accept the induction chemotherapy followed by surgery with curative intent for gastric cancer patients with positive peritoneal cytology as only the evidence of metastasis.

**4051 General Poster Session (Board #138), Sat, 8:00 AM-11:45 AM**

**Safety, tolerability, and pharmacokinetics (PK) of rilotumumab (R) combined with cisplatin (C) and capecitabine (X) in Japanese patients (pts) with MET-positive metastatic gastric or gastroesophageal junction (G/GEJ) adenocarcinoma.** *Presenting Author: Toshihiko Doi, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** R is an investigational, fully human monoclonal antibody to hepatocyte growth factor, the MET receptor ligand. This study assessed the safety, PK, and tumor response of R + CX in Japanese pts with MET-positive G/GEJ cancer. **Methods:** An initial cohort evaluating dose-limiting toxicities (DLTs) is described; an expansion cohort has fully enrolled and will be reported. Eligible pts were Japanese, age ≥20 years, ECOG ≤1, and had pathologically confirmed MET-positive unresectable, locally advanced/metastatic G/GEJ adenocarcinoma. In each 21-day cycle, pts received R 15 mg/kg IV (day 1), C 80 mg/m$^2$ IV (day 1; up to 6 cycles), and X 1000 mg/m$^2$ BID orally (days 1−14). Endpoints included DLTs, adverse events (AEs), PK of R and CX, and objective response. **Results:** The initial cohort enrolled 6 pts; there was 1 DLT (grade 3 decreased appetite). All pts had treatment-emergent AEs (TEAEs). TEAEs occurring in >3 pts were decreased appetite (n=5), nausea (n=5), fatigue (n=4), and palmar-plantar erythrodysesthesia (n=4). Three pts had grade ≥3 TEAEs (diarrhea and neutropenia [n=2 each]; decreased appetite, hypoalbuminemia, hypocalcemia, hyponatremia, hypophosphatemia, leukopenia, and stomatitis [n=1 each]). Grade ≥3 treatment-related AEs (TRAEs) were diarrhea (n=2), neutropenia (n=2), decreased appetite, leukopenia, and stomatitis (n=1 each). There was 1 grade 4 TRAE (neutropenia). One pt discontinued R due to nonserious arterial thrombosis. There were no life-threatening or fatal R-related AEs. The mean end-of-infusion concentrations of R were 212, 275 and 272 μg/mL in cycles 1, 2 and 3, respectively. Exposures to CX were similar across cycles. The mean $C_{max}$ of X and its metabolite 5-FU was 6.1 and 0.3 μg/mL. The mean $C_{max}$ of total and unbound C was 3.8 and 1.4 μg/mL. The mean $t_{1/2}$was 0.5, 0.7, and 12.3 h for X, 5-FU, and unbound C. Two pts had a partial response. **Conclusions:** The toxicity profile of R + CX in Japanese pts with MET-positive G/GEJ cancer was consistent with that of Western pts. Safety and PK results support further evaluation of R + chemotherapy in MET-positive G/GEJ cancer. Clinical trial information: NCT01791374.

**4052 General Poster Session (Board #139), Sat, 8:00 AM-11:45 AM**

**Association of polymorphisms in the CCL2/CCR2 axis with clinical outcome in localized advanced gastric cancer (AGC) patients (pts) from the United States and Japan.** *Presenting Author: Yu Sunakawa, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** CCL2/CCR2 chemokine axis controls the recruitment of leukocytes to tissues during inflammation and has a number of tumor-promoting activities including the polarization of tumor associated macrophages which play immunosuppressive roles. Overexpression of CCL2 was associated with a higher risk of gastric cancer. We hypothesized that single nucleotide polymorphisms (SNPs) in genes encoding for CCL2/CCR2 axis may be associated with clinical outcome in pts with localized AGC. **Methods:** This study included 160 Japanese pts for evaluation set and 104 U.S. pts for validation set, with localized AGC treated with surgery alone or plus adjuvant therapy (stage Ib-IV; AJCC-6$^{th}$). The median age were 68 (31-88) and 59 (26-85) years-old, median follow-up were 4 and 3.3 years, respectively. Genomic DNA was extracted from pts' blood or tissues. Seven functional SNPs in genes encoding for CCL2/CCR2 axis, *CCL2* (rs4586 and rs1024611) and *CCR2* (rs743660, rs1799864, rs3138042, rs3918358, and rs3092964), were analyzed by PCR-based direct sequencing for association with disease-free survival (DFS) / time to recurrence (TTR) and overall survival (OS). **Results:** In the evaluation set, the univariate analysis showed pts with any T allele of *CCL2* rs4586 had significantly longer DFS and OS compared to those with the C/C genotype (HR: 0.61; 95% CI: 0.39-0.96; P=0.03, HR: 0.58; 95% CI: 0.36-0.93; P=0.02, log-rank test, respectively) although median DFS and OS both had not been reached yet. This remained no significant upon multivariate analysis. In the validation set, pts with any T allele of *CCL2* rs4586 had a trend toward shorter TTR (HR: 1.73; P=0.07) and significantly shorter OS compared to those with the C/C genotype (3.8 vs. 7.3 yrs; HR: 2.43; 95% CI: 1.14-5.18; P=0.01, log-rank test) in univariate analysis. Interestingly, the impact of the T allele on OS in the U.S. cohort was the opposite to that in the JPN cohort and reached statistical significance (P=0.001). **Conclusions:** Our results suggest that the CCL2 polymorphism, rs4586, may serve as a prognostic marker in pts with localized AGC and that there may be ethnic differences in immunoesurveillance impacting clinical outcome.

**4053 General Poster Session (Board #140), Sat, 8:00 AM-11:45 AM**

**A phase II study of preoperative chemotherapy and chemoradiation for localized gastric and gastroesophageal junction adenocarcinoma (LGCA).** *Presenting Author: Elena Elimova, MD Anderson Cancer Center, Houston, TX*

**Background:** For patients with LGCA, adjunctive therapies improve the 5-year survival rates by ≈10% over surgery alone. We studied preoperative oxaliplatin/5-FU-based chemotherapy followed by chemoradiation. **Methods:** Patients with LGCA with baseline eusT2-T3 any N, M0 (M stage by laparoscopy and imaging) were eligible. Patients received ≤4 doses of oxaliplatin and infusional 5-FU q 2 weeks then oxaliplatin and infusional 5-FU with 45 Gy of conformal radiation in 25 fractions. 5-6 weeks after chemoradiation, patients underwent an attempted D2 dissection and were followed. **Results:** Between Feb. 2004 and Nov. 2010 a total of 58 patients were enrolled. Most patients were men (66%) and had clinical stage IIIA cancer (52%). 14% (95%CI: 6%, 25%) of patients achieved a pathCR. With a median follow-up of 37.4 months, the median survival was 39.4 (95%CI: 27.6, NR) months. The 5-yr OS was 44% and the 5-yr PFS was 42%. 72% of patients proceeded to surgery and 86% of these had an R0 resection. The 5-yr OS for patients who had surgery was 56%. 44.8% of patients experienced grade 3 and/or 4 toxicities (commonly, fatigue, anorexia and insomnia) due to induction chemotherapy. 58.6% experienced grade 3 and/or 4 toxicities due to chemoradiation (commonly, fatigue, myelosuppression, vomiting, and dysphagia). No treatment-related death occurred. **Conclusions:** The 5-yr OS for all patients treated on this study was 44%. Our data show that if LGCA patients can complete the described therapeutic strategy (i.e., including surgery), their outcome may be excellent. Therefore, we must refine patient selection for future trials based on clinical variables and biomarkers. This will help in identifying patients who are likely to respond to pre-operative treatment versus those who are not. Biomarker studies (with mTOR, Gli-1, Sox9, ALDH-1, and Shh, etc.) are underway and will be presented. Clinical trial information: 2003-0769.

**4054 General Poster Session (Board #141), Sat, 8:00 AM-11:45 AM**

**Visceral fat content, clinical features, and prognosis in a database of 507 upper gastrointestinal cancers.** *Presenting Author: Kazuto Harada, Department of Gastroenterological Surgery, Graduate School of Medical Science, Kumamoto University, Japan, Kumamoto, Japan*

**Background:** Excess visceral adipose tissue may promote cancer development and progression through obesity-related metabolic disturbances, such as adipocytokine-related Inflammation, insulin resistance, and hypoxia. Although the relationship between visceral fat content and patient prognosis has been reported in some cancer types, the clinical, pathological and prognostic value of visceral fat volume in upper gastrointestinal cancers has yet to be investigated. We therefore examined the relationship between visceral fat status and clinical outcome in patients with the upper gastrointestinal cancers (esophageal cancer and gastric cancer) treated by surgical resection. **Methods:** Preoperative visceral fat content in 507 upper gastrointestinal cancer patients was retrospectively quantified by radiologic measures using standard computed tomography scans. The Cox proportional hazards model was used to compute mortality hazard ratio, adjusting for clinical and tumoral features. Throughout this study, the term "prognostic marker" is used in the context of the REMARK Guidelines. **Results:** Higher visceral fat content was correlated with male sex ($p = 0.0012$), presence of preoperative comorbidity ($p = 0.0009$), absence of preoperative therapy ($p < 0.0001$), low tumor stage ($p = 0.029$), low tumor depth ($p = 0.0032$) and gastric cancer ($p = 0.0053$). Subjects with low visceral fat experienced a higher overall mortality rate than their high visceral fat counterparts [log-rank p=0.0050; univariate HR= 1.73, 95% confidence interval (CI) 1.16–2.54; p=0.0075; multivariate HR 1.57; 95% CI, 1.02–2.37; p=0.031]. Interestingly, the influence of low visceral fat on patient outcome was modified by age at surgery (p for interaction = 0.036); low visceral fat was associated with a poor prognosis, especially in elderly patients (log rank p<0.0001). **Conclusions:** We identified a correlation between low visceral fat in upper gastrointestinal cancer patients and poor prognosis, suggesting that low visceral fat may provide a biomarker for identifying patients likely to experience an inferior outcome

**4055 General Poster Session (Board #142), Sat, 8:00 AM-11:45 AM**

**The survival difference between gastric cancer patients from the United Kingdom and Japan after using weighted propensity score for adjustment of differing background factors.** *Presenting Author: Takaki Yoshikawa, Department of Gastrointestinal Surgery, Kanagawa Cancer Center, Yokohama, Japan*

**Background:** Previous studies comparing survival between gastric cancer (GC) patients (pts) from the East and the West either used calibrated survival based on a Western nomogram, only considered a highly selected set of background factors in multivariate analyses or did not consider differences in background factors and prognostic factors at all . The present study aimed to first compare all available characteristics from GC pts from the UK and Japan and then compare the survival of the two cohorts after adjusting for all significantly different background factors using weighted propensity score. **Methods:** Data from 654 pts from the Kanagawa Cancer Center, Yokohama, Japan (KCCH) and 680 pts from the Leeds Teaching Hospital NHS Trust, Leeds, UK (LTHT) who had surgery for GC were analyzed. Patient characteristics, surgery, pathology, and outcome were compared. Prognostic factors for overall survival (OS) and cancer specific survival (CSS) were identified by univariate and multivariate analyses. After initial comparison of 'unadjusted' survival, survival was compared after adjusting for all significantly different background factors. **Results:** Significant differences between KCCH and LTHT pts were observed for age, gender, tumor location, type of gastrectomy, splenectomy, pancreatectomy, residual tumor (R), number of examined lymph nodes, and histological tumor type. Unadjusted stage-specific OS and CSS were significantly better in KCCH. Independent prognostic factors for unadjusted OS and CSS were age, tumor location, depth of invasion (T), nodal metastasis (N), and distant metastasis (M) in KCCH; and age, tumor location, splenectomy, T, N, M, R status and number of examined lymph nodes in LTHT. Even after adjusting for all background characteristics, survival remained better in KCCH in TNM stages I, II, and III for OS and TNM stages II and III for CSS. **Conclusions:** These results suggest that the differences in background factors between GC pts from UK and Japan cannot fully explain differences in survival. Further studies are needed to investigate whether survival differences are due to GC tumor biology and/or host specific factors.

**4056 General Poster Session (Board #143), Sat, 8:00 AM-11:45 AM**

**Pretreatment neutrophil to lymphocyte ratio as an independent predictor of disease-specific survival in resectable GE junction and gastric adenocarcinoma.** *Presenting Author: Sam C Wang, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Preoperative methods to estimate disease specific survival (DSS) for resectable gastroesophageal junction and gastric adenocarcinoma (GEJ/GA) are inadequate. The patient's inflammatory state may impact cancer outcome, as suggested by the consistent association of decreased DSS with postoperative complications or transfusions. The aim of this study was to evaluate the relationship between DSS and pretreatment neutrophil to lymphocyte ratio (NLR), which may reflect the systemic inflammatory state, following complete resection of GEJ/GA. **Methods:** Review of a prospective database identified all patients diagnosed with primary GEJ/GA who underwent complete resection from 1998-2013. Patient, tumor, treatment characteristics and pretreatment neutrophil and lymphocyte counts were recorded. Patients were stratified into quartiles based on NLR values. Five year DSS was estimated by the Kaplan-Meier method. A Cox proportional hazards model was used to evaluate the independent associations between clinicopathologic variables and DSS. **Results:** We identified 1,498 patients, with median follow-up of four years. On univariate analysis, elevated NLR was associated with increased age, male gender, Caucasian race, increased T and N stage, and neoadjuvant therapy. On multivariate analysis, decreased DSS was associated with Caucasian race (p=0.02), increased T stage (p<0.01), increased N stage (p<0.01) and neoadjuvant therapy (p<0.01). Elevated pre-treatment NLR was also independently associated with worse DSS (HR=1.09 [95%CI: 1.05-1.13], p<0.01, Table). **Conclusions:** In patients with resectable GEJ/GA, pretreatment NLR is significantly and independently associated with DSS. NLR is a simple and effective value available during treatment planning to help risk stratify patients with GEJ/GA for cancer specific outcome.

**Five-year DSS and multivariate DSS using NLR as quartiles.**

| | NLR | N | Five-year DSS | Adjusted HR* | 95% CI |
|---|---|---|---|---|---|
| **Quartile 1** | 0.23-2.00 | 389 | 70% | Ref | |
| **Quartile 2** | 2.00-2.76 | 362 | 66% | 1.1 | 0.8-1.4 |
| **Quartile 3** | 2.76-3.85 | 374 | 56% | 1.2 | 0.9-1.5 |
| **Quartile 4** | >3.85 | 372 | 50% | 1.5 | 1.1-1.9 |

*Adjusted for age, gender, race, T stage, N stage, and neoadjuvant therapy.

**4057 General Poster Session (Board #144), Sat, 8:00 AM-11:45 AM**

**REGARD: A phase 3, randomized, double-blind trial of ramucirumab (RAM) and best supportive care (BSC) versus placebo (PL) and BSC in the treatment of metastatic gastric or gastroesophageal junction (GEJ) adenocarcinoma following disease progression (PD) on first-line platinum- and/or fluoropyrimidine-containing combination therapy: Age subgroup analysis.** *Presenting Author: Charles S. Fuchs, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The REGARD trial demonstrated significant improvements in overall survival (OS), progression free survival (PFS), and disease control rates in pts receiving RAM, a human IgG1 receptor targeted antibody. We examined outcomes by age (<65 and ≥65 years [yrs]). **Methods:** Pts were randomized 2:1 to receive RAM (8 mg/kg IV) plus BSC or PL plus BSC every 2 wks until PD, unacceptable toxicity, or death. Eligible patients had PD within 4 months (m) after 1st-line therapy for metastatic disease or within 6 m after adjuvant therapy. The primary endpoint was OS. Secondary endpoints included PFS, 12-wk PFS rate, overall response rate (ORR) and safety. **Results:** 355 pts. were randomized; 227 were age <65 yrs (RAM 156; PL 71) and 128 were ≥ 65 yrs (RAM 82; PL 46).Baseline characteristics were well balanced between the treatment arms and subgroups. RAM efficacy was similar in younger and older patients. Median OS was 5.3 vs 4.1 m in the RAM:PL arms for pts <65 yrs and 5.2 vs 3.8 m in the RAM:PL arms for pts ≥65 yrs. The OS HR was 0.846 (95% CI, 0.611-1.171) in pts <65 years and 0.722 (95% CI 0.471-1.106) in pts ≥65 yrs (treatment-by-age group interaction p = 0.5569). Median PFS was 1.9 vs 1.3m in the RAM:PL arm for pts <65 yrs and 2.8 vs 1.4 m for Ram:PL for pts ≥65 yrs. The PFS HR was 0.450 (95% CI, 0.327-0.620) <65 yrs and 0.490 (95% CI, 0.319-0.752) (interaction p=0.9445). The incidence of Grade ≥3 adverse events was comparable between treatment arms for both age groups (55% vs 57% pts <65 yrs; 60% pts ≥65 yrs in both arms). The most frequent grade ≥ 3 AEs in ≥ 5% of pts RAM arm were: hypertension (7.8% RAM; 1.4% PL [<65 yrs] and 7.3% RAM; 4.4% PL [≥65 yrs]), abdominal pain (7.1% RAM; 4.3% PL [<65 yrs]), fatigue (7.3% RAM; 2.2% PL ≥ 65 yrs) and anemia (9.1% RAM; 7.1% PL [<65 yrs]. No specific AE was observed at grade ≥ 3 in > 10% of patients.**Conclusions:** When compared to placebo, RAM conferred similar improvements for OS and PFS between pts age < 65 yrs and those age ≥ 65; AE profiles were also similar for pts ≥ 65 and <65 yrs. Clinical trial information: NCT00917384.

**4058 General Poster Session (Board #145), Sat, 8:00 AM-11:45 AM**

**RAINBOW: A global, phase III, randomized, double-blind study of ramucirumab plus paclitaxel versus placebo plus paclitaxel patients with previously treated gastric or gastroesophageal junction (GEJ) adenocarcinoma: Quality-of-life (QoL) results.** *Presenting Author: Salah-Eddin Al-Batran, Krankenhaus Nordwest, Frankfurt, Germany*

**Background:** Ramucirumab (RAM) added to paclitaxel (PTX) resulted in statistically significantly improved overall survival, progression-free survival and response rate for previously treated patients (pts) with advanced gastric or GEJ cancer (Wilke et al, GI Cancer Symposium 2014). Here we present the secondary endpoint of QoL. **Methods:** Pts who had previously received fluoropyrimidine- and platinum-based therapy were randomized to receive RAM 8 mg/kg IV or placebo (PL) on Days 1 and 15 every 4 weeks (wks); both arms received PTX 80 mg/m$^2$on Days 1, 8 and 15. Pts completed the EORTC QLQ-C30 (v3) at baseline, every 6 wks from start of therapy and at discontinuation. Time to deterioration (TtD) in each QoL parameter was defined as randomization to first worsening of ≥10 points (on 100-point scale). Hazard ratios (HRs) for treatment effect were estimated using stratified Cox proportional hazards models. In addition, scores were classified as improved or worsened if changed by ≥10 points relative to baseline, otherwise classified as stable. **Results:** Of 665 pts randomized, 322/330 (98%) of RAM+PTX and 328/335 (98%) of PL+PTX pts provided baseline (BL) QoL data and 87% and 81%, respectively, provided both BL and post-BL data. BL scores were similar between arms. Of the 15 QoL parameters, 14 had HRs <1, indicating similar or longer TtD in QoL for RAM+PTX. HRs <0.75 were observed for emotional functioning and nausea/vomiting and >1 for diarrhea. For all QoL parameters and at all on-therapy assessment times, the proportion of pts reporting improved or stable scores was numerically greater for RAM+PTX; in general, more pts were classified as stable than improved. **Conclusions:** For pts with advanced gastric cancer, addition of RAM to PTX did not impair QoL. Compared with PL+PTX, QoL was maintained for a longer time and more pts reported stable or improved scores. Clinical trial information: NCT01170663.

**Patient-derived xenografts as models for the identification of predictive biomarkers in esophagogastric cancer.** *Presenting Author: Yelena Yuriy Janjigian, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Individual EG cancer subtypes have heterogeneous tumor characteristics and clinical outcome, making EG adenocarcinoma a complex disease to treat. Cytotoxic agents are applied to all disease subtypes with only modest success. Emergence of HER2 and MET as therapeutic targets underscores the importance of tumor profiling to allow optimal treatment planning. Preclinical models that recapitulate tumor biology may aid in discovery of new biomarkers and therapeutic targets. The purpose of this study is to establish PDXs accompanied by annotated molecular and clinical data for identification of predictive biomarkers and testing of targeted therapies. **Methods**: Fresh specimens obtained under aseptic conditions, mixed with matrigel and inoculated into 8 wks old NOD scid gamma mice subcutaneously (SQ) into flanks or orthotopically (OT) into the gastric wall. PDXs are kept in an *in vivo* microenvironment to retain a degree of the polyclonality of the tumors from which they were derived. Once established, tumor material is collected for molecular analysis, histology, and primary cultures. **Results**: To date 90 tumor samples have been implanted SQ, 20 of which were also implanted OT. To date, 22 PDXs have been established and 12 additional tumors (5 SQ, 7 OT) are being monitored for engraftment. Tumor engraftment rate was 46% for OT and 26% for SQ implants. The table below summarizes the results including molecular tumor characteristics. The established PDXs include HER2+ trastuzumab refractory models, MET+ models, and a signet ring gastric cancer model with germ line CDH1mutation. **Conclusions:** The established EG PDXs provide a platform to further validate differences in tumor biology and guide rational design of clinical trials. Comprehensive molecular profiling and therapeutic experiments with PDXs are underway.

**4060 General Poster Session (Board #147), Sat, 8:00 AM-11:45 AM**

**Neoadjuvant versus adjuvant treatment: Which one is better for resectable locally advanced esophageal squamous cell carcinoma?** *Presenting Author: Qixun Chen, Zhejiang Cancer Hospital, Hangzhou, China*

**Background:** In China, the main treatment of esophageal squamous cell carcinoma (ESCC) is surgery combined with postoperative adjuvant chemoradiotherapy.The role of preoperative neoadjuvant chemoradiotherapy is not well established. We compared neoadjuvant chemoradiotherapy followed by surgery with surgery followed by adjuvant chemoradiotherapy in a Chinese ESCC population. **Methods:** We randomly assigned patients with resectable locally advanced tumors (T3-4N0-1M0, T1-2N1M0) to receive surgery and weekly administration of carboplatin (AUC=2) and paclitaxel (50 mg/m$^2$) for 6 weeks and concurrent radiotherapy (50.4 Gy/28f, 5 days per week) at preoperative (the neoadjuvant group) or postoperative (the adjuvant group). **Results:** From April 2011 through December 2013, we enrolled 42 patients: 23 were randomly assigned to chemoradiotherapy followed by surgery, and 19 to surgery followed by adjuvant chemoradiotherapy. Among these 42 patients, the most common major hematologic toxic effects were leukopenia (9.5%), neutropenia (11.9%), thrombocytopenia (14.3%), and anaemia (16.6%); the most common major nonhematologic toxic effects were anorexia (14.3%), fatigue (11.9%), and cervical anastomotic fistula (19.1%). Complete resection with no tumor of the resection margins (R0) was achieved in 100% of patients in the neoadjuvant group versus 90.4% in the adjuvant group. A pathological complete response was achieved in 8 of 23 patients (34.8%) who underwent resection after chemoradiotherapy. Postoperative complications and treatment-related mortality were similar in the two groups. The disease free survival rate at 18 months was 78.7% in the neoadjuvant group as compared with 63.6% in the adjuvant group, which exceeded the goal of this study design. **Conclusions:** Our preliminary result suggests that, in patients with resectable locally advanced ESCC, there is a benefit tendency for the preoperative neoadjuvant chemoradiotherapy compared with postoperative adjuvant chemoradiotherapy. The regimen was associated with acceptable adverse-event rates. These trends warrant further study. Clinical trial information: ChiCTR-TRC-12002665.

**4061 General Poster Session (Board #148), Sat, 8:00 AM-11:45 AM**

**Metabolic landscape and prognostic value of HER2 in advanced gastric cancer.** *Presenting Author: Chan-Young Ock, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea*

**Background:** In advanced gastric cancer (AGC), HER2 is a validated therapeutic target. However, the metabolic landscape of AGC based on the HER2 status has not been reported. Furthermore, the prognostic value of HER2 in AGC is under debate. Purpose of this study is to elaborate the metabolic landscape and prognosis based on HER2 status in AGC. **Methods:** We consecutively enrolled the 615 AGC patients treated with chemotherapy and whose HER2 status was evaluated from 2004 to 2013 (225 HER2+, 390 HER2-). Among them, 248 patients were evaluated with 18F FDG-PET before chemotherapy. Among 225 HER2+ patients, 67 patients were not exposed to any HER2-targeting agents. We analyzed overall survival (OS) according to HER2 IHC, FISH (HER2/CEP17 ratio, HER2 copy number) and maxSUV (mSUV). **Results:** The mSUV of HER2+ GC was significantly higher than those of HER2- GC (11.2 vs 7.5, p=0.001). Increased HER2 IHC positivity was correlated with higher mSUV (IHC-: 7.4, IHC 1+: 6.5, 2+: 9.4, 3+: 11.2, p=0.001), and high HER2/CEP17 ratio showed the trend for higher mSUV (<2: 8.9, 2-4: 9.2, ≥4: 10.5, p=0.925). Excluding HER2+ patients who received HER2-targeting agents, OS of AGC patients treated with cytotoxic chemotherapy was not different based on HER2 status (HER2+: 12.6 vs HER2-: 12.5 months, p=0.663). In parallel, neither increased HER2 IHC positivity (IHC-: 12.4, IHC 1+: 13.4, 2+: 11.8, 3+: 12.9 months, p=0.891) nor HER2/CEP17 ratio (<2: 12.1, 2-4: 17.8, ≥4: 13.4 months, p=0.448) nor HER2 copy number (copy<4: 11.2, 4-6: 13.0, ≥6: 11.3 months, p=0.273) influenced on OS. However, based on tumor metabolism, patients with higher mSUV showed higher response rate, but worse OS regardless of HER2 positivity (HER2-: mSUV<12.5: 13.4 vs mSUV≥12.5: 8.9 months, p=0.01, HER2+: mSUV<14.3: 18.5 vs mSUV≥14.3: 6.4 months, p=0.001). **Conclusions:** Tumor metabolism is higher in HER2+ AGC and this metabolic activity influenced on the OS. However, HER2 is not prognostic factor in AGC patients who receive cytotoxic chemotherapy.

**4062 General Poster Session (Board #149), Sat, 8:00 AM-11:45 AM**

**Biomarkers to predict sensitivity to HER2-targeting treatment in HER2-positive advanced gastric cancer.** *Presenting Author: Tae Yong Kim, Department of Internal Medicine and Cancer Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea*

**Background:** Trastuzumab-based chemotherapy is considered as standard treatment for patients with HER2-positive advanced gastric cancer (AGC). However, the biomarkers to predict the sensitivity to this HER2-targeting treatment have not been clarified. We evaluated the association of sensitivity to HER2-targeting treatment with HER2 status and tumor metabolic activity in HER2-positive AGC. **Methods:** We consecutively enrolled 133 patients with HER2-positive AGC treated with trastuzumab-based chemotherapy. HER2 IHC status, HER2/CEP17 ratio, HER2 copy number and maximum standardized uptake value (maxSUV) from 18F FDG-PET were analyzed for the clinical outcomes. **Results:** Overall survival (OS) of patients with HER2 IHC 3+ was significantly longer than that of IHC 2+/FISH+ (26.9 vs 15.2 months, p=0.012). A median number of HER2/CEP17 ratio and HER2 gene copy number were 5.4 (95% CI, 1.1-14.6) and 10.2 (95% CI, 2.1-30.3), respectively. A higher HER2/CEP17 ratio more than 5.4 was identified as a good predictor to treatment sensitivity (<5.4: OS 11.9 vs ≥5.4: OS 25.7 months, p=0.040). For HER2 copy number, patients with higher HER2 copy number showed the tendency for better OS (HER2 copy number <10.2: 14.7 vs ≥10.2: 25.7 months, p=0.20). Patients with HER2/CEP17 ratio>5.4 and HER2 copy>6 showed best OS than the others (26.9 vs 11.9 months, p=0.044). Contrary to this, patients with IHC same or less than 2+ and HER2/CEP17 ratio<5.4 showed worst prognosis than the others (7.7 vs 26.9 months, p<0.001). However, there was no significant impact of maxSUV on predicting treatment sensitivity so far, even though tendency of higher response rate in high maxSUV patients. **Conclusions:** The higher HER2/CEP17 ratio and higher HER2 copy number could be biomarkers for sensitivity to HER2 targeting treatment in HER2-positive AGC. Further study on the role of tumor metabolism in this area is needed.

**4063 General Poster Session (Board #150), Sat, 8:00 AM-11:45 AM**

**Impact of age on the feasibility and efficacy of neoadjuvant chemotherapy in patients with locally advanced gastroesophageal cancer: A retrospective pooled analysis of individual patient data.** *Presenting Author: Silvia Spörl, 3rd Department of Internal Medicine (Hematology/Medical Oncology), Klinikum rechts der Isar, Technische Universität München, Munich, Germany*

**Background:** Neoadjuvant chemotherapy (neoCTx) improves the prognosis of patients (pts) with locally advanced esophagogastric adenocarcinoma (EGC), but its value is unknown in elderly patients (pts). **Methods:** Pts from 4 institutions who received neoCTx followed by surgery for EGC between 2000 and 2012 were analyzed. We compared the feasibility and outcome of neoCTx in pts aged ≥70 (cohort I) and their younger counterparts (cohort II). **Results:** Data were available for 460 pts among which 173 (37.6%) were ≥70 years. The median age in cohort 1 and 2 was 59 and 73 years, respectively. Older age was associated with an increased rate of comorbidities (66.0% vs. 42.1%, p<0,001). As compared to the younger, elderly pts were more likely to receive doublet instead of triplet neoCTx (64% vs 38%, p<0.001) and oxaliplatin- instead of cisplatin-based regimens (60% vs 32%, p<0.001). Of the 460 pts who started neoCTx, 83% and 90% in cohort I and II completed neoCTx without major alterations. Dose reductions to < 80% were necessary in 27% and 20% in cohort I and II (p=0.129). No significant difference was observed in the rate of ≥ grade 3 toxicities for cohort I and II (47% vs. 41%) and postoperative morbidity was also not different (24% vs. 28%). 60 day mortality for cohort I and II was 1.8% and 3.5%. After a median follow up of 30.4 months, median DFS in cohort I and II was 30 and 31 months, with a 3-years DFS of 48% and 46%, respectively. Median OS was 78 and 81 months, with a 3-year OS of 69% and 65%, respectively. On multivariate analysis, age was not significantly correlated with overall survival after adjustment for the rate of co-morbidities, gender and the number of neoCTx drugs applied (HR for age: 0.947; p=0.80). **Conclusions:** Despite slightly more adverse events and dose reductions, neoCTx is feasible in elderly pts with EGC. Elderly pts achieve comparable survival outcomes compared with their younger counterparts.

**4064 General Poster Session (Board #151), Sat, 8:00 AM-11:45 AM**

**Randomized phase II study of CPT-11 versus PTX versus each combination chemotherapy with S-1 in patients with advanced gastric cancer refractory to S-1 or S-1 plus CDDP.** *Presenting Author: Tomono Kawase, Department of Surgery, Sakai City Hospital, Sakai, Japan*

**Background:** S-1 plus cisplatin (SP) is recognized as standard first-line chemotherapy for advanced gastric cancer (AGC) and S-1 monotherapy is recognized as standard adjuvant chemotherapy for locally AGC in Japan. Taxane and CPT-11 are two main options and a retrospective analysis has reported that S-1 combination chemotherapy extended overall survival (OS) as second-line chemotherapy for AGC refractory to S1-based chemotherapy. Thus, this prospective multicenter phase II study was carried out to examine efficacy and safety comparing CPT-11, PTX, and each combination chemotherapy with S-1 refractory to S-1 or SP. **Methods:** Patients with AGC after first-line chemotherapy with S-1 or SP, or during adjuvant chemotherapy or within 26 weeks after adjuvant chemotherapy completion with S-1 who confirmed disease progression by imaging were eligible. Patients were randomly divided into four groups by treatment as follows; Group A: CPT-11 150 mg/m$^2$, day1, q14days, Group B: PTX 80 mg/m$^2$, day1, 8, 15, q28days, Group C1: CPT-11 80 mg/m$^2$, day1, 15, S-1 80 mg/m$^2$, day1-21, q35days, Group C2: PTX 50 mg/m$^2$, day1, 8, S-1 80 mg/m$^2$, day1-14, q21days. Primary endpoint was OS, and secondary endpoints were progression free survival (PFS), response rate and safety. **Results:** From July 2008 to March 2012, 127 patients were enrolled. Median OS was 11.3/11.3/14.6/10.5 months(M) (Group A/B/C1/C2), 11.8 M in Group A+C1 and 11.1 M in Group B+C2 (p=0.922, HR: 0.981 [0.679-1.419]), and 11.3 M in Group A+B and 11.1 M in Group C1+C2 (p=0.808, HR: 0.952 [0.643-1.412]), respectively. Median PFS was 3.0/4.4/3.8/3.5 M (Group A/B/C1/C2), 3.6 M in Group A+C1 and 4.1 M in Group B+C2 (p=0.035, HR:0.674 [0.468-0.972]), and 3.7 M in Group A+B and 3.7 M in Group C1+C2 (p=0.931, HR: 1.017 [0.643-1.412]) , respectively. Grade 3 or 4 adverse events (Group A/B/C1/C2, %) were leukopenia (12/7/5/0), neutropenia (29/16/24/24), anemia (7/9/14/14), anorexia (10/2/14/10), nausea (7/2/10/5), diarrhea (5/0/10/0), and fatigue (5/2/10/5). **Conclusions:** The difference in OS between CPT-11 and PTX, and the efficacy of S-1 sequential therapy were not observed in second-line chemotherapy for AGC refractory to S-1 or SP. Clinical trial information: 000000677.

**4065 General Poster Session (Board #152), Sat, 8:00 AM-11:45 AM**

**The relationship between HER2 expression and Lauren classification in Chinese gastric cancer patients.** *Presenting Author: Rui-hua Xu, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

**Background:** Intestinal type of gastric cancer has a better prognosis than diffuse type and intestinal type tends to have a higher incidence rate of HER2 positive. However the prognosis value of HER2 is still controversial. There might be some factors affecting the HER2's survival value. What is the relationship between HER2 expression and Lauren classification? We would also analyze the survival differences among the gastric cancer patients with different HER2 and Lauren classification status. **Methods:** All the patients received the detection of human epidermal growth factor receptor 2 (HER2) by immunohistochemistry (IHC). HER2 amplification levels were detected when the result of IHC was 2+. Fluorescence in situ hybridization (FISH) analysis was carried out according to the manufacturer's protocol using the PathVysion HER2 DNA Probe kit (LSI HER2/neu Spectrum OrangeTM/ chromosome 7 centromere probe (CEP) 17 Spectrum GreenTM). FISH positive was defined as HER2:CEP17 ratio ≥2. Any case with IHC 3+ or IHC2+/FISH+ was considered to be HER2-positive, while the cases with IHC 0 and IHC 1+ as well as IHC 2+/FISH− were considered to be HER2-negative according to the European Medicines Agency. Two pathologists were responsible for the Lauren classification. There were totally 840 patients for analysis. Survival was defined as the time from metastasis to the time of death. **Results:** The positive rate of HER2 is 11.2% (94/840). As for the Lauren classifications, there are 51.8% (435/840) diffuse type, 33.0% (277/840) intestinal type and 15.2% (128/840) mixed type. The HER2 positive rate was 25.6%, 2.8% and 8.6% in intestinal type, diffuse type and mixed type, respectively (P<0.001). We ignored the mixed type and divided the rest patients into four groups: A, HER2 positive and diffuse type; B, HER2 positive and intestinal type; C, HER2 negative and diffuse type; D, HER2 negative and intestinal type. The median overall survival was 7.9months, 10.2 months, 10.8 months and 13.7 months, P=0.001. **Conclusions:** Intestinal cancer has a higher incidence rate of HER2 positive. Patients with HER2 negative and intestinal type have a best survival, while patients with HER2 positive and diffuse type have a worst survival.

**4066 General Poster Session (Board #153), Sat, 8:00 AM-11:45 AM**

**Simvastatin plus capecitabine-cisplatin (XP) versus placebo plus capecitabine-cisplatin (XP) in patients with previously untreated advanced gastric cancer: A double-blind randomized phase 3 study.** *Presenting Author: Seung Kim, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea*

**Background:** Patients with advanced gastric cancer (AGC) have a poor prognosis and few efficacious systemic treatment options. We aimed to the addition of synthetic 3-hydroxy-3-methyglutaryl coenzyme A (HMG-CoA) reductase inhibitor, simvastin to capecitabine-cisplatin (XP) in patients with previously untreated advanced gastric cancer. **Methods:** In this double-blind, placebo-controlled, phase III study, we enrolled patients aged 18 years or older with histological or cytological confirmed metastatic (M1) adenocarcinoma of stomach or gastroesophageal junction at 9 centres in the KOREA. Patients, stratified by disease measurability and participating site, were randomly assigned (1:1) to receive capecitabine 1,000mg/m2 twice daily for 14 days and cisplatin 80 mg/m2 on day 1 every 3 weeks plus either simvastatin 40 mg or placebo, once daily. Cisplatin was given for 8 cycles; capecitabine and simvastatin were administered until disease progression or unacceptable toxicities. The primary end point was progression free survival (PFS). We assessed safety in all patients who received at least one dose of study drugs. This study is registered with ClinicalTrials-.gov, number NCT01099085. **Results:** Between February 2009 and November 2012, 244 patients were enrolled and assigned to treatment groups (120 simvastatin, 124 placebo). Median PFS for 120 patients allocated XP plus simvastatin was 5.2 months (95% CI 4.3-6.1) compared with 4.63 months (95% CI 3.5 -5.7) for 124 patients who were to allocated to XP plus placebo (hazard ratio 0.930, 95% CI 0.684-1.264; p=0.642). 63 (52.5%) of 120 patients in simvastatin group and 70 (56.4%) of 124 had grade 3 or higher adverse events. Most common grade 3 or higher adverse events were neutropenia (40.5%, simvastatin plus XP; 51% placebo plus XP), anemia (13.3% v 10.5%) and anorexia (7.5% v 10.5%). **Conclusions:** Addition of 40 mg simvastatin to XP does not increase PFS in our trial, although it does not increase toxicity. Low dose of simvastatin (40mg) to chemotherapy is not recommended in untargeted population with advance gastric cancer. Clinical trial information: NCT01099085.

**4067 General Poster Session (Board #154), Sat, 8:00 AM-11:45 AM**

**Quality of life (QoL) analysis from the randomized phase III REAL3 trial of epirubicin, oxaliplatin, and capecitabine (EOC) with or without panitumumab (P) in advanced esophagogastric adenocarcinoma.** *Presenting Author: Tom Samuel Waddell, The Royal Marsden NHS Foundation Trust, London and Surrey, United Kingdom*

**Background:** REAL3 evaluated EOC + P in advanced oesophago-gastric adenocarcinoma. We previously reported that addition of P was associated with increased diarrhoea, skin rash and mucositis without improvement in survival endpoints. This analysis reports QoL outcomes for participants in both arms of the trial. **Methods:** QoL was assessed via EORTC QLQ-C30 questionnaires requested at baseline (BA), post-cycles 4 (C4) and 8 (C8), and at 3 months follow-up (3M). Functional and symptomatic scores were calculated using recommended EORTC methods. Comparison of differences between study arms was performed using one sample t-test with 2-sided p-values and repeated measures analysis investigated scores over time. A threshold of 0.05 indicated statistical significance. Data in both arms was censored at time of early trial closure (Oct 2011) when all patients crossed to EOC. **Results:** 553 patients were recruited between June 2008 and October 2011. Excluding duplicates and those censored, the questionnaire response rate at each timepoint was: BA 470/553 (85%); C4 163/418 (39%); C8 72/196 (37%); 3M 35/64 (55%) with similar response rate in both arms. Irrespective of treatment allocation there was a non-significant decrease in global health score during chemotherapy which recovered by 3M. A similar trend was observed for physical, role and social function scales with no difference between arms. Cognitive function scores showed more marked deterioration in patients receiving EOC+P with mean decrease of 15 points between BA and 3M, compared to no change in patients receiving EOC (p=0.026). Chemotherapy was associated with a trend towards improved nausea and vomiting, appetite, and pain scores in both arms. Conversely it worsened scores related to fatigue, dyspnoea and diarrhoea. Diarrhoea was increased by addition of P (p=0.007) with no other significant differences in symptom scores between arms. **Conclusions:** Chemotherapy did not have a detrimental effect on global QoL and seemed to improve some disease-related symptoms. Increased scores related to diarrhoea with addition of P are in keeping with the known toxicity profile. Clinical trial information: 2007-005976-15.

**4068 General Poster Session (Board #155), Sat, 8:00 AM-11:45 AM**

**MAGIC germline polymorphism analysis.** *Presenting Author: Elizabeth Catherine Smyth, The Royal Marsden NHS Foundation Trust, London & Surrey, United Kingdom*

**Background:** Germline polymorphisms may affect chemotherapy efficacy and survival. We examined the effect of polymorphisms in drug metabolism and DNA repair genes on survival for patients (pts) randomised to surgery alone or perioperative ECF chemotherapy in the MRC MAGIC trial. **Methods:** DNA was extracted from nontumor resection FFPE blocks. ERCC1, ERCC2, XRCC1, DYPD, and OPRT SNPs were evaluated using Sequenom, GSTP1, GSTT1 deletion and TS 5' 2R/3R using multiplex PCR. Post PCR amplification TS 2R/3R and GSTT1 samples underwent gel electrophoresis. **Results:** Results are available on 289/456 resected pts. Duplicate pair concordance with Sequenom was excellent (98%). Discrepancy was significant for duplicate pairs analysed for 5' TS 2R/3R and GSTT1 length based polymorphisms; these were not analysed further. For genotype frequency and survival see Table. There was no evidence of an interaction between any genotype and treatment. **Conclusions:** No polymorphism examined was predictive of survival in MAGIC. SNP analyses from FFPE are reproducible but due to DNA fragmentation length based polymorphisms may not be; results from such studies should be interpreted with caution.

**4069 General Poster Session (Board #156), Sat, 8:00 AM-11:45 AM**

**Randomized, multicenter, phase III trial to compare S-1 plus docetaxel (DS) with S-1 plus cisplatin (SP) in gastric cancer patients with stage III (POST trial).** *Presenting Author: Choong-kun Lee, Division of Medical Oncology, Yonsei University College of Medicine, Seoul, South Korea*

**Background**: Even among completely resected gastric cancer patients treated with adjuvant chemotherapy, stage III patients show bad prognosis and somewhat better treatment option is needed. Docetaxel or cisplatin each added to S1 monotherapy showed survival benefits in advanced gastric cancer. **Methods**: We conducted randomized, multicenter, phase III trial to compare S-1 plus docetaxel (DS) with S1 plus cisplatin (SP) in stage III gastric cancer patients. Gastric cancer patients (AJCC 7$^{th}$ stage III) who had had curative D2 gastrectomy were randomized 1:1 to receive adjuvant chemotherapy of eight 3 week cycles of DS (S-1 70mg/m$^2$/day on day 1-14 plus docetaxel 35mg/m$^2$ on day 1, and day 8) or SP (S-1 70mg/m$^2$/day on day 1-14 plus cisplatin 60mg/m$^2$on day 1). The primary endpoint was 3-year disease-free survival (3Y-DFS). Secondary endpoints include overall survival (OS) and safety. (NCT01283217) **Results**: As a result of early closure due to slow accrual, 153 patients of planned 290 patients were randomly assigned (75 patients to DS and 78 patients to SP) from 8 institutions for 31 months. The median follow up duration was 15.8 months (range, 0.8 to 36.2 months). There was no difference in DFS (HR, 1.088; 95% CI, 0.589 to 2.01; p=0.787) or OS (HR, 1.621; 95% CI, 0.707 to 3.720; p=0.254) between DS and SP. Most common grade 3 or 4 adverse event was neutropenia (42.7% among DS group and 38.5% among SP group, p=0.351). SP group suffered more grade 3 or 4 anemia (1.3% vs. 11.5%, p=0.037), where grade 3 or 4 hand-foot syndrome (4.1% vs. 0%, p=0.025) and mucositis (10.7% vs. 2.6%, p=0.001) were more common among DS group. **Conclusions**: Although the trial closed prematurely and had short follow up duration, S-1 plus cisplatin or docetaxel is an effective and tolerable option for patients with stage III advanced gastric cancer patients. Clinical trial information: NCT01283217.

**4070 General Poster Session (Board #157), Sat, 8:00 AM-11:45 AM**

**Nimotuzumab plus paclitaxel and cisplatin as first-line treatment for esophageal squamous cell cancer: Final results of a single-center prospective clinical trial.** *Presenting Author: Ming Lu, Peking University School of Oncology, Beijing Cancer Hospital & Institute, Beijing, China*

**Background:** Nimotuzumab (N) was a humanized anti-EGFR monoclonal antibody. We conducted a prospective, single-armed, open label phase II study to evaluate the efficacy and safety of paclitaxel (T)/cisplatin (C)/ Nimotuzumab (N) as first-line treatment in advanced ESCC. **Methods:** Patients with pathologic confirmed unresectable local-regional advanced or metastatic ESCC were treated with the TPN regimen: Nimotuzumab 200mg weekly, Paclitaxel 175mg/m2 on d1, and Cisplatin 30mg/m2 on day1 and 2, repeat cycle every 3 weeks for six cycles. Local-regional advanced disease was defined as tumor lesion limited in 1 radiation field without organ metastasis. Metastatic disease was defined as organ (liver, lung et al) metastasis or lymph nodes metastasis exceeding 1 radiation field. Radiotherapy was allowed to be admitted after 4 cycle of TPN treatment.The primary endpoint is the objective response rate (ORR) and the safety. The secondary endpoint is the progression free survival (PFS) and the overall survival (OS). **Results:** 59 pts were enrolled from 2011 to 2013 and 56 were eligible. 29 pts were local-regional advanced disease and 27 pts were metastatic disease. Overall RR was 51.8%(29/56) and DCR was 92.9%(52/56). As a median follow-up of 24 months, 33 pts had progressed, of which 22 pts were metastatic disease. The median PFS for patients with metastatic disease and local-regional advanced disease were 8.2 months (95% CI 5.3 to 11.2 months) and more than 23 months (95% CI: 9.0 to 37.1).The overall survival for patients with metastatic disease was 13.9 months (95% CI: 6.8 to 21.2). The most common G3/4 toxicities were Neutropenia (58.9%), Leukopenia(32.1%), Nausea/Vomiting (7.1%), Anorexia (5%). Febrile neutropenia was reported in 3.6% of patients. No chemotherapy related death occurred. **Conclusions:** The TPN regimen, as first-line chemotherapy, was a more active treatment option in patients with advanced ESCC compared to other regimens published in previous studies. The addition of anti-EGFR treatment of nimotuzumab to standard chemotherapy was well tolerated with no serious AEs. Clinical trial information: NCT01336049.

**4071 General Poster Session (Board #158), Sat, 8:00 AM-11:45 AM**

**Preoperative chemoradiation versus preoperative chemotherapy alone for esophageal cancer: Higher response rates but equivalent survival.** *Presenting Author: Brendon Matthew Stiles, Weill Cornell Medical College, New York, NY*

**Background:** Controversy exists over the optimal neoadjuvant therapy in patients with locally advanced esophageal cancer (EC). While most groups favor neoadjuvant chemoradiation (nCRT), some advocate preoperative chemotherapy (nCT) without radiation. The objective of this study was to compare outcomes in EC patients undergoing either regimen, followed by surgery. **Methods:** We reviewed a prospectively collected database of EC patients undergoing esophagectomy following nCT or nCRT (1989-2013). Choice of therapy was at the discretion of the multidisciplinary team. Demographic data, clinical and pathologic staging, and survival (KM) were compared. **Results:** From 600 patients, 261 patients were identified with EC treated with nCRT (n=63) or nCT (n=199) followed by surgery. Patients were well matched for age, gender, PS, histology, and clinical stage. Following therapy, more nCRT patients had a complete clinical response (36% vs. 14%, p<0.001) by post-induction endoscopy and CT/PET. At surgery, 88% and 92% of CRT and CT patients underwent transthoracic esophagectomy. nCRT, in comparison to nCT, was associated with similar rates of cardiovascular (23% vs. 28%, p=0.43), pulmonary (24% vs. 25%, p=0.95), and infectious (13% vs. 9%, p=0.38) postoperative complications, and higher anastomotic leaks (23% vs. 14%, p=0.09). Perioperative (6% vs. 2%, p=0.06) and 90-day (11% vs. 4%, p=0.03) mortality was higher in nCRT than nCT patients. Following nCRT, 30% of patients had complete pathologic response vs. 6% of nCT patients (p<0.01). nCRT patients were more often node negative on final pathology (62% vs. 33%, p<0.001). Despite improved pathologic downstaging, nCRT patients had no improvement in 3-year disease-free (33% vs. 39%, p=0.84) or overall (54% vs. 52%, p=0.36) survival. No benefit of nCRT vs. nCT was apparent in 3-year overall survival in either adenocarcinoma (52% vs. 47%, p=0.25) or squamous cell carcinoma (44% vs. 61%, p=0.51). **Conclusions:** For patients undergoing surgery for EC, nCRT leads to increased local tumor response compared to nCT alone. However, nCRT is associated with increased early mortality and did not translate to improved long-term survival.

**4072^ General Poster Session (Board #159), Sat, 8:00 AM-11:45 AM**

**Concordance study of *HER2* fluorescence in situ hybridization (FISH) assays in upper gastrointestinal (UGI) adenocarcinomas.** *Presenting Author: Michael F. Press, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** Patient inclusion to the primary efficacy population of TRIO-013/LOGiC trial of lapatinib in combination with chemotherapy in advanced HER2-positive UGI adenocarcinomas required evidence of *HER2* gene amplification confirmed by central lab. As no HER2 tests were approved for use in UGI cancers at trial start, the HER2 FISH assay used in the 2 trial central labs was PathVysion. A study was conducted in a cohort of UGI adenocarcinomas to determine concordance of PathVysion HER2 FISH assay between the 2 central labs and concordance between PathVysion HER2 FISH and HER2 IQFISH pharmDx, an assay recently approved in UGI adenocarcinomas. **Methods:** 488 UGI adenocarcinoma cases, procured as formalin-fixed, paraffin-embedded blocks, were screened by HercepTest to ensure representation of 4 immunochemistry (IHC) staining intensities. All IHC3+ and 2+cases were included; IHC1+ and 0 cases were binned by primary tumor (gastric, gastro-esophageal junction [GEJ] and esophageal) then randomly selected. Selected cases were sent to 2 trial central labs for HER2 FISH testing, blinded to the IHC results. Overall acceptance criteria were predefined as positive percent agreement (PPA) and N (negative) PA of at least 90%. **Results:** 159 cases were selected: 31 IHC3+; 20 IHC2+; 55 IHC1+; 53 IHC0. Of the 159 cases, 105 were gastric, 35 GEJ and 19 esophageal adenocarcinomas. All 159 cases were tested by 1 central lab using both assays; the PPA (95% Confidence Interval [CI]) and NPA (95% CI) were 97.9% (89.1, 99.6) and 99.1% (94.8, 99.8), respectively. Preliminary analysis in 126 cases tested by both central labs resulted in PPA of 95.6% (85.2, 98.8) and NPA of 94.5% (86.7, 97.8). Majority of IHC1+/0 cases were *HER2* non-amplified by both assays (89%) and in both central labs (89% versus 93%). Of the 31 IHC3+ cases, 2 were considered *HER2* non-amplified; both exhibited heterogeneity in HER2 IHC staining: 1 case was *HER2* non-amplified by 1 central lab for both assays, yet amplified by the other central lab; other case was *HER2* non-amplified by PharmDx assay only. **Conclusions:** There was reasonably high level of concordance within laboratory for different *HER2* FISH assays as well as between labs for the same *HER2* FISH assay. Clinical trial information: NCT00680901.

**4073^ General Poster Session (Board #160), Sat, 8:00 AM-11:45 AM**

**HER-FLOT: Trastuzumab in combination with FLOT as perioperative treatment for patients with HER2-positive locally advanced esophagogastric adenocarcinoma: A phase II trial of the AIO Gastric Cancer Study Group.** *Presenting Author: Ralf Hofheinz, University Hospital Mannheim, Mannheim, Germany*

**Background:** Perioperative chemotherapy is a mainstay in the treatment of locally advanced esophagogastric adenocarcinomas (EGA). Trastuzumab improved survival when added to chemotherapy in pts with HER-2-positive metastatic EGA. We investigated the combination of trastuzumab and FLOT as perioperative treatment in pts with locally advanced EGA. **Methods:** A multicenter phase II study evaluated the efficacy & toxicity of perioperative HER-FLOT (24-h 5-FU 2,600 mg/m$^2$, leucovorin 200mg/m$^2$, oxaliplatin 85mg/mg$^2$, docetaxel 50 mg/m$^2$, trastuzumab 6mg/kg then 4 mg/kg d1, repeated d15 for four cycles pre- and postoperatively followed by 9 cycles of trastuzumab monotherapy 6mg/kg 3-weekly) in pts with HER-2 positive EGA (IHC 3+ or IHC 2+/ ISH+). Pts had to have ≥cT2, any N, M0 EGA. The primary endpoint was the rate of centrally tested pathological complete remissions (pCR). Secondary endpoints comprised disease-free and overall survival, R0 resection rate, toxicity and surgical morbidity. Here we report data of an interim safety analysis conducted in the first n=25 pts as well as surgical and pathological results of the first n=45 pts. **Results:** n=58 pts with a median age of 62 years were included. n=40 pts had tumors originating from the esophagogastric junction. T stage was: (cT2/3/4/unk) 4/44/9/1. n= 52 pts had cN+ disease. The interim safety analysis of four cycles of preoperative HER-FLOT revealed no unexpected safety findings (adverse events grade 3-4: neutropenia 28%, diarrhea 8%, nausea 8%). Thus far, data on surgery and central pathology of 45 patients are evaluable. R0 resection rate was 93.3%. In five pts anastomotic leakage was diagnosed, and five pts came in need of operative revision. One postoperative death occurred. Regarding the primary endpoint, pCR was found in 10 /45 pts (22.2%) and a further n=11 pts (24.4%) had near complete regression (<10 % residual tumor cells). **Conclusions:** HER-FLOT was found to be safe and no new or unexpected safety issues were noticed. Preliminary data on centrally assessed pCR rate is very promising with >20% achieving a pCR. Final analysis will be presented at the meeting. Clinical trial information: NCT01472029.

**4074 General Poster Session (Board #161), Sat, 8:00 AM-11:45 AM**

**A Bayesian multiple-treatments meta-analysis of neoadjuvant treatments for locally advanced, resectable esophageal cancer.** *Presenting Author: Kelvin K. Chan, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

**Background:** While many studies have compared the different neoadjuvant treatments in patients with locally advanced, resectable esophageal cancer, the relative benefit and risk across these treatments remain unclear. **Methods:** A systematic review was conducted using MEDLINE, EMBASE and Cochrane Central of Registered Trials to identify randomized controlled trials (RCTs) up to June 2013 investigating the following regimens in esophageal cancer patients: resection alone, neoadjuvant chemotherapy (N-CT), neoadjuvant radiotherapy (N-RT) and neoadjuvant chemoradiotherapy (N-CRT). Two reviewers independently reviewed the studies and discrepancies were resolved either by discussion or by a third reviewer. Data including characteristics of studies and outcomes such as overall survival (OS), postoperative mortality, site of recurrence and quality of the studies were extracted. Parmar method was used to extract survival outcomes. A Bayesian multiple treatments meta-analysis (MTM) with random effect was constructed using WinBUGS to compare the relative efficacy and postoperative mortality of all neoadjuvant treatments simultaneously. **Results:** Thirty-three RCTs involving 6710 patients were identified. For the comparison between N-CRT vs. N-CT, 2 RCTs involving 194 patients were identified. Direct pairwise meta-analysis showed that there is a trend that N-CRT might result in better OS when compared to N-CT but not reaching statistical significance (HR: 0.83 95% CI (0.59-1.18)). When combining both direct and indirect evidence in MTM to improve precision, N-CRT was found to be statistically superior to N-CT for OS (HR: 0.84 95% credible regions (CR) (0.71-0.97)). In addition, there was no direct RCT comparing N-CRT to N-RT identified. The results of MTM showed that N-CRT was better than N-RT for OS (HR: 0.80 95% CR (0.67 – 0.97)). Probabilistically, N-CRT has a 98% chance of being the best treatment. There were no significant differences in the risk for postoperative mortality. **Conclusions:** This study provides additional evidence that N-CRT is the optimal neoadjuvant therapy with respect to OS without increasing postoperative mortality when compared with N-CT or N-RT.

**4075 General Poster Session (Board #162), Sat, 8:00 AM-11:45 AM**

**Outcomes of asymptomatic metastatic gastric cancer (MGC) patients when the initiation of systemic therapy is delayed.** *Presenting Author: Roopma Wadhwa, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Despite many investigations, the median survival of MGC patients remains well below 12 months. The purpose of this analysis was to assess if the onset (instant or delayed) of systemic chemotherapy affected patient survival. **Methods:** We retrospectively compared the outcome of MGC patients who received first line systemic treatment based on symptoms (symptomatic versus asymptomatic) and treatment timing (instant or delayed). The OS was calculated from time of initiation of chemotherapy. **Results:** 125 patients with MGC were analyzed. Patients were mostly men (65%) with good PS (0-1) but most (70%) were symptomatic. In all asymptomatic patients, the median time to start of chemotherapy was 7 weeks (95% CI: 5, 10). More treated asymptomatic patients were alive at 1 year (71%) post-therapy compared to symptomatic patients (45%; p=0.03). Patients were also grouped based on treatment delay of >4 weeks or no delay. Patients with >4-week delay were more likely to be alive 1 year after treatment (61%) compared to those treated within ≤4 weeks (34%; p =0.01). Asymptomatic patients in whom chemotherapy was delayed >4 weeks had 78% 1-year survival after treatment versus 53% in patients who started treatment ≤4 weeks but this was not significant (p=0.06). **Conclusions:** Acknowledging that asymptomatic MGC patients are likely to have a lower tumor burden than those with symptoms, our data suggest that we need not rush to initiate systemic treatment in asymptomatic MGC patients, thus allowing them time without chemotherapy toxicities. Frequent patient evaluations (q 8-10 weeks) are routine.

**4076 General Poster Session (Board #163), Sat, 8:00 AM-11:45 AM**

**RAINBOW: A global, phase 3, randomized, double-blind study of ramucirumab plus paclitaxel versus placebo plus paclitaxel in the treatment of metastatic gastric adenocarcinoma following disease progression on first-line platinum- and fluoropyrimidine-containing combination therapy: Results of a multiple Cox regression analysis adjusting for prognostic factors.** *Presenting Author: Hansjochen Wilke, Kliniken Essen Mitte Center of Pallative Care, Essen, Germany*

**Background:** RAINBOW, a global, randomized, double-blind, phase 3 trial demonstrated significant improvements in overall survival (OS), progression-free survival (PFS), and response rate in metastatic gastric adenocarcinoma patients receiving ramucirumab (RAM), a human IgG1 VEGF2-receptor targeted antibody, plus paclitaxel (PTX) after prior chemotherapy. **Methods:** 665 pts were randomized 1:1 to receive RAM (8 mg/kg IV q2w) or placebo (PL) plus PTX (80 mg/m$^2$d1, 8, 15 of a 4 week cycle) until disease progression, unacceptable toxicity, or death. Primary analysis was a log-rank test stratified by geographic region, time to progression on first-line therapy and disease measurability. A prespecified stepwise Cox multiple regression analysis selected baseline covariates that were significantly associated with OS and PFS using the pooled (RAM+PTX;PL+PTX) data, and then adjusted for these potential prognostic factors in a Cox proportional hazards model that included a term for treatment arm. **Results:** The primary stratified analysis showed a statistically significant benefit in OS (stratified HR=0.807, 95% CI 0.678, 0.962; p=0.0169) and PFS (stratified HR=0.635, 95% CI 0.536, 0.752; p<0.0001) for the RAM+PTX arm. Factors significantly associated with OS were geographical region, ECOG PS, weight loss, number of metastatic sites, presence of ascites, tumor differentiation, and prior gastrectomy; for PFS liver metastasis, number of metastatic sites, sex, and weight loss. The HR for both OS and PFS improved after adjusting for these factors (OS HR= 0.745, 95% CI: 0.626, 0.888; p=0.0010; PFS HR=0.599, 95% CI 0.506, 0.708; p <0.0001). **Conclusions:** The study showed statistically significant and clinically meaningful benefit in OS and PFS for RAM+PTX as compared to PL+PTX. After adjusting for prognostic factors in the Cox regression analyses, the benefits seen in both OS and PFS improved, confirming the robustness of the primary analysis results. Clinical trial information: NCT01170663.

**4077 General Poster Session (Board #164), Sat, 8:00 AM-11:45 AM**

**Association of adjuvant chemotherapy with improved survival after esophagectomy without induction therapy for node-positive adenocarinoma.** *Presenting Author: Paul J Speicher, Duke University Medical Center, Durham, NC*

**Background**: Adjuvant therapy is recommended when patients undergo esophagectomy without induction therapy for node-positive (pN+) adenocarcinoma, but some patients may not receive adjuvant treatment due to complications related to surgery (CRS). This study investigated adjuvant chemotherapy (AC) use in this clinical setting using the National Cancer Database (NCDB). **Methods**: In the NCDB, 2,442 patients from 2003-2011 who underwent R0 esophagectomy without induction therapy for pN+ adenocarcinoma of the middle or lower esophagus and survived at least 30 days were reviewed. Predictors of AC were identified with multivariable logistic regression. The impact of AC on survival was estimated using Kaplan-Meier and Cox proportional hazards methods. **Results**: AC was given to 874 of 2,442 (35.8%) patients; 618 (70.7%) AC patients received radiation. Older age (AOR 0.58/decade, p<.001), longer travel distance (AOR 0.78/100 miles, p=.03) and CRS (AOR 0.45, p<.001) predicted that AC was not used. Patients given AC had better 5-year survival than patients not given AC (24.2% vs 14.3%, p<.001), and AC use predicted improved survival in multivariate analysis (HR 0.67, p=0.008, Table). Receiving radiation in addition to AC did not improve survival (p=0.3). Although CRS was associated with worse survival, patients who had CRS but received AC had superior survival compared to patients who did not have CRS or get AC (p=.016). **Conclusions**: AC is associated with significantly improved survival but used in a minority of patients treated with esophagectomy without induction therapy for pN+ esophageal adenocarinoma. CRS lower the chance of getting AC and predict worse long-term survival, but even patients with CRS had improved survival when given AC.

**Predictors of long-term mortality.**

| Predictor | HR | Upper 95% CI | Lower 95% CI | P |
|---|---|---|---|---|
| **Adjuvant chemotherapy** | 0.67 | 0.49 | 0.9 | 0.008 |
| **Age (per decade)** | 1.1 | 0.97 | 1.2 | 0.13 |

**4078 General Poster Session (Board #165), Sat, 8:00 AM-11:45 AM**

**Chemoradiation with or without nimotuzumab in locally advanced esophageal cancer (LAEC): A randomized phase II study (NICE trial).** *Presenting Author: Gilberto Castro, Instituto do Cancer do Estado de Sao Paulo, São Paulo, Brazil*

**Background:** Chemoradiation is the standard therapy for patients (pts) with inoperable LAEC. We sought to assess the safety and activity of chemoradiation combined with nimotuzumab, a humanized antibody against the epidermal growth factor receptor, in LAEC. **Methods:** We randomized pts with inoperable LAEC, previously untreated, and with no distant metastases 1:1 to chemoradiation (cisplatin 75 mg/m$^2$ D1, and 5-FU 1 g/m$^2$/d CI D1-4, both for four 28-day cycles, combined with external-beam radiation 50.4 Gy) or the same chemoradiation plus nimotuzumab 200 mg IV, once weekly for 26 wks. The primary endpoint was endoscopic complete response (eCR, defined as absence of elevated, vegetative or exophytic lesions), whereas combined eCR/pathologic CR (pCR), overall survival (OS), quality of life and safety were secondary endpoints. **Results:** We enrolled 107 pts, 82% male, mean age 59 y. 100 pts (93%) had squamous cell carcinoma (SCC); performance status (ECOG-PS) was 0/1 in 34%/60% of cases. The relative dose intensity of chemotherapy and radiotherapy was nearly identical in both arms, and the median number of nimotuzumab doses was 24. We performed post-treatment endoscopy in 67 pts, in 60 of whom with biopsy. In the ITT population, eCR rates with vs. without nimotuzumab were 47.2% vs. 33.3% (p=0.17), whereas combined eCR/pCR rates were 62.3% vs. 37.0% (p=0.02). In a median follow-up of 14.7 mo., the hazard ratio (HR) for OS was 0.68 (95%CI 0.44-1.07; p=0.09), with a median OS of 15.9 vs. 11.5 months, respectively. In an unplanned subgroup analyses, the HR for OS in pts with ECOG-PS 0 was 0.32 (95%CI 0.12-0.85; p=0.02). We found no significant differences in quality of life between arms. Toxicity was manageable in both arms, with no significant differences in adverse events or serious adverse events. **Conclusions:** Combined chemoradiation and nimotuzumab is safe in pts with LAEC, and appears to increase the combined eCR/pCR rate and to impact favorably on OS. This is a promising regimen in pts with locally advanced esophageal SCC, and a phase III trial is under consideration. Clinical trial information: NCT01249352.

**4079 General Poster Session (Board #166), Sat, 8:00 AM-11:45 AM**

**Survivin expression in peripheral blood as a prognostic marker in patients with gastric cancer.** *Presenting Author: Masanori Terashima, Shizuoka Cancer Center, Nagaizumi, Japan*

**Background:** Detection of circulating tumor cells (CTC) in peripheral blood is thought to be a promising method to evaluate the extent of minimal residual disease. However, unlike breast or lung cancer, little information is available in gastric cancer. Among them, evaluation of survivin, a member of the inhibitor of apoptosis (IAP) family, mRNA expression in peripheral blood appears to be a promising procedure with relative good performance for predicting recurrence after curative resection. In order to evaluate the clinical significance of surviving expression in peripheral blood, we performed real-time RT-PCR analysis using whole blood obtained from healthy volunteers and patients with gastric cancer. **Methods:** A total of 22 healthy volunteers and 96 patients with gastric cancer were enrolled in this study. Peripheral blood samples were collected using PAXgene and RNA was isolated using Boom method. After cDNA synthesis, quantitative real-time PCR targeting survivin gene was performed. The relative expression level of survivin mRNA was calculated with actin beta as an internal standard. Correlation between survivin expression and clinicopathologic factors and survival was investigated. **Results:** Survivin mRNA expression level in peripheral blood was significantly higher in gastric cancer (median: 370, range: 35-1890) than in healthy volunteers (median:117, range: 46 to 538) in healthy volunteers. Tere was no significant correlation between survivin mRNA expression level and clinicopathologic factors. If the cut-off level of survivin was determined at 540 from ROC analysis, survivin was positive in 28 of 96 patients (29%). Disease-free survival was significantly worse in survivin positive patients than in negative patients (p=0.0216). In multivariate analysis, survivin was selected as independent prognostic factor as well as lymph node involvement. **Conclusions:** Survivin expression in peripheral blood was significantly higher in gastric cancer patients than in healthy volunteers. In addition, survivin was selected as an independent prognostic factor in patients with gastric cancer.

**4080 General Poster Session (Board #167), Sat, 8:00 AM-11:45 AM**

**Increased circulating levels of VEGF-C to predict outcome in resectable gastric cancer patients.** *Presenting Author: Fernando De Vita, Medical Oncology Division, Second University of Naples, Naples, Italy*

**Background:** Vascular Endothelial Growth Factor C (VEGF-C), is a VEGF growth factor family member playing a key-role in lymphangiogenesis. It is overexpressed in 30-60% of gastric cancer patients, showing a strong correlation with an advanced stage and a poor survival. Based on this background we investigated the meaning of serum levels of VEGF-C in gastric cancer patients suitable for surgery. **Methods:** Preoperative VEGF-C serum levels were determined by enzyme-linked immunoadsorbent assay (ELISA) in 183 patients with gastric carcinoma and 51 healthy subjects (control group) observed at our department from January 2008 until December 2012. **Results:** Patients characteristics were the following: median age was 64 years (range 22 - 91), the male/female ratio was 115/68. The stage at diagnosis was 1A: 2.2%, 1B: 10.9%, 2A: 13.1%, 2B: 11.5%, 3A: 25.1%, 3B: 15.3%, 4: 21.9%. 29% of patients showed a proximal primary site of tumor, 32.2% a middle and 38.8% a distal primary site localization. Preoperative VEGF-C serum levels were significantly higher in gastric cancer patients (mean, 295 pg/mL; range, 55–865 pg/mL) if compared with the control group (mean, 30 pg/mL; range, 11.8–60,2 pg/mL; *P*< 0.001). High VEGF-C serum levels correlated with nodal diffusion: in fact, node positive patients showed significantly higher levels (mean, 339 pg/mL – 95% C.I, 307.4 – 370.6; *P< 0.001*) when compared to node negative ones (mean 93 pg/mL – 95%C.I, 72 – 114; *P<0.001*). Moreover, preoperative VEGF-C serum levels were significantly lower in patients who underwent curative surgery (248.7 pg/mL, range: 54.9 – 865.2 pg/mL) compared with patients who underwent palliative surgery (mean 461.1 pg/mL, range: 120.5 - 805.8; *P* < 0.001). Pearson correlation analysis demonstrated a significant negative correlation between preoperative VEGF-C serum levels and OS (Pearson correlation -0.281; *Sig.2 tails 0,001*). Finally at multivariate analysis elevated serum VEGF-C levels were an independent prognostic factor in our population. **Conclusions:** Our data obtained in this setting suggest that increased serum VEGF-levels appear as a poor prognostic factor correlating with a wide nodal involvement, a palliative surgery, and a worse overall survival.

**4081 General Poster Session (Board #168), Sat, 8:00 AM-11:45 AM**

**LEOPARD-II: A randomized phase II study of radiochemotherapy (RCT) with 5FU and cisplatin plus/minus cetuximab (Cet) in unresectable locally advanced esophageal cancer (LAEC).** *Presenting Author: Dirk Rades, Department of Radiation Oncology, University of Lübeck, Lübeck, Germany*

**Background**: Patients (pts) with LAEC have a poor prognosis; new therapies are required. A study showed the addition of Cet to RCT to be safe and effective for resectable EC [Ruhstaller et al, *J Clin Oncol* 29;2011:626-31]. A phase II/III trial showed increased grade ≥3 acute toxicity and worse OS if Cet was added for localized EC [Crosby et al, *J Clin Oncol* 30;2012(suppl 34;abstr LBA3)]. However, increased toxicity in the Cet-arm was due to skin and metabolic toxicity, which usually can be easily managed. Furtermore, capecitabine (Cap) was used; Cap+Cet is less effective than 5-FU+Cet. More trials are required investigating RCT+Cet for LAEC, particularly unresectable EC. **Methods**: This is an open-label, randomized (1:1) multicenter phase II study. Pts with unresectable non-metastatic EC, age 18-75 yrs, + KPS ≥70 are eligible. Pts receive RCT+Cet (Arm A) or RCT alone (Arm B). RCT included 5-FU (1000 mg/m²/d iv, d 1-4 + 29-32, and 750 mg/m²/d, d 64-67 + 92-95), cisplatin (20 mg/m²/d iv, same days as 5-FU) and RT (59.4 Gy/6.5 wks). If resectability is achieved at 45 Gy, surgery is performed. In Arm A, Cet starts 1 wk pre RCT (400 mg/m² iv), followed by 250 mg/m² weekly for a total of 14 wks. Endpoints of this planned interim analysis (20/134 pts) are toxicity, response (RECIST 1.1), and PFS. **Results:** GI toxicity occurred in all pts of both arms (9 arm A, 11 arm B). Skin toxicity was more frequent in arm A (100% vs. 36%). All skin toxicities were gr. 1-2. Regarding all toxicities, in arm A, 19 gr. 3 + 4 gr. 4 events occurred; in arm B, 20 gr. 3 + 2 gr. 4 events. 1 Cet-related SAE (nail toxicity) occurred. 2 fatal SAEs occurred in arm B. Response rates were 67% (95%CI [30-90]) in Arm A and 27% in arm B (95%CI [8-61]) (p=0.051). 5 (56%) pts in arm A and 1 (9%) pt in arm B had CR (p=0.01), 1 (11%) pt and 2 (18%) pts PR, and 0 pt (0%) and 3 (27%) pts PD. Median PFS was 15.5 mos (95%CI [3.6-19.3]) in arm A and 4.1 mos (95%CI [1,0]) in arm B. 6-mos PFS was 78% in arm A and 48% in arm B. **Conclusions:** Treatment was similarly tolerated in both groups. Most adverse events were mild to moderate. This interim analysis showed a trend towards higher response for RCT+Cet than for RCT. CR was significantly higher in the RCT+Cet group. Clinical trial information: NCT01787006.

**4082 General Poster Session (Board #169), Sat, 8:00 AM-11:45 AM**

**Difference in outcomes among patients undergoing open versus laparoscopy-assisted approach for gastric cancer: A multi-institutional analysis.** *Presenting Author: Gaya Spolverato, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** In the United States, gastric cancer is a relatively uncommon tumor. Overall surgical experience with minimally invasive surgery (MIS) has increased, however published reports on laparoscopic resection of gastric cancer are mostly limited to small, single institution experiences. **Methods:** Between 2000 and 2012, 880 patients who underwent surgical resection of a gastric cancer were identified from a multi-center database. Clinicopathological characteristics, receipt of peri-operative therapy, operative details, and oncologic outcomes were analyzed and defined. **Results:** Median patient age was 65.8 years and 42.6% (375/880) were female. Median tumor size at diagnosis was 4.0 cm (2.5-6.8 cm). A minority of patients received neoadjuvant therapy (207, 32.7%). Overall, 70 (8%) patients had a minimally invasive (MIS) approach: laparoscopic (60, 85.7%) and laparoscopic hand assist (10, 14.3%). Patients who underwent MIS resections were more likely to a smaller tumor (MIS: 3.0 cm vs. open: 4.5 cm) (p<0.001). MIS resections were associated with similar estimated blood loss (MIS: 150 cc vs. open: 250 cc, p=0.14) and similar operative time (MIS: 271 min vs. open: 232 min, p=0.07) compare to open surgery. An R0 resection was achieved in the overwhelming majority of patients (MIS: 98.6% vs. open: 90.9%; p=0.03). Post-operatively, MIS patients had a similar incidence of complications (MIS: 20% vs. open: 33.1%, p=0.07) and a similar length of stay (MIS: 7 d vs. open: 9 d, p=0.13) compare to open surgery patients. For the entire cohort, median recurrence-free survival was 27.34 months and median overall survival was 33.42 months. In analyzing the entire cohort, the overall 5-year survival of patients treated with MIS was 42.6% vs. 35.8% for patients treated with an open approach (p=0.05). In the propensity score-matched multivariate model, laparoscopy remained associated with an improved long-term overall (HR 0.34) survival (P<0.001). **Conclusions:** An MIS approach to select patients with gastric cancer is associated with a high R0 resection rate. The long-term oncological outcome following MIS is excellent and therefore the MIS approach should be considered.

**4083 General Poster Session (Board #170), Sat, 8:00 AM-11:45 AM**

**A phase II and biomarker study of an irreversible pan-human EGF receptor (HER) tyrosine kinase inhibitor dacomitinib in patients with recurrent and/or metastatic squamous cell carcinoma of esophagus.** *Presenting Author: Hyo Song Kim, Department of Internal Medicine, Division of Medical Oncology, Yonsei University College of Medicine, Seoul, South Korea*

**Background:** Dacomitinib is an oral irreversible tyrosine kinase inhibitor of EGFR, HER2 and HER4 signaling. The goals of this study were to investigate the clinical activity, safety and predictive biomarkers of dacomitinib in patients with advanced esophageal squamous cell carcinoma (ESCC). **Methods:** Forty-nine patients with advanced ESCC, who had failed one line of prior platinum-based chemotherapy, were administered dacomitinib 45mg/day. The primary endpoint was objective response rate and predictive biomarkers were evaluated using tumor material obtained before dacomitinib treatment. We characterized somatic mutations using the Ion AmpliSeq platform (2,800 mutations from 50 genes), gene copy number (86 genes) and gene expression (230 genes) using NanoString nCounter. **Results:** The median age was 64 years (range 47-83) and the majority of patients were male (93.3%), had 0-1 ECOG performance status (91.8%). In terms of previous chemotherapy, 40 (81.3%) and 9 (18.4%) patients received 1 and 2 prior chemotherapy, respectively. Of the 48 evaluable patients, 10 (20.8%) achieved partial responses (PR), of these, 6 (12.2%) showed confirmed PRs. Twenty-nine patients (61.2%) had stable disease. The median treatment duration is 82 days (range 16-335 days), and main reason of treatment discontinuation was progression (n=34, 69.4%) and toxicity (n=4, 8.2%). Seven (14.3%) patients are on treatment and they are all progression free more than 120 days. Among the 34 patients with progression, the median time to progression was 80 days (95% CI, 59-102 days). With a median 169 days of follow up, the median overall survival was 4.5 months (95% CI, 3.1-6 months). Nineteen patients (38.8%) had treatment interruption due to toxicity, and 14 (28.5%) of them had dose reduction. The most common dacomitinib-related adverse effects were diarrhea (69.4%) followed by rash (57.1%). **Conclusions:** Dacomitinib demonstrated promising efficacy with manageable toxicity in platinum-failed ESCC patients. We attempted to identify predictive biomarker for dacomitinib treatment. Updated clinical outcome and final biomarker data will be presented at ASCO 2014. Clinical trial information: NCT01608022.

**4084 General Poster Session (Board #171), Sat, 8:00 AM-11:45 AM**

**Effect of the distribution of lymph node metastases on outcomes for trimodality-eligible patients with esophageal and esophagogastric junction adenocarcinoma (EAC).** *Presenting Author: Hironori Shiozaki, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** In patients with trimodality-eligible EAC, the presence of malignant nodes at baseline portends a poor prognosis. It is difficult to quantify the number of positive lymph nodes using imaging modalities. For clinical staging, distribution of lymph node metastasis on imaging may be a potential surrogate for number and a useful tool to consider prognosis. We hypothesized that the distribution of baseline nodes (above and/or below the diaphragm) will have a correlation with overall and relapse-free survival. **Methods:** We identified 209 EAC patients with baseline malignant nodes. All patients underwent trimodality therapy. Patients were grouped based on the presence of (A) nodes above the diaphragm, (B) nodes below the diaphragm, and (C) nodes above and below the diaphragm. Survival estimates were calculated using the Kaplan-Meier method. The differences in OS and RFS among patient subgroups were assessed using log-rank tests. Differences were considered significant if the 2-sided p-value was less than 0.05. **Results:** The patients were primarily Caucasians (91%), males (93%), and had stage III EAC (89%).The median follow-up was 2.2 years (range, 0.4 to 10.8 years). Of the 209 patients, 35% (73) were in group A, 20% (41) were in group B, and 45% (95) in group C. Patients in group C had the worst 5-year overall survival (33%) compared to those patients in groups A (55%) or B (60%; P=0.02). Patients with high histology grade were also at higher risk of relapse and poor survival outcome (P<0.01 for each). **Conclusions:** The presence of suspicious or confirmed malignant lymph nodes above and below the diaphragm leads to the worst prognosis for EAC patients undergoing trimodality therapy. Therefore, novel therapeutic strategies are needed for these patients.

**4085 General Poster Session (Board #172), Sat, 8:00 AM-11:45 AM**

**A proprietary multi-analyte test to predict neoadjuvant treatment response for esophageal and rectal adenocarcinoma patients.** *Presenting Author: Sunil S. Badve, Indiana University School of Medicine, Indianapolis, IN*

**Background:** Standard of care for locoregional esophageal (EC) and rectal (RC) adenocarcinoma is chemotherapy/radiotherapy (CTRT) followed by surgery. 25-30% of EC and RC patients exhibit extreme resistance to pre-operative CTRT (exCTRT) and receive no therapeutic benefit. A similar number have a pathologic complete response (pathCR) and may benefit from avoiding surgery. We previously reported an IHC-based multi-center study that accurately identified EC patients as exCTRT or non-exCTRT (CTRT responders). The present multi-center study applies the assay for prediction of EC patient pathCR, and extends the test to predict RC patient exCTRT and pathCR. **Methods:** Formalin-fixed, paraffin-embedded (FFPE) tissue sections from diagnostic biopsies were processed by IHC to detect three predictive biomarkers: NF-kB, SHh, and Gli1. Sections were reviewed by a pathologist to determine a labeling index (LI) score for each biomarker correlating with the number of positively stained EC or RC cells within a tissue section. LI scores from each case were compared to a training set of 167 adenocarcinoma tumor samples using logistic regression analysis to predict pathCR in a cohort of 65 EC cases, or pathCR and exCTRT in a cohort of 10 RC cases (5 pathCR and 5 exCTRT). Predicted outcomes were compared to Tumor Regression Grade (TRG), determined by blinded, independent pathology. **Results:** Prediction of EC pathCR achieved an uncorrected area under the curve (AUC) of 0.83 with a specificity of 87%. Initial application of the pathCR assay to RC cases resulted in 100% specificity (5/5 non-pathCR cases called non-pathCR) and 60% sensitivity (3/5 pathCR cases called pathCR). Conversely, application of the exCTRT assay to RC cases resulted in 100% specificity (5/5 non-exCTRT cases called non-exCTRT) and 60% sensitivity (3/5 exCTRT cases called exCTRT). **Conclusions:** The current study demonstrates the potential of this assay to predict pathCR in EC and pathCR and exCTRT in RC. Predicting response to CTRT in both EC and RC will enable design of treatment regimens specific to a patient's response, thereby improving the risk to benefit ratio for both CTRT and surgery.

**4086 General Poster Session (Board #173), Sat, 8:00 AM-11:45 AM**

**Gastric cancer (GC) among California Asians: Analysis of California Cancer Registry (CCR).** *Presenting Author: Afsaneh Barzi, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** GC is the 4th cause of cancer death worldwide and is associated with significant morbidity in the affected individuals. In the US, California has the highest number of GC cases per year. We designed a study to explore the disparities in the presentation and outcome of GC in the Asians. **Methods:** Using data from CCR, we investigated the GC incidence, presentation, and survival among Asians from 2000-2010. We explored the significance of race in the anatomic presentation and survival of GC in the Asians compared to non-Hispanic Whites (NHW). We identified 18,377 GC cases in this time period, 70% were NHW, 8% Chinese, 7% Korean and 5% Japanese, the rest included Filipino, Vietnamese and other Asian sub-groups. **Results:** The frequency of GC by anatomical sites were statistically significantly different between Asians and NWH for both males and females ($p<0.001$). Compared to NHW, Asians had significantly lower frequency of cardia and fundus cancers (44% in NHW and 14% in Asians). Asians presented at a younger age ($p<0.001$) and had lower rates of de-novo metastatic disease compared to NHW ($p<0.001$). Survival rates were higher in Asians compared to NHW when adjusted for age, gender, socio-economic status, nativity, stage, anatomical site, and type of treatment received. Prognostic factors for death from gastric cancer included age $>$ 65 and immigration status, with immigrants doing better than US born. There was significant amount of disparity among Asians form different countries, Koreans had the highest age adjusted incidence rate of GC compared to all other Asians. **Conclusions:** The differences in the demographics, anatomical distribution of GC, and outcome in the Asians may be due to differences in etiologic factors that deserve further exploration. In Japan and Korea, early detection had resulted in a dramatic decline in mortality and morbidity. Although overall low incidence of the disease in US is prohibitive for a generalized screening program, there are subpopulations that may benefit from screening. Given that early detection has proven to be effective and cost saving in Asian countries with high incidence of gastric cancer consideration of screening for this population is intriguing and should be explored.

**4087 General Poster Session (Board #174), Sat, 8:00 AM-11:45 AM**

**A comparative study of ultrasonography and non-contrast computerized tomography of upper abdomen as a screening tool for biliary tract cancer detection in endemic community.** *Presenting Author: Teerapat Ungtrakul, Chulabhorn Hospital, Bangkok, Thailand*

**Background:** Biliary tract cancer is the leading cause of cancer-related death among men and women in the north and northeastern region of Thailand. Over 21 million people in this region are at risk for this type of cancer. However, no reliable test is currently available for its detection at the earliest stage. Despite the suggested use of ultrasonography in some reports, it is still not feasible for implementation as a screening tool across the country due to its high operational dependency and difficult quality control. This study aimed to compare the effectiveness between abdominal ultrasonography (AUS) and computerized tomography of upper abdomen (CT) without contrast for better outcome of detecting biliary tract cancer in the endemic area. **Methods:** Both male and female participants, aged 50-60 years old, from Phanomphrai district, Roi Et province, Thailand were enrolled. All of them were sent for AUS screening by a mobile imaging unit while CT without contrast was done using a standard protocol at a nearby imaging center. Confirmation of diagnostic studies or tissue biopsy was subsequently performed in the cases with liver nodules or bile duct dilatation. Experienced radiologists proceeded with CT scan and imaging data interpretation through tele-imaging system. **Results:** Of 839 participants, either liver nodule or bile duct dilatation was found in 54 cases (6%) by US and 44 cases (5%) by CT, respectively. Biliary tract cancer was diagnosed in 7 cases (5 cases of intrahepatic cholangiocarcinoma and 2 cases of extrahepatic cholangiocarcinoma). Five out of 7 cases were successfully treated with a curative intent. In addition, all cases were detected by AUS and CT without contrast, with the sensitivity and specificity of 100% and 94% for AUS and 100% and 95% for CT, respectively. **Conclusions:** Both CT without contrast and ultrasonography were effective screening tools for the detection of biliary tract cancer at an early stage in the endemic area. Nevertheless, the feasibility, cumulative radiation exposure, false positive rates, and operational costs need to be considered before implementation in the screening.

**4088 General Poster Session (Board #175), Sat, 8:00 AM-11:45 AM**

**Final analysis of European patients from the Global Investigation of Therapeutic Decisions in Hepatocellular Carcinoma and of its Treatment with Sorafenib (GIDEON) study: Baseline characteristics and staging systems.** *Presenting Author: Bruno Daniele, G. Rummo Hospital, Benevento, Italy*

**Background:** The global, prospective, non-interventional GIDEON study recruiting >3,000 patients with unresectable hepatocellular carcinoma treated with sorafenib is complete. We report the final analysis of the prognostic value of baseline characteristics and staging systems in European patients. **Methods:** Baseline characteristics were recorded at study entry; safety/outcomes were collected at follow-up. **Results:** Median overall survival (OS) and time to progression (TTP) for baseline characteristics and staging systems in the intent-to-treat population (n=1115) are shown (Table). The safety profile of sorafenib in European patients was consistent with that reported for the interim analyses and in phase III studies. **Conclusions:** Data from European patients indicates that baseline characteristics and staging systems, including Child-Pugh status, BCLC stage, and CLIP and MELD scores, appear to be useful prognostic factors for OS and TTP, while TNM and ECOG PS appear to be predictive of OS only. Clinical trial information: NCT00812175.

**Overall survival and time to progression by baseline characteristics/staging system.**

| | n | Median OS (months) | Median TTP (months) |

**4089 General Poster Session (Board #176), Sat, 8:00 AM-11:45 AM**

**Radiogenomics of hepatocellular carcinoma: Computed tomography biomarker to predict microvascular invasion and clinical outcome.** *Presenting Author: Sudeep Banerjee, University of California, Los Angeles, Los Angeles, CA*

**Background:** Microvascular invasion (MVI) is an independent predictor of poor outcome following surgical resection or liver transplantation (LT) in hepatocellular carcinoma (HCC); however, MVI currently cannot be adequately determined until after surgery. **Methods:** We conducted a multicenter evaluation of a computed tomography (CT) biomarker for MVI, termed radiogenomic venous invasion (RVI), in surgical candidates with HCC. RVI is a prospectively-defined imaging surrogate for a 91-gene HCC "venous invasion" gene expression signature. Preoperative contrast enhanced CTs of 203 patients with HCC who underwent surgical resection (n=91) or LT (n=112) between 2000 and 2009 were scored for the presence or absence of RVI. **Results:** Interobserver agreement for scoring RVI was good among 3 radiologists (k=0.62, P<0.001). Diagnostic accuracy, sensitivity and specificity in the overall cohort were 87%, 72% and 93%, respectively. Positive RVI score was associated with lower overall survival than negative RVI score in the overall cohort (P<0.001; 49 vs >147 months), in Barcelona Clinic Liver Cancer (BCLC) A (P = 0.01; 22 vs 105 months), BCLC B (P = 0.044; 66 vs >147 months) and in LT patients within the Milan criteria (P<0.001; 22 vs >147 months). Positive RVI score had lower recurrence-free survival at 3-years than negative RVI score (P<0.001; 62% vs 85.4%). **Conclusions:** RVI is a noninvasive radiogenomic biomarker that accurately predicts histologic MVI in HCC surgical candidates. Its presence is associated with early disease recurrence and poor overall survival and may be useful for stratifying patients less likely to derive a durable benefit from surgical treatment.

**4090 General Poster Session (Board #177), Sat, 8:00 AM-11:45 AM**

**ABC-04: A phase 1b trial of cisplatin, gemcitabine, and selumetinib in patients with advanced biliary tract cancer.** *Presenting Author: John A. Bridgewater, Department of Medical Oncology, University College London Cancer Institute, London, United Kingdom*

**Background.** Cisplatin + gemcitabine (CisGem) is a standard of care for advanced biliary tract cancer (ABC; Valle et al. 2010). Selumetinib (S; AZD6244, ARRY-142886) potently and selectively inhibits MEK1/2, an intracellular kinase (Adjei et al., 2008; Yeh et al., 2007), and has shown activity in ABC (Bekaii-Saab et al., 2009). The objective of the ABC-04 trial was to establish the recommended dose (RD) of S to give in combination with CisGem. **Methods.** Eligible patients (pts) were ≥ 18 years, had histology/cytology confirmed unresectable recurrent or metastatic biliary tract, gallbladder or ampullary carcinoma, WHO performance status 0-2, adequate major organ function. Pts may have had prior surgery, radiotherapy or adjuvant chemotherapy (CT), but no prior CisGem or CT for locally advanced or metastatic disease. Pts received cisplatin 25 mg/m$^2$ plus gemcitabine 1000 mg/m$^2$ intravenously on days 1 and 8 of a 21-day cycle. S capsules were taken daily. A dose de-escalation scheme was used to determine the RD of S. The first dose level was 75 mg bd. Pts were recruited in cohorts of 3 and assessed for dose limiting toxicity (DLT) during the first cycle of treatment. Pts received up to 8 cycles of CisGem and could receive S until disease progression. **Results.** Thirteen pts were recruited of whom 12 were evaluable for DLT (1 did not start treatment). All evaluable pts received the starting dose of 75 mg bd and only one patient experienced a DLT (ischaemic heart disease). Median number of days S taken (adjusted for the number of days of dose interruptions) was 167 (IQR: 75.5 to 311.5). Two pts remained on treatment at 14 and 19 months post registration. There were 3 temporary and 1 permanent interruptions of S in cycle 1. Eight pts had measurable disease (RECIST v1.1) and were evaluable for objective response: 3 had partial response and 5 stable disease. Toxicities related to S included oedema and rash; most were modest and manageable. Pharmacokinetic analysis did not show a significant interaction between gemcitabine and S. **Conclusion.** The RD of S when combined with CisGem is 75 mg bd. Translational studies are underway to determine any potential molecularly favoured subgroup. Clinical trial information: NCT01242605.

**4091 General Poster Session (Board #178), Sat, 8:00 AM-11:45 AM**

**Screening and 6-month surveillance interval ultrasonography in early detection of cholangiocarcinoma in an endemic area.** *Presenting Author: Prakongboon Sungkasubun, Chulabhorn Hospital, Bangkok, Thailand*

**Background:** Very high incidence rates of cholangiocarcinoma have been reported in Southeast Asia, especially in the north and northeastern parts of Thailand where the prevalence of this cancer is the highest in the world. Ban Luang district of Nan province in the northern Thailand is known to have a very high mortality rate from cholangiocarcinoma. Objectives: To ascertain the prevalence of cholangiocarcinoma in Ban Luang districtof Nan province and to implement a screening and surveillance program to identify early-stage cases for better treatment outcome. **Methods:** A 5-year prospective cohort study was conducted in Thai individuals, aged 30-60 years, in Ban Luang district. The initial cholangiocarcinoma screening program included blood testing, stool examination and ultrasonography every 6 months. **Results:** During the first 2 years, from 6,327 targeted participants, screening with abdominal ultrasonography could be completed in 4,337 subjects (68.5%). Cholangiocarcinoma was diagnosed in 22 cases from 4 repeated ultrasonography, 16 of which were in the curative and resectable stages. The prevalence of cholangiocarcinoma was 8 cases (184.5:100,000) and the average 6-month incidence was 4.7 cases (108.4:100,000).The 2-year survival was observed in 19 of 22 cases(86.4%) and the 2-year progression- or recurrence-free survival was found in 13 of 22 cases(59.1%). **Conclusions:** The high prevalence of cholangiocarcinoma in Ban Luang district was confirmed through this population-based study, with satisfactory results from ultrasonography-based screening and surveillance program. Early-stage cholangiocarcinoma cases were uncovered leading to better prognosis.

**4092 General Poster Session (Board #179), Sat, 8:00 AM-11:45 AM**

**A phase II trial of second-line axitinib following prior antiangiogenic therapy in advanced hepatocellular carcinoma (HCC).** *Presenting Author: Mairead Geraldine McNamara, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Second line treatment options in advanced HCC are limited. Axitinib, a selective tyrosine kinase inhibitor (TKI) of VEGFRs 1, 2, 3, merits exploration in HCC. **Methods:** This was a single arm, phase II trial of axitinib in advanced HCC. Eligible patients (pts) were Child-Pugh (CP) A/B7, with measurable progressive disease (PD) after TKIs/antiangiogenic drugs. Axitinib started at 5 mg bid orally, titrated from 2-10 mg bid as tolerated; 28 days=1 cycle. Treatment continued to PD or intolerable toxicity. Primary endpoint was tumor control; PR, CR or SD at 16 wks by RECIST 1.1 ($P_0$=5%, $P_1$=20%), secondary endpoints; compare response by RECIST 1.1 to Choi and modified RECIST, explore dynamic contrast enhanced imaging models, safety, PFS and OS. **Results:** Thirty pts were enrolled from 01/11-10/13. Median age; 64y (range 18-78), 21 males (70%) with ECOG PS 0/1 (9/21 pts), CP A (73%), BCLC staging C (100%), etiology hepatitis B/C (30%/30%), alcohol (17%) with prior therapy; Temsirolimus/Bevacizumab (2pts), sorafenib/doxorubicin (2pts) and sorafenib alone (26pts). Med duration of treatment; 4 cycles (range 1-17). Out of 26pts evaluable for response, there were 2 confirmed PRs per RECIST 1.1; 10 PR by Choi, 8 PR and 1 CR by modified RECIST. Tumor control rate at 16 wks; 42% (95%CI 22.3-63.1), 7 pts had SD >28 wks. 2 week perfusion changes were noted on functional imaging. Of 22 pts with evaluable AFP response, 8 (36%) had >50% decrease from baseline. Most common axitinib related grade 3 (G3) AEs were hypertension (HTN) (17%) and diarrhea (10%), 2 had G4 thrombocytopenia. Only 20% of pts tolerated dose escalation above 5 mg bid. Of 11 pts with any grade HTN, 7 had disease control >28 wks. Dose interruptions due to AEs were common (40%); included anorexia (13%), fatigue (10%), HTN (7%). 4 pts discontinued treatment due to related AEs. PFS + OS data are maturing. Current 3 mo PFS rate; 59%. 80% have progressed at this time, 4 pts remain on treatment. **Conclusions:** With 42% tumor control at 16 wks, primary endpoint was met.Axitinib has shown encouraging tolerable clinical activity in this VEGF pretreated HCC pt population and warrants further study incorporating potential biomarkers of response. Clinical trial information: NCT 01334112.

**4093 General Poster Session (Board #180), Sat, 8:00 AM-11:45 AM**

**Second-line chemotherapy for advanced biliary tract cancer after failure of gemcitabine plus platinum: Results of an AGEO multicenter retrospective study.** *Presenting Author: Bertrand Brieau, Hôpital Cochin, Paris, France*

**Background:** First-line chemotherapy (CT1) with the combination of gemcitabine (gem) + platinum has become a new standard in advanced biliary tract cancer (ABTC) but data on second-line CT (CT2) are lacking. The aim of this study was to evaluate the efficacy and tolerability of CT2 in patients (pts) with ABTC who received gem-platinum in CT1. **Methods:** We retrospectively reviewed data of consecutive patients who received CT2 for ABTC after failure to gem-platinum in 17 French institutions from November 2002 to December 2013. Progression-free survival (PFS) and overall survival (OS) were estimated from the start of L2 CT using Kaplan Meier method. Cox models were applied for multivariate analyses. **Results:** Among 603 pts who were treated by gem-platinum in CT1, 196 pts (median age, 63 years, range: 28-82; male, 51.5 %) received a CT2. CT1 included gem + cisplatin (7%) or oxaliplatin (ox) (93%), with a median PFS of 9.7 months (mo) and an ORR of 31%. Characteristics at the beginning of CT2 were: metastatic disease, 94% ; 1-2 metastatic sites, 68%; ECOG PS 0-1, 68%. CT2 CT was 5FU-irinotecan (iri) (n=62), 5FU-ox (n=17), 5FU-cisplatin (n=37), 5FU/capecitabine (CAP) (n=39) or other various regimens (n=41). Among the 186 evaluable pts, there were 22 PR (12%) and 70 SD (38%). After a median follow-up of 26.4 months, median PFS and OS were 3.2 and 6.7 mo respectively. There was no significant difference between CT regimens in terms of PFS (5FU-iri, 2.6 mo; 5FU-ox/5FU-cisplatine, 4.0 mo; 5FU/CAP, 3.2 mo and others, 3.7 mo; p=0,27) and OS (6.0 mo, 6.3 mo, 5.6 mo and 9.7 mo respectively; p=0.27) In multivariate analysis, PS 2-3, bilirubine $>$ 17 $\mu$mol/L and CA19.9 $>$ 400 UI/mL were significantly associated with a shorter PFS while PS 2-3, CA19.9 $>$ 400 UI/mL and non-response to CT1 with a shorter OS. A grade 3-4 toxicity was observed in 32% of pts (neutropenia, 33%; diarrhea, 17%) and a toxic death occurred in 1.4% of pts. **Conclusions:** CT2 is associated with a disease control in a half of pts with ABTC who received gem-platinum in CT1. Nevertheless, the short median PFS observed in this study should encourage the evaluation of new treatments in pts with good clinical conditions and an adequate biliary drainage.

**4094 General Poster Session (Board #181), Sat, 8:00 AM-11:45 AM**

**Assessment of liver dysfunction in hepatocellular carcinoma (HCC): An international collaborative study.** *Presenting Author: Philip James Johnson, Department of Molecular and Clinical Cancer Medicine, Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom*

**Background:** Survival in HCC depends on tumour-related features and liver dysfunction, the latter currently characterised by Child-Pugh score (C-P.S). Since some constituents of C-P.S are interrelated and subjective and the tumour may contribute to liver dysfunction, C-P may not be ideal for HCC assessment. Aim:To assess how much discrimination in liver dysfunction is afforded by the C-P.S and develop a simpler evidence-based approach. **Methods:** 5,269 patients were recruited from 4 specialist HCC centres: Japan (n=2,599, predominantly HCV), Hong Kong (1 112, predominantly HBV), Spain (n=834, predominantly HCV and alcohol) and the UK (n=724, multiple aetiologies). Patients undergoing liver transplantation were excluded. A model explaining variation in survival according to liver function was developed in 1,313 Japanese subjects and then validated in the remaining 3,716 cases. **Results:** Overall the classification in C-P.S was A, 69%, B, 25% and C 6%; figures were similar in all ethnic groups. After allowing for tumour size the variation in survival could be accounted for by just serum bilirubin and albumin; these were incorporated into a simple Cox regression model (the 'ALBIS' score) which allows classification into 3 risk groups. Statistical analysis showed that the degree of discrimination was as good as, or better than, C-P.S. Irrespective of country, or tumour stage the ALBIS score showed clear survival differences among C-P. S 'A' patients (Table). **Conclusions:** The "ALBIS score" is simple, objective, and evidence-based and permits classification of patients to a risk group based on liver dysfunction.

**Survival among 777 European patients with Child-Pugh stage A HCC.**

| ALBIS risk group | N | Median survival (months) | Std. err. | [95% CI] | |
|---|---|---|---|---|---|
| **1** | 409 | 26.4 | 1.5 | 24.0 | 29.9 |
| **2** | 367 | 16.3 | 1.1 | 14.2 | 18.9 |
| **3** | 1 | . | . | . | . |

Median survival = 22.6 months.

**4095 General Poster Session (Board #182), Sat, 8:00 AM-11:45 AM**

**Phase 1 study of PF-03446962 (anti-ALK-1 mAb) in hepatocellular carcinoma (HCC): Correlation of tumor and serum biomarker data with disease control.** *Presenting Author: Matteo Simonelli, Humanitas Cancer Center, Rozzano, Italy*

**Background:** PF-03446962 ,a fully human IgG2 mAb against ALK-1 (Activin-Receptor Like Kinase-1, a specific TGF-$\beta$ receptor selectively expressed on vasculature), demonstrated a favorable safety profile in a Phase 1 expansion cohort of HCC patients (pts) whose disease progressed after sorafenib $\pm$ other systemic anti-angiogenic therapies. Tumor immunohistochemistry (IHC), multiplex serum soluble protein, and pharmacokinetic (PK) results are reported here along with disease control data. **Methods:** Child-Pugh A HCC pts progressive on/intolerant to VEGFR TKI were included. Pts were treated with PF-03446962 at 7 mg/kg IV on Day 1, Day 29 and then q 2 weeks. PF-03446962 PK was also monitored. Archival (pre-sorafenib) and *de novo* (pre-PF-03446962) tumor specimens were assessed by IHC for TGF-$\beta$ (low affinity ALK-1 ligand), ALK-1, c-MET and CD31. A multiplex approach was used for assessment of 15 serum soluble proteins involved in angiogenesis and TGF-$\beta$ pathways, including BMP-9 (a high affinity ALK-1 ligand) at baseline, Cycle2 Day1, Cycle3 Day1 and end of treatment. Biomarker data were correlated with Disease Control at 12 weeks (DC) and Objective Tumor Response (OR) by RECIST. **Results:** Higher mean tumor tissue archival (ratio = 15) and *de novo* (1.7) c-MET expression, higher (1.5) mean baseline serum levels of BMP-9, and lower mean baseline serum levels of TGF-$\beta$ (0.44) and VEGFR3 (0.66) were found in the patients with disease control at 12 weeks vs. those patients with progressive disease. No ORs were reported, DCR was 29.2% and mTTP was 3.0 months. In 7 pts, PF-03446962 achieved stable disease $\geq$ 12 weeks, suggesting a role of ALK-1 in sustaining tumor growth. PF-03446962 serum trough concentrations in these pts well exceeded the therapeutic level suggested by non-clinical data. **Conclusions:** Higher tumor c-MET and serum BMP-9, and low serum TGF-$\beta$ and VEGFR3 were found in patients with disease control at 12 weeks vs. those patients with progressive disease. Expanded molecular approaches to identify biomarkers for PF-03446962 are being assessed in an ongoing phase 2 study. The selection of 7 mg/kg every 2 weeks as the RP2D dose is supported by PK results in this population. Clinical trial information: NCT00557856.

**4096 General Poster Session (Board #183), Sat, 8:00 AM-11:45 AM**

**Next-generation sequencing of serum microRNA (miRNA) in hepatocellular carcinoma (HCC) patients on targeted therapy.** *Presenting Author: Robin Kate Kelley, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

**Background:** Circulating biomarkers are urgently needed in HCC. miRNA are noncoding RNA that regulate mRNA expression and are detectable in tumor tissue and extracellular compartments. This pilot study explored the feasibility of using next-generation RNA sequencing to characterize miRNA abundance in serum from HCC patients at baseline and on targeted therapy. **Methods:** Banked serum samples (400$\mu$L) were obtained from HCC patients enrolled on a phase I clinical trial of sorafenib plus the mTOR inhibitor, temsirolimus. Control sera were obtained from patients with non-malignant liver diseases (NMLD). Total RNA was purified using Trizol-LS and miRNeasy kit. Mature miRNA were size-selected by gel electrophoresis. Samples were sequenced by Illumina HiSeq 2500, 5M reads per sample. Raw reads were mapped using Novoalign, quantified, and normalized to total reads and exogenous spike-in miRNA recovery. Comparisons between HCC vs. NMLD and baseline vs. on treatment cohorts were performed using one-way ANOVA and false discovery rate (FDR) correction. Candidate signature miRNA were derived by fold change, p-value, and abundance cutoffs and cross-referenced to literature. **Results:** Cohorts: HCC baseline (n=23) and paired on treatment (n=20 cases, 30 samples), NMLD (n=12). HCC cohort: HBV+/dual 40%, HCV+ 32%. NMLD cohort: HCV+ 83%. 38 of 65 (58%) total samples qualified. Candidate miRNA were identified which showed up-regulation in HCC vs. NMLD (non-significant) and in elevated vs. normal alpha-fetoprotein (AFP) (FDR p$<$0.05). Multiple miRNA families showed a trend toward down-regulation on treatment with temsirolimus plus sorafenib including Let-7 and miR-17/92 family members. Serum signatures for HCC vs. NMLD and elevated AFP overlapped with miRNA expression in a published dataset of HCC tumors. **Conclusions:** Serum miRNA in HCC patients can be characterized by next-generation sequencing. Differences in miRNA abundance were observed between HCC cases and NMLD controls, and within HCC cases according to clinical covariates including treatment status and AFP. Serum miRNA warrant further study as novel biomarkers in HCC.

**4097 General Poster Session (Board #184), Sat, 8:00 AM-11:45 AM**

**Molecular profiling of bile duct and gallbladder cancer to identify different therapeutic options.** *Presenting Author: Randall F. Holcombe, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background:** Biliary tree carcinomas arising in different anatomic locations (intrahepatic IHBC; extrahepatic, EHBC) and gallbladder (GBC) are rare tumors with a poor prognosis. An unmet medical need exists in identifying biomarkers of drug response. We interrogated biomarkers from a large cohort of patient samples with a multiplatform approach and considered associated therapeutic options. **Methods:** 643 cases (291 IHBC, 115 EHBC, 237 GBC) were evaluated using a commercial multiplatform profiling service (Caris Life Sciences, Phoenix, AZ). Specific testing performed included a combination of gene sequencing (Sanger, NGS), protein expression (IHC) and gene amplification (CISH or FISH). **Results:** OverallIHC showed high TOP2A (51%), TOPO1 (43%), SPARC (39%) and low RRM1 (76%), ERCC1 (72%) and TS (70%), indicating potential benefit from anthracycline, irinotecan, nab-paclitaxel, gemcitabine, platinum and fluoropyrimidine, respectively. 16 of 45 genes had mutations, with the highest rates seen in TP53 (29%), KRAS (19%), SMAD4 (9%) and IDH1 (9%). When comparing IHBC, EHBC and GBC, a number of statistically significant differences were observed (p values ranged from <0.0001 to 0.03). IHBC was characterized by the presence of IDH1 mutation (18% vs. 0% vs. 0%), low TP53 mutation (15% vs. 40% vs. 46%), and low HER2 amplification (2% vs.17% vs. 16%); IDH1 and TP53 mutations were mutually exclusive, and IDH1 was associated with high Pgp IHC (89% vs. 47%). EHBC had the highest KRAS mutation rate (EHBC 32% vs. IHBC 18% vs. GBC 13%). GBC had higher TOP2A IHC than IHBC and EHBC (71% vs. 36% vs. 46%) and higher RRM1 IHC (34% vs. 17% vs. 15%). Further, SMAD4 mutation was found in 20% (6/30) of metastatic tumors and 2.3% (1/44) of primary tumors (p=0.02). **Conclusions:** Multiplatform cancer profiling revealsdifferentbiomarker characteristics of biliary tree carcinomas arising in different locations, suggesting a different biology and the need for different therapeutic approaches. Biomarker differences detected by IHC and ISH prompt considerations of HER2-targeted therapies in EHBC and GBC, and anthracylines in GBC, highlighting the need for individualizing patient treatment based on tumor profiling in biliary tree carcinomas.

**4098 General Poster Session (Board #185), Sat, 8:00 AM-11:45 AM**

**A phase II study of temsirolimus in previously treated advanced hepatocellular carcinoma (HCC).** *Presenting Author: Jasgit C. Sachdev, TGen - Virginia G. Piper Cancer Center at Scottsdale Healthcare, Scottsdale, AZ*

**Background**: After Sorafenib failure,there is no effective systemic therapy for advanced HCC. Preclinical data show upregulated mTOR signaling in HCC. We tested the IV mTOR inhibitor (i), Temsirolimus (T), as salvage therapy for HCC. **Methods**: Patients (Pts) had locally advanced or metastatic HCC, progressed on or intolerant of sorafenib, Child Pugh A/B liver cirrhosis, ECOG 0-2. Primary end point of this Simon 2-stage, single-arm phase II study was 3 month PFS. ≥ 1/15 Pts in stage 1 and ≥ 4/25 Pts overall had to achieve this endpoint to reject the $H_0$ (Type I and II errors 0.05 and 0.1). We gave 25 mg T weekly until progression or intolerance, with CT/MRI scans Q 6 wks. Modified (m) RECIST for HCC was used. **Results**: See the Table for Pt characteristics. 17 Pts progressed or died (4 still on study, 4 off study without progression). 13/23 (57%; 95% CI: 34-77%) evaluable Pts were alive without progression at 3 months. Median PFS, 17 wks (95% CI 12-35 wks); PFS at 24 wks, 37%; median OS, 30 wks (95% CI: 27-44 wks). Of 21 Pts evaluable by mRECIST, best responses were 8 PR (38%), 10 SD (48%) and 3 PD (14%) for a disease control rate at ≥ 12 weeks of 43% (9/21). Mean and median decreases in target lesions from baseline were 33% and 23% respectively. Exploratory textural analysis of baseline scans correlated with response (p = 0.008) suggesting a predictive CT marker for anti-tumor activity. Grade 3/4 treatment related AE in ≥10% Pts: thrombocytopenia, neutropenia, AST elevation and hyperglycemia. 2 on-treatment deaths occurred, both unrelated to drug. **Conclusions:** T showed higher responses than previously reported with systemic Rx for HCC. The primary end point was met with >1/2 of the Pts progression free at 3 months, and >1/3 at 6 months. We speculate that IV administration may have overcome compliance issues in drug administration, favorably impacting efficacy, as reflected by the response rates in this study, in contrast with those reported with the oral mTORi. Confirmatory studies with novel correlative biomarkers should clarify the role of this mTORi in HCC. Clinical trial information: NCT01567930.

**Sorafenib with or without everolimus in patients with unresectable hepatocellular carcinoma (HCC): A randomized multicenter phase II trial (SAKK 77/08 and SASL 29).** *Presenting Author: Dieter Koeberle, Claraspital, Basel, Switzerland*

**Background:** Sorafenib (S), a multitargeted tyrosine kinase inhibitor, has become standard of care for first-line systemic treatment of advanced HCC. Everolimus (E) is a potent inhibitor of the mTOR, a pathway frequently up-regulated in HCC. In preclinical HCC-models, S+E has additive effects compared to S. The objective of this trial was to investigate the antitumor activity of combined treatment with S+E. **Methods:** Patients (pts) with unresectable or metastatic HCC and Child-Pugh ≤7 liver dysfunction were randomly assigned to receive daily S 800 mg alone or S 800 mg + E 5 mg until progression or unacceptable toxicity. The primary endpoint was progression free survival at 12 weeks (PFS12). In the S+E arm a PFS12 of ≤ 55% was considered uninteresting and promising if ≥ 75% using a Fleming's single-stage design with 90% power and 5% significance level. The S arm was used for calibration. Secondary endpoints included response rate, PFS, TTP, OS, duration of disease stabilization (DS), safety and quality of life (QoL) assessments. **Results:** 106 pts were randomized;46 pts received S and 60 pts S+E. 93 pts are evaluable for the primary endpoint, 105 pts for the safety analysis. Main reasons for stopping therapy were: progressive disease (S: 64%; S+E: 51%), toxicity (S: 21%; S+E: 28%), or death 5% (both arms). PFS12 rate was 70% in S (95% CI: 54-83) and 68% in S+E (95% CI: 53-81). Response rate was 0% in S arm and 10% in S+E arm. Median PFS was 6.6 vs. 5.7, median TTP was 7.6 vs. 6.3, median DS 6.7 vs. 6.7, and median OS 10 vs. 12 months in the S vs. S+E arm. Activation of Hepatitis C virus was observed in 3 pts in each arm. No re-activation of Hepatitis B virus infection occurred. Grade 3 and 4 adverse events occurred in 72% (S) and in 86% (S+E). Pts receiving S+E had worse QoL scores over time compared to pts receiving S with significant differences for physical well-being and mood. **Conclusions:** Addition of a reduced dose of E to full doses of S is feasible, equally effective, but more toxic than S alone. Phase III testing of S 800 mg + E 5 mg daily appears not warranted in patients with unselected advanced HCC. Clinical trial information: NCT01005199.

**4100 General Poster Session (Board #187), Sat, 8:00 AM-11:45 AM**

**Phase Ib study of RO5137382/GC33 in combination with sorafenib in patients with advanced hepatocellular carcinoma (HCC) (NCT00976170).** *Presenting Author: Ghassan K. Abou-Alfa, Memorial Sloan-Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

**Background:** GC33 is a recombinant humanized monoclonal antibody against Glypican-3 (GPC3) which is highly expressed in HCC. GC33 elicits antibody-dependent cellular cytotoxicity against human HCC cell lines in vitro. GC33 and sorafenib showed an additive anti-tumor effect in xenograft mouse model. This is a phase I dose escalation study to evaluate safety/tolerability and pharmacokinetics (PK) of combination therapy in HCC. **Methods:** In a 3+3 design dose escalation design GC33 given intravenously 2.5, 5 and 10 mg/kg weekly, then 1,600 mg every 2 weeks, and then 1,600mg weekly, all in combination with sorafenib 400mg twice daily. Patients with advanced HCC patients, age ≥18, ECOG 0-1, Child-Pugh A, adequate organ functions (platelets ≥ 100 x$10^9$/L, ANC ≥ 1500, AST/ALT ≤ 5 x ULN, Bilirubin ≤ 1.5 mg/dL, and creatinine ≤ 2 x ULN), and no prior therapy with sorafenib were eligible. Primary endpoints were safety and tolerability and secondary endpoints PK of GC33 and sorafenib and efficacy. Tumor assessment was based on investigators using RECIST 1.0. Safety was evaluated by CTCAE 3.0. **Results:** 40 patients were enrolled between September 2009 and July 2013 as follows (n): 2.5 mg/kg weekly (qw) (12), 5 mg/kg qw(12), 10 mg/kg qw(3), 1,600mg q2w (6) and 1,600mg qw (7). There were 35 men/5 women, median age 60, Asian 21/Non-Asian 19, HBV /HCV/neither 19/9/13, ECOG 0/1 17/23. There were 3 DLT: Grade 3 hyponatremia at 5 mg/kg GC33 cohort, grade 3 hyponatremia and hypoglycemia at 1600mg q2w, and grade 3 ALT increase at 1600 mg qw. Thirty-six patients developed AE's ≥ Grade 3, including 10 (25%) with increased Lipase, 10 (25%) with increased AST, and 3 (7.5%) with increased ALT. Dose delays occurred in 6/7 patients receiving GC33 1600mg qw due to known sorafenib-related toxicities. There were no complete responses, one partial response (unconfirmed), and 6 patients (15%) have experienced stable disease for ≥ 5 months. PK parameters $C_{max}$ and $AUC_t$ of GC33 and sorafenib following combination therapy were comparable to previously reported data of either single agent. **Conclusions:** No maximum tolerated dose of GC33 could be defined when given in combination with sorafenib at the dose of 400mg bid in this study population. Clinical trial information: NCT00976170.

**4101 General Poster Session (Board #188), Sat, 8:00 AM-11:45 AM**

**Phase II study of everolimus monotherapy as first-line treatment in advanced biliary tract cancer: RADichol.** *Presenting Author: Yvonne H. Yeung, Ludwig Institute for Cancer Research, Heidelberg, Australia*

**Background:** Advanced biliary tract cancers (BTC) have a poor prognosis with limited standard chemotherapy options. The PI-3Kinase signalling pathway is frequently dysregulated in BTC and preclinical studies using mTOR inhibitors have shown activity in BTC cell lines. This exploratory phase II study aims to evaluate the clinical activity and safety of the mTOR inhibitor RAD001 (everolimus) in BTC, as well as to evaluate potential biomarkers of response in vivo and in vitro. **Methods:** Inclusion criteria included advanced BTC, no prior chemotherapy, adequate organ function and written informed consent. Treatment involved everolimus (10mg/d) and continued until tumour progression. The primary endpoint was disease control (DC) at 12 weeks (w). Secondary endpoints were response rate, progression free survival (PFS), overall survival (OS) and adverse events (AE). The two-stage study allowed progression to stage 2 when $>3$ of 9 patients had DC at 12w and would be declared active when $>13$ of 27 had DC. Correlative in vitro studies evaluated biomarkers predictive of benefit to everolimus and exploratory endpoints include correlation with these biomarkers in vivo. **Results:** 27 eligible patients (median age 64 y) were enrolled between 2009 and 2011. At 12w, 48% had SD, 8% PR and 56% had DC. Median PFS was 6.0 months (95% CI, 2.1-11.2), median OS was 9.5 months (95% CI, 5.5-16.6) and DCR 76%. Treatment was well tolerated with stomatitis (63%) and rash (52%) being the most frequent AEs. The most common grade 3/4 AEs were infection (26%), pain (15%), hyperglycemia and hypercholesterolemia (11%). After progression, 26% received 2$^{nd}$ line chemotherapy. In vitro studies showed that *k-ras* mutation was associated with everolimus resistance ($p=0.03$). There was significant negative correlation between basal pAKT: tAKT and drug resistance regardless of *k-ras* status ($r=-0.57$, 95% CI -0.81 to -0.17, $p=0.007$). Mutation profiling for Ras and PIK3Ca mutations in tumour tissue from the trial is ongoing. **Conclusions:** Single agent everolimus demonstrates activity as monotherapy in advanced BTC, with an acceptable side effect profile. Two potential predictive biomarkers have been identified in vitro and are undergoing evaluation in vivo. Clinical trial information: NCT00973713.

**4102 General Poster Session (Board #189), Sat, 8:00 AM-11:45 AM**

**Randomized phase II trial of intravenous RO5137382/GC33 at 1600 mg every other week and placebo in previously treated patients with unresectable advanced hepatocellular carcinoma (HCC; NCT01507168).** *Presenting Author: Chia-Jui Yen, Internal Medicine Department, National Cheng Kung University Hospital, Tainan, Taiwan*

**Background:** RO5137382/GC33 (GC33) is a humanized monoclonal antibody against GPC3 that is frequently expressed in HCC. GC33 interacts with CD16/Fc$\gamma$R3 and triggers antibody-dependent cytotoxicity. GC33 was compared with placebo in a randomized phase II study in advanced HCC patients (pts) who had failed prior systemic therapy. **Methods:** Pts with advanced HCC who had failed prior systemic therapy, $\geq$18 years, ECOG 0-1, Child-Pugh A were randomized in a 2:1 ratio to GC33 1600 mg Q2W after two weekly doses versus placebo. Prior to randomization, pts were assigned into 3 cohorts based degree of GPC3 immunohistochemical expression: A (GPC3 2-3+), B (GPC3 1+) and C (GPC3 no expression). Primary endpoint was progression free survival (PFS). Secondary endpoints include overall survival (OS), time to progression (TTP), tolerability, and pharmacokinetics (PK). Tumor assessment was based on RECIST1.0 criteria and safety on CTCAE 4.0. **Results:** Between February 2012 to March 2013, 185 pts were enrolled: 121 received GC33 and 64 placebo: Median age 64/63, 85/75% male, 46/42% Asian, ECOG 0 65/63%, 74/77% having vascular invasion and/or extra-hepatic metastasis. 49/41% had prior single agent sorafenib. Drug exposure was 98.6% of planned dose, with an identical adverse events profile between the 2 groups. The median PFS, OS, and TTP in the GC33 vs placebo groups in months were: 2.6 vs 1.5 (HR 0.97, $p=0.87$), 6.8 vs 6.7 (HR 0.99, $p=0.97$), and 2.9 vs 1.7 (HR 0.96, $p=0.85$). A subsequent exposure-efficacy analysis showed that increased exposure based on projected $C_{trough}$at cycle 3 day 1 was associated with prolonged PFS and OS. Median PFS for high GC33 exposure group ($n=60$) was 4 vs 1.5 months for placebo ($n=60$), and OS 9.7 vs 6.7 months, respectively. Combining higher exposure with Fc$\gamma$R3A-158V polymorphism or CD16 expression intensity may correlate with improved PFS and OS. **Conclusions:** GC33 did not show a clinical benefit in this advanced, previously treated HCC population, potentially due to suboptimal dosing. Further studies are needed to investigate whether higher GC33 drug exposure and a favored CD16/FcgR3 immune environment may help. Clinical trial information: NCT01507168.

**4103 General Poster Session (Board #190), Sat, 8:00 AM-11:45 AM**

**Final results of a phase II trial of stereotactic body radiotherapy (SBRT) in patients with hepatocellular carcinoma (HCC) with Child-Pugh class A (CPC-A).** *Presenting Author: Foster D Lasley, Indiana University Department of Radiation Oncology, Indianapolis, IN*

**Background:** After confirming the safety and appropriate radiation dose in phase I dose escalation trial, a phase II trial was completed to evaluate the efficacy of SBRT for HCC in CPC-A patients. **Methods:** Thirty-eight patients with HCC in the context of liver cirrhosis, CPC-A, were treated with SBRT in a Phase II trial at Indiana University. All patients received three fractions, 1,600 cGy per fraction (total dose 4800 cGy), 1-2 fractions per week. Dose was prescribed to the 80-90% isodose line covering the planning target volume (PTV). Demographics, clinical variables, treatment –related toxicities within 90 days of end of treatment, and local control at 6 months were tabulated and 95% exact binomial confidence intervals for local control (LC) at 6 months was calculated. A modified RECIST criteria was used to determine local failure. Progression Free Survival (PFS), and Overall Survival (OS) estimates were calculated using Kaplan-Meier methodology. **Results:** Median follow-up time was 31.0 months (2.8-64.4 months). There were 28 males and 10 female; median age of 61 years (range 24-86). Thirty-six (94.7%) patients had stage T1 disease and one patient each (2.6%) with T2 and T3 disease. Pre-treatment AFP ng/ml median (range): 8.3 (1.5-2931.9). All patients had 1 treated lesion. Median (range) for gross tumor volume (cc) was 30.9 (2.0-79.1); PTV volume (cc) was 99.1 (20.8-196.0); and uninvolved liver volume (cc) was 1607.3 (939.0-3214.0). There was 1 grade 4 toxicity of elevated GGT and 3 grade 3 toxicities including, 1 each of GGT, increased INR, and thrombocytopenia. Of the 38 patients enrolled, 1 did not return for their 6 month follow-up. Of the 37 evaluable patients, 35 (94.6%), 95% C.I. (81.8%, 99.3%) had LC at 6 months. Median PFS was 30.9 months (95% CI: 13.9 months, 64.4 months). Median OS is 38.3 months (95% CI: 28.2 months, 64.4 months). OS at 1, 2 and 3 years was 94%, 77% and 52% respectively. **Conclusions:** In selected patients with hepatocellular carcinoma in the context of CPC-A liver cirrhosis, SBRT is an effective therapy with good toxicity profile. Clinical trial information: NCT00243841.

**4104 General Poster Session (Board #191), Sat, 8:00 AM-11:45 AM**

**Role of FDG-PET-CT (PET) in predicting outcome of advanced hepatocellular carcinoma (aHCC) patients (pts) treated with sorafenib (SB): A prospective controlled study.** *Presenting Author: Roberto A. Pazo Cid, Medical Oncology Department, Miguel Servet University Hospital, Zaragoza, Spain*

**Background:** SB remains since 2007 the only drug that improves overall survival (OS) of aHCC pts. Predicting early response to SB could save costs and toxicity. PET has never been properly tested as biomarker in this setting. **Methods:** This prospective study recruitedaHCC pts eligible for first-line SB therapy. RECIST response to treatment was evaluated by CT scan every 6 weeks, and metabolic PET response after two weeks on SB (1999 EORTC criteria). PET response cut-off: a minimum of 15% reduction in the sum of SUVmax of up to 5 target lesions. CT (CR+PR+SD *vs* PD) and PET (CR+PR *vs* SD+PD) responses were categorized as dichotomous variables. OS and time to progression (TTP) were calculated by the Kaplan–Meier test and statistically evaluated by the log-rank test. Association between OS/TTP and several meaningful clinical variables (including PET and CT response) were evaluated using univariate Cox proportional hazards regression analysis and significant parameters were included in a multivariate analysis. **Results:** Accrual: 55pts Characteristics: Median age: 71 years. Male 62%. PS 0-1/2(%) 60/40. Cirrhosis etiology: HCV/HBV/Alcohol/Other/unknown(%) 34/18/20/11/17. Child-Pugh A/B(%) 75/25. Extrahepatic spread(%) yes/no 60/40. Macroscopic vascular invasion(%) yes/no 30/70. Median AFP level 24.0 (range 2.0-85520.0). BCLC stage B/C(%) 12/88. CLIP stage 0/1/2/3/4(%) 13/25/25/23/12. Baseline PET+/-(%) 86/14. SB median dose: 400mg/d. Second-line therapy (Bevacizumab): yes/no(%) 44/56. Median TTP/OS 3.7 and 7.3 months (95%CI 2.30-5.12/ 4.87-9.77). Multivariate analysis showed that CLIP stage and CT and PET responses were independent prognostic factors for TTP. For OS CLIP stage, second-line therapy and PET response retained significance but not CT response. **Conclusions:** Early metabolic response strongly predicted survival benefit from first-line SB therapy in aHCC pts. Clinical trial information: NCT01157013.

**A phase I trial of of cixutumumab (C) (IMC-A12) and sorafenib (S) for treatment of advanced hepatocellular carcinoma (HCC).** *Presenting Author: Anthony B. El-Khoueiry, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** The insulin growth factor (IGF) pathway is activated in hepatocarcinogenesis. C is a monoclonal antibody against insulin-like growth factor-1 receptor (IGF-1R). *In vivo* HCC models showed activated IGF signaling and antitumor effects due to C. Given the cross-talk between the IGF and VEGF pathways, the combination of C and S was chosen. **Methods:** This study evaluated the safety of C (2, 4 or 6 mg/kg) IV weekly with standard doses of S (400 mg po bid) in patients (pts) with HCC. Eligibility criteria included: no prior systemic therapy for HCC, Child-Pugh score of A or B7, ECOG 0 or 1, platelets > 75,000/mm3, and albumin > 2.8 g/dl. The study used a standard 3+3 design. One cycle was 28 days. **Results:** A total of 21 pts (17 males and 4 females) were enrolled; mean age was 63 years (43-85); 10 Asian, 4 Hispanic, 5 White, 1 Black, and 1 Native American. There were 3 dose limiting toxicities (DLTs); grade 3 hyperglycemia, grade 3 hypophosphatemia, and grade 5 peritonitis (see table). The maximum tolerated dose (MTD) was C 4 mg/Kg and S 400 mg BID. 18 of 21 (86%) pts had ≥grade 3 toxicities attributable to treatment. Grade 3 adverse events that occurred in ≥ 2 pts were: diarrhea (4; 19%), hypertension (4; 19%), thrombocytopenia (3; 14%), palmar-plantar erythrodysesthesia (2; 10%), hyperglycemia (2; 10%), and fatigue (2; 10%). There was 1 grade 4 colonic perforation and 1 grade 5 peritoneal infection in the same pt. The median number of cycles was 4 (0-19 cycles). Sixteen of the 21 pts completed 2 cycles and were evaluated for response. 13 of the 16 (81%) (95% CI: 54%-96%) achieved stable disease. The median event free survival was 3.8 months (95%CI: 1.9, 11.3). The median OS was 13.1 months (95% CI: 7.6, undefined). An increase of 0.5 in baseline natural log of hepatocyte growth factor and insulin growth factor binding protein 3 were associated with risk of death (log rank p value 0.01 and 0.03). **Conclusions:** The majority of adverse events in pts treated with the combination of C and S were typical of sorafenib toxicity. There was preliminary evidence of efficacy as seen in the median OS. Clinical trial information: NCT01008566.

**Prognostic factors of overall survival of stage III or IV adrenocortical carcinomas (ACC): A multicenter ENS@T study.** *Presenting Author: Rossella Libe, Hopital Cochin, Paris, France*

**Background:** Several reports suggest heterogeneity of advanced ACC.The primary objectives of our study were to provide evidence for an improved staging and grading system and refine the prognostic classification of stage III-IV ACC**. Methods**: 444 patients registered with the ENS@T ACC database (diagnosed 2000-2009) were enrolled (210 stage III; 234 stage IV). Inclusion criteria were: age>18 yrs, pathological review, synchronous stage III-IV, follow-up available. Primary endpoint was overall survival. Parameters captured were: age, modality of diagnosis, TNM, pathological grading (Weiss score,Ki 67%), R status at first surgery. Univariate and multivariate analyses were performed according two models. Model 1 "prior surgery"; model 2 "post surgery." **Results:** 301 patients (68%) died due to ACC (median follow-up: 55.2 mo). Median overall survival was 24 mo. N positive status, but not venous invasion, was confirmed to behave like stage IV. A modified ENSAT (mENSAT) classification was therefore used: stage III in case of invasion in surrounding tissues/organs or vena renalis/cava; stage IVa, IVb, IVc if the number of metasatic organs (including N positive status) was 2, 3 or >3, respectively. ACC tumors with Ki 67>20% and/or Weiss score>6 was confirmed to behave significantly more aggressively. At multivariate analysis within model 1: age>50 years (HR:1.6,P<0.0001), presence of tumor- (HR:1.6, P=0.01) or hormone-related symptoms (HR: 1.6, p=0.03), mENS@T stage, (HR:2.6, HR:3.8 or HR:4.9 for stage IVa, IVb, or IVc respectively, all P<0.0001) were found significant. Within multivariate model 2: age>50 years (HR:1.1,P<0.01), presence of tumoral- (HR:1.7,P=0.01) or hormone-related symptoms (HR: 1.6,P=0.04), mENS@T stage, (HR:2.1,HR:2.7 or HR:3.7 for stage IVa, IVb, IVc respectively, all P<0.0001), R status (for R1/2/x HR:1.7,P=0.0006), grade (Weiss >6 and Ki67> 20%, HR:1.3,P=0.06) were found significant. By combining the different parameters 2 years-OS for mENSAT stage IV ranges between 17-67% in model 2. **Conclusions:** This largest prognostic study on advanced ACC patients allows to refine the prognostic stratification and future therapeutic management of advanced ACC patients.

**4107^ General Poster Session (Board #194), Sat, 8:00 AM-11:45 AM**

**Progression-free survival (PFS) with lanreotide autogel/depot (LAN) in enteropancreatic NETs patients: The CLARINET extension study.** *Presenting Author: Martyn E. Caplin, Neuroendocrine Tumour Unit, Royal Free Hospital, London, United Kingdom*

**Background:** The CLARINET core study showed that the long-acting somatostatin analog (SSA) LAN 120 mg significantly prolonged PFS vs placebo (PBO) in patients (pts) with metastatic enteropancreatic NETs (p=0.0002). Median PFS not reached with LAN vs 18.0 months with PBO. This study was the first randomized PBO-controlled trial investigating PFS with an SSA in a population that included pts with pancreatic NETs and pts with grade G2 tumors (Ki-67 <10%). Here, we report PFS data and safety findings from the open-label extension (OLE) to CLARINET. **Methods:** Pts enrolled in CLARINEThad: well/moderately differentiated non-functioning enteropancreatic NETs with Ki-67 <10%; no prior SSAs, or other medical therapies in last 6 months; metastatic disease. In CLARINET, pts were randomized to LAN 120 mg (n=101) or PBO (n=103) every 28 days for 96 wks or until death/disease progression (PD; according to RECIST 1.0). LAN pts with stable disease and PBO pts with/without PD could then enter the single-arm (LAN) OLE (NCT00842348, max. expected duration 5 yrs). The primary objective of the OLE was safety (safety population). The main efficacy endpoint was PFS (i.e. time from randomization in core study to death/PD) for the core study intent-to-treat population, using survival analysis based on Kaplan–Meier estimates. **Results:** 88 pts from the CLARINET core study (LAN arm, 41; PBO arm, 47) participated in OLE. At core study enrollment, 96% of OLE patients did not have tumor progression; 38% had pancreatic primary tumors, 39% had midgut, and 8% hindgut. The median PFS for LAN was reached during the OLE: 32.8 months. For subset of pts who had PD while on PBO in the core study, median time to further PD with LAN in the OLE was 14.0 months. During the OLE, 27% who continued LAN vs 40% switched to LAN had treatment-related adverse events (TRAE); most frequent TRAE was diarrhea. No new safety concerns were identified in the extension. **Conclusions:** CLARINET extension data suggest there were antitumor effects with LAN 120 mg in enteropancreatic NET patients with progressive disease. Long-term safety/tolerability of lanreotide in the extension was consistent with its known profile. Clinical trial information: NCT00842348.

**4108 General Poster Session (Board #195), Sat, 8:00 AM-11:45 AM**

**The association between octreotide dose and tumor control in gastroenteropancreatic neuroendocrine tumors (NETs).** *Presenting Author: Sally Chui Mei Lau, University of British Columbia, Vancouver, BC, Canada*

**Background:** Gastroenteropancreatic NETs represent a heterogeneous group of cancers that are associated with an indolent, protracted course. Octreotide has been used as a mainstay in the symptom management of these tumors. However, the recent PROMID study showed that octreotide 30 mg contributed to disease stabilization in well-differentiated midgut NETs, but a meaningful survival analysis was limited due to insufficient events. Our aim was to examine the relationship between octreotide dose and overall survival (OS) in a population-based setting. **Methods:** Patients diagnosed with NETS from 1987 to 2013, referred to any 1 of 5 regional cancer centers in British Columbia, and who initiated octreotide were reviewed. To account for variations in the duration of therapy, we determined the mean octreotide dose per 28-day cycle and compared OS based on dose of octreotide. Dose was dichotomized into high vs. low based on the median as well as 30mg as per the PROMID study. **Results:** A total of 170 patients were included: mean age 60 years (SD=13) and 54% were men. NETs most commonly originated from the midgut (47%) and the pancreas (21%). A significant proportion had unresectable, metastatic disease (81%) among whom the majority (87%) had hepatic involvement. Carcinoid symptoms that included diarrhea, flushing and wheezing were prevalent (72%). Octreotide was offered to patients with the intent of symptom management (71%), disease stabilization (23%), and tumor marker control (6%). The mean dose per 28-day cycle was 27 mg (SD=9). After accounting for symptoms and tumor burden, patients who received > 27 mg (n=78) experienced significantly longer median OS when compared to those who received </= 27 mg (n=92) of octreotide (82 vs. 39 months, respectively, p<0.0001). Likewise, median OS was also superior among those who were given > 30 mg (n=65) of octreotide as per the PROMID study, relative to those on </= 30 mg (n=105) of the drug (83 vs. 46 months, p=0.0001). **Conclusions:** Our findings suggest that higher doses of octreotide may confer OS benefits in selected patients with gastroenteropancreatic NETs and that titration of this drug to manage symptoms may not represent the optimal treatment strategy for all patients.

**4109 General Poster Session (Board #196), Sat, 8:00 AM-11:45 AM**

**Study of the gastroenteropancreatic neuroendocrine tumor (gep-net) microenvironment beyond angiogenesis: The role of lysyl oxidase-like 2 (LOXL2).** *Presenting Author: Jorge Barriuso, Translational Oncology and Pathology Group. La Paz University Hospital-IdiPAZ / Molecular Cancer Group. Faculty of Life Sciences. University of Manchester, Manchester, United Kingdom*

**Background:** A better understanding of the tumour microenvironment beyond angiogenesis of this heterogeneous group of malignancies remains a challenge. In this study, we present an exploratory analysis of the microenvironment protein expression and its relation with prognosis and previously described biomarkers. **Methods:** Formalin-fixed and paraffin embedded samples (FFPEs) of patients (pts) who underwent surgery for gep-net and their clinical data were collected consecutively from 1980 to 2012.Tissue microarrays were constructed from non-necrotic areas of tumour foci. Microenvironment related proteins (LOXL2, LOX, CXCR4, TWIST, $\beta$-catenin and E-cadherin) were studied by inmunohistochemistry and compared to the expression of SSTR2, ATRX and members of the mTOR pathway. The study was approved by the local Ethic Committee. Univariate (UVA) and multivariate analysis (MVA) was performed. Kaplan-Meier method, log rank test and cox regression was used to study disease free survival (DFS) and overall survival (OS). **Results:** A total of 115 FFPEswere analysed**.** Median age was 46 years; female/male ratio 1:1; 78 were intestinal. Grades were: G1 64.3%, G2 11.3%, G3 7 %, unknown 17.4%. Median follow up was 12 years. Stage and grade were statistically significant for DFS and OS ($p<0.001$) and remain so in the MVA. LOXL2 over expression was associated with better DFS and OS ($p<0.001$). $\beta$-catenin nuclear expression (BCAT) was related to worst DFS and OS ($p<0.001$). PTEN presence was associated with better DFS ($p<0.001$). MVA for DFS showed BCAT ($p=0.019$) and PTEN presence ($p=0.024$) as independent factors and LOXL2 ($p=0.024$) and BCAT ($p=0.004$) were significant for OS after adjustment for stage and grade. LOXL2 expression was associated with SSTR2 ($p=0.004$). **Conclusions:** LOXL2 is a druggable novel biomarker candidate for gep-nets.

**Antiproliferative activity of octreotide LAR in advanced neuroendocrine tumors.** *Presenting Author: Christos Toumpanakis, Neuroendocrine Tumour Unit, Royal Free Hospital, London, United Kingdom*

**Background:** The antiproliferative activity of Octreotide LAR in Neuroendocrine Tumors (NETs) has been demonstrated by small retrospective studies and confirmed by a prospective phase III trial (PROMID). However, there are limited data about the duration and predictors of response. The aim of our retrospective study was to determine the time to radiological progression (TTRP) of disease and the factors that were associated with better response **Methods:** Overall, 254 patients with advanced NETs and positive somatostatin receptor scintigraphy were included. Radiological assessment was based on RECIST criteria. Univariate and multivariate analyses were used to identify predictive factors. Median TTRP and 95% confidence intervals were calculated using Kaplan-Meier analysis. **Results:** The patients' mean age was 60.5 +/- 12.8 years. Male to female ratio was 1.1. Mean follow-up was 42 months. The location of primary was in small bowel in 204, pancreas in 22, lungs in 14, rectum in 7 and unknown in 7 patients. Tumors were well-differentiated, G1 (71%) and G2 (29%). Octreotide LAR was commenced for functional symptoms in 68%, radiological progression in 13%, whilst 29% of patients were asymptomatic with stable disease and started treatment on the basis of PROMID data. Partial response occurred in 5%. For all patients, the median TTRP was 37 months (95% confidence interval, CI: 32-52 months). There was a statistically significant shorter TTRP in patients with pancreatic primary (p: 0.001), G2 tumors (p: 0.001), high hepatic tumor volume (p: 0.006), and baseline Chromogranin-A (CgA) levels >10 times the upper normal limit (p: 0.006). Mean time to progression was longer in patients with stable disease at presentation (53 months). Age, mesenteric mestastases, desmoplasia and previous resection of primary did not affect progression. Female sex and skeletal metastases had some negative, but no statistically significant, effect. **Conclusions:** The duration of anti-proliferative effect of Octreotide LAR seems to be longer than previously reported. Small bowel primary and G1 tumors, as well as low hepatic tumor volume, lower CgA levels and stable disease at the time of commencement of treatment seem to be associated with a more favorable response.

**4111^ General Poster Session (Board #198), Sat, 8:00 AM-11:45 AM**

**Lanreotide autogel/depot (LAN) treatment for carcinoid syndrome (CS) symptoms: Patient-reported outcomes (PROs) from the SYMNET study.** *Presenting Author: Philippe B. Ruszniewski, Beaujon Hospital, Clichy, France*

**Background:** Somatostatin analogs can provide CS symptom relief, but associated PROs in clinical practice, in particular patient (pt) treatment satisfaction, are less clear. **Methods:** SymNET was a large multinational observational study of PRO after >3 months' LAN for CS-related diarrhea (NCT01234168). At a routine clinic visit (CV), 273 pts reported their satisfaction with diarrhea control (primary endpoint) on a 5-point Likert scale. Secondary endpoints included health-related quality of life (HRQoL) assessed with EORTC QLQ-C30 and G.I.NET 21 questionnaires completed by pts. HRQoL scores were transformed for some items/scales so that all had a range 0–100. Summary statistics were derived from evaluable data (enrolled population). **Results:** 58% (157/273) of pts were >60 yrs, 66% (176/267) had small-bowel primary tumors, and 80% (217/271) had liver metastases. At the CV, median LAN treatment duration was 11 months and 76% (203/268) [95% CI: 70–81%] were satisfied with diarrhea control (primary endpoint). QLQ-C30: problematic symptoms were fatigue, insomnia, diarrhea and, to a lesser extent, pain; in contrast, the majority of pts had no problems with other symptoms, levels of functioning were high, and global QoL only slightly lower (Table). G.I.NET 21: problematic symptoms were disease-related worries, social function, and muscle/bone pain and, to a lesser extent, gastrointestinal and endocrine symptoms; the majority of pts had no problems with other symptoms, including treatment-related effects. **Conclusions:** High levels of pt satisfaction with LAN for CS-related diarrhea were generally accompanied by high levels of HRQoL functioning. These data show HRQoL levels that are currently attained in a real-world setting and may help guide future efforts in CS management. Clinical trial information: NCT01234168.

**Octreotide LAR (OCT-L) among elderly patients with stage IV neuroendocrine tumors (NETs): A survival analysis of SEER-Medicare data.** *Presenting Author: Chan Shen, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** OCT-L is approved in the US for the management of secretory syndromes among patients with NETs. Two placebo-controlled studies have recently demonstrated that somatostatin analogues delay time to progression. The effect of OCT-L on overall survival (OS) has not been evaluated. **Methods:** Stage IV NET patients diagnosed between 1/1999 and 12/2009 were identified from the SEER-Medicare database. Those under age 65, with poorly differentiated histology, enrolled in HMOs, or without continuous enrollment were excluded. HCPCS codes, J2352 and J2353, were used to identify OCT-L use. Current analysis compares the OS of those who started OCT-L within 12 months of diagnosis to those who did not receive OCT-L during the observation period. Presence of secretory syndrome was defined as having ≥ 2 claims for carcinoid syndrome, flushing, diarrhea, or malignant islet cell neoplasm either before the start of OCT-L for those who received it; or within 12 months of diagnosis for those who did not receive OCT-L. Analyses included Kaplan-Meier estimation and Cox proportional hazard modeling with covariates including age, gender, race, region, comorbidity score, urban/rural status, tumor characteristics, other treatments received, neighborhood socioeconomic status and year of diagnosis. **Results:** Among 1,149 patients, 231 (20%) received OCT-L within 12 months of diagnosis, 394 (34%) had secretory syndrome. Median OS from diagnosis among patients who started OCT-L within 12 months (35.4 [95%CI, 28.3 – 49.3] months) was longer than those who did not receive OCT-L during the observational period (20.3 [95%CI, 17.3 – 24.2] months; $P<0.001$). Multivariate Cox proportional hazard regression showed that OCT-L was associated with significant improvement in survival both for the whole study group ($HR=0.69$, $P<0.001$) and in the subgroups with ($HR=0.64$, $P=0.003$) and without ($HR=0.56$, $P=0.002$) secretory syndrome. Other significant predictors were age, gender, race, comorbidity score, primary tumor site, and surgery. **Conclusions:** This population-based study suggests potential survival benefits for use of OCT-L among elderly stage IV NET patients with or without secretory syndrome.

**4113 General Poster Session (Board #200), Sat, 8:00 AM-11:45 AM**

**Profiling of 1,350 neuroendocrine tumors for identification of multiple potential drug targets.** *Presenting Author: Igor A. Astsaturov, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Identification of new drug targets may extend treatment options for neuroendocrine tumors (NET) regardless of histologic classification or primary organ site. **Methods:** 1,350 cases of infradiaphragmatic neuroendocrine tumors (all grades and sites) were identified among >60,000 cases profiled in a CLIA-certified laboratory. Biomarker profiling utilized multiple platforms: gene sequencing (next generation sequencing [NGS], Sanger or pyrosequencing), gene copy number (*in-situ*hybridization), and protein expression (immunohistochemistry [IHC]). The results are shown relative to the total number of tests performed. **Results:** Overall, drug therapy-relevant alterations were identified in 1255 of 1350 (93%) of cases. Low or absent (0 or 1+ by IHC) expression of MGMT a biomarker of sensitivity to alkylating agents, was found in 149/243 pancreatic cases (61%), and in 488/1015 (48%) of non-pancreatic NET. Low or absent (0 or 1+ by IHC) expression of RRM1, a biomarker of gemcitabine sensitivity, was found in 927/1193 of NET (78%) and low or absent thymidine synthase, TS, a biomarker of fluoropyrimidines sensitivity, was shown for 950/1187 (80%) of NET by IHC. Sequencing of tumors showed oncogenic mutations in BRAF (6/446 (V600E in 4, and G596R in 2), CTNNB1 (3/223), KIT (4/357), EGFR (1/245), FGFR2 (2/224), GNAS (1/224), HRAS (2/192), PIK3CA (10/418), RB1 (4/222) VHL (2/203), KRAS (23/472), NRAS (2/349), and APC (14/224) and amplifications of EGFR (46/688) and MET (4/306. Therapies guided by mechanism-based biomarkers produced durable responses in documented cases: partial response (PR) >1 year to imatinib in a patient with KIT-mutant metastatic NET, and in cases of $MGMT^{low}/TS^{low}$treated with streptozocin or temozolomide plus fluoropyrimidine chemotherapy, thus supporting the clinical relevance of target profiling in NET. **Conclusions:** Comprehensive multiplatform profiling of a large series (n=1350) of NET, despite low frequency of individual biomarkers, identified clinically relevant targets in >90% of patients.Given the increasing utilization of chemotherapy for NET, our results provide the basis for future clinical trials to assess the efficacy of biomarker-based therapy for NET.

**4114 General Poster Session (Board #201), Sat, 8:00 AM-11:45 AM**

**Defining the neuroendocrine tumors landscape: A 15-year population-based analysis of incidence, outcomes, and therapies.** *Presenting Author: Julie I. Hallet, Odette Cancer Centre, Sunnybrook Health Sciences Centre; University of Toronto, Toronto, ON, Canada*

**Background:** Neuroendocrine Tumors (NETs) are poorly understood malignancies. We sought to define epidemiologic characteristics and outcomes, and describe systemic, interventional and surgical therapies use for NETs. **Methods:** We conducted a population-based retrospective cohort study of all adult patients with NETs in Ontario from 1994 to 2009, linking propsective databases linked at the Institute of Clinical Evaluative Sciences. We looked at incidence, proportion of metastatic disease, overall survival (OS), and use of systemic therapy (ST), liver embolization (LE), and surgery. **Results:** We identified 5619 NET cases. Incidence of NETs increased from 2.48 to 5.86 per 100 000 per year over 15 years. Synchronous metastases were found in 20.8% and metachronous metastases in 38%. Incidence and metastases varied according to primary NET site. Around time of diagnosis (60 days pre/post diagnosis), 56.8% did not consult a surgeon and 97.2% did not see a medical oncologist. Initial primary site resection was performed in 63.9% broncho-pulomnary (BP), 57.1% gastrointestinal (GI) and 46.4% pancreas (PA) NETs (p <0.001). 53.7% of all liver metastases were resected. ST was used in 46% of PA, 23.2% GI and 25.4% BP NETs, and LE in 8.1% BP, 11.9% GI, and 19.2% PA NETs. 10-year OS was 42.8%, with independent predictors of worse OS being: advanced age, male gender, low socioeconomic status, rural living, and pancreas and small intestine sites. **Conclusions:** NETs incidence has markedly increased over 15 years, with outcomes disparities based on demographics, social, and tumor characteristics. Patterns of care for NETs were irregular and sporadic. Numerous NETs were not assessed by a surgeon or medical oncologist, indicating worrisome potential under treatment and non-optimal management. Future work is needed to define mechanisms explaining this portrait in order to improve outcomes through early diagnosis, more frequent surgical referrals and standardization of therapies.

**4115 General Poster Session (Board #202), Sat, 8:00 AM-11:45 AM**

**Retrospective analysis of CA19-9 decrease in patients with metastatic pancreatic carcinoma (MPC) treated with FOLFIRINOX or gemcitabine (gem) in a randomized phase III study (ACCORD11/PRODIGE4).** *Presenting Author: Marie Robert, Institut de cancérologie de l'Ouest, Nantes, France*

**Background:** RECIST criteria remain the reference for tumor response evaluation. Carbohydrate antigen 19-9 (CA19-9) is known to be a sensitive and specific serum marker in pancreatic cancer. Its determination could be helpful to assess early therapeutic efficacy (MPACT trial, ASCO 2013, abstract 4058). Our retrospective analysis aims to evaluate CA19-9 decrease in patients included in the randomized phase III study ACCORD11/PRODIGE4 comparing FOLFIRINOX and gem in MPC. **Methods:** 342 patients were treated in the ACCORD11/PRODIGE4 study. CA19-9 levels were available at inclusion for all patients and 283 had abnormal values. CA19-9 measures were performed at 8 weeks ± 2 for 160 patients (gem arm, 75 patients and FOLFIRINOX arm, 85 patients). In this retrospective study, best CA19-9 decrease, or 8-week CA19-9 decrease ≥ 20 % were analysed. According to these CA19-9 rates, efficacy parameters, progression free survival (PFS) and overall survival (OS) were estimated. **Results:** FOLFIRINOX superiority compared with gem is confirmed in this population subgroup with a better PFS (6.7 vs 3.9 months; HR 0.52, IC95%: 0.36-0.73, p<0.001) and OS (12.0 vs 7.6 months; HR 0.55; IC95%: 0.38-0.79, p=0.001). 8-week CA19.9 decrease ≥20% was correlated with a better OS [10.3 vs 7.8 months; HR 0.57, (IC95%: 0.40-0.81); p=0.002] and PFS [6.1 vs 3.0 months, HR=0.58 (IC95%: 0.42-0.81), p=0.001]. A higher proportion of patients in the FOLFIRINOX arm had an 8-week CA19-9 and a best CA 19-9 decreases ≥20%. Median OS, PFS and ORR for those patients were improved (Table). **Conclusions:** CA19-9 response was increased in patients treated with FOLFIRINOX regimen and correlated with OS, PFS and ORR. CA19-9 could be considered as a potential early surrogate marker and therefore help to evaluate the efficacy of FOLFIRINOX and gem regimen.

**4116 General Poster Session (Board #203), Sat, 8:00 AM-11:45 AM**

**A phase I trial of the γ-secretase inhibitor (GSI) MK-0752 in combination with gemcitabine in patients with pancreatic ductal adenocarcinoma (PDAC).** *Presenting Author: Natalie Cook, Cancer Research UK, Cambridge Research Institute, University of Cambridge, Cambridge, United Kingdom*

**Background:** The Notch pathway is frequently activated in cancer. Pathway inhibition by GSIs has been shown to be effective in models of PDAC, in combination with gemcitabine (GEM). **Methods:** A multi-centre, non-randomised Bayesian adaptive design study of MK-0752, administered p.o. weekly (starting dose; 1,200mg), and GEM i.v. on days 1, 8 and 15 (28 day cycle) at 800 or 1000 mg/m$^2$, is being performed to determine the safety (using CTCAE v4.02) of combination treatment and recommend a Phase 2 dose (RP2D) combination. Other objectives are tumor response (RECIST 1.1), plasma and tumor MK-0752 concentration, and inhibition of the Notch pathway in hair follicles (expression profiling) and tumor (IHC). **Results:** 29 patients (pts) were registered on the study, of whom 27 received treatment (17 WHO PS 1; 10 PS 0). All patients received GEM/MK-0752 as first line treatment for metastatic disease. The RP2D of both single agents could be administered in combination (MK-0752 1800mg and GEM 1000 mg/m$^2$). As no DLTs were experienced at this dose combination, the Bayesian algorithm allowed further dose escalation, but dose limiting toxicity (G3 hypokalaemia) was observed at MK-0752 2,400mg in 1 pt. Gastrointestinal related adverse events (AEs) were common (diarrhoea 18 pts; nausea 19 pts; vomiting 17 pts). Other (>10% pts) AEs included fatigue, thrombocytopenia (G4 in 1 pt) and transaminitis. Tumor response evaluation was available after 10 weeks of treatment in 18 pts (6 withdrew early due to AEs, 1 pt was not evaluable, 2 pts still on treatment): 11/18 achieved stable disease and a confirmed partial response was observed at 12 weeks (time to subsequent progression 38 weeks). Plasma PK analysis revealed Cmax at 1,800mg of 61-104 μg/mL (n=7, Tmax, 4-8 hours) with a long half-life: quantifiable (>50 ng/mL) MK-0752 in plasma, 7 days after a single administration in 5/7 pts. A signature of Notch pathway inhibition was observed in 16/18 pts in hair follicles and paired biopsies (20 pts) are being analysed for tumor PK and Hes1 IHC. **Conclusions:** GEM and MK-0752, can be combined at full, single agent RP2Ds and the regimen is well tolerated. Clinical activity was seen, which will require confirmation in a Phase II trial. Clinical trial information: NCT01098344.

**4117 General Poster Session (Board #204), Sat, 8:00 AM-11:45 AM**

**Statin use and risk of pancreatic cancer: Results from a large clinic-based case-control study.** *Presenting Author: Evan J. Walker, University of California, San Francisco, School of Medicine, San Francisco, CA*

**Background:** Statins are cholesterol-lowering medications whose pleiotropic effects include alterations in growth signaling as well as immunomodulatory and anti-inflammatory effects that may alter cancer risk. Evidence from epidemiologic studies to date is conflicting as to whether statin use is associated with a reduced risk of pancreatic cancer (PC). The current case-control study investigates the association between statins and PC risk overall and by sex. **Methods:** Patients with a confirmed diagnosis of PC (cases) were recruited from medical and surgical oncology clinics at the University of California, San Francisco, with controls (frequency-matched by sex and age) recruited from general medicine clinics, from 2006-2011. Direct interviews were conducted using an epidemiological risk factor questionnaire covering topics such as lifestyle factors, diet, and medication usage. Adjusted multivariable logistic regression was used to compute odds ratios (OR) and 95% confidence intervals (CI) as estimates of the relative risk of PC. **Results:** Data were obtained from 536 cases and 869 controls. Ever use of statins was associated with 34% reduced PC risk (OR=0.66, 95%CI 0.47-0.92). In sex-stratified analyses, risk was statistically significantly reduced in men only (men: OR=0.51, 95%CI 0.32-0.80; women: OR=0.86, 95%CI 0.52-1.43). Duration of use was inversely associated with PC risk in men (long-term use: OR= 0.41, 95%CI 0.21-0.79; $p_{trend}$=0.005). Exploratory analyses of statins classified according to pharmacologic characteristics showed reduced PC risk in participants using statins with high compared to low bioavailability (p=0.01), whereas no significant differences were observed according to statin potency, solubility, or pattern of metabolism. **Conclusions:** This is the largest case-control study to demonstrate an inverse association between statin use and PC risk. Risk reduction from statins appears to be sex-specific and is more pronounced in long-term users. Further research is warranted to better characterize this association and clarify the role of underlying biologic mechanisms. If validated, statins could prove useful as preventive drug therapy for this disease. Supported by NIH R01 CA 109767.

**4118 General Poster Session (Board #205), Sat, 8:00 AM-11:45 AM**

**Serum procarboxypeptidase combined with CA19-9 and accuracy of detection of pancreatic cancer.** *Presenting Author: Michelle A. Orlowski, Princeton University, Princeton, NJ*

**Background:** Pancreatic cancer continues to have a dismal prognosis when diagnosed at an advanced stage. Thus, there is need for an early detection test. CA19-9 is the "gold standard", but fails as a means for detecting early stage disease. Previous studies have shown that pancreatic cancer, particularly in its early stages, is characterized by elevation in serum procarboxypeptidase A (PCPA) and high ratios of PCPA to free carboxypeptidase A (FCPA). The ratio can also enhance the diagnostic efficacy for some late stage tumors when the PCPA is within the normal range. The purpose of this study was to evaluate the performance of the assay alone and with CA19-9 in an independent cohort. **Methods:** Pre-treatment serum from 224 subjects recruited at Mayo Clinic were used (74 early and 75 late stage clinically and/or histologically proven pancreatic adenocarcinoma patients, and 75 healthy primary care controls). 111 cases had a head lesion and 38 had a body/tail lesion. All had CA19-9 measured. Blinded to clinical status, PCPA and FCPA were measured using a newly-automated method on the Beckman Coulter UniCel DxC 800 Synchron Clinical System. Patients were classified as having cancer if they had CA19-9 >55 and/or PCPA/FCPA ratio either <1 or >33, based on previous studies. **Results:** As single biomarkers, CA19-9 and PCPA/FCPA ratio have similar sensitivity (73.2 vs. 72.5, respectively), but specificity was higher for CA19-9 (98.7 vs. 78.7, respectively). A biomarker panel containing both the PCPA/FCPA ratio and CA19-9 improves sensitivity (73.2% to 87.2%, McNemar's test p-value < 0.0001) when compared to CA19-9 alone; specificity is decreased (98.7% to 82.7%, McNemar's test p-value = 0.0005). However, overall accuracy is increased relative to CA19-9 alone (81.7% to 85.7%). **Conclusions:** In a blinded, single draw independent sample, the combination of the PCPA/FCPA ratio and CA19-9 has demonstrated 87.2% sensitivity and 82.7% specificity for pancreatic cancer in a heterogeneous patient population. The addition of the PCPA assay may provide some promise for the development of a screening tool for the early detection of pancreatic cancer in high risk patients and studies are needed to further validate the utility of the assay.

**4119 General Poster Session (Board #206), Sat, 8:00 AM-11:45 AM**

**Treatment, outcomes, and clinical trial participation in very elderly patients (pts) with metastatic pancreas cancer (mPC).** *Presenting Author: Daneng Li, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** PC has a median age at diagnosis of 72 years. Aldoss et al. (Veterans Affairs Cancer Registry) and Vijayvergia et al. have reported that elderly pts are less likely to receive standard therapy compared to younger pts. Limited other studies in the very elderly (>80 years) with PC have been undertaken. **Methods:** A retrospective analysis on 237 pts with mPC >75 years of age who received care at Memorial Sloan Kettering Cancer Center between 2005 to 2013 was performed. Age groups: 75-79, 80-84, and 85+ years were analyzed and compared with respect to demographics, comorbidities, performance status, primary site of tumor, location and number of metastatic sites, laboratory data, treatment including type and number of systemic agents, clinical trial participation and overall survival (OS) after diagnosis. **Results:** A total of 196 (83%) pts received systemic therapy. The median OS of the entire cohort was 7 months. Use of therapy versus no therapy was significantly associated with longer OS (p<0.01). No significant difference was detected in survival between the different age groups among those receiving chemotherapy (p=0.49). Seventy-seven (32%) pts participated in a clinical study (biospecimen collection, psychosocial, therapeutic, etc); however, only 13 (5%) pts were enrolled in a therapeutic clinical trial with no pt age 85+ participating in a therapeutic study. **Conclusions:** Use of systemic therapy has a survival benefit in selected very elderly pts with mPC. While participation in any study was high, the number of very elderly pts enrolled in a therapeutic trial remains very low and similar to overall PC clinical trial participation (4.57%, Hoos et al. J Clin Oncol, 2013). In the future, therapeutic trials participation in this age group should be further encouraged.

| Age | Total cohort | 75-79 | 80-84 | 85+ |

**4120 General Poster Session (Board #207), Sat, 8:00 AM-11:45 AM**

**A phase II study of perioperative therapy for patients with resectable and borderline-resectable pancreatic adenocarcinoma.** *Presenting Author: Andrew L. Coveler, University of Washington, Seattle, WA*

**Background:** Most patients (pts) who undergo surgical resection (SR) for pancreatic ductal adenocarcinoma (PDA) relapse and die. Adjuvant chemotherapy (CT) improves survival compared to observation in randomized trials, but median disease-free survival (DFS) and overall survival (OS) are only 13.4m and 22.1m, respectively. Multiagent CT in the metastatic setting improves DFS and OS compared to gemcitabine (G) alone. Neoadjuvant (NA) treatment of resectable PDA is a rational though unproven strategy to improve standard results. We hypothesized NA multiagent CT and chemoradiotherapy (CRT) paired with SR and adjuvant CT would be manageable and improve the OS of pts with borderline (BR)/resectable (R) PDA. **Methods:** This was a prospective, single arm, single institution phase II trial. Eligibility included confirmed PDA, R/BR disease, ECOG ≤ 2, and adequate organ function. NA CT (3 cycles of GTX (G 750mg/m$^2$ over 75 minutes and docetaxel 30mg/m$^2$ days (d) 4 and 11, capecitabine (C) 750mg/m$^2$ BID d1-14)) followed by CRT (IMRT 3 Gy/fraction on days 1-5 and 8-12 (30 Gy total) with C 650mg/m$^2$ BID d1-14 and oxaliplatin (O) 60mg/m$^2$ d1 and 8. Adjuvant CT was 2m of GemOx (G 1000mg/m$^2$ and O 85mg/m$^2$ d1 every 14d) and 2m of standard G. The primary objective was to estimate the OS of pts treated in this fashion. Secondary objectives included DFS, Response Rate (RR), pathologic RR, SR completion and safety. **Results:** 35 pts were enrolled, 16 had BR disease and 16 were clinically node positive. One pt had progression during NA CT and 32 (91%) completed NA CRT. 31 (89%) pts went to surgery, 6 had occult metastases, 2 were locally advanced and 23 had SR (74% R0 and 26% R1). Pathology demonstrated 1 pCR and 87% N0. Among 35 pts enrolled, 21 (60%) are alive with a median follow-up of 23.6m. Median OS of all 35 patients is 31.1m and mDFS is 27.6m. Of 23 pts who underwent SR, 18 remain alive with a median follow-up of 25.7m. Estimated mDFS is 35.1m with a lower 95% confidence limit of 18.9m and mOS is not reached to date. **Conclusions:** In this phase II study, peri-operative multiagent CT and CRT was feasible and resulted in promising DFS and OS outcomes relative to historical controls. The current results are encouraging and warrant further evaluation. Clinical trial information: NCT00609336.

**4121 General Poster Session (Board #208), Sat, 8:00 AM-11:45 AM**

**Predictive cytokine biomarkers for survival in patients with advanced pancreatic cancer randomized to sequential chemoimmunotherapy comprising gemcitabine and capecitabine (GemCap) followed by the telomerase vaccine GV1001 compared to concurrent chemoimmunotherapy in the TeloVac phase III trial.** *Presenting Author: John P. Neoptolemos, University of Liverpool, Liverpool, United Kingdom*

**Background:** The TeloVac trial randomized 1,062 patients with advanced pancreatic cancer to a control chemotherapy Arm1, using GemCap; sequential chemoimmunotherapy Arm 2, GemCap for 8 wks followed by GV1001 and GMCSF (d1, 2, 5 during wk 9, then once on wks 10, 11, 12, 14, followed by once 4-wkly) with further GemCap given if there was PD at wk 8; and concurrent chemoimmunotherapy Arm 3, GemCap and GV1001 and GMCSF (d1, 2, 5 during wk1, then once on wks 2, 3, 4, 6, andthen once 4-wkly) . The final results (ASCO 2013) did not show improved survival with the addition of GV1001 to GemCap. A translational component examined predictive cytokine biomarkers **Methods:** 27 cytokines plus CRP were measured (Luminex) in 38 patients in Arm2 at baseline and in 50 at wk8 (after 2 cycles of GemCap, no vaccine) and in 41 patients in Arm3 at baseline and in 51 at wk10 (3rdcycle GemCap, 4 wks after the previous vaccine dose). The results at baseline and post-treatment were compared between the two arms and survival. **Results:** 19 cytokines showed a significant fall ($P<0.05$) between pre- and post-treatment in Arm2 (PDGF, IL1b, 1ra, 2, 4, 5, 7, 10, 12, 13 and 17, GCSF, IFNg, eotaxin, FGFb, MIP1b, RANTES, TNFa, VEGF; but not CRP, IL6, 8, 9, and 15, GMCSF, IP10, MCP1, MIP1a) and none in Arm3. Baseline eotaxin levels predicted median (95% CI) overall survival in Arm3 (high eotaxin=14.8 [10.1-20.5] mths; low eotaxin=7.9 [5.9-11.3] mths; p=0.0135) but not in Arm2 (high eotaxin=9.8 [5.5-11.8] mths; low eotaxin=6.2 [3.4-10.5] mths; p=0.1138 **Conclusions:** GemCap chemotherapy induced a fall of a distinct range of cytokines which was prevented by GV1001 given with GemCap. High eotaxin (CLL11) levels may predict improved survival in patients given GV1001 with GemCap but its role in advanced pancreatic cancer is subject to prospective trial validation Clinical trial information: 43482138.

**4122 General Poster Session (Board #209), Sat, 8:00 AM-11:45 AM**

**Gemcitabine(G)/erlotinib(E) versus gemcitabine/erlotinib/capecitabine(C) in the first-line treatment of patients with metastatic pancreatic cancer (mPC): Efficacy and safety results of a phase IIb randomized study from the Spanish TTD Collaborative Group.** *Presenting Author: Manuel Benavides, Hospital Universitario Carlos Haya, Malaga, Spain*

**Background:** G and E have shown a survival benefit in the 1st-line setting in mPC. The aim of this study was to assess whether combining C with G+E was safe and effective as compared with G-E in patients(pts) with mPC. **Methods:** Previously untreated pts with mPC were randomized in a 1:1 ratio to receive G(1000 mg/m2, d1,8,15)+E(100 mg, d1–28)+C(1660 mg/m2, d1-21) or G+E, q4-wk, until progression or unacceptable toxicity. Primary endpoint: progression-free survival (PFS); secondary endpoints: overall survival (OS), response rate (RR), relationship of rash with PFS/OS, and safety. A sample size of 118 pts was required for a hazard ratio(HR) of 0.63, assuming a median PFS of 6 months (m) in pts treated with GEC; unilateral $\alpha=0.05$; $\beta=0.8$. **Results:** 120 pts were randomized. Median age: 63 years; ECOG status 0/1/2(%), 33/58/8. Median follow-up was 16.5 m (95%CI:13.7-26.2). Median PFS was 4.3 m in the GEC arm and 3.8m in the GE arm (HR:0.88; 95%CI:0.58-1.31; p=0.52). The estimated median OS was 6.8 m in the GEC arm as compared with 7.7 m in the GE group (HR:1.09, 95%CI:0.72-1.63; p=0.69). Neutropenia grade 3/4 (GEC 43% vs GE 15%; p=0.0008) and mucositis (GEC 9% vs GE 0%;p=0.03), were the only statistically significant differences in grade 3/4 adverse events. PFS and OS were significantly longer in pts with rash (grade $\geq$ 1) vs no rash (grade=0): PFS 5.5 vs 2.0 m; HR=0.39 95%CI:0.26-0.6; $p<0.0001$ and OS: 9.5 vs 4.0 m; HR=0.51 95%CI:0.33-0.77; p=0.0014). **Conclusions:** PFS with GEC was not different to that with GE as it did not meet the criterion for statistical significance. Skin rash strongly predicted erlotinib efficacy, deserving further investigation for patient selection. Clinical trial information: NCT01303029.

**4123 General Poster Session (Board #210), Sat, 8:00 AM-11:45 AM**

**Nab-paclitaxel (nab-P) combined with FOLFOX for advanced pancreatic cancer: A phase I study.** *Presenting Author: Howard Safran, Brown University Oncology Research Group, Providence, RI*

**Background:** The contribution of irinotecan to the efficacy of FOLFIRINOX in pancreatic cancer is uncertain. The addition of irinotecan to gemcitabine was not superior to gemcitabine alone in pancreatic cancer, however nab-P demonstrates a survival benefit. This phase I study was designed to evaluate the addition of nab-P to fluorouracil, leucovorin, oxaliplatin (FOLFOX-A). **Methods:** Patients with metastatic or locally advanced pancreatic adenocarcinoma without prior treatment received oxaliplatin, 85 mg/m$^2$, leucovorin 400 mg/m$^2$ and 5-FU 2400 mg/m$^2$ with 3 dose levels of nab-P (125, 150 and 175 mg/m$^2$) every 2 weeks for up to 12 cycles. Patients with locally advanced disease could receive locoregional therapy after 6 cycles. The maximum tolerated dose (MTD) was established from dose limiting toxicities (DLTs) in the first 2 cycles of therapy. A study amendment, to include an expansion phase allowing a dose reduction of oxaliplatin to 68 mg/m$^2$for patients developing grade 2 neuropathy to facilitate administration of $>$ 10 cycles of FOLFOX-A, was activated after the MTD was determined. **Results:** 25 patients (pts) have been entered: Dose level 1 (n=6), dose level 2 (N=16), dose level 3 (N=3). The median age was 65 (35-82). Eighteen had metastatic and 7 had locally advanced disease. 15 pts were entered to determine the MTD. DLTs of nausea and fatigue occurred in 2 of 3 pts at dose level 3. Eight of the first 9 pts (89%) who received 10 or more cycles of FOLFOX-A had grade 2 or greater neuropathy including 2 of 9 (22%) with grade 3 neuropathy. None of the pts receiving less than 10 cycles of FOLFOX-A developed grade 2 neuropathy. One patient had grade 3 and one patient had grade 4 neutropenia. Eight of the first fifteen pts (53%) had a partial response. Following activation of the amendment allowing a dose reduction of oxaliplatin for grade 2 neuropathy, 10 additional pts have been enrolled. **Conclusions:** The MTD of nab-P is 150mg/m$^2$ every 2 weeks with FOLFOX. FOLFOX-A has substantial activity and may represent a promising regimen in pancreatic cancer. Supported by the Davis and Browning families and LIFEcycle. Clinical trial information: NCT01744353.

**4124 General Poster Session (Board #211), Sat, 8:00 AM-11:45 AM**

**Hent1 expression in patients with pancreatic cancer treated with gemcitabine after curative intended resection: Results from the CONKO-001 trial.** *Presenting Author: Marianne Sinn, Medical Department, Division of Hematology, Oncology and Tumor Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany*

**Background:** High expression of human equilibrative nucleosid transporter 1 (hent1) is considered to predict disease-free (DFS) and overall survival (OS) in patients (pts) treated with adjuvant gemcitabine for pancreatic cancer. No standard evaluation system for immunohistochemical analysis (antibody, scoring system) is established so far. **Methods:** CONKO-001, a prospective randomized phase III study investigated the role of adjuvant gemcitabine (gem) as compared to observation (obs). Representative formalin-fixed, paraffin-embedded (FFPE) tumor samples of 156 patients were collected and tissue microarrays (TMA) built. TMA slides (4 $\mu$m) were evaluated by immunohistochemistry for expression of hent1 (rabbit monoclonal antibody SP120 Ventana Medical Systems). The analysis was performed by an experienced pathologist blinded to clinical outcome. Hent1 high was defined as unequivocal membranous staining in more than 50% of tumor cells, all other cases were classified as hENT1 low. Kaplan-Meier analyses for median DFS (mDFS) and median OS (mOS) were performed in dependence of hent1 expression. **Results:** For the 88 gem and 68 obs pts, mDFS (mOS) was 12.9 (22.7) months and 6.2 (19.1) months, respectively and thus comparable to the overall study population of CONKO-001 (mDFS gem 13.4 vs obs 6.7 months, mOS gem 22.8 vs obs 20.2 months). High hent1 expression was not associated with improved mDFS (high hent1 11.5 months vs low hent1 13.2 months, p= 0.5; HR 1.19, 95% CI 0.72-2.0) or mOS (high hent1 19.7 months vs low hent1 24.4 months, p=0.92; HR 1.03, 95% CI 0.63-1.68) in the gem group nor in the obs group (median DFS high hent1 5.9 months vs low hent1 6.2 months, p=0.83; median OS high hent1 20.4 months vs low hent1 17.7 months, p=0.65). **Conclusions:** Corresponding to previously available and contradictory data, we can not confirm a predictive role of hent1 in our study population. Reproducible standard procedures and further investigations are urgently needed prior to the implementation or exclusion of hent1 as predictive biomarker in the treatment of pancreatic cancer.

**4125 General Poster Session (Board #212), Sat, 8:00 AM-11:45 AM**

**A UGT1A1 genotype-guided dosing study of modified FOLFIRINOX (mFOLFIRINOX) in previously untreated patients (pts) with advanced gastrointestinal malignancies.** *Presenting Author: Manish Sharma, The University of Chicago Medicine, Chicago, IL*

**Background:** FOLFIRINOX improves survival compared with gemcitabine in advanced pancreatic cancer (PC), but at the cost of significant toxicity (Conroy, *NEJM*2011). UGT1A1 clears SN-38, the active metabolite of irinotecan (IRI); UGT1A1 gene polymorphisms that reduce enzymatic activity predispose to severe IRI toxicity. We hypothesized that dosing mFOLFIRINOX based on UGT1A1*28 genotype could prevent toxicity. Thus, the primary objective of this study (NCT01643499) was to determine whether genotype-guided dosing of IRI in mFOLFIRINOX is tolerable. A secondary objective was to describe objective response rates (ORR; by RECIST 1.1) in PC, biliary tract cancers (BTC), and gastric cancer (GC). **Methods:** mFOLFIRINOX was given every 14 days. CT scans were obtained every 8 weeks. UGT1A1 *1/*1, *1/*28, and *28/*28 pts received initial IRI doses of 180, 135, and 90 mg/m$^2$, respectively. 5-FU dose was 2400 mg/m$^2$ over 46 hours (no bolus); leucovorin 400 mg/m$^2$; oxaliplatin 85 mg/m$^2$. Prophylactic pegfilgrastim was not allowed in cycle 1 (28 days), unless clinically indicated. DLT during cycle 1 was defined as Grade (Gr) 3/4 neutropenia with fever; Gr 4 neutropenia lasting $\geq$ 5 days; Gr 4 thrombocytopenia, or Gr 3/4 non-hematologic toxicity despite optimal medical management. Doses were tolerable if the DLT rate during cycle 1 was $\leq$ 33% with 70-80% statistical confidence, which required $\leq$ 2 DLTs in 15 pts. **Results:** 40 pts were evaluable for tolerability: 19 PC, 14 BTC, 7 GC. DLTs were observed in 2 of 15 *1/*1 pts (both neutropenic fevers); 2 of 16 *1/*28 pts (Gr 3 fatigue, diarrhea; Gr 3 fatigue); and 3 of 9 *28/*28 pts (2 neutropenic fevers; Gr 3 abdominal pain). Neutropenic fever was the most common DLT (4/7; 57%). To date, 35 pts are evaluable for response. ORR: 10/18 (56%) PC; 4/13 (31%) BTC; 3/4 (75%) GC. **Conclusions:** mFOLFIRINOX is tolerable in UGT1A1*1/*1 pts at the standard IRI dose of 180 mg/m$^2$ and in *1/*28 pts at a reduced dose of 135 mg/m$^2$. *28/*28 pts cannot tolerate a reduced dose of 90 mg/m$^2$. Accrual is ongoing for expansion cohorts in PC and BTC with prophylactic pegfilgrastim. Clinical trial information: NCT01643499.

| UGT1A1 genotype | Initial IRI dose (mg/m$^2$) | # DLTs / # pts |
|---|---|---|
| ***1/*1** | 180 | 2/15 |
| ***1/*28** | 135 | 2/16 |

**4126 General Poster Session (Board #213), Sat, 8:00 AM-11:45 AM**

**Impact of gemcitabine (Gem)- or capecitabine (Cape)-based chemoradiation (CRT) on health-related quality of life (HRQL) in patients with locally advanced pancreatic cancer (LAPC): Outcomes from the randomized phase II SCALOP trial.** *Presenting Author: Somnath Mukherjee, Gray Institute for Radiation Oncology and Biology, University of Oxford, Oxford, United Kingdom*

**Background:** HRQL in pancreatic CRT trials have not been widely reported. In SCALOP, registered patients (n=114) received Gem and Cape induction chemotherapy (4 cycles) and non-progressing patients (n=74) were randomized to conformal RT (50.4Gy/28 fractions/5.5 weeks) in combination with Gem (300mg/m$^2$ weekly) or Cape (830mg/m$^2$ bd on days of RT). SCALOP demonstrated superior overall survival (15.2 mo vs 13.4 mo, HR 0.39, p=0.012) and lower Grade 3/4 hematological toxicity (18% v 0%, p=0.008) in the Cape-CRT arm (Mukherjee, Lancet Oncol, Apr 2013). The SCALOP trial was funded by Cancer Research UK (CR UK 07/040). **Methods:** HRQL was assessed with EORTC QLQ-C30 (generic domains) and EORTC PAN26 (pancreas specific) at Week 0 (pre-treatment), Week17 (pre-CRT), Week23 (post-CRT) and follow-up (Weeks 26, 39). The difference in change in function and symptom scores between trial arms from pre-CRT baseline (week 17) to later time-points were analysed using Wilcoxon rank sum tests. **Results:** HRQL form completion was 93%, 82%, 65%, 68% and 58% respectively across the time-points. Compared to pre-CRT baseline (week 17), at the end of CRT (week 23), patients on Cape-CRT arm experienced significantly better HRQL outcomes in terms of cognitive functioning (p=0.04), fatigue (p=0.05), bloating (p=0.04) and dry mouth (p=0.03). The differences were no longer significant at week 26 or 39 apart from cognitive function scores (p=0.01) and dry mouth (p<0.01), which remained significant at week 39. **Conclusions:** The better HRQL in the Cape-CRT arm complements the outcome from the main trial and further supports the use of Cape rather than Gem as concomitant chemotherapy with radiation in LAPC. Clinical trial information: NCT01032057.

**4127 General Poster Session (Board #214), Sat, 8:00 AM-11:45 AM**

**Association of recurrence patterns following resection of pancreatic adenocarcinoma with overall survival.** *Presenting Author: Jin He, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Although recurrence is common after curative resection of pancreatic ductal adenocarcinoma (PDAC), little is known regarding the pattern of recurrence. **Methods:** We reviewed clinical data of 1,138 consecutive patients with PDAC who underwent pancreatectomy from 2000 to 2010 to document the pattern of recurrence based on CT and/or MRI and/or FDG-PET scan. Local recurrence (LR) was defined as cancer recurrence at the pancreatectomy site. Recurrence in the omentum, peritoneum, liver, lung, spine, pelvic or supraclavicular lymph nodes was considered as distal recurrence (DR). **Results:** The median follow up was 17 months (IQR 26 months). Of 845 patients with complete follow-up, 470 (55.6%) had recurrence with the following pattern: LR only in 111 (23.6%), liver recurrence only in 128 (27.2%), lung recurrence only in 55 (11.7%), local and DR in 84 (17.9%), and other recurrences in 92 (19.6%). 405 (86.2%) patients had only intra-abdominal recurrence. In the patients who recurred, 49.8% and 80.2% recurred within 1 year and 2 years from the resection respectively. The incidence of recurrence at different time after pancreatectomy was summarized in the Table. More patients with liver only recurrence occurred within 6 months after resection comparing to that with LR only (41% vs 9%, p<0.001). The median overall survival (OS) of the entire cohort is 22.6 month and varied significantly based on recurrence pattern (Table). The median OS of patients with lung only recurrence is longer than that with liver only recurrence (31.6 vs 16.7 months, p<0.001). **Conclusions:** The pattern of recurrence is associated with distinct survival and supports the observation that PDAC is genetically diverse. Our findings are important in selecting patients for personalized treatment combinations and laying the groundwork for defining the molecular basis behind the biological diversity of PDAC.

**Effect of molecular genotyping to predict outcomes in patients with metastatic pancreatic cancer.** *Presenting Author: Jason Edward Faris, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background:** The majority (85-90%) of patients (pts) with MPC have mutations in KRAS. Pts with wild type (WT) KRAS, as well as pts with codon-specific KRAS mutations (KRASm) may be associated with distinct presentations and survival. We utilized a molecular genotyping test, SNaPshot, to detect tumor-specific mutations. **Methods:** The molecular genotypes of 150 pts with MPC that received treatment at the MGH Cancer Center were analyzed. The SNaPshot assay utilizes DNA extracted from formalin-fixed paraffin-embedded tissue and detects sequence variants in a panel of 14 cancer genes. Demographic and clinical characteristics were tabulated, and statistical analysis performed to evaluate correlations between genotype, demographics, clinical characteristics, and outcomes. Overall survival (OS) since diagnosis and OS since metastatic disease were analyzed using Kaplan Meier method and compared using log-rank test. Categorical variables were compared using chi-square test or Fisher's exact test. Continuous variables were compared using ANOVA or nonparametric test. **Results:** Median age was 63. There were 92 males and 58 females. 98 pts presented with tumors of the head/uncinate and 52 of the body/tail. 71 patients underwent Whipple surgery prior to development of MPC. There were 49 pts with G12D, 38 with G12V, 22 with G12R, and 13 with other KRASm. 28 pts were KRAS WT, including 24 pts without detectable mutations in any gene assayed. Median OS since metastatic disease for the entire cohort was 10 mo (CI: 8.6-12.2). Patients with KRAS G12R had superior OS since metastatic disease (15.6 months, CI 9.4-47.6 mo) relative to patients with G12D mutations (6.1 mo, CI 4.5-12.2 mo) and to patients with KRAS non-G12R mutations (8.9mo, CI 6.0-11.3mo) (p=0.02 for each comparison). 25 pts presented with lung-only metastatic disease at diagnosis, with median OS of 22.4 mo (CI, 10-47.5 mo); 10/25 (40%) were KRAS WT or KRAS 12R. **Conclusions:** Molecular genotyping of pancreatic cancer identified subgroups of patients with distinct clinical presentation and survival.

| KRAS mutation | n | OS since metastatic disease (mo) |
|---|---|---|
| **G12R** | 22 | 15.6 (9.4-47.6) |
| **WT** | 28 | 12.1 (9.5-17.1) |
| **Non-G12R** | 100 | 8.9 (6.0-11.3) |
| **G12V** | 38 | 8.2 (5.2-14.5) |
| **G12D** | 49 | 6.1 (4.5-12.2) |

**4129 General Poster Session (Board #216), Sat, 8:00 AM-11:45 AM**

**Phase II study of the MEK inhibitor refametinib (BAY 86-9766) in combination with gemcitabine in patients with unresectable, locally advanced, or metastatic pancreatic cancer: Biomarker results.** *Presenting Author: Hanno Riess, Charité Comprehensive Cancer Center and Department of Oncology and Haematology, Berlin, Germany*

**Background:** Refametinib is a potent oral allosteric MEK 1/2 inhibitor with both single-agent and synergistic activity in combination with gemcitabine in preclinical models of pancreas cancer (PC). A synergistic effect between refametinib and erlotinib was also reported in KRAS wild-type human PC in vitro (Diep et al, Clin Cance Res 2011). We report the biomarker results of a single-arm, open label, phase 2a study combining refametinib and gemcitabine in advanced PC. **Methods:** Refametinib was administered 50 mg bid in combination with gemcitabine. The primary objective was overall response rate (ORR). Secondary objectives included progression-free survival (PFS), overall survival (OS) and biomarker assessment. KRAS mutational analysis was performed from plasma collected at baseline on circulating tumor DNA (ctDNA) by BEAMing. Circulating miRNA were obtained from plasma collected at baseline and post-dose and analyzed by qPCR. Targeted tumor gene next-generation sequencing, gene expression analysis by RNA sequencing and the proliferation index were conducted. **Results:** Of the 60 patients treated, 39 (65%) had KRAS mutations. In the KRAS subgroups (mut/WT, respectively), the ORR, mPFS and OS were 28%/48% (p=0.136), 4.6/9.0 mo (HR 0.26) and 6.6/18.2 mo (HR 0.27). There was a trend correlating allele frequency with response. KRAS G12D, G12V and G12R were the most frequent mutations. Mutations of codon 38 or 436 were not observed. Tumor exome sequencing was performed from 16 patients, 15 of which had a KRAS mutation (G12D or G12V). The most frequent co-occurring somatic mutations or amplifications were TP53, CDKN2A, and cMYC. Tumor proliferation index and miRNA signatures were not correlated with response. Gene expression data were tested for correlation with response or the presence of published KRAS pathway signatures. Additional subgroup analyses were performed. **Conclusions:** The high prevalence of KRAS mutations in patients with PC has been confirmed using BEAMing. There was a trend towards improved response, mPFS and OS in the wild-type KRAS subset and for KRAS allele frequency to correlate with response. Clinical trial information: NCT01251640.

**4130 General Poster Session (Board #217), Sat, 8:00 AM-11:45 AM**

**Pharmacogenomic modeling of pancreatic cancer (PDAC) for prediction of chemotherapy response and resistance in second-line treatment setting.** *Presenting Author: Kenneth H. Yu, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

**Background:** PDAC is a leading and rising cause of cancer mortality. Despite this, modern cytotoxics (C) can induce tumor responses and extend life. Xenograft models have shown that pharmacogenomic (PGx) modeling of C can predict efficacy. We previously presented results supporting PGx profiling of circulating tumor and invasive cells (CTICs) to predict effective C in the 1st line setting. We now present results in the second-line setting. **Methods:** PGx models for five common PDAC C regimens were created from the GI50 data obtained from the NCI-60 cell lines. These PGx models were validated in a prospective study of 50 patients with unresectable PDAC. 10 mL of peripheral blood was collected prior to C and at disease progression. CTICs were isolated, total RNA extracted and gene-expression analysis performed. Gene and pathway analyses were performed comparing patients with short v long TTP and for an individual patient at baseline v at time of progression. **Results:** CTICs were isolated, and gene expression profiles were obtained in all 50 patients prior to initiating C and in 25 patients at first-line disease progression. In the 1st line setting, we previously presented that CTIC PGx profiling predicted effective versus ineffective C treatment. In the 2nd line setting, 15 patients were evaluable for C response. Clinical benefit was again seen for patients treated with C predicted to be effective versus ineffective (PFS 5.7 mo v 2.5 mo, p=0.027, HR 0.15; OS 8.6 mo v 3.4 mo, p=0.020, HR 0.14). Changes in PGx profiles at disease progression reflected resistance to first-line C treatment. Widespread dysregulation in 32 gene pathways was found in CTICs at disease progression. CTIC SMAD4, ATM and XPO1 expression levels correlated with TTP in the first-line setting. **Conclusions:** PGx profiling of CTICs from patients with unresectable PDAC can predict effective C, both in the first- and second-line setting. Repeat PGx profiling identifies key gene pathways associated with treatment resistance. Clinical trial information: NCT01474564.

**4131 General Poster Session (Board #218), Sat, 8:00 AM-11:45 AM**

**Patterns of chemotherapy (CT) use in a population-based US-wide cohort of patients (pts) with metastatic pancreatic cancer (MPC).** *Presenting Author: Thomas Adam Abrams, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Few population studies have examined the frequencies and durations of specific CT treatment regimens in MPC. **Methods:** We assessed 3,796 consecutive MPC pts who received CT between Jan 2005 and Aug 2013 at academic, private and community hospital-based practices participating in a US-wide CT order entry system that captures pt, provider and treatment data. Multivariate analyses of prospectively recorded pt and provider characteristics identified predictors of specific therapeutic approaches. **Results:** Among all pts, median age was 70; 55% male. In 1st-line CT, 48% of pts received gemcitabine (GEM) monotherapy, 16% received a GEM-based doublet (incl. GEM + nab-paclitaxel [NAB-P]), 9% received fluoropyrimidine (FU) + oxaliplatin (OX) + irinotecan (FOLFIRINOX), 9% received FU monotherapy, and 5% received FU + OX (FOLFOX). The remaining 13% received other regimens. GEM monotherapy use peaked at 58% in 2009 but declined to 28% in 2013. FOLFIRINOX use emerged in 2010 with 4% usage and peaked at 23% in 2012. Since 2012, GEM + NAB-P use has risen substantially, representing 20% of first-line therapy in 2013. GEM + cisplatin use declined steadily from 2010 (9%) to 2013 (3%). Pts under age 60 and those treated at academic centers were more likely to receive first-line FOLFIRINOX and less likely to receive GEM monotherapy (both p<0.05). Mean duration of all 1st-line treatments was 87 days. 31% of all pts received 2nd-line treatment, 13% third-line, and 5% fourth-line. Second-line CTs included GEM monotherapy (28%), FOLFOX (14%), FOLFIRINOX (7%) and GEM + NAB-P (6%). 37% of pts who received second-line GEM + NAB-P received 1st-line FOLFIRINOX. **Conclusions:** This population-based study provides insight into US MPC treatment patterns. Treatments vary significantly according to patient and practice characteristics.

**MPC first-line CT treatment trends (2005-2013).**

**Use of first-line chemotherapy for advanced pancreatic cancer: FOLFIRINOX versus gemcitabine-based therapy.** *Presenting Author: Thomas H. Cartwright, Ocala Oncology, Ocala, FL*

**Background:** Pancreatic cancer (PC) is the fourth leading cause of death in the United States. It is estimated that 46,420 patients will be diagnosed in 2014 and 35,590 will die (Siegel, CA Cancer J Clin 2014). Gemcitabine has long been the standard of care chemotherapy. Recent advances in treatment created the combination regimens (oxaliplatin, irinotecan, leucovorin, fluorouracil [FOLFIRINOX]) and gemcitabine, nab-paclitaxel (GN) for patients with good Karnofsky performance status (PS) (Conroy, NEJM 2011; Von Hoff, NEJM 2013). This retrospective analysis was conducted as an update to results reported at ASCO 2013 (Cartwright, JCO 2013) to evaluate characteristics and overall survival (OS) of patients receiving FOLFIRINOX and gemcitabine-based treatments in a large outpatient community setting. This is the largest study describing FOLFIRINOX patients to date. **Methods:** Patients with advanced PC treated at practices in The US Oncology Network entered into the iKnowMed (iKM) database between June 2010 and November 2013 were included. Patterns of treatment were characterized by the median age at diagnosis, sex, PS, and first-line metastatic chemotherapy prescribed. The primary endpoints of the analysis were OS and uptake of FOLFIRINOX within The Network. **Results:** Compared to ASCO 2013 results, 700 additional patients were identified. Of the 2,422 total patients, 27% received FOLFIRINOX (24% in 2013) and 73% received gemcitabine-based therapy (76% in 2013). Increased utilization of FOLFIRINOX for good PS patients began in June 2010 and GN April 2013. For all patients (55% male), the median age at diagnosis was 67 and 95% had a PS of 70% or greater. When controlled for age and PS, the OS was significantly longer for FOLFIRINOX (11.2 mos) versus gemcitabine (7.2 mos) (p<0.0001). Median OS for GN (n=189) was 10.2 mos, despite shorter follow up time. **Conclusions:** Utilization of FOLFIRINOX and GN has continued to increase after the publication of phase III trials. Our data in a community setting continues to support a survival advantage for FOLFIRINOX as well as GN. The magnitude of benefit appears slightly better in the community; therefore, we agree that FOLFIRINOX should become a standard of care for good PS patients.

**4133 General Poster Session (Board #220), Sat, 8:00 AM-11:45 AM**

**A novel biomarker panel examining response to gemcitabine (G) with or without erlotinib (E) for pancreatic cancer (PA) therapy in NCIC clinical trials group PA.3.** *Presenting Author: David Shultz, Stanford University, School of Medicine, Stanford, CA*

**Background:** NCIC Clinical Trials Group PA.3 (NCIC CTG PA.3) was a randomized control trial that demonstrated an overall survival (OS) benefit in patients receiving E in addition to G for locally advanced or metastatic PA. Prior to therapy, patients had baseline plasma samples drawn and archived for future study. **Methods:** By using the multiplex capabilities and high sensitivity detection of the proximity ligation assay (PLA), a probe panel was built from commercially available antibodies capable of quantifying 35 key proteins, selected from a global genetic analysis of pancreatic caners followed by a k-means clustering, from 20 uLof patient plasma. To determine if any of these proteins independently associated with OS, multivariate Cox models adjusting for gender, age, race, stage, and pain intensity at baseline were used. **Results:** Of the 559 eligible patients, 483 had samples available for study. Samples were randomly allocated into training (T) (253) and validation (V) sets (230). Elevated levels of interleukin-8 (IL-8) was the only protein found independently associated with lower OS in patients treated with G alone in both T and V sets, while elevated levels of IL-8, carcinoembryonicantigen (CEA), and hypoxia-inducible factor 1-alpha (HIF-1 alpha) were the proteins in patients treated with G+E or among patients from both treatment arms. Conclusions**:** PLA is a powerful tool for identifying potential biomarkers from archived, small volume serum samples. These data suggest that pancreatic cancer patients with low IL-8, CEA, or HIF-1 alpha plasma levels were most likely to have longer OS from the addition of E to G while patients with lower IL-8 levels had improved survival when treated with G alone, which may also be useful to stratify patient outcomes regardless of therapeutic intervention.

**4135 General Poster Session (Board #222), Sat, 8:00 AM-11:45 AM**

**A phase 2 trial of low-dose multiagent chemotherapy with gemcitabine, docetaxel, capecitabine, and cisplatin (GTX-C) in subjects with metastatic pancreatic cancer.** *Presenting Author: Dung T. Le, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Triplet chemotherapy has been shown to delay the emergence of resistance and extend survival in patients with metastatic pancreatic adenocarcinoma. Four drug regimens, even at low doses, may further improve survival by simultaneously targeting multiple oncogenic pathways. **Methods:** A phase 2 study of GTX-C (capecitabine 500 mg bid on days 1-14, and the combination of gemcitabine 500 mg/m2 [10 mg/m$^2$/min], docetaxel 20 mg/m$^2$ and cisplatin 20 mg/m$^2$ on days 4 and 11) was initiated in newly diagnosed untreated metastatic pancreatic cancer patients. The primary endpoint was progression-free survival rate at 6 months and designed such that the regimen would be considered active if the 6-month PFS rate was >75% and inactive if < 50%. **Results:** Twenty-eight patients were enrolled. All patients were ECOG 0-1. Eighty-six percent of patients had evidence of liver metastases and 25% had biliary stents in place at time of study initiation. Median CA19-9 was 6,159 U/mL (37-154,323 U/mL). Median length of follow-up was 10.1 months. Grade 3/4 related adverse events included: nausea/vomiting (7%), transaminitis (10%), anemia (14%), thrombocytopenia (24%), and neutropenia (55%). However, febrile neutropenia occurred in only 3 patients (10%) and not until cycles 6, 14, and 15. PFS rate at 6 months was 74.2% (95% CI: 53.3% - 86.8%). The partial response (PR) rate was 50%, stable disease (SD) rate was 39% and the disease control rate (DCR) was 89%. CA19-9 declines of >80% occurred in 77% of patients with measurable levels. Estimated median PFS was 8.4 months (95% CI: 6.1-10.6 months) and OS was 12.9 months (95% CI: 10.0-NA months) as of 11/14/2013. Ten additional patients have been enrolled onto an expansion cohort in which the period off between cycles has been changed from 7 to 14 days. **Conclusions:** GTX-C is highly active and well-tolerated in patients with metastatic pancreatic cancer and should be tested in a larger, comparative study. Clinical trial information: NCT01459614.

**4136 General Poster Session (Board #223), Sat, 8:00 AM-11:45 AM**

**Multiplatform molecular profiling of 2,400 pancreatic adenocarcinomas to identify targets for therapeutic intent.** *Presenting Author: Sherri Z. Millis, Caris Life Sciences, Phoenix, AZ*

**Background:** Pancreas adenocarcinoma (PC) is a challenging disease with overall single digit 5-year survivorship. Few validated biomarkers exist for directing treatment in PC. Only one targeted agent (erlotinib) is FDA-approved and was developed in an unselected population (Moore, et al, J Clin Oncol, 2007). Identification of individual PC genomic and phenotypic profiles may yield targets with novel therapeutic application. **Methods:** 2400 cases referred internationally to Caris Life Sciences were evaluated using a combination of sequencing (Sanger or next generation sequencing (NGS)), protein expression (immunohistochemistry), and/or gene amplification (CISH or FISH). **Results:** The published PC molecular profile (24 cases, Jones, et al, Science, 2008) is consistent with the 2400 cases evaluated; KRAS was the most common mutation N=1190/1460 (82%) followed by TP53, N=175/310 (56%), and SMAD4, N=39/324 (12%). Mutations in BRAF, EGFR, HER2, FLT3, HRAS, PDGFRA and PTEN were identified exclusively in KRAS WT cases. **Conclusions:** 18% of PC cases were KRAS WT, representing a significant minority of patients with PC. Aberrant signaling through the RAS/MAPK pathway through oncogenic mutations in HRAS, BRAF, EGFR, HER2 and PDGFR was found in a very small subset of KRAS WT cases (8%), and the likely benefit of anti-EGFR-based therapies is limited to those patients with KRAS wild-type tumors lacking downstream oncogenic activation of this pathway. IHC evaluation of certain markers, e.g., RRM1, SPARC, etc. may help select drugs and refine treatment decision making for certain patients. Evaluating these profiles with clinical outcomes will provide valuable insight into the clinical behavior in genomically defined subsets and will assist in developing rational combinations of targeted agents in PC.

**Infiltrating neutrophils and malignant progression in intraductal papillary mucinous neoplasms (IPMN): An opportunity for identification of high-risk disease.** *Presenting Author: Eran Sadot, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** There is a strong link between neutrophil infiltration and malignant progression. Inflammatory proteins (IP) released by these cells play a pivotal role in the crosstalk between neoplastic and inflammatory cells. We evaluated tumor associated neutrophils (TAN) and their association with malignant progression in IPMN, and studied the cyst fluid from these lesions for biomarkers of the inflammation-carcinogenesis association. **Methods:** We evaluated 78 patients with resected IPMN (2004-2013). Patients were divided into 3 groups: low-risk (low and moderate grade dysplasia: n=48), high grade dysplasia (HGD, n=21), and invasive carcinoma (n=9). TAN were examined in representative areas on 2 slides of a given tumor. The number of TAN was assessed using the mean value of high power fields. Areas with <10 TAN/100 tumor cells were considered 'negative' and areas with 11–15 TAN/100 tumor cells were designated as 'low' while those with >15 TAN/100 tumor cells were regarded as 'high'. A multiplexed protein assay (Luminex Corp.) was performed on cyst fluid to evaluate for inflammatory cytokines and tumor-associated markers. **Results:** Significant positive correlation between grade of dysplasia and TAN level was found. High TAN were identified in 2.1%, 33.3%, and 88.9% of patients from the low risk, HGD, and invasive carcinoma groups, respectively ($p$<0.001). Within the cyst fluid, IP(e.g. IFN-g, TIMP-1, MIF, TNF-a, and MMP-9) were also found to have positive correlation with higher grades of dysplasia. Higher levels of TAN correlated with increased cyst fluid concentrations of the IP (e.g. IL-1b, TNF-a, IFN-g, IL-4), and 90% of these proteins were also found to be associated with higher grades of dysplasia. Multivariate analysis of clinical, radiographic, and molecular findings identified cyst fluid MMP-9 and CA 72-4 to be independent predictors for higher grades of dysplasia. **Conclusions:** Tumor associated neutrophils are strongly associated with malignant progression in IPMN. Measurement of IP in the cyst fluid may be a surrogate marker for IPMN progression and allow for the identification of high-risk disease.

**4138 General Poster Session (Board #225), Sat, 8:00 AM-11:45 AM**

**FG-3019, a human monoclonal antibody to connective tissue growth factor (CTGF), with gemcitabine/erlotinib (G/E) in patients with locally advanced or metastatic pancreatic ductal adenocarcinoma (PDAC).** *Presenting Author: Vincent J. Picozzi, Virginia Mason Medical Center, Seattle, WA*

**Background:** CTGF is overexpressed in PDAC and facilitates local desmoplasia, tumor survival and metastasis. FG-3019 is a CTGF-specific monoclonal antibody that decreases tumor growth and metastases and prolongs survival in the KPC mouse model of pancreatic cancer. This study evaluated safety and efficacy of FG-3019 with G/E in patients (Pts) with PDAC. **Methods:** FG-3019 was combined with G/E in Pts with previously untreated, measurable, Stage 3 or 4 PDAC. Cohorts 1−6 received FG-3019 Q2W at 3, 10, 15, 25, 35 or 45 mg/kg. Cohort 7 received 35 mg/kg on Day 1, then 17.5 mg/kg QW. Cohort 8 received 45 mg/kg on Day 1, then 22.5 mg/kg QW. **Results:** 75 Pts were enrolled. Baseline characteristics: Stage 3 / 4 (11/64); ECOG=0/1 (30/45). Median of 9 FG-3019 doses were administered (range: 1-73). FG-3019 was well tolerated with no DLT. MTD is > 45 mg/kg. Median OS was 9.4 months in the per-protocol population. Best RECIST response was 2(3%) CR, 8(11%) PR, 39(52%) SD, 12(16%) PD, (14 no RECIST data). OS generally correlated with FG-3019 exposure in Cycle 1. Day 15 $C_{min} \geq 150$ ug/mL was associated with improved OS (p=0.03) and 1 year survival (p=0.03). CA 19.9 response was 52% ($C_{min} \geq 150$) and 38% ($C_{min} < 150$). Pts with ascites had low $C_{min}$ and poor OS. High FG-3019 doses with $C_{min}$ >150 ug/mL appeared to improve OS. Baseline plasma CTGF correlated inversely with OS (p=0.006). In bivariate analysis, Day 15 $C_{min} \geq 150$ ug/mL and baseline CTGF < median were associated with better survival (p=0.04 and 0.02 respectively). Greatest survival was in Pts with Day 15 $C_{min}$> 150 ug/mL and baseline CTGF < median. **Conclusions:** FG-3019 did not add to toxicity of G/E. Results suggest OS improves with increasing exposure to FG-3019, and the combination of baseline CTGF and plasma FG-3019 levels could be a predictor of efficacy. Given its advantageous safety profile, FG-3019 could be combined with other chemotherapeutic regimens. Clinical trial information: NCT01181245.

| FG-3019 Day 15 $C_{min}$ (ug/mL) | Baseline CTGF (ng/mL) | Median OS (months) | 1-year OS (%) |

**4139 General Poster Session (Board #226), Sat, 8:00 AM-11:45 AM**

**A phase I study of veliparib (ABT-888) in combination with low-dose fractionated whole abdominal radiation therapy (LDFWAR) in patients with advanced solid malignancies and peritoneal carcinomatosis.** *Presenting Author: Kim Anna Reiss, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** The combination of low-dose radiation therapy with poly (ADP-ribose) polymerase (PARP) inhibition has been shown to enhance anti-tumor efficacy through potentiating DNA damage in tumor cells. In this phase I study, we combined low dose fractionated whole abdominal radiation (LDFWAR) with escalating doses of veliparib (ABT-888), an orally available, small molecule PARP inhibitor, in patients (pts) with peritoneal carcinomatosis from advanced solid tumor malignancies. **Methods:** Pts were treated with escalating doses of veliparib, starting at 40mg PO BID on days 5-21 of the first 28-day cycle and on days 1-21 of the subsequent 2 cycles. LDFWAR consisted of 21.6Gy in 36 fractions, 0.6 Gy twice daily on days 1 and 5 for weeks 1-3 of each cycle. Circulating tumor cells (CTCs) were serially collected. Quality of life (QoL) was assessed using the EORTC-QLQ-C30 questionnaire. **Results:** 22 pts were treated. Treatment-related gr3 and 4 toxicites included lymphopenia (68%), anemia (9%), thrombocytopenia (14%), neutropenia (4%), leukopenia (9%), ascites (4%), vomiting (4%) and dyspnea (4%). Of 21 pts evaluable for response, disease stabilization (≥24 wks) was observed in 7 (33%) patients. Median progression free survival (PFS) was 4.7 months and overall survival (OS) was 15.5 months. In the subset of 8 ovarian and fallopian cancers (OV), median PFS was 6.9 months and OS was 17.6 months compared to PFS 2.9 months and OS 13.4 months in others. QoL data assessed at baseline and after cycle 2 showed no significant worsening with dose escalation. Pts with OV had better QoL over time than those with other cancers. Lower baseline CTCs trended towards improved OS. **Conclusions:** The combination of veliparib and LDFWAR is a well-tolerated regimen that results in remarkable disease stability in a refractory, pretreated pt population with advanced solid tumors and carcinomatosis, particularly in the OV subpopulation. Clinical trial information: NCT01264432.

| | Durable disease stability (≥24wk) No. pts (%) | PFS median, months (95% CI) | OS median, months (95% CI) |
|---|---|---|---|
| All patients (n=21) | 7/21 (33) | 4.6 | 15.5 |
| Ovarian (n=8) | 4/7 (57) | 6.9 | 17.6 |
| Non-ovarian (n=13) | 3/14 (21) | 2.9 | 13.4 |

**4140 General Poster Session (Board #227), Sat, 8:00 AM-11:45 AM**

**Cancer of unknown primary in adolescents and young adults: Clinicopathologic features, prognostic factors, and survival outcomes.** *Presenting Author: Kanwal Pratap Singh Raghav, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Cancer in adolescents and young adults (AYAs) (15-39 yrs) is increasingly recognized as a distinct clinical and biological entity. Cancer of unknown primary (CUP) although rare in young adults, poses a complex and unique challenge. Our study describes clinicopathologic features and outcomes in AYA-CUP patients (pts). **Methods:** We performed a retrospective review of 47 AYA pts diagnosed with CUP at The Univ. of Texas, MD Anderson Cancer Center, between 6/2006 and 6/2013. Data on demographics, imaging, pathology and treatment was collected from a prospectively maintained CUP database. Kaplan-Meier product limit method was used to estimate median overall survival (OS) and log-rank test was used for comparison. Cox proportional hazards model was used for multivariate analysis. **Results:** Median age was 35 years (19–39 yrs). Pts had comprehensive workup (CT 100%); PET scan, upper endoscopy, colonoscopy and mammography was performed in 60%, 51%, 47% and 40% pts, respectively; none yielding a primary diagnosis. Adenocarcinoma was the predominant histology (70%) with a median of 9 immunostains (range 2–29). Most common putative primary (tissue of origin) was biliary profile based on clinicopathologic parameters as well as gene expression profiling. Patients presented with a median of 2 metastatic sites, most common being lymph node (60%), lung (47%), liver (38%) and bone (34%). Systemic chemotherapy used included gemcitabine, fluorouracil, taxanes and platinum agents. Median OS for the entire cohort was 9.9 months. On multivariate analysis, elevated LDH (HR 3.86; 95%CI 1.58-9.44; P=0.003) and multiple metastatic sites (2 sites: HR 4.45; 95%CI 1.05-18.9; P=0.043; 3 or more sites: HR 8.5; 95%CI 1.9-37.9; P = 0.001) compared to 1 site were associated with poor OS. Culine CUP prognostic model (performance status, liver metastasis, LDH) was validated in this cohort (median OS: good risk 25.2 months vs. poor risk 6.1 months). **Conclusions:** AYA-CUP is associated with a poor prognosis. In the current "-omics" era collaborative research efforts towards understanding tumor biology and therapeutic targets in AYA-CUP is an unmet need, necessary for improving outcomes in young CUP patients.

**4141 General Poster Session (Board #228), Sat, 8:00 AM-11:45 AM**

**Molecular classification of ampullary adenocarcinoma: Comparative prognostic performance of the 92-gene assay versus histomolecular analysis.** *Presenting Author: Aaron Schueneman, MD Anderson Cancer Center, Houston, TX*

**Background:** As distinct epithelia coalesce within the ampulla (duodenal, pancreatic, and biliary), the exact epithelial origin of ampullary carcinomas remains unclear and in part contributes to the clinical heterogeneity for these cancers. Differential expression of CDX2 and MUC1 along with histological subtype [intestinal (INT), pancreaticobiliary (PB), and mixed] have been used to subclassify ampullary tumors by histomolecular phenotype (Chang et al. JCO 2013). We compared the ability of a 92-gene RT-PCR Assay (CancerTYPE ID, bioTheranostics. Inc.) and histomolecular phenotype to prognostically stratify ampullary adenocarcinomas. **Methods:** In this prospectively-defined, blinded study, ampullary adenocarcinoma samples (N=77) were evaluated by the 92-gene assay and histomolecular phenotype. A total of 54 ampullary adenocarcinomas were compared after the exclusion of 23 samples that failed QC. A reference diagnosis was established by independent histopathological review prior to sample blinding. Relapse-free survival (RFS) and overall survival (OS) for patients were evaluated by Kaplan-Meier analysis with log-rank P-values. **Results:** For tumor subtyping, the sensitivity of the 92-gene assay and histomolecular classification were similar for the intestinal subtype, however the 92-gene assay demonstrated higher sensitivity for the Pb subtype (P=0.045). While the 92-gene assay was prognostic for both RFS (HR=2.81, P=0.02) and OS (HR=2.49, median OS 114 m vs. 36.4 m, P=0.03), histomolecular classification failed to demonstrate a significant difference in RFS (HR = 1.02, P=0.96) or OS (HR=1.07, P=0.87). Stratification of the cohort to include lymph node status revealed three distinct prognostic groups for ampullary subtypes predicted by the 92-gene Assay (P=0.04), but not for histomolecular phenotype (P=0.39). **Conclusions:** Molecular classification of ampullary adenocarcinomas into intestinal and pancreaticobiliary subtypes is prognostically relevant and may have therapeutic implications. Further validation of this novel 92-gene assay in comparison to histomolecular phenotype in a larger ampullary adenocarcinoma dataset is needed.

**4142 General Poster Session (Board #229), Sat, 8:00 AM-11:45 AM**

**Comprehensive genomic profiling of gallbladder adenocarcinoma and frequent genomic-derived targets of therapy.** *Presenting Author: Phil Stephens, Foundation Medicine, Inc., Cambridge, MA*

**Background:** Metastatic gallbladder adenocarcinoma (GBCA) has a poor prognosis and systemic therapies are commonly extrapolated from those used in other gastrointestinal malignancies. In this study, next generation sequencing-based comprehensive genomic profiling of 83 clinical GBCA samples was performed to identify genomic-derived targets of therapy for patients with this lethal cancer. **Methods:** Hybridization capture of 3,769 exons from 236 cancer-related genes and 47 introns of 19 genes commonly rearranged in cancer was applied to ≥ 50ng of DNA extracted from 83 GBCA FFPE specimens and sequenced to high, uniform coverage. Potentially actionable alterations were defined as those identifying anti-cancer drugs on the market or in registered clinical trials. **Results:** Sequencing was performed on 34 primary and 49 metastatic GBCA biopsies, Grade I/II/III, 5, 55 and 23 cases, respectively. A total of 329 alterations were identified with an average of 4.0 alterations per tumor (range 1-15). The most frequently altered genes were: *TP53* (63%), *CDKN2A* (49%), *ARID1A* (18%), *ERBB2* (17%), *PIK3CA* (12%), *SMAD4* (11%) and *CCNE1* (11%). Forty-three additional genes were altered in multiple cases including: *BRCA2*, *CCND1*, *ERBB3*, *EGFR*, *FGFR3*, *GNAS*, *KRAS*, *MET*, *NF1*, *NF2*, *NRAS, PDGFRA*, *PTEN*, *STK11* and *TSC2*. One case of *FGFR3-TACC* fusion gene was noted. At least one alteration associated with agents that are FDA approved or being studied in clinical trials was identified in 71/83 (86%) of cases. Clinical follow up of a small subset of patients to date, revealed two patients with focal amplification of *EGFR* and *ERBB2* had sustained PR with erlotinib and trastuzumab, respectively. **Conclusions:** This is the largest known series of GBCA cases analyzed using next generation sequencing-based genomic profiling. The long tail of genomic-derived targets of therapy identified, necessitate broad diagnostic assays capable of accurately profiling tumors from limited biopsy material to maximize targeted treatment options. Our results indicate that genomic profiling can identify clinically meaningful alterations that can potentially guide targeted treatment decisions in the majority of patients with this orphan tumor.

**4143 General Poster Session (Board #230), Sat, 8:00 AM-11:45 AM**

**Potential actionable targets in appendiceal cancer detected by immunohistochemistry (IHC), fluorescent in situ hybridization (FISH), and mutational analysis.** *Presenting Author: Erkut Borazanci, TGen - Virginia G. Piper Cancer Center at Scottsdale Healthcare, Scottsdale, AZ*

**Background:** Appendiceal cancers are rare and consist of carcinoid, mucocele, pseudomyxoma peritonei, goblet cell carcinoma, lymphoma, and adenocarcinoma histologies. Current treatment involves surgical resection or debulking, but no standard exists for adjuvant chemotherapy or treatment for metastatic disease. **Methods:** Samples were identified from 60,000 global tumors analyzed at a referral molecular profiling CLIA-certified laboratory. 460 samples with appendix primary tumor sites were identified (male/female ratio of 2:3; mean age = 55). 62% of samples were adenocarcinomas (used for analysis); the rest consisted of 9% goblet cell, 15% mucinous; 6% pseudomyxoma, and less than 5% carcinoids and 2% neuroendocrine. Tests included sequencing (Sanger or next generation sequencing [NGS]), protein expression (immunohistochemistry [IHC]), and gene amplification (FISH or CISH). **Results:** % positive of total adenocarcinoma cohort are shown (see Table). **Conclusions:** Appendiceal adenocarcinomas show high levels of drug resistance proteins (BCRP and MRP1), which highlight the difficulty in treating these tumors and suggest an individualized approach to treatment. Therapeutic options include TOPO1 inhibitors (irinotecan/topotecan), PDGFR antagonists (regorafenib, axitinib), MGMT (temozolamide), and SPARC (nab-paclitaxel). These findings indicate the need to evaluate patient samples for patterns in marker expression and alteration, in order to better understand the molecular biology and formulate a personalized therapy approach in these difficult to treat cancers (supported by a grant from Caris Life Sciences).

**TPS4144 General Poster Session (Board #231A), Sat, 8:00 AM-11:45 AM**

**NeoSCOPE: A phase II randomized comparison of neoadjuvant oxaliplatin/capecitabine versus carboplatin/paclitaxel-based chemoradiation in operable esophageal cancer.** *Presenting Author: Thomas Crosby, Velindre Hospital NHS Foundation Trust, Cardiff, United Kingdom*

**Background**: Both oxaliplatin/capecitabine-based chemoradiation (OXCAP-RT) and carboplatin-paclitaxel based radiation (CarPac-RT) are active regimens in oesophageal cancer, but no randomized study has compared their efficacy/toxicity. This study compares the two regimens to identify the optimum regimen to take forward to a phase III trial against neo-adjuvant chemotherapy, the current standard in the UK. **Methods**: Eligibility: Resectable adenocarcinoma of oesophagus and Type 1-2 Gastro-Osophageal Junction; ≥T3 and/or ≥N1 staged with EUS and PET-CT; PS 0-1. Intervention: Both arms receive 2 cycles induction OXCAP (oxaliplatin 130mg/m2 D1, Cape 625mg/m2 D1-21, q 3wk) followed by randomization to OXCAP-RT (oxali 85mg/m2 Day 1,15,29; cape 625mg/m2 on days of RT; RT-45Gy/25 fractions/5weeks) or CarPac-RT (Carbo AUC2 and paclitaxel 50mg/m2 Day 1,8,15,22,29; RT-45Gy/25 fractions/5weeks). Restaging CT/PET-CT 4-6 weeks after CRT, and 2-phase oesophagectomy with 2-field lymphadenectomy 6-8 weeks after CRT. Primary End-Point: Pathological complete response. Secondary: 1) Feasibility of recruitment; Toxicity; 30-day surgical morbidity/mortality; resection margin positivity rate; median, 3- and 5-yr OS. Statistics: Randomised phase II with 1:1 randomisation; planned accrual 76 patients (38/arm) over 18 months. In each arm, this sample size gives 90% power and one-sided type 1 error of 10% to detect that pCR is not <15% but could be >35%. Interim safety analysis: Toxicity analysis after 10 patients have completed treatment. RT Quality Assurance: Pre-trial: Detailed RT protocol and guidance document, RT workshop, central evaluation of test-case contours and adequacy of RT plan. On-trial: Real-time central review of contours and plans of first 20 patients on trial, 1st case from each centre, and 10% of cases selected at random. Current Status: Activation: September 2013; Centres open: 10, in set-up:10; Recruitment: 13. Funding: Cancer Research UK. Sponsor: Velindre NHS Trust. Trials Unit: Wales Cancer Trials Unit. Eudract No: 2012-000640-10. Clinical trial information: NCT01843829.

**TPS4145 General Poster Session (Board #231B), Sat, 8:00 AM-11:45 AM**

**ICORG 10-14: Neo-AEGIS: A randomized clinical trial of neoadjuvant and adjuvant chemotherapy (modified MAGIC regimen) versus neoadjuvant chemoradiation (CROSS protocol) in adenocarcinoma of the esophagus and esophagogastric junction.** *Presenting Author: Niamh Keegan, St. James's Hospital, Dublin, Ireland*

**Background:** Neoadjuvant therapy is increasingly the standard of care in the management of locally advanced adenocarcinoma of the esophagus and junction (AEG). The MAGIC and CROSS regimens were superior to surgery only in randomized controlled trials (RCTs) that included AEG but were not powered on this cohort, and no completed RCT has directly compared neoadjuvant chemotherapy and chemoradiation. This trial, uniquely powered on AEG, and including comprehensive modern staging, compares both these Level I regimens. **Methods:** This open label, phase III RCT randomizes patients in a 1:1 fashion to receive either pre and postoperative chemotherapy as per the MAGIC regimen [Etoposide, Cisplatin, Fluorouracil (Capecitabine)] or neoadjuvant chemoradiation as per the CROSS protocol (Carboplatin and Paclitaxel with concurrent radiotherapy, 41.4Gy/23Fr, over 5 weeks). The power calculation is a 15% difference in 3 year overall survival, power at 80%, two-sided alpha level of 0.05, requiring 366 subjects over a five year period, with analysis performed one year after last subject recruited. Eligibility includes: AEG, types I, II, and III, staged (CT-PET and EUS) as cT2-3, N0-3, M0 and surgically resectable, with good performance status and no major co-morbidities. The primary endpoint is overall survival, with a minimum 3 year follow up. Secondary endpoints include: disease free survival, recurrence rates, clinical and pathological response rates, toxicities of induction regimens, post-operative pathology and tumor regression grade, operative in-hospital complications, and health-related quality of life. Pre-treatment bio-resourcing of tumor and blood will enable correlative translational studies. Conduct to Date: The trial activated in February 2013 at the national center in Ireland, 35 patients are randomized to date. Other centers in Ireland and Europe will commence in 2014. Clinical trial information: NCT01726452.

**TPS4146 General Poster Session (Board #232A), Sat, 8:00 AM-11:45 AM**

**A phase III clinical trial of neoadjuvant chemoradiotherapy followed by surgery versus surgery alone for locally advanced squamous cell carcinoma of the esophagus.** *Presenting Author: Hong Yang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

**Background:** Surgery is the main treatment of esophageal squamous cell carcinoma (ESCC), but the prognosis of patients with locally advanced ESCC is rather poor. Preoperative chemoradiotherapy followed by surgery seems to hopefully improve the survival of ESCC. Nevertheless, the results of different studies were inconsistent. We are to carry out a phased III clinical trial to investigate the effect of this multidisciplinary therapy for the overall survival of patients with locally advanced ESCC. **Methods:** This study is a multi-centered randomized controlled phase III clinical trial. According to Sixth Edition AJCC Cancer Staging, patients with IIB-III staged squamous cell carcinoma of the thoracic esophagus are randomly allocated to either preoperative chemoradiotherapy followed by surgery (arm A), or surgery alone(arm B). The intended number of randomized patients will be 430, 215 per arm. In the arm A, Chemotherapy and radiotherapy are performed concurrently. Patients received two cycles of vinorelbine and cisplatin. Vinorelbine at 25 mg/m$^2$ per day is administered in bolus infusion on d1, d8, d22 and d29. Cisplatin at 75 mg/m$^2$ is administered by intravenously infusion on d1 and d22 (or 25 mg/m$^2$days 1 to 4 and 22 to 25). A total radiotherapy dose of 40 Gy is delivered in 20 daily fractions of 2.0 Gy each (given 5 d/wk for 4 weeks). McKeown esophagectomy or Ivor Lewis esophagectomy will be performed 4-6 weeks after chemoradiotherapy. Two-field lymphadenectomy with total mediastinal lymph node dissection is performed during sugery. Primary outcomes are 3 and 5 years overall survival. From 2007 July to 2013 December, over 300 eligible patients were randomly assigned in eight cooperative cancer centers. The patient enrollment will be completed in 2014. Clinical trial information: NCT01216527.

**TPS4147 General Poster Session (Board #232B), Sat, 8:00 AM-11:45 AM**

**JAGUAR: A randomized phase II study of the AKT inhibitor ipatasertib (GDC-0068) versus placebo in combination with mFOLFOX6 chemotherapy in patients (pts) with locally advanced or metastatic HER2-negative gastric (G) or gastroesophageal junction (GEJ) adenocarcinoma.** *Presenting Author: Yung-Jue Bang, Department of Internal Medicine and Cancer Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea*

**Background:** Activation of PI3K/Akt signaling occurs in greater than 60% of G/GEJ cancers by decreased PTEN and/or mutations or amplifications of *PIK3CA*, and may contribute to chemoresistance. Pts with G/GEJ cancers that have PI3K/Akt activation have been reported to have poor prognosis and decreased overall survival. Ipatasertib (GDC-0068) is an oral, potent ATP-competitive small molecule inhibitor of all three isoforms of Akt that specifically targets cancer cells with activated Akt. In preclinical models, ipatasertib synergistically combines with fluorouracil (5-FU) and platinum chemotherapy. In Phase Ib clinical studies, the combination of ipatasertib and mFOLFOX6 chemotherapy is well-tolerated; the most commonly reported adverse events associated with ipatasertib are grade 1-2 diarrhea, nausea, vomiting, fatigue, and decreased appetite. RECIST responses and prolonged stable disease were seen with the combination, including pts with tumors having PI3K/Akt activation. **Methods:** JAGUAR is a randomized, double-blind, placebo-controlled, global Phase II study in pts with previously untreated locally advanced or metastatic G/GEJ cancers. Approximately 120 patients with measurable HER2-negative or HER2-unknown G/GEJ cancer will be randomized (1:1) to receive mFOLFOX6 plus ipatasertib or mFOLFOX6 plus placebo. Patients will be stratified by PTEN status. A maximum of 8 cycles of mFOLFOX6 are permitted, and ipatasertib or placebo in combination with 5-FU and leucovorin will be continued until disease progression or intolerable toxicity. The primary endpoint is progression free survival. Additional endpoints include overall survival, objective response rate, duration of response, safety, pharmacokinetics, and correlative biomarkers. This study is open for accrual. Clinical trial information: NCT01896531.

**TPS4148 General Poster Session (Board #233A), Sat, 8:00 AM-11:45 AM**

**Randomized open-label phase 2 study of MM-111 and paclitaxel (PTX) with trastuzumab (TRAS) in patients with HER2-expressing carcinomas of the distal esophagus, gastroesophageal (GE) junction, and stomach who have failed front-line metastatic or locally advanced therapy.** *Presenting Author: Crystal Shereen Denlinger, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** HER2 overexpression occurs in $\leq$ 20% of GE cancers, and front-line fluoropyrimidine/platinum with TRAS increases survival in HER2+ GE junction/gastric cancer patients. Weekly PTX has activity after front-line therapy in GE cancers. HER3 is overexpressed in $<$ 87% of GE cancers and expression is associated with poor prognosis. HER3 is activated by its ligand, heregulin, to form a potent signaling heterodimer with HER2 and is emerging as a key tumorigenic node and mediator of drug resistance. MM-111 is a novel molecule that inhibits heregulin-activated HER3 signaling in HER2+ tumors. In preclinical gastric cancer models, MM-111 potentiates the antitumor activity of TRAS and PTX, and also mitigates HER3-mediated resistance. MM-111 has been combined with PTX and TRAS in a multi-arm, dose escalation phase 1 trial. Most common dose-limiting toxicities include myelosuppression, GI toxicities, and electrolyte abnormalities. **Methods:** This is a randomized open-label multi-center Phase 2 study of PTX and TRAS +/- MM-111 in patients with HER2 expressing advanced GE adenocarcinoma. Arms are stratified for prior TRAS exposure, geographic region, and ECOG performance status. Patients are dosed with PTX at 80 mg/m$^2$ on days 1, 8, and 15 of a 28 day cycle; TRAS at 4 mg/kg loading dose then 2 mg/kg/weekly and MM-111 at 20 mg/kg/weekly. Pretreatment tumor biopsies and archived tumor tissue will be collected to explore the correlation of biomarkers associated with HER2, HER3 and heregulin signaling activity (1) between archived and pretreatment samples and (2) with clinical response. The primary objective is progression-free survival. Secondary objectives are overall survival, time to treatment failure, objective response rate, duration of response, safety, and health-related quality of life. Pharmacokinetic and immunogenicity analysis of MM-111 will be performed. Enrollment is ongoing. Clinical trial information: NCT01774851.

**TPS4149 General Poster Session (Board #233B), Sat, 8:00 AM-11:45 AM**

**Randomized phase III study of gemcitabine plus S-1 combination therapy versus gemcitabine plus cisplatin combination therapy in advanced biliary tract cancer: A Japan Clinical Oncology Group study (JCOG1113).** *Presenting Author: Chigusa Morizane, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan*

**Background:** Gemcitabine plus cisplatin (GC) therapy is the standard of care for advanced biliary tract cancer (BTC). However, GC is considered to be toxic because of nausea, vomiting, appetite loss and inconvenient due to requiring hydration before and after cisplatin administration. Our previous JCOG0805 trial, a randomized phase II selection design study of gemcitabine plus S-1 combination therapy (GS) vs. S-1, demonstrated superiority of GS over S-1 in terms of 1-year survival with acceptable toxicity profile and showed GS to be a more promising regimen. This phase III study aims to confirm the non-inferiority of GS to GC in terms of overall survival in patients with recurrent or unresectable BTC. **Methods:** Eligibility criteria include chemotherapy-naïve patients with recurrent or unresectable biliary tract adenocarcinoma (gallbladder, intrahepatic biliary tract, extrahepatic biliary tract, or ampulla of Vater), an Eastern Cooperative Oncology Group performance status of 0–1, and adequate organ function. Eligible patients are randomized into either GC arm or GS arm. In the GS arm, 1000 mg/m$^2$ of gemcitabine is infused on days 1 and 8, and 30 mg/m$^2$ of S-1 is administered orally twice a day from days 1 to 14; the regimen is repeated every 3 weeks. In the GC arm, 1000 mg/m$^2$ of gemcitabine and 25 mg/m$^2$ of cisplatin are infused on days 1 and 8 and repeated every 3 weeks. The primary endpoint is overall survival and the secondary endpoints are progression-free survival, %response rate, %planned dose, adverse events, clinically relevant adverse events defined as any of grade 2 or more fatigue, appetite loss, nausea, vomiting, mucositis, diarrhea, and serious adverse events. The sample size was calculated to be 350 (175 patients per arm), with a one-sided alpha of 5%, a power of $>$=80%, assumed median survival time of 11.2 months in GC and of 13 months in GS, an non-inferiority margin of 1.155 in terms of hazard ratio, an accrual period of 4 years, and a follow-up period of 1 year. Twenty-eight institutions are participating in this study. The study was activated in May 2013. Clinical trial information: UMIN000010667.

**TPS4150 General Poster Session (Board #234A), Sat, 8:00 AM-11:45 AM**

**Phase 3 randomized, double-blind, controlled study of cabozantinib (XL184) versus placebo in subjects with hepatocellular carcinoma who have received prior sorafenib (CELESTIAL; NCT01908426).** *Presenting Author: Ghassan K. Abou-Alfa, Memorial Sloan-Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

**Background:** Currently, there are no approved systemic therapies for patients with advanced hepatocellular carcinoma (HCC) who fail sorafenib. Cabozantinib is an oral receptor tyrosine kinase inhibitor (TKI) with activity against tyrosine kinases including MET, RET and VEGFRs. MET and VEGFR signaling have been implicated in tumor neo-angiogenesis and invasion. MET is overexpressed in HCC compared with non-tumor liver tissue, with higher MET expression linked to poor prognosis. Cabozantinib prolonged survival in a MET-driven transgenic mouse model of HCC, and has demonstrated clinical activity in multiple solid tumor types, including 41 subjects with advanced HCC treated in a phase 2 randomized discontinuation study. **Methods:** This phase 3, randomized, double-blind study evaluates the efficacy and safety of cabozantinib compared with placebo in subjects with advanced HCC previously treated with sorafenib and have progressed following 1-2 prior systemic treatments for HCC. Subjects must be $\geq$ 18 year old, have Child-Pugh Score of A and ECOG PS $\leq$ 1. Subjects are randomized 2:1 to receive either cabozantinib or placebo. Stratification factors are etiology of disease, geographic region and the presence of extrahepatic spread of disease and/or macrovascular invasion. The primary endpoint is overall survival. Secondary endpoints are progression-free survival and objective response rate by RECIST 1.1. Additional endpoints include safety, tolerability, circulating tumor cells, serum bone markers and plasma biomarkers, effects on bony disease assessed by bone scan and health-related quality of life (HRQoL) using the EuroQol Health questionnaire (EQ-5D-5L). Enrollment was initiated in September 2013. Target recruitment is 760 subjects. A total of 621 events planned with 2 interim analyses (at 311 and 466 events) would provide 90% power to detect a 31.6% increase in OS (HR=0.76). Clinical trial information: NCT01908426.

**TPS4151 General Poster Session (Board #234B), Sat, 8:00 AM-11:45 AM**

**A multicenter, randomized, phase Ib/II trial of the oral c-Met inhibitor MSC2156119J as monotherapy versus sorafenib in Asian patients with MET-positive (MET+) advanced hepatocellular carcinoma (HCC) and Child-Pugh Class A liver function.** *Presenting Author: Shukui Qin, Medical Oncology Department, Nanjing Bayi Hospital, Nanjing, China*

**Background:** Patients (pts) with HCC have a poor prognosis. Effective treatments are limited, particularly in Asia, which carries about 80% of the HCC burden. In a Phase I trial (Falchook et al. *J Clin Oncol* 2013:31(Suppl): 2506), the highly selective c-Met inhibitor MSC2156119J showed promising antitumor activity and a recommended Phase II dose was determined (RP2D; 500 mg/d). This Phase Ib/II, multicenter, open-label trial evaluates the efficacy of MSC2156119J monotherapy in first-line treatment vs sorafenib in pts with MET+ advanced HCC (NCT01988493). **Methods:** Primary objectives are to confirm the RP2D of 500 mg MSC2156119J in HCC pts (Phase Ib) and to assess efficacy of MSC2156119J monotherapy vs sorafenib, as determined by time to progression (TTP) per independent read (Phase II). Secondary objectives include pharmacokinetics, preliminary antitumor activity of MSC2156119J (Phase Ib), safety, tolerability, and antitumor activity of MSC2156119J vs sorafenib (Phase II: progression-free survival and TTP per investigator read, overall survival, time to symptomatic progression, objective response, and disease control). Adults with confirmed, advanced HCC of BCLC Stage C, Child-Pugh Class A liver function, life expectancy >3 mo, and ECOG status 0–2 (Phase II only: MET+, defined as moderate or strong protein overexpression determined by immunohistochemistry, eligible for sorafenib treatment, and measurable disease according to RECIST v1.1) are recruited in mainland China, South Korea, Taiwan, and other Asian countries. Key exclusion criteria: prior treatment with a c-Met/HGF pathway-targeting agent or systemic anticancer therapy (Phase II only), history of liver transplant or neoplasms other than HCC, impaired cardiac function, and chronic gastrointestinal disease. Up to 18 pts are planned for the Phase Ib part (3+3 design; 300 or 500 mg MSC2156119J p.o./d; 21-d cycle). In the Phase II part, 140 pts are planned to be randomized 1:1 to receive either MSC2156119J at the RP2D p.o./d or 400 mg sorafenib p.o./twice daily (21-d cycle). Enrollment began on Jan 9, 2014. Clinical trial information: NCT01988493.

**TPS4152 General Poster Session (Board #235A), Sat, 8:00 AM-11:45 AM**

**A randomized controlled trial comparing modified gemcitabine plus oxaliplatin (mGEMOX) to gemcitabine plus cisplatin in management of unresectable gall bladder cancer.** *Presenting Author: Atul Sharma, All India Institute of Medical Sciences, New Delhi, India*

**Background:** Gemcitabine and platinum compound have become preferred regimen for treatment of advanced/unresectable gall bladder cancer (Best supportive care compared with chemotherapy for unresectable gall bladder cancer:A randomized controlled study. Sharma A, Dwary A D, Mohanti B K,et al. *J Clin Oncol*. 2010; 28: 4581-4586; Cisplatin plus gemcitabine versus gemcitabine for biliary tract cancer. J W Valle, H S Wasan, D D Palmer, et al. *N Eng J Med*. 2010; 362:1273-81). This ongoing equivalence study has been planned to see whether the combination of gemcitabine and oxaliplatin (mGEMOX) is equivalent to gemcitabine and cisplatin (GemCis). **Methods:** Primary end point of the study is overall survival in subjects receiving mGEMOX or GemCis regimen. Secondary end points are: A-Comparison of progression free survival in 2 groups, B- Response rates in two groups,C-Identification of genes predictive of responses in a subset of patients, D-To evaluate role of PET CT in GBC patients predicting disease activity Sample size was calculated taking median survival of 9.5 months in our previous study with mGEMOX and 11.7 months with GemCis. For this total of 216 patients are required (108 in each arm); to make for major protocol violation and lost to follow up additional 22 patients in each arm will be enrolled. Thus in total 260 patients (130) in each arm will be recruited. This will have alpha and beta values of 0.05 and 0.20 respectively. So far 152 patients have been enrolled. Treatment protocol: Cycles will be repeated every 3 weeks Arm A- mGEMOX Inj Oxaliplatin 80 mg/m$^2$ 2 hours infusion in Dextrose 5% Day 1 and 8 Inj Gemcitabine 900 mg/m$^2$ IV 30 minutes infusion day1 and 8 maximum of 6 cycles Arm B-GEMCIS Inj Cisplatin 25 mg/m$^2$ PO Days 1 and 8 Inj Gemcitabine 1,000 mg/m$^2$ IV 30 minutes infusion day 1 and 8 maximum of 8 cycles. Clinical trial information: CTRI/2010/091/001406.

**TPS4153 General Poster Session (Board #235B), Sat, 8:00 AM-11:45 AM**

**A multicenter, open-label, phase 3 trial to compare the efficacy and safety of lenvatinib (E7080) versus sorafenib in first-line treatment of subjects with unresectable hepatocellular carcinoma.** *Presenting Author: Richard S. Finn, Geffen School of Medicine at UCLA, Los Angeles, CA*

**Background:** Lenvatinib (L, E7080) is an oral multi-targeted tyrosine kinase inhibitor of VEGFR1-3, FGFR1-4, PDGFR$\beta$, RET and KIT. Given the role of angiogenesis in hepatocellular carcinoma (HCC), a phase 1/2 open-label study evaluated the safety and efficacy of L in 46 patients with advanced disease and Childs-Pugh (CP) A liver function status (Kudo ILCA 2013). Patients were treated with a starting dose of L 12 mg qd (28-d cycles) until disease progression or development of unmanageable toxicities. Median time to progression (TTP) was 12.8 months (mo; 95% confidence interval [CI] 7.23–14.7) and median overall survival (OS) was 18.7 mo (95% CI 12.8–25.1). The most common adverse events were hypertension 76% (Gr3 54%), palmar-plantar erythrodysesthesia syndrome 61% (Gr3 7%), proteinuria 59% (Gr3 20%), anorexia 57% (Gr3 2%), thrombocytopenia 50% (Gr3 33%), and fatigue 48% (Gr3 0%). Overall response rate (ORR) was 37%; 45.7% had stable disease. **Methods:** Based on these phase 2 data, a global, randomized, open-label phase 3 trial was designed to determine if L is non-inferior or superior compared to sorafenib (S) in advanced HCC. Eligible patients (N=940) with Barcelona Clinic Liver Cancer Stage B or C HCC, CP A status, and ECOG 0-1 will be randomized 1:1 to either L 12 mg or 8 mg orally qd (based on body weight [BW]) or S 400 mg orally bid. Patients will be stratified by region; macroscopic portal vein invasion, extrahepatic spread, or both; ECOG-PS; and BW ($<$60 vs $\geq$60 kg). The primary endpoint is OS. Secondary endpoints include progression-free survival, TTP, ORR (modified RECIST criteria), safety and PK/PD. Given an estimated median OS for S of approximately 10 mo, a 2.5 mo improvement was derived to achieve a hazard ratio (HR) of 0.8. Statistical study power (using a non-inferiority test by the 95% CI lower-limit method on log HR for OS) was determined based on this HR and a non-inferiority margin of 1.08, corresponding to 60% retention of S effect vs placebo. Based on these assumptions, the study power to declare non-inferiority or superiority is approximately 97% and 82%, respectively. The overall false positive rate is 0.05 (2-sided). Clinical trial information: NCT01761266.

**TPS4154 General Poster Session (Board #236A), Sat, 8:00 AM-11:45 AM**

**Sorafenib in combination with local microtherapy guided by gadolinium-EOB-DTPA enhanced MRI in patients with inoperable hepatocellular carcinoma (SORAMIC).** *Presenting Author: Jens Ricke, Otto von Guericke University of Magdeburg, Magdeburg, Germany*

**Background:** Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality with an increasing incidence. For the individual patient tumor stage , liver function and general health status are the principal prognostic factors. The clinical management of HCC requires a comprehensive, multidisciplinary approach. In early HCC curative treatment can be achieved by local ablation, resection or liver transplantation. In intermediate stages patients with HCC are offered locoregional treatment with palliative intent. Yttrium-90-radioembolisation (SIRT)) is currently evaluated in this setting with promising results. In advanced disease systemic therapy with sorafenib is standard of care in patients with preserved liver function. Studies on the combined use of locoregional and systemic therapy with their potential of a beneficial synergism are few and conducted in a small number of patients. The critical question is whether the combination is more benefit or more harm. **Methods:** This phase II-study is composed of three substudies with the following primary objectives: 1. In patients in whom local ablation is appropriate to determine if sorafenib in combination with RFA prolongs the time-to-recurrence in comparison with RFA plus placebo. Primary endpoint: time to recurrence, n = 290 patients 2. In patients in whom RFA is not appropriate (palliative treatment group) to determine if the combination of SIRT and sorafenib improves the overall survival in comparison to sorafenib alone. Primary endpoint: overall survival, n = 375 patients 3. To confirm in a 2-step procedure that Gd-EOB-DTPA enhanced MRI is non-inferior or superior compared with contrast-enhanced multislice CT for stratification of patients to a palliative or a local ablation treatment strategy. Primary endpoint: correct stratification of patients to a palliative versus local ablation treatment strategy; n = 830 patients The trial has started in December 2010 as a multinational and multicentric study. 349 patients have been enrolled until January 31$^{st}$ 2014 with 200 patients randomized in the palliative arm and 57 patients treated in the curative arm. Clinical trial information: 01126645.

**TPS4155 General Poster Session (Board #236B), Sat, 8:00 AM-11:45 AM**

**OPTIMIS: An international observational study to assess the use of sorafenib after transarterial chemoembolization (TACE) in patients with hepatocellular carcinoma (HCC).** *Presenting Author: Markus Peck-Radosavljevic, Medizinische Universitaet Wien, Vienna, Austria*

**Background:** TACE is currently recommended for the treatment of patients with intermediate-stage HCC (Barcelona Clinic Liver Cancer [BCLC] stage B). However, it remains unclear which patients are most likely to benefit from TACE, or when TACE should be stopped and alternative treatments considered. The multikinase inhibitor sorafenib is the only systemic therapy currently approved for the treatment of advanced HCC. The aim of this observational study is to prospectively collect data from patients with HCC who either receive or do not receive sorafenib subsequent to TACE. **Methods:** Patients are eligible if ≥18 years of age, have histologically/cytologically documented or radiographically diagnosed HCC classified as BCLC stage B or higher, have a life expectancy of ≥8 weeks, and a decision to treat with TACE has been made at the time of study enrollment (one prior TACE treatment is allowed if performed at the same center and all required data about the procedure are available). Treatment decisions made before a patient is enrolled, and during the observation period, must be according to investigators' regular practice. Exclusion criteria include any systemic anti-cancer therapy prior to the first TACE, or participation in an interventional study of locoregional or systemic therapy. The primary objective is evaluation of overall survival in patients who received sorafenib subsequent to TACE non-eligibility (early sorafenib) compared with those who did not (non-early sorafenib). The non-early sorafenib group includes patients who did not receive sorafenib or received it at a later point. Secondary objectives include progression-free survival, time to progression, tumor response, and safety. Planned enrollment is approximately 1600 patients from about 30 countries across Europe, Latin America, and Asia-Pacific, and from Canada. One interim analysis is planned once 500 patients have been observed for at least 6 months. Final analysis will be performed once the last enrolled patient has been followed for 18 months, has been lost to follow-up, or has died. The study began in October 2013 and 69 patients have been enrolled as of January 2014. Clinical trial information: NCT01933945.

**TPS4156^ General Poster Session (Board #237A), Sat, 8:00 AM-11:45 AM**

**RESORCE: An ongoing randomized, double-blind, phase III trial of regorafenib (REG) in patients with hepatocellular carcinoma (HCC) progressing on sorafenib (SOR).** *Presenting Author: Jordi Bruix, BCLC Group, Liver Unit, Hospital Clinic, University of Barcelona, Barcelona, Spain*

**Background:** No standard treatment options are available for patients with HCC that has progressed despite SOR treatment. The oral multikinase inhibitor REG has been shown to have an acceptable safety profile and evidence of antitumor activity in patients with SOR-pretreated HCC (Bruix *et al. Eur J Cancer* 2013): disease control was achieved in 26/36 patients (72%), and median time to progression (TTP) was 4.3 months; median overall survival (OS) was 13.8 months. On the basis of these results, a phase III trial was designed. **Methods:** This randomized, double-blind, placebo (Pbo)-controlled, multinational study (ClinicalTrials.gov identifier NCT01774344) will compare the efficacy and tolerability of REG *vs* Pbo in adults with HCC that has progressed on SOR. Inclusion criteria include Barcelona Clinic Liver Cancer stage B or C disease that cannot benefit from established treatments, Child–Pugh Class A liver function, and Eastern Cooperative Oncology Group performance status (ECOG PS) 0 or 1. Patients discontinuing SOR >10 weeks before study entry or who received other previous systemic therapy for HCC will be excluded. Patients are randomized 2:1 to receive REG 160 mg or Pbo once daily for weeks 1–3 of each 4-week cycle; all patients also receive best supportive care. Treatment continues until disease progression, death, intolerable toxicity, or patient/investigator decision to stop. Doses of study drug may be delayed or reduced to manage clinically significant drug-related toxicities. The primary endpoint is OS; secondary endpoints are TTP, progression-free survival, objective tumor response, disease control, and safety. Analysis will be according to randomized group, stratified by geographic region (Asia *vs* rest of world), ECOG PS (0 *vs* 1), alfa-fetoprotein level (<400 *vs* ≥400 ng/ml), extrahepatic disease (yes *vs* no), and macrovascular invasion (yes *vs* no). In addition, blood, plasma, and archival tissue will be assessed for pharmacokinetic and biomarker analyses, and health-related quality of life will be measured. As of February 2014, 137 out of the planned 530 patients have been randomized. Clinical trial information: NCT01774344.

**TPS4157 General Poster Session (Board #237B), Sat, 8:00 AM-11:45 AM**

**A phase II trial of cabozantinib in patients with carcinoid and pancreatic neuroendocrine tumors.** *Presenting Author: Jason Edward Faris, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background:** Neuroendocrine tumors are highly vascularized cancers. Sunitinib, a multitargeted tyrosine kinase inhibitor (TKI), whose targets include vascular endothelial growth factor receptors (VEGFRs) and stem-cell factor receptor (c-KIT), was recently approved for the treatment of patients with pancreatic neuroendocrine tumors (PNET). PNETs often express c-KIT, and more than half of PNET metastatic to lymph nodes or liver express MET, which is a putative mechanism of resistance to VEGF inhibitors. We are conducting a phase II trial of cabozantinib, a TKI with activity against VEGFRs, MET, RET, and KIT, which is approved for advanced medullary thyroid cancer. Cabozantinib has been demonstrated to inhibit development of hepatic metastases, with improved survival compared to VEGF inhibitor treatment in the RIP-Tag2 transgenic mouse model of PNET. **Methods:** The study is an open-label Phase II trial, with planned enrollment of 35 patients to each of two cohorts for patients with carcinoid and PNET. Eligible patients must have well or moderately differentiated tumors, and patients must be receiving or have progressed on octreotide if a carcinoid tumor. Patients receive 60mg of cabozantinib daily in 28-day cycles. The primary objective of this study is to evaluate the activity of cabozantinib in patients with PNET and carcinoid tumors as assessed by overall response rate (ORR). Secondary objectives include evaluation of progression free survival and overall survival, as well as correlative studies of circulating tumor cells and pro-angiogenic biomarkers at baseline and on-treatment. Imaging is performed every two cycles for the first three months, followed by every three cycles. For both cohorts, we hypothesize that cabozantinib will have an ORR≥12%. A sample size of 35 in each cohort achieves >80% power to detect a difference of 10% in ORR using a one-sided binomial test, with type I error of 3% and population proportion under the null hypothesis of 2%. Results and Conclusions: As of January 26, 2013, 31/70 (44%) of planned patients have been enrolled: 18 with carcinoid, and 13 with PNET. Clinical trial information: 01466036.

**TPS4158 General Poster Session (Board #238A), Sat, 8:00 AM-11:45 AM**

**NEONAX: Neoadjuvant plus adjuvant or only adjuvant nab-paclitaxel plus gemcitabine for resectable pancreatic cancer—A phase II study of the AIO Pancreatic Cancer Group.** *Presenting Author: Thomas Jens Ettrich, Ulm University Hospital, Ulm, Germany*

**Background:** Resectable pancreatic cancer still has an unfavourable prognosis. Neoadjuvant or perioperative therapies might improve the prognosis of these patients. Recently, two phase III trials demonstrated for the first time, a substantial improvement in overall response, PFS and OS in patients with metastatic pancreatic cancer compared to standard gemcitabine (FOLFIRINOX and nab-paclitaxel/gemcitabine). The combination of nab-paclitaxel/gemcitabine has a more favourable toxicity profile compared to the FOLFIRINOX protocol and appears applicable in a perioperative setting. **Methods:** NEONAX is a study for patients (to be enrolled: n=162) with resectable ductal adenocarcinoma of the pancreas ≤ T3 in two arms: Arm A (perioperative arm): 2 cycles nab-paclitaxel (125 mg/m2)/ gemcitabine (1000 mg/m2, d1, 8 and 15 of an 28 day-cycle) - tumor surgery - 4 cycles nab-paclitaxel/gemcitabine, Arm B (adjuvant only arm): tumor surgery - 6 cycles nab-paclitaxel/gemcitabine. NEONAX is an interventional, prospective, randomized, controlled, open label, two sided phase II study with an unconnected analysis of the results in both experimental arms against a fixed survival probability (38% at 18 month with adjuvant gemcitabine). The randomization (1:1) is eminent to achieve two comparable patient groups. Primary objective is DFS at 18 months after randomization. Key secondary objectives are 3-year OS and DFS, progression during neoadjuvant therapy and QoL. In the perioperative group tumor tissue will be collected prior to and post-surgery and subjected to microdissection and exome sequencing of tumor tissue. Tumor regression will be assessed both in the perioperative and the adjuvant group, respectively. In addition, circulating tumor-DNA will be analyzed in patients with the best and the worst responses to the neoadjuvant treatment Start of trial will be in II/2014 in 20 high-volume centers for pancreatic surgery in Germany. Clinical trial information: NCT02047513.

**TPS4159 General Poster Session (Board #238B), Sat, 8:00 AM-11:45 AM**

**A phase 2b, randomized, controlled, multicenter, open-label study of the efficacy and immune response of GVAX pancreas vaccine and CRS-207 compared to chemotherapy or to CRS-207 alone in adults with previously treated metastatic pancreatic adenocarcinoma (ECLIPSE Study).** *Presenting Author: Dung T. Le, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** A heterologous prime-boost vaccination strategy using GVAX pancreas vaccine and CRS-207 is showing promise in patients with metastatic pancreatic adenocarcinoma (PDA). GVAX is composed of lethally-irradiated, allogeneic pancreatic cancer cells modified to express GM-CSF and induces a broad response against multiple tumor antigens. GVAX is given with low-dose cyclophosphamide (CY) to inhibit regulatory T cells. CRS-207 is live-attenuated *Listeria monocytogenes* engineered to express the tumor-associated antigen mesothelin. CRS-207 boosts responses against mesothelin and is unique in its capacity to stimulate both innate and adaptive immunity by activating T cells and NK cells. Results from a phase 2 study demonstrated the CY/GVAX plus CRS-207 combination improved overall survival (OS) compared to CY/GVAX alone (p-value<0.05; Le, GI ASCO 2014). **Methods:** This is a phase 2b study comparing CY/GVAX and CRS-207 to chemotherapy or to CRS-207 alone in adults with previously-treated metastatic PDA. Subjects will be enrolled in two cohorts: 150 subjects into a primary cohort of patients with at least two prior treatment regimens for metastatic disease (3$^{rd}$+ line) and 90 subjects into an exploratory cohort of patients with only one prior treatment regimen for metastatic disease (2$^{nd}$ line). Subjects will be randomized in a 1:1:1 ratio to receive either 2 doses of CY/GVAX and 4 doses of CRS-207 (Arm A), six doses of CRS-207 (Arm B) or physician's choice of select single-agent chemotherapy (Arm C). The primary objective is to compare OS in the primary cohort between Arms A and C. Secondary/exploratory objectives include: comparison of OS in both primary and exploratory cohorts between all treatment arms, assessment of safety and clinical responses (tumor assessments and CA19-9 levels) and correlation of *Lm*- and mesothelin-specific T cell and other immunological responses with OS, progression-free survival and best overall response. (Sponsor: Aduro BioTech, Inc.). Clinical trial information: NCT02004262.

**TPS4160 General Poster Session (Board #239A), Sat, 8:00 AM-11:45 AM**

**A phase 2, multicenter study of FOLFIRINOX followed by ipilimumab in combination with allogeneic GM-CSF transfected pancreatic tumor vaccine in the treatment of metastatic pancreatic cancer.** *Presenting Author: Rina Khatri Patel, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Combinatorial strategies aimed at priming tumor antigen-specific T cells while simultaneously blocking negative immune checkpoints may improve immunotherapy for immune tolerant cancers such as pancreatic adenocarcinoma (PDA). In a previously reported trial, concurrent administration of an allogeneic GM-CSF transfected pancreatic tumor vaccine and the cytotoxic T-lymphocyte antigen-4 (CTLA-4) antibody, ipilimumab (IPI), which blocks an inhibitory signal on T cells resulted in both CT scan regressions and CA19-9 declines in heavily preteated patients. This proposal will test vaccine + IPI in patients with metastatic PDA who have stable disease (SD) with upfront FOLFIRINOX (5-FU/ irinotecan/oxaliplatin) chemotherapy. Integrating immunotherapy after upfront chemotherapy has several advantages. Chemotherapy can debulk the tumor and predispose cancer cells to cell death mediated by immune cells. Immunotherapy can take weeks to months to be effective and is therefore more likely to work in patients with SD. Vaccine + IPI showed promise in heavily pre-treated patients and giving it immediately after front line chemotherapy may improve activity. **Methods:** This is a phase 2, multicenter, randomized, controlled, open-label trial in patients with metastatic PDA who have SD after 8-12 doses of FOLFIRINOX. 92 patients will be randomized 1:1 to Arm A (vaccine + IPI) or Arm B (continue chemotherapy per standard of care). Patients on Arm A will receive vaccine + IPI (10mg/kg) every 3 weeks for 4 doses then every 8 weeks. The primary objective of the study is to compare the overall survival (OS) of Arm A vs Arm B. Secondary objectives include: assessment of safety, progression-free survival (PFS), immune-related PFS, duration of response, objective response rate by RECIST and immune-related response criteria, and tumor marker kinetics (CA 19-9). Exploratory objectives include: identification of predictors of response and toxicity using proteomic techniques, assessment of T cell responses and genomic and IHC analyses of tumor tissue. (FDA Office of Orphan Products Development, R01FD004819-01). Clinical trial information: NCT01896869.

**TPS4161 General Poster Session (Board #239B), Sat, 8:00 AM-11:45 AM**

**A phase 2, open-label study of rucaparib in patients with pancreatic cancer and a known deleterious BRCA mutation.** *Presenting Author: Susan M. Domchek, Basser Research Center for BRCA, University of Pennsylvania, Philadelphia, PA*

**Background:** Approximately 5% of unselected pancreatic cancer (PC) patients (pts), 10% of PC pts of Ashkenazi Jewish descent, and up to 19% of familial PC families, harbor a germline BRCA mutation. PARP inhibitors (PARPi) have exhibited clinical activity in pts with a BRCA mutation. Rucaparib, an oral PARPi, is being developed for treatment of cancers associated with homologous recombination repair (HRR) deficiency due to a BRCA mutation or other HRR pathway defect. Rucaparib has demonstrated clinical activity (RECIST and CA-125 responses) in pts with BRCA$^{mut}$ pancreatic, ovarian, or breast cancer in an ongoing Phase 1/2 study (NCT01482715). Clinical activity of PARPi in BRCA$^{mut}$ PC combined with the paucity of active 2$^{nd}$-line therapies support evaluation of rucaparib in PC pts with a deleterious BRCA mutation. **Methods:** Study CO-338-023 (NCT02042378) is a single-arm, open-label Phase 2 trial of continuous rucaparib in up to 100 pts with pancreatic ductal adenocarcinoma (or related subtype) and a known deleterious BRCA mutation (germline or somatic). Pts must have received at least 1, but no more than 2, prior regimens for locally advanced or metastatic disease and have relapsed disease, or are no longer able to tolerate chemotherapy due to toxicity and radiologic assessment confirms no response to such treatment. Other key inclusion criteria include measurable disease, ECOG PS 0 or 1, and adequate organ function. Pts with endocrine tumors or prior PARPi treatment are excluded. Pts will take rucaparib continuously and be evaluated for safety every 2–4 wks, disease status (CT scans, CA19–9) every 4–8 wks until disease progression, and then survival every 4 wks. Blood and archival tumor tissue (if available) will be collected from all pts. The primary endpoint is ORR by RECIST v1.1. Key secondary endpoints include duration of response, PFS, OS, and safety. Exploratory analyses include gene sequence and structural rearrangements of tumor DNA, and evaluation of circulating tumor DNA. A group sequential interim monitoring plan will be implemented to stop the study early for either superior efficacy or futility. Interim analyses will occur after every 10$^{th}$ pt enrolled has sufficient disease assessment data available. Clinical trial information: NCT02042378.

**TPS4162^ General Poster Session (Board #240A), Sat, 8:00 AM-11:45 AM**

**APACT: A phase 3 randomized, open-label, multicenter trial evaluating the use of adjuvant *nab*-paclitaxel (*nab*-P) plus gemcitabine (G) versus G alone in patients (pts) with surgically resected ductal pancreatic adenocarcinoma (PDA).** *Presenting Author: Margaret A. Tempero, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

**Background:** Resection is the only curative treatment for PDA. Adjuvant chemotherapy following resection is associated with improved disease-free survival (DFS), median overall survival (OS), and 5-year survival for pts with resectable PDA. Despite these improvements, recurrence rates are still high, and survival rates remain poor, requiring more effective adjuvant therapies. In the phase 3 MPACT trial, *nab*-P plus G was manageable and demonstrated superiority to G alone for OS (median 8.5 vs 6.7 months; HR 0.72; 95% CI, 0.617 - 0.835; $P < 0.001$) and all secondary efficacy endpoints in pts with metastatic PDA [Von Hoff et al. *N Engl J Med*. 2013]. The current phase 3 trial (APACT) will evaluate the efficacy and safety of *nab*-P plus G vs G alone as adjuvant chemotherapy in pts with surgically resected PDA. **Methods:** Approximately 800 eligible pts will be randomized 1:1 (stratified by resection status [R0 vs R1], lymph node status [positive vs negative], and region) to receive *nab*-P 125 mg/m$^2$ plus G 1000 mg/m$^2$ or G 1000 mg/m$^2$ on days 1, 8, and 15 of a 28-day cycle for 6 cycles. Eligibility criteria include histologically confirmed resected PDA with macroscopic complete resection (R0 and R1); surgical staging T 1-3, N0-1, M0; ECOG PS 0 or 1; acceptable hematologic function; and no prior neoadjuvant therapy or radiation for PDA. Pts will be assessed by CT scan every 8 weeks for the first 24 weeks, every 12 weeks for the first 3 years, and every 24 weeks thereafter until disease recurrence for up to 5 years. The primary endpoint is DFS by independent review. Secondary endpoints include: OS and safety. Exploratory endpoints include tumor markers and quality of life by EORTC QLQ-C30 and QLQ-PAN26. One interim analysis for safety and 2 interim analyses for efficacy are planned. This design provides 90% power to detect a hazard ratio of 0.74 for DFS, with a 2-sided 5% significance level, which represents a 36% improvement in median DFS with *nab*-P plus G vs G alone. Biospecimen collection will be integrated with the trial process to ensure a high yield of material for biomarker discovery. Clinical trial information: NCT01964430.

**TPS4163 General Poster Session (Board #240B), Sat, 8:00 AM-11:45 AM**

**A randomized, double-blinded, placebo-controlled phase II trial of gemcitabine (gem) plus nab-paclitaxel (n-pac) combined with OGX-427 (apatorsen) or placebo in patients (pts) with metastatic pancreatic cancer (mPaCa): The Rainier Trial.** *Presenting Author: Johanna C. Bendell, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** Hsp27 (heat shock protein 27) is over-expressed in a variety of tumor types causing initiation, growth, and metastasis of cancer cells. OGX-427 (apatorsen) is an antisense oligonucleotide that binds to Hsp27 mRNA, inhibiting production of the Hsp27 protein. Pts with pancreatic adenocarcinoma have significantly higher levels of Hsp27 than healthy individuals. Preclinical studies with apatorsen showed inhibited proliferation, induced apoptosis, and enhancement of the effect of chemotherapy in pancreatic cancer models. This randomized, phase II trial evaluates the efficacy of gem/n-pac chemotherapy with or without apatorsen in patients with mPaCa. The primary endpoint is overall survival. Secondary endpoints include progression-free survival, objective response rate, CA19-9 response, and safety. Archival tissue will be collected and assessed for expression of Hsp27, PTEN (protein expression by IHC), and a panel of gene mutations for correlative analyses. **Methods:** A total of 130 patients are planned to be randomized in a 1:1 ratio to Arm A (gem, n-pac, apatorsen) or Arm B (gem, n-pac, placebo). Three loading doses of apatorsen 600 mg or placebo are given prior to start of chemotherapy. Apatorsen 600 mg or placebo IV is then administered weekly in 28 day cycles. Gem 1000 mg/m$^2$ and n-pac 125 mg/m$^2$ are administered IV on days 1, 8, and 15. Patients will be re-staged every 2 cycles per RECIST v 1.1 and will continue treatment until disease progression or other reasons for discontinuation. Key eligibility includes: stage IV pancreatic adenocarcinoma, ECOG PS of 0 or 1, adequate bone marrow and organ function, and no known CNS metastases or clinically significant cardiac disease. Serum Hsp27 levels will be collected at screening, baseline, and during treatment. Correlative analyses of clinical outcomes and between Hsp27 expression/percentage of tumors expressing Hsp27 will be explored. This trial is currently open to enrollment. Clinical trial information: NCT01844817.

**4500 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Final results of EORTC intergroup randomized phase III trial comparing immediate versus deferred chemotherapy after radical cystectomy in patients with pT3T4 and/or N+ M0 transitional cell carcinoma (TCC) of the bladder.** *Presenting Author: Cora N. Sternberg, Hospital San Camillo-Forlanini, Rome, Italy*

**Background:** Patients (pts) with muscle invasive TCC of the bladder have poor overall survival (OS) due to systemic disease at diagnosis. This randomized intergroup phase III trial compared immediate vs deferred chemotherapy after radical cystectomy in pts with pT3T4 and/or N+ M0 TCC of the bladder. **Methods:** Within 90 days after cystectomy, pts were randomized to 4 cycles of GC, HD-MVAC or MVAC adjuvant chemotherapy or 6 cycles of deferred chemotherapy at relapse. Main endpoint was OS with PFS a secondary endpoint. Analysis was by intent-to-treat using Cox models stratified by group and adjusted for T stage (pT1T2 vs pT3T4) and nodal status (N- vs N+). **Results:** 284 of 660 pts were enrolled in 63 sites from 13 countries from 4/2002 to 8/2008 when the trial closed for poor accrual. Follow up (f/u) continued for 5 yrs to 8/2013. Pt characteristics were well balanced in the treatment groups; median age was 61 yrs with similar pT and nodal status (70% N+). Most received GC. Median and maximum f/u is 7.0 and 10.4 yrs in the immediate and 7.2 and 10.6 yrs in the deferred arm. An IDMC reviewed the trial twice and recommended continuation. 176 pts (62.0%) progressed or died, 73 (51.8%) on the immediate and 103 (72.0%) on the deferred arm. Median and 5 yr PFS are 2.9 yrs and 46.8% on the immediate and 0.9 yrs and 29.5% on the deferred arm ($p< 0.0001$). 148 pts (52.1%) died, 66 (46.8%) on the immediate and 82 (57.3%) on the deferred arm. Median and 5 yr OS are 6.8 yrs and 53.6% on the immediate and 4.6 yrs and 47.7% on the deferred arm, HR=0.78 (95.09% CI: 0.56, 1.10, $p=0.13$). Grade 3/4 AEs in the immediate arm included myelosuppression (26%), neutropenia (38%) and thrombocytopenia (28%). One pt died due to toxicity in the immediate arm. **Conclusions:** This is the largest reported randomized trial of adjuvant chemotherapy in pts with muscle invasive bladder cancer. Immediate adjuvant cisplatin based combination chemotherapy led to a statistically significant improvement in the secondary endpoint PFS and a non-significant decrease of 22% in the risk of death after radical cystectomy, the primary endpoint. The 2005 IPD meta-analysis should be updated. Clinical trial information: NCT00028756.

**4501 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Effect of cabozantinib on immunosuppressive subsets in metastatic urothelial carcinoma.** *Presenting Author: Andrea Borghese Apolo, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

**Background:** Myeloid-derived suppressor cells (MDSC) and regulatory T cells (Treg) are major components of the immune suppressive tumor microenvironment. Both cell types promote effector T-cell dysfunction and tumor progression. The effect of cabozantinib, a tyrosine kinase inhibitor primarily targeting MET and VEGFR2 on specific immunosuppressive subsets, is unclear. In this study we assess MDSC and Tregs in patients undergoing treatment with cabozantinib and correlate with clinical response to therapy. **Methods:** Peripheral blood samples were obtained from patients with advanced/refractory metastatic urothelial carcinoma undergoing treatment with cabozantinib under a clinical trial at the National Cancer Institute (NCT01688999). MDSC (CD11b+CD33+CD14-) and Tregs (CD4+CD25hi Foxp3+) were measured in 24 patients at baseline and after 2 cycles of continuous cabozantinib treatment. MDSC and Tregs were further analyzed for CD40 and PD-1, respectively, as suppressive functional markers. **Results:** Patients with low Tregs at baseline had an improved partial response (PR) rate ($p=0.014$), progression free survival (PFS) ($p=0.059$) and overall survival (OS) ($p=0.0071$). Tregs decreased with cabozantinib treatment ($p=0.015$). Overall, PD-1 expression in Tregs increased after cabozantinib ($p=0.011$). However, patients with a PD-1 change below the median showed a strong trend to improved PFS compared to those with increased PD-1 above the median ($p=0.035$). The percent MDSC did not change with treatment. However, MDSC CD40 expression was increased after cabozantinib treatment compared to baseline ($p=0.0005$). Though, a decrease in MDSC CD40 expression after treatment was associated with an improved PFS ($p=0.020$). **Conclusions:** Treg levels prior to cabozantinib treatment are predictive of therapeutic responsiveness and OS. Changes in Treg PD-1 expression and MDSC CD40 expression may be prognostic markers in patients with advanced/refractory metastatic urothelial carcinoma treated with cabozantinib.

**4502 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Validation of a 16-gene signature for prediction of recurrence after nephrectomy in stage I-III clear cell renal cell carcinoma (ccRCC).** *Presenting Author: Bernard J. Escudier, Institut Gustave Roussy, Villejuif, France*

**Background:** New molecular diagnostics are needed to improve assessment of recurrence risk after nephrectomy in ccRCC. The 16-gene (11 cancer-related, 5 reference) Recurrence Score (RS) was previously developed in a cohort of 931 stage I-III ccRCC patients (pts) from Cleveland Clinic, requiring validation in an independent study. **Methods:** A prospective clinical validation study of the Onco*type* DX RS in stage I-III ccRCC pts treated with nephrectomy from 1995 to 2007 was conducted by a French consortium. Genes, algorithm, endpoints, methods, and analysis plan were pre-specified and locked prior to merging clinical and molecular data. Gene expression was quantitated by RT-PCR in fixed paraffin-embedded primary ccRCC tissue without knowledge of pt clinical characteristics or outcomes. Recurrence-free interval (RFI, primary endpoint), renal cancer-specific survival (RCSS), disease-free survival (DFS) and overall survival (OS) were analyzed using Cox PH regression stratified by stage with data censored at 5 years, and Kaplan-Meier methods. **Results:** RT-PCR was successful in 626/645 pts (97%): 398 stage I, 54 stage II, 174 stage III. Median follow up was 5.5 yrs. 5-yr recurrence risk was dependent upon stage (7%, 16% and 30% in stage I, II and III). Continuous RS predicted recurrence risk (HR per 25 point increase in RS (HR/25) = 3.9, 95% CI 2.6-5.8, $p<0.001$). RS predicted RCSS, DFS and OS (all with $p<0.001$). In multivariable analyses, RS continued to predict recurrence (HR/25 =2.7, 95% CI 1.6-4.5, $p<.001$) after adjustment for tumor size, Fuhrman grade and necrosis. RS identified 39% of stage I pts with an average 5-yr recurrence risk of 2% (95% CI 0-7%) and 15% of pts with a 23% (95% CI 13-39%) risk. In stages II-III, RS identified 19% of pts with a 2% (95% CI 0-16%) and 44% of pts with a 39% (95% CI 29-50%) recurrence risk. **Conclusions:** The 16-gene Onco*type* DX RS is validated as a predictor of clinical outcome in pts with stage I-III ccRCC and provides significant information beyond conventional clinical and pathologic characteristics. The RS may be useful to select patients for adjuvant treatment trials, for active surveillance of small renal masses, and for surveillance strategies after surgery.

**4503 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Genome-wide association study (GWAS) of efficacy and safety endpoints in pazopanib- or sunitinib-treated patients with renal cell carcinoma (RCC).** *Presenting Author: Toby Johnson, GlaxoSmithKline, Hertfordshire, United Kingdom*

**Background:** Pazopanib and sunitinib are angiogenesis inhibitors approved for treatment of advanced RCC, but there is substantial heterogeneity in response to either treatment. We hypothesized that patient's germline genetic variation may affect treatment efficacy or safety endpoints. **Methods:** N=1099 patients, from the COMPARZ study (NCT00720941, NCT01147822, N=374 pazopanib, N=355 sunitinib) and three other phase II/III pazopanib studies (NCT00244764, NCT00334282, NCT00387764, N=370), provided consent for pharmacogenetic research. GWAS analyses used normal, ordinal, and Cox regression models to test 30M genetic variants (genotyped or imputed) for association with progression free survival (PFS), overall survival (OS), and best response (BR) in pazopanib or sunitinib treated patients, and with safety endpoints in pazopanib treated patients (bilirubin elevation, transaminase elevation, blood pressure change, hand foot syndrome [HFS], diarrhoea, fatigue, cardiotoxicity, hypothyroidism, proteinuria). **Results:** At the GWAS significance level for common variants ($P\leq 5\times10^{-8}$), combined analysis of PFS, OS and BR identified an association with a common variant intronic in *LOXL2* and *ENTPD4* ($P=1.7\times10^{-8}$). No common variants reached $P\leq 5\times10^{-8}$ for individual efficacy endpoints, but hypothesis-generating efficacy associations approaching GWAS significance ($P\leq 5\times10^{-7}$) were observed in and near biologically plausible genes for RCC (e.g. *IL2RA, LRRC2*). For safety endpoints, common variants near *UGT1A1* were associated with bilirubin elevation in pazopanib treated patients ($P=2.9\times10^{-17}$), consistent with our previous candidate gene analysis results. A common variant intergenic between *ANAPC4* and *SLC34A2* was associated with HFS ($P=4.6\times10^{-8}$). **Conclusions:** To our knowledge, this is the largest GWAS for response and toxicity to anti-angiogenesis therapies in RCC reported to date. We identified genetic markers associated with combined efficacy endpoints as well as safety endpoints. If replicated in independent studies, these associations may provide insight into biological mechanisms underlying differential outcome to treatment.

**4504 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Phase I study of nivolumab in combination with ipilimumab in metastatic renal cell carcinoma (mRCC).** *Presenting Author: Hans J. Hammers, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** There is a need for agents that result in durable responses and improved tolerability in patients (pts) with mRCC. Nivolumab, a fully human IgG4 programmed death-1 (PD-1) immune checkpoint inhibitor antibody, has shown activity in mRCC. Combining nivolumab + ipilimumab, a fully human monoclonal antibody to CTLA-4, showed encouraging clinical activity and acceptable safety in advanced melanoma. We report preliminary results of the combination in mRCC. **Methods:** Pts with mRCC (favorable/intermediate MSKCC score; Karnofsky performance status ≥80%; untreated or any number of prior therapies) were randomized to receive nivolumab 3 mg/kg + ipilimumab 1 mg/kg (arm N3 + I1) or nivolumab 1 mg/kg + ipilimumab 3 mg/kg (arm N1 + I3) IV Q3W for 4 doses then nivolumab 3 mg/kg IV Q2W until progression/toxicity. The primary objective was to assess safety/tolerability; secondary objective was to assess antitumor activity. **Results:** Pts were randomized to N3 + I1 (n=21) and N1 + I3 (n=23). Most pts (n=34; 77%) had prior systemic therapy (N3 + I1: 16; N1 + I3: 18). Treatment-related adverse events (AEs) were seen in 39/44 pts (89%); 7 pts (16%; N3 + I1: 2; N1 + I3: 5) discontinued due to any-grade related AEs. Grade 3–4 related AEs occurred in 19 pts (43%; N3 + I1: 5; N1 + I3: 14), most commonly ↑ lipase (16%, n=7), ↑ ALT (11%, n=5), diarrhea (9%, n=4), colitis (5%, n=2), ↑ amylase (5%, n=2). No grade 3–4 pneumonitis was seen. Objective response rate (ORR) was 29% (N3 + I1) and 39% (N1 + I3) (Table). Duration of response (DOR) was 4.1+ to 22.1+ wks (all 6 responses ongoing) in N3 + I1, and 6.1+ to 18.3+ wks (8/9 responses ongoing) in N1 + I3. Responses occurred by first tumor assessment (wk 6) in 67% of responding pts in both N3 + I1 and N1 + I3. Stable disease (SD) was seen in 7 (33%) pts (N3 + I1) and 9 (39%) pts (N1 + I3). **Conclusions:** Nivolumab + ipilimumab showed acceptable safety and encouraging antitumor activity in mRCC, with most responses ongoing. Follow-up, expansion cohorts at these doses and an additional dose cohort (nivolumab 3 mg/kg + ipilimumab 3 mg/kg) are being assessed. Clinical trial information: NCT01472081.

**4505 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Everolimus versus sunitinib prospective evaluation in metastatic non-clear cell renal cell carcinoma (The ESPN Trial): A multicenter randomized phase 2 trial.** *Presenting Author: Nizar M. Tannir, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** In a single-arm phase II trial of sunitinib in non-clear cell RCC (nccRCC) we previously reported (Tannir et al. Eur Urol 2012), objective response rate [ORR] was 5% and median progression-free survival [PFS] was 2.7 months. Temsirolimus was previously shown to produce overall survival (OS) benefit in poor-risk RCC including nccRCC (Hudes et al. NEJM 2007). **Methods:** This is a randomized phase II trial of everolimus (E) vs. sunitinib (S) with crossover design in metastatic nccRCC. Primary endpoint was PFS in first-line (1L). Secondary endpoints were PFS in second-line (2L), safety, and OS. A sample size calculation of 108 pts (54/arm) was based on an assumption of improved median PFS from 12 weeks with S to 20 weeks with E. Pts were stratified by histology (papillary vs. others), and MSKCC risk groups. Kaplan-Meier curves were used to estimate unadjusted time-to-event distributions. Stratified log rank tests were used to compare each time-to-event variable between groups. **Results:** Seventy-three pts were enrolled. Sixty-eight pts were eligible and evaluable (median age 59, 43 males [63%], 52 pts [77%] had prior nephrectomy). Twenty-seven pts had papillary, 11 pts had chromophobe, 9 pts had unclassified, 7 pts had translocation, 13 pts had sarcomatoid, and 1 pt had oncocytic RCC. Thirty-five pts received E (good-risk 4, intermediate-risk 29, poor-risk 2). Thirty-three pts received S (good-risk 4, intermediate-risk 29). ORR with S in 1L was 12% (2 pts had chromophobe, 1 pt had papillary type 1 and 1 pt had 99% sarcomatoid); ORR with E in 1L was 0%. Median PFS in 1L with S was 6.1 mos (95% CI: 4.7, 10.8) and 4.1 mos with E (95% CI: 2.7, 7.4); p = 0.25. Thirty-eight pts received 2L therapy (S 19, E 19). Median PFS in 2L with S was 1.8 mos (95% CI: 1.5, NA) and 4.3 mos with E (95% CI: 1.4, NA). A total of 27 pts have died (8 had S and 19 had E). Median OS with E in 1L was 10.5 mos (95% CI: 7.4, NA); median OS with S in 1L was not reached; p=0.01. Toxicity was consistent with previous reports of E and S. **Conclusions:** Based on futility analysis for PFS and inferior OS with E compared to S in 1L, the DSMB recommended termination of further pt accrual on this trial. E cannot be recommended as 1L option in nccRCC.

**4507 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**International randomized, double-blind, placebo-controlled, phase 3 study of linsitinib (OSI-906, L) in patients (pts) with locally advanced or metastatic adrenocortical carcinoma (ACC).** *Presenting Author: David I. Quinn, Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

**Background**: ACC is an uncommon but frequently fatal cancer. For pts with metastatic or recurrent nonoperable ACC, there are very limited treatment options. Insulin-like growth factor 2 (IGF2) overexpression occurs in >90% of ACC, hence the IGF pathway is a potential therapeutic target. We assessed the activity of a potent IGF-1 receptor TKIlinsitinib in ACC. **Methods:** In a double-blind phase III trial accruing over 21 months, pts with measurable locally advanced or recurrent ACC following 1st- or 2nd-line treatment were randomly assigned to linsitinib 150mg BID orally or best supportive care & placebo (P), in a 2:1 ratio, respectively. The primary endpoint was overall survival (OS; power 80% for ñOS from 9 to 15.6 months); secondary endpoints: PFS, disease-control & objective response rate (blinded central review by RECIST 1.1), QoL & safety/toxicity (CTCAEv4.02). **Results**: 139 pts (median age 50yrs, 67% female, ECOG 0/1: 44.6, 51.1%) were enrolled with 90 assigned to linsitinib & 49 to P. Prior therapies included surgery: 90.6%; radiotherapy: 30.9%; mitotane: 100% & cytotoxic chemotherapy: 73.4%. The median time from diagnosis to trial initiation was 26.5 months. There was no difference between linsitinib and placebo in overall survival (median 323 days (10.8 months) vs 356d (11.8); p=0.77, HR 0.94); PFS (44 vs 46d; p=0.3, HR 0.83) & DCR (32.2 vs 34.7%). However, 3 pts on linsitinib experienced PR and 8 had prolonged PFS >100d (4 on drug >400d), whereas these events did not occur with placebo. Dose modification: L: 43.3, P 29.2%. Treatment-emerged adverse events (TEAEs) occurred in 97.8 vs 93.8%, grade 5: 5.6 vs 10.4%, gr 4: 10.1 vs 2.1%, gr 3: 45.6 vs 31.3% for L vs P respectively. Common TEAEs: fatigue (33.3 vs 22.9%), nausea (26.7 vs 31.3%), vomiting (20.0 vs 20.8%), abdominal pain (20.0 vs 20.8%), QTc prolonged (20 vs 6.3%) for L vs P. **Conclusions:** Targeting the IGF pathway with linsitinib did not improve overall or progression-free survival in adrenocortical cancer patients, although a small subgroup of patients seemed to benefit from this drug. Timely and efficient accrual to phase III trials in rare cancers is internationally feasible. Clinical trial information: NCT00924989.

**4508 Oral Abstract Session, Mon, 9:45 AM-12:45 PM**

**Management of clinical stage I seminomatous testicular cancer: A report from SWENOTECA.** *Presenting Author: Torgrim Tandstad, The Cancer Clinic, St. Olavs University Hospital, Trondheim, Norway*

**Background:** Clinical stage I seminoma testicular cancer is the most frequent presentation of testicular cancer. Current treatment option include surveillance (SURV) or adjuvant chemotherapy. Following a large randomized phase III study, 1 course of adjuvant carboplatin (AC) AUC7 became the preferred adjuvant treatment option. **Methods:** A risk-adapted protocol (SWENOTECA VII) was initiated in 2007, based on the proposed risk factors; invasion of rete testis and tumor size >4cm. Patients with 0-1 risk factor were recommended SURV, but could choose 1 course of AC (AUC7). Patients with 2 risk factors were recommended 1 course of AC, but could choose SURV. We also report treatment results from patients treated with AC in an earlier protocol during 2004-2007. **Results:** 839 patients were included in the SWENOTECA VII protocol. In addition 225 patients were treated with AC before 2007. Median follow-up is 4.0 years, 3.6 years for patients on SURV and 4.2 years for patients treated with AC. In total 675 patients were treated with AC, and 389 patients chose SURV. Complete information regarding risk factors was available in 946 patients. The relapse-rate (RR) following AC was 6.2 %; in patients without risk factors 2.7 % compared to 9.4 % in patients with 1-2 risk factors. In patients followed by SURV the RR was 10 %; in patients without risk factors 2.9 %, compared to 21.7 % in patients with 1-2 risk factors. **Conclusions:** In this modern, large, population-based prospective study we confirm the low relapse rate previously reported for patients with 0 risk factors on SURV, thus patients with no risk factors should be followed by SURV. The RR with AC was somewhat higher than reported in MRC TE19/EORTC 30982. This may be due to the risk-adapted approach, with a higher proportion of patients with 1-2 risk factors treated with AC. The RR following AC indicated a relatively modest effect in preventing relapse. Data regarding exact doses are being collected to assess if inadequate dosing may have affected the RR following AC.

**4509 Poster Highlights Session (Board #1), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Comprehensive molecular profiling of urothelial bladder cancer at the DNA, RNA, and protein levels: A TCGA project.** *Presenting Author: John N. Weinstein, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Urothelial carcinoma (UC) is a major cause of mortality with no approved molecularly targeted agents or good treatment options beyond cisplatin-based chemotherapy. **Methods:** For The Cancer Genome Atlas (TCGA), we profiled muscle-invasive UCs for mutations, DNA copy number variants (CNVs), mRNA and microRNA expression, protein expression and phosphorylation, DNA methylation, transcript splicing, gene fusion, viral integration, pathway perturbation, clinical correlates, and histopathology. The finding here are based on the first 131 tumors, but >250 more are being processed as of 1/2014. **Results:** Whole-exome sequencing revealed 29 recurrently mutated genes. Potential therapeutic targets included altered PIK3CA, ERBB2, FGFR3, TSC1, and ERBB3, plus mutated chromatin-regulating genes MLL, MLL2, MLL3, CREBBP, CHD7, SRCAP, ARID1A, KDM6A (UTX), and EP300. There were 27 focal CNVs, including CDKN2A deletion in 47%. Low-pass whole-genome sequencing identified 3 tumors with FGFR3-TACC3 fusions. Viral DNA was found in 6% (CMV, HHV6B, HPV16, BK polyoma), and viral transcripts were identified in 4% (CMV, BK polyoma, HPV16). mRNA-seq showed 4 tumor clusters: (I) papillary morphology, FGFR3 dysregulation. (I and II) high HER2 (ERBB2), estrogen receptor beta signaling signature (like Luminal A breast cancer). (III) similar to basal-like breast and squamous cell head and neck. Integrated analyses confirmed changes in cell cycle regulation (93%), kinase and PI3-K signaling (72%), and epigenetic regulation (histone-modifiers: 89%; SWI/SNF nucleosome remodeling complex: 64%). Recurrent defects in PI3-kinase/AKT/mTOR (42%) and RTK/RAS (44%) pathways may be actionable. **Conclusions:** This study and others identify druggable targets in UC. FGFR3 is activated by mutation, gene fusion, and overexpression, suggesting trials of FGFR3 inhibitors. PI3-kinase/mTOR/AKT/TSC1 pathway defects are frequent, and mutations in TSC1 suggest trial of mTOR inhibitors. ERBB2 amplifications and activating mutations suggest agents such as trastuzumab, trastuzumab-DM1, lapatinib, and neratinib. The mutations in epigenetic regulatory genes suggest potential for chromatin modifying agents.

**4510 Poster Highlights Session (Board #2), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Association of somatic *ERCC2* mutations with cisplatin sensitivity in muscle-invasive urothelial carcinoma.** *Presenting Author: Jonathan E. Rosenberg, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Cisplatin-based combination chemotherapy is the standard of care for patients with muscle invasive urothelial carcinoma. Pathologic downstaging to pT0/pTis after neoadjuvant cisplatin-based chemotherapy is associated with improved survival, although the molecular determinants of cisplatin sensitivity are incompletely understood. Recent reports have identified somatic mutations in ERCC2, a nucleotide excision repair gene, in 7-12% of bladder cancers. Preclinical evidence suggests that defects in the nucleotide excision repair (NER) pathway mediate cisplatin sensitivity. **Methods:** We performed whole exome sequencing of pre-treatment tumor and germline DNA from 51 patients with muscle invasive urothelial carcinoma who received neoadjuvant cisplatin-based chemotherapy followed by cystectomy (26 pT0/pTis "responders", 25 pT2+ "non-responders"). Computational methods were employed to identify somatic mutations that occurred preferentially in cisplatin responders. Functional validation of significantly enriched mutations was performed using cellular cisplatin and UV sensitivity assays. **Results:** Somatic *ERCC2* mutations were observed in 38.5% of responders and 0% of non-responders ($q < 0.01$). *ERCC2* was the only gene enriched in the cisplatin responders compared with non-responders. *ERCC2* mutations clustered within or near conserved helicase domains required for ERCC2 function. Expression of the identified *ERCC2* mutants in an *ERCC2*-deficient cell line failed to rescue cisplatin and UV sensitivity compared to wild-type *ERCC2*. **Conclusions:** Somatic *ERCC2* mutation is associated with cisplatin sensitivity in muscle invasive urothelial carcinoma. These results may inform the use of cisplatin-containing regimens in muscle invasive urothelial carcinoma, and potentially other *ERCC2*-mutated tumors.

**4511 Poster Highlights Session (Board #3), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Somatic copy number abnormalities (SCNAs) and mutations in PI3K/AKT pathway as prognostic factors for overall survival (OS) in platinum-treated locally advanced or metastatic urothelial tumors.** *Presenting Author: Joaquim Bellmunt, Bladder Cancer Center, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

**Background:** An integrative analysis was conducted to identify genomic alterations and mutational status on the gene pathway level that could predict OS in pts with urothelial cancers (UC) treated with platinum chemotherapy. **Methods:** DNA was extracted from FFPE samples from invasive UC and screened for mutations and CNAs. Of those, complete clinical data was available from 85 pts. Mutations were analyzed by a mass-spectrometry based genotyping platform (Oncomap v3) and genomic imbalances were detected by comparative genomic hybridization (CGH) analysis. Regions with threshold of $\log^2$ ratio $\geq 0.4$, or $\leq -0.3$ were defined as either having copy number gain or loss with significant CNAs determined using a GISTIC analysis.To better define the co-occurrence pattern of mutations and CNAs, we grouped genes into 3 core signal transduction pathways: 1) TP53 pathway; 2) RTK-RAS-RAF pathway including ERBB2, FGFR3, MET, FGFR1, KRAS BRAF, RAF1 and NF1; 3) PI3K/AKT pathway including PTEN, PIK3CA, AKT1, TSC1 and MTOR. OS was measured from treatment to time of death or censored. Cox regression was used to assess pathways abnormalities and mutations with outcome. **Results:** 35 out of 94 samples (41%) platinum treated pts with advanced UT, harbored mutations on at least 1 gene, mainly *TP53* (16%), *PIK3CA* (9%), *FGFR3* (2%), HRAS/KRAS (5%) and CTNNB1 (1%). 66%of pts had some sort of CNA. PI3K/AKT was the most affected pathway and was associated with shorter overall survival (hazard ratio (HR) 2.3, 95% CI: 1.3-4.2). There was no significant association between mutational status and OS. PIK3CA/AKT pathway alteration (mutations +CNV) may have the greatest impact on OS (p=0.055). Over-expression of CTNNB1 (p=0.0008) and PIK3CA (p=0.02) was associated with decreased OS. Among other individual genomic alterations, TP53 mutations (p=0.07) ,mTOR gain (p=0.07) and PTEN over expression (p=0.08) were marginally significant negative impact on OS. **Conclusions:** Our results suggest that targeted therapies focusing on the PIK3CA pathway alterations can generate the greatest impact in the overall patient population of metastatic UC.

**4512 Poster Highlights Session (Board #4), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Comparative effectiveness of gemcitabine plus cisplatin (GC) versus methotrexate, vinblastine, doxorubicin, plus cisplatin (MVAC) as neoadjuvant therapy for muscle-invasive bladder cancer (MIBC).** *Presenting Author: Matt D. Galsky, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY*

**Background**: GC has been adopted as a standard neoadjuvant regimen for MIBC, supported by practice guidelines, despite a lack of prospective (randomized) data in this setting. Given the historical difficulties completing perioperative chemotherapy trials in MIBC, an adequately powered clinical trial to definitively address whether GC is comparable to regimens supported by Level I evidence (MVAC, CMV) may not be completed and additional levels of evidence are needed to support or refute current practice. **Methods:** Data were collected via an electronic data capture platform from 25 international centers. Eligible pts had cT2-4aN0M0 urothelial cancer of the bladder and received neoadjuvant GC or MVAC prior to cystectomy. Logistic regression was used to compute propensity scores as the predicted probabilities of patients being assigned to MVAC vs. GC given their: age, calculated creatinine clearance (CrCl), number of cycles of chemotherapy, pure versus mixed histology, Eastern Cooperative Oncology Group performance status, year of diagnosis, cT-stage, and gender. These propensity scores were then included in a log binomial model used to estimate an adjusted relative risk comparing the probability of complete pathologic response (pCR) between patients who received MVAC vs. GC. Survival between the two groups was analyzed as an exploratory endpoint. **Results:** 244 patients met eligibility for the analysis (GC: 175, MVAC: 69). Patients were median age 64, predominantly male (77%), had a median CrCl of 72, and received a median of 3 cycles of neoadjuvant chemotherapy. The pCR rate, adjusted for propensity scores, is shown in the Table. Overall survival was not significantly different between the groups. **Conclusions:** Neoadjuvant GC and MVAC achieved comparable rates of pCR, in this large retrospective cohort, providing additional evidence to support current practice.

**pCR adjusted for propensity scores.**

| pCR | GC N=175 | MVAC N=69 | Relative risk [95% CI] P value |
|---|---|---|---|
| Yes | 47 (27%) | 19 (28%) | 0.97 [0.60-1.56] |
| No | 128 (73%) | 50 (72%) | P=0.9 |

**4513 Poster Highlights Session (Board #5), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Neoadjuvant dose-dense gemcitabine and cisplatin (DDGC) in patients (pts) with muscle-invasive bladder cancer (MIBC): Final results of a multicenter phase II study.** *Presenting Author: Elizabeth R. Plimack, Fox Chase Cancer Center, Philadelphia, PA*

**Background**: Neoadjuvant cisplatin (cis) based chemotherapy prior to radical cystectomy (RC) is standard of care for localized MIBC. Combination gemcitabine (gem) and cis is frequently used, but has not been tested prospectively. We sought to evaluate the activity of this combination when given in a dose dense fashion. **Methods**: Pts with MIBC, cT2-T4a, cN0-N1 with CrCl >=50 were eligible. Pts received 3 cycles of DDGC (gem 1200 mg/m2, cis 70mg/m2) on day 1, with pegfilgrastim 6 mg day 2 or 3, every 2 wks. Pts with CrCl 50-60 could receive cis split over 2 days. RC with lymph node dissection was to be performed 4-8 weeks after the last dose of DDGC. Primary endpoint was pathologic complete response (pT0) rate. **Results**: 32 pts were enrolled at 2 institutions (FCCC, TJU) over 14 months. One withdrew consent prior to receipt of DDGC. Among the 31 evaluable pts, median age was 69 (range 51 – 82). Baseline clinical stage was T2N0M0 (11), T3N0M0 (15), T4aN0M0/TxN1M0 (5). 25 pts received all 3 cycles of DDGC, with 1/25 requiring dose reduction of gem for thrombocytopenia. 6 discontinued DDGC early due to gr 3/4 vascular (3), gr 2/3 renal (2), or gr 3 hematologic (1) toxicity. Analysis of toxicities among the first 13 pts revealed 2 pts with MI (1 in cycle 1 (C1) with resulting CHF precluding surgery, 1 D#3 post-op) and 2 pts with VTE (1 PE in C2, 1 DVT D#15 post-op), and 1 pt who required CABG between DDGC and RC. The protocol was then amended to require cardiac clearance prior to study entry. Despite this, further vascular toxicity was seen with 1 DVT in C3 and 1 CVA in C1. The study was thus closed prior to target accrual of 44 pts. 30/31 pts underwent RC, 28 within 8 weeks of last DDGC. Median time from start of DDGC to RC was 9.3 weeks (range 5-29). 10/31 pts had pT0 (32%, 95% CI 16-48%). An additional 4 (13%) were downstaged to non-muscle invasive disease. Median f/up is 36 wks. 4 pts have recurred. 5 pts have died, 2 due to metastases. **Conclusions**: DDGC yielded pT0 rates similar to those reported with Accelerated MVAC. However significant vascular toxicity precluding, delaying or increasing the risk of surgery was noted, leading to early study closure. Clinical trial information: NCT01611662.

**4514 Poster Highlights Session (Board #6), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Patient eligibility and trial design for the salvage therapy of advanced urothelial carcinoma (UC) based on the impact of prognostic factors.** *Presenting Author: Guru Sonpavde, The University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

**Background:** The prognostic impact of number of lines of prior chemotherapy, prior perioperative chemotherapy, prior platinum agent and site of primary tumor in salvage trials for advanced UC is unknown. This knowledge can inform trial design, stratification and eligibility criteria. **Methods:** Ten phase II trials of salvage therapy for advanced UC were pooled for data on the number of prior lines, prior perioperative chemotherapy, prior platinum (cisplatin, carboplatin) and site of primary (bladder vs. other) in addition to TFPC (time from prior chemotherapy), Hb (hemoglobin), PS (performance status), and LM (liver metastasis) status. Cox proportional hazards regression was used to evaluate the association of variables with overall survival (OS). Trial was included as a stratification factor. **Results:** The trials evaluated vinflunine (N=151), docetaxel +/- vandetanib (N=148), paclitaxel-gemcitabine (N=98), sunitinib (N=77), volasertib (N=50), nab-paclitaxel (N=48), everolimus (N=45), pazopanib (N=43), cetuximab +/-paclitaxel (N=39) and paclitaxel-cyclophosphamide (N=32). Of 731pts, 711 were evaluable for prior number of lines and perioperative chemotherapy, 663 for prior platinum and 512 for site of primary. The number of prior lines of therapy were 1 in 559 (78.6%), 2 in 111 (15.6%), and ≥3 in 41 (5.8%) pts. Prior perioperative chemotherapy was given to 277 (39.1%) and chemotherapy for metastatic disease to 454 (64.1%) pts. Prior platinum was cisplatin in 501 (75.6%), carboplatin in 216 (32.6%) and both in 57 (8.6%). Bladder was the primary site in 388 (75.8%). On univariate analyses, shorter TFPC, low Hb, low PS, LM, prior carboplatin and non-administration of prior perioperative chemotherapy were associated with worse OS ($p<0.05$ for all). On multivariate analyses, TFPC, Hb, PS and LM were significantly associated with OS, but none of the other factors were independently significant. **Conclusions:** These data imply that randomized trials in previously treated pts with advanced UC should stratify for TFPC, Hb, PS and LM status and may allow prior perioperative chemotherapy and not limit eligibility to only one prior therapy.

**4515 Poster Highlights Session (Board #7), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Molecular profiling of testicular cancer.** *Presenting Author: Carsten Bokemeyer, Department of Oncology, Hematology and BMT with Section of Pneumology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

**Background:** The incidence of testicular cancer (TC) has been increasing in many western countries for several decades. For 2013, about 7900 new TC cases with 370 deaths are estimated in the United States. While the overall prognosis in metastatic TC is excellent, treatment options for patients (pts) relapsing with cisplatin-refractory disease are limited. A personalized approach to therapy based upon molecular diagnostic tools to predict response to specific therapeutic agents may help pts in whom standard chemotherapy has failed. **Methods:** Eighty-five TC cases referred to Caris Life Sciences between 2009 and January 2014 were evaluated; diagnoses were collected from referring physicians and classified at intake based on pathology and clinical history. Specific testing was performed per physician request and included a combination of sequencing (Sanger, NGS or pyrosequencing), protein expression (immunohistochemistry), gene amplification (CISH or FISH), and/or RNA fragment analysis. **Results:** In this cohort of pts with advanced / refractory TC, the most commonly observed changes in protein expression were upregulation of TOPO2A (66%), TLE3 (45%), SPARC (44%), and TS (42%) and downregulation of PTEN observed in 40% of patients. PIK3CA gene amplification was observed in a single case tested, amplification of EGFR, cMET, and HER2 was observed in 14%, 7%, and 7% of cases, respectively. In 16 cases analyzed by NGS, KRAS was the most common mutation (13%) followed by TP53 (7%) and cKIT mutations (7%). No NRAS or HRAS mutations were found. Further 5 KRAS mutations were detected by PCR or sanger sequencing. Two of seven pts with KRAS mutations also had HER2 amplification, one had a cKIT mutation. All pts with TP53 mutations also had a loss of PTEN protein expression but no other mutations. Pathway profiling revealed that with the exception of loss of PTEN, 93% of patients were predominantly ERK and mTOR pathway wildtype, and activation of the ERK pathway only occurred through the presence of mutations in the KRAS gene. **Conclusions:** A low prevalence of mutations was observed in advanced / refractory TC. Predictive biomarkers may be used to guide treatment decisions. Targeting the cKIT, HER2 or cMET pathways may warrant treatment options in single pts.

**4516 Poster Highlights Session (Board #8), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Tumor genomic mutation profiling of germ cell tumors using "Profile".** *Presenting Author: Elizabeth O'Donnell, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Malignant germ cell tumors (GCTs) are the most common solid malignancy affecting males between the ages of 15 and 35. To date, little is known about the genomic landscape of GCTs. **Methods:** We used "*Profile*", an enterprise-wide mutation detection protocol. OncoMap, the platform used for this work detects 471 mutations in 41 well characterized oncogenes in formalin-fixed paraffin-embedded (FFPE) tissue samples including KIT, KRAS and BRAF which have previously been described in GCT. After informed consent, tumor DNA isolation from 33 unique patients, and a battery of quality assurance tests, the samples were run on the OncoMap platform. **Results:** 33% (11/33) tumor samples harbored mutations. 9/11 were orchiectomy specimens from newly diagnosed patients and 2/11 were samples from metastatic disease sites in relapsed disease. One mutation was noted in each of the 11 samples. Somatic oncogene mutations were found in *NRAS (4), KIT (3), MET (2), KRAS (1),* and *p53 (1).* 9/16 seminoma specimens had mutations (8 cured with orchiectomy, 2 cured with radiation therapy, and 6 cured with chemotherapy). 2/17 non-seminoma GCT pts had metastatic disease and mutations and both were cured with chemotherapy. **Conclusions:** Genomic analysis of tumor DNA extracted from FFPE orchiectomy specimen is feasible and may provide novel insights into GCT biology. Sequenom analysis using OncoMap details presence of genetic mutations in some GCT pts and supports the feasibility and rationale for further analysis (more samples and sequencing).

**4517 Poster Highlights Session (Board #9), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase 2 trial of bevacizumab (BEV)/high-dose chemotherapy (HDC) with autologous stem-cell transplant (ASCT) for refractory germ-cell tumors (GCT).** *Presenting Author: Yago Nieto, Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** HDC is curative therapy for relapsed GCT. The Beyer model identifies groups with poor (5% EFS at 1-year post-HDC), intermediate (25% EFS), or good risk (≥50% EFS). Given high VEGF expression in metastatic GCT and BEV-chemotherapy synergy, we studied concurrent BEV/HDC and the efficacy of a novel regimen of infusional gemcitabine, docetaxel, melphalan, carboplatin (GDMC) (BBMT 2005;11:297) in refractory GCT. **Methods:** Eligibility: GCT in poor/interm-risk 1t relapse or in ≥2nd relapse. Patients (pts) received tandem HDC/ASCT with BEV (5 mg/kg) 1 week before each cycle. HDC#1: GDMC; HDC#2: ifosfamide/carboplatin/etoposide. Trial powered to distinguish an expected 1-yr EFS of 15% from a goal of 50%. **Results:** We treated 42 pts, median age 22 (19-45) (Table). HDC#1 main toxicities: mucositis (31 G3, 11 G2) and rash (3 G3, 12 G2). Among 7 pts with marginal renal function, there were 4 HDC-related deaths (3 sepsis, 1 fungal pneumonia). Protocol was amended to reduce HDC doses by 15% in 8 subsequent pts with high creatinine (1.5–1.8 mg/dl), with no more deaths. Tumor markers normalized in 83% pts. Surgery of residual lesions (N=9) showed necrosis (5), mature teratoma (1), necrosis+teratoma (2) and teratocarcinoma (1). Median follow-up from HDC#1 for alive pts is 22 (1-69) months. The 1- and 2-yr EFS rates are both 63% (95% CI, 49-81%). The 1- and 2-yr OS rates are 72% (59-89%) and 65% (50-84%), respectively. **Conclusions:** Tandem HDC with BEV/GDMC followed by BEV/ICE showed promising EFS in pts with heavily pretreated and refractory GCT, exceeding the expected results with carboplatin/etoposide and no BEV, and warrants testing in less heavily pretreated pts. Clinical trial information: NCI-2011-01631.

**Impact of long-term serum platinum on neuro- and ototoxicity, cardiovascular disease, and hypogonadism in testicular cancer survivors.** *Presenting Author: Line veronika Hjelle, Department of Oncology, Univesity Hospital of North Norway, Tromsø, Norway*

**Background:** Previous studies have identified several long-term complications following cisplatin-based treatment in testicular cancer survivors (TCS). We evaluated the impact of long-term serum levels of platinum (Pt) on neuro- and ototoxicity (NTX), cardiovascular disease (CVD) and hypogonadism in TCS. **Methods:** 292 cisplatin-treated TCS (1980-1994) participated in a national follow-up study (2007-2008), including laboratory tests and a questionnaire. Serum Pt was quantified by Inductively Coupled Plasma-Mass Spectrometry. Symptoms of NTX were assessed with Scale for Chemotherapy-Induced Neurotoxicity (SCIN), with each symptom categorized in 4 categories ranging from 0, "not at all" to 3, "very much". Total SCIN score was the sum of six scores, ranging from 0 to 18, and categorized into quartiles. Information about CVD (validated) and medication were retrieved from the questionnaire. Hypogonadism was defined as using testosterone substitution and/or having testosterone <10nmol/l. Associations between NTX and long-term Pt levels were analyzed with ordinal logistic regression. Cox regression was performed to evaluate the risk for CVD, and logistic regression for hypogonadism according to levels of Pt and cisplatin dose. The results are presented as odds ratio (OR) or hazard ratio (HR) with 95% confidence intervals (CI), and are adjusted for age. **Results:** Median follow-up was 20 years (range 11-28). Median Pt was 86 ng/L (range 0-725). There was a significant association between the highest Pt quartile (yes/no) and quartiles of total SCIN-score (OR 1.67, 95% CI 1.03-2.70), tinnitus (OR 1.77, 95% CI 1.08-2.89) and hearing impairment (OR 1.79, 95% CI 1.10-2.92). In total 24 (8.2%) TCS had a CVD event during follow-up. Increasing cisplatin dose, per 100 mg, was significantly associated with CVD (HR 1.14, 95% CI 1.01- 1.28) and hypogonadism (OR 1.09, 95% CI 1.00-1.19). No association was found between residual Pt versus CVD and hypogonadism. **Conclusions:** 20 years after chemotherapy, residual serum Pt was significantly associated with NTX. The risk of CVD and hypogonadism increased with higher cisplatin dose, but was not associated with serum Pt.

**4519 Poster Highlights Session (Board #11), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Association of higher institutional volume with improved overall survival in clinical stage III testicular cancer: Results from the National Cancer Data Base (1998-2011).** *Presenting Author: Claudio Jeldres, Virginia Mason Medical Center, Seattle, WA*

**Background:** Improvements in survival have been achieved with the introduction of cisplatin-based chemotherapy and refinements of local therapies, such as post-chemotherapy retroperitoneal lymphadenectomy (PC-RPLND) in the setting of metastatic testicular germ cell tumors (TGCT). However, there have been no comprehensive efforts to measure the effect of expertise in TGCT in the US. We hypothesized that hospital volume is associated with overall survival in clinical stage III (CSIII) TGCT. **Methods:** Within the National Cancer Data Base [NCDB] we retrospectively identified all patients with CSIII TGCT between 1998 and 2011. Inclusion criteria were CSIII at diagnosis and chemotherapy treatment. Hospital volume was defined as the number of TGCTs diagnosed per hospital per year, and since its distribution was bimodal with an early peak and a second peak of volumes above 60, we categorized by tertiles below 60 (1-5, 6-10, 11-60) and a fourth group of ">60". Association between overall survival and hospital volume categories were assessed by Kaplan-Meier and Cox regression. **Results:** Within the NCDB, of 79119 patients with TGCT, 8205 (10.4%) were diagnosed with CSIII. Median age at diagnosis was 32 years (range 18-84) and median follow-up was 5.7 years (range 0.1-14.9). Therapy was delivered in community, "comprehensive" community and academic hospitals in 10.0%, 47.3% and 40.5%, respectively. PC-RPLND was performed in 1295 (15.8%) patients. Median hospital volume was 8 and ranged from 1 to 115 cases per year. Death occurred in 1225 (24.8%) patients. At 5 years, overall survival was 74.3%, 76.9%, 75.2%, 86.1% for hospital volume categories 1-5, 6-10, 11-60 and >60, respectively. The greatest disparity for risk of death was recorded between groups 1-5 and >60 (HR: 0.85, p=0.03). **Conclusions:** Patients with advanced metastatic testicular cancer treated at high volume hospitals exhibit better overall survival rates compared to their counterparts. These results suggest that broad efforts should be made to develop and improve collaborative care models among institutions in order to disseminate the experience of higher volume centers.

**4520 Poster Highlights Session (Board #12), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A prospective observational study of metastatic renal cell carcinoma (mRCC) prior to initiation of systemic therapy.** *Presenting Author: Brian I. Rini, Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH*

**Background:** The biology of mRCC includes a subpopulation of patients (pts) with indolent growth. Because of the toxicity and non-curative nature of current systemic therapy, select pts may be better served with initial surveillance. A prospective phase II observation trial was conducted in pts with mRCC prior to initial systemic treatment. **Methods:** Pts with treatment-naïve, asymptomatic, histologically-confirmed mRCC and metastases were enrolled. Local therapy prior to and during the study was permitted. Radiographic assessment was performed at baseline, every 3 months for year 1, every 4 months for year 2, then every 6 months. The primary objective was to characterize time to initiation of systemic treatment. Secondary endpoints included assessment of depression/anxiety using standardized questionnaires (FKSI-DRS and HADS) and peripheral blood immune repertoire (TH1/TH2, MDSC, Tregs). Target accrual of 50 pts provided adequate power for the primary descriptive endpoint and 80% power to detect changes in correlate endpoints based on a two-sided Wilcoxon signed rank test. **Results**: 52 pts were accrued; median age 67 (range, 47-88); 75% male; 94% ECOG 0; 96% clear cell; 8% prior metastasectomy and Heng risk group favorable/intermediate 26%/74%. Baseline tumor burden (per RECIST 1.0) was 3.2cm (0.8-19.6cm). Median time on observation until systemic therapy was started was 14.1 months (95% C.I. 10.6-19.3), with estimated 12 month and 24 month rates of continued surveillance of 58% and 33%, respectively. Median change in tumor burden on study was 0.8cm (0-6.5cm); relative change +34% (0-311%) and median growth rate 0.14 cm/month (0-1.75). 31 pts have come off observation (61% for PD), and 25 pts have received systemic therapy. Pts with baseline tumor burden ≤1.5 cm vs. >1.5 cm had a median observation period of 31.6 months vs. 13.8 months (p=0.06). Neither location nor number of metastatic sites impacted the length of observation. Anxiety/depression were not prevalent at baseline, and scores did not worsen over time. There were no significant changes in immunologic parameters. **Conclusions**: A subset of mRCC pts can be safely observed for a period of time before starting systemic therapy.

**4521 Poster Highlights Session (Board #13), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Outcomes of treatment cessation in select metastatic renal cell carcinoma (mRCC) patients.** *Presenting Author: Kriti Mittal, Cleveland Clinic, Cleveland, OH*

**Background:** Tyrosine kinase inhibitors (TKIs) demonstrate efficacy in mRCC, but may cause significant adverse effects (AEs). We have previously evaluated outcomes in patients (pts) receiving prolonged treatment breaks on TKIs and expand and update this experience herein. **Methods:** mRCC pts on targeted therapy who discontinued treatment for ≥3 months were analyzed retrospectively. Treatment break was defined as a period of drug cessation for reasons other than progressive disease. Pts could receive treatment breaks with multiple lines of therapy (defined sequentially as treatment A, B, C etc.) A number of patients continue on treatment/observation, hence durations were estimated using the Kaplan-Meier method. **Results:** Baseline characteristics (n=112) were: 75% male; median age at diagnosis 56; 95% clear cell. 19% pts had received prior systemic therapy. 48% pts were favorable, 48% intermediate and 4% poor risk by Heng criteria. Table 1 depicts outcomes with sequential lines of therapy. Overall, pts received a median of 2 treatments. Treatment A primarily included sunitinib (55%), sorafenib (13%), or bevacizumab in combination with temsirolimus (10%)/ interferon (9%). Common reasons for breaks in treatment A were toxicity/AEs (57%) & physician choice (26%). 40 (36%) pts remain on treatment break from the first treatment (A). 25 (22%) pts have undergone 2 treatment breaks. 68 (61%) pts restarted treatment (B); 33 (49%) of these were rechallenged with previously used therapy & 35 (51%) received alternative TKIs. Overall, 30 patients have died; median survival is 71.7 months (range 1.3- 93+ months). Achievement of CR prior to the initial treatment break (n=15) was associated with a longer surveillance period (p=.0004). **Conclusions:** A treatment break is feasible in selected pts, especially after achievement of CR with TKIs. This strategy may be associated with acceptable overall disease control and reduced toxicity.

| Treatment | Number of pts starting treatment | Median duration of therapy in months (95% CI) | Number of pts on treatment break | Median duration of break in months (95% CI) |
|---|---|---|---|---|
| A | 112 | 13.5 (11-16.4) | 112 | 16.8 (12.5-26.4) |
| B | 68 | 16.1 ( 11.4-20) | 24 | 9.5 (4.6-10.3) |
| C | 43 | 14.8 ( 12-17.2) | 10 | 7.1 |
| D | 15 | 13.8 (5.7-18.6) | 3 | 15.9 |

**4522 Poster Highlights Session (Board #14), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase II study of pazopanib (P) in patients (Pts) with localized renal cell carcinoma (RCC) to enable partial nephrectomy (PN).** *Presenting Author: Adriana L. Alvarez, Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH*

**Background:** PN is the preferred surgical approach for localized renal masses in order to preserve renal function, but is not always possible due to tumor size/location. VEGF-targeted agents such as a Paz have shown safety and anti-tumor effect in primary RCC tumors, thus allowing for potential conversion to PN in patients who would otherwise require radical nephrectomy (RN). **Methods:** Pts with treatment-naïve, localized clear cell RCC meeting one or more of the following criteria were enrolled on a prospective phase II trial: estimated GFR < 30 mL/min if RN was performed, risk of morbidity > 30% with PN due to tumor anatomy (e.g. proximity to renal vasculature) or Renal Nephrometry Score (RNS) 10-12. Paz 800 mg po daily was given continuously with repeat imaging at 8 and 16 weeks, and PN performed if/when adequate tumor reduction per primary surgeon discretion. The primary endpoint was rate of conversion to PN ($H_o$ 15% vs. $H_a$ 40%; p=0.05; power 90%). **Results:** Twenty-three pts were enrolled; 85% male, median age 64, 70% PS 0, 60% had baseline GFR<60. 90% of pts were able to undergo PN; 2 pts required RN. The median time from the start of Paz to surgery was 10.6 weeks (range, 5.4-18.9). Median baseline tumor size was 7.6 cm (range, 3.7-10.7cm); median RNS was 11 (range, 8-12); 82% were considered highly complex by RNS. 95% of tumors shrank (median decrease 1.8 cm; range 0.2-3.8); median change relative to baseline -26% (range, +6.3% to -40.9%). RECIST PR rate was 32%. RNS decreased in 81% of tumors and complexity group decreased in 43%. The estimated median post-PN change in GFR relative to baseline (ml/minute/1.73 $m^2$ per 2005 MDRD equation) was an 18.0% decrease (range, -46% to +21%). No unexpected surgical complications or unexpected Paz toxicity was observed. **Conclusions:** Neoadjuvant Paz leads to tumor downsizing in clear cell RCC tumors and allows for PN in a subset of patients in whom RN is otherwise required. Clinical trial information: NCT01158521.

**4523 Poster Highlights Session (Board #15), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**High-dose (HD) IL-2 for metastatic renal cell carcinoma (mRCC) in the targeted therapy era: Extension of OS benefits beyond complete response (CR) and partial response (PR).** *Presenting Author: Michael Morse, Duke University Medical Center, Durham, NC*

**Background:** HD IL-2 has been reported to have a overall response rate (ORR) for mRCC of 15% and a median OS of 19 months (Fyfe,1995), however, the studies that led to its regulatory approval are >15 years old and were performed in an era preceding targeted therapies. **Methods:** The PROCLAIM registry (www.proclaimregistry.com), a HD IL-2 observational database currently with over 30 participating sites, consists of a retrospective cohort (treated between 2007 and 2012) informing an ongoing prospective cohort (~ 600 patients). We report on the retrospective mRCC subjects (n=97, 13 sites) with survival status determined as of November 2013 and a median follow-up of 32 months. Sites were encouraged to enroll patients sequentially. Inclusion criteria required that patients have received at least one dose of HD IL-2. **Results:** The ORR was 22% (8% CR and 14% PR). Of 97 subjects, 36 were confirmed deceased and 61 were known to be alive, none were lost to follow-up. The median OS was 51 months, compared to a median OS range of 5-35 months for FDA-approved targeted agents (Harrison, 2013). There was significant clinical benefit in patients with CR, PR, and stable disease (SD), none of which reached median OS compared to 37.9 months in patients with progressive disease (PD). There is a significant advantage in PROCLAIM for those patients treated 1st vs. 2nd line HD IL-2; the median OS was 61.8 months (n=82) vs 15.3 months (n=15), respectively. The clinical benefit of HD IL-2 therapy as front line is consistent with published data (Birkhauser, 2013). No deaths due to IL-2 related toxicity were reported in the retrospective cohort. **Conclusions:** The PROCLAIM registry documents a vastly improved OS for HD IL-2 compared to historical results during a time interval marked by the advent of targeted therapy for advanced RCC. Response to IL-2 (CR or PR) is associated with prolonged survival, however, stable disease as well as front line use also appears to positively impact survival. Issues including patient selection characteristics and treatment sequencing are hypotheses currently being explored in the prospective database.

**4524^ Poster Highlights Session (Board #16), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Long-term survival in unfavorable-risk mRCC patients treated with a combination of autologous immunotherapy (AGS-003) plus sunitinib.** *Presenting Author: Asim Amin, Levine Cancer Institute, Charlotte, NC*

**Background:** Treatment for metastatic renal cell carcinoma (mRCC) has evolved significantly over the last decade due to enhanced understanding of the biology of RCC resulting in availability of number of agents targeting the VEGF axis and mTOR pathway. These treatments however, usually do not elicit durable responses and may have significant toxicities. AGS-003 is an autologous immunotherapy designed to induce an immune response to patient's own tumor. In a phase 2 trial, AGS-003 in combination with sunitinib was studied for safety and efficacy. Updated survival data is presented. **Methods:** In this open label, phase 2 study, subjects with newly diagnosed metastatic clear cell RCC were enrolled. Subjects received sunitinib (4wks on, 2wks off) combined with AGS-003 (every 3wks X 5 doses, then every 12wks) until progression. Subjects were followed for PFS and OS throughout the trial and during a rollover protocol. **Results:** For the twenty-one subjects (11 intermediate risk, 10 poor risk) treated, the median PFS was 11.2 months and the median OS was 30.2 months. The recently achieved median OS for the intermediate risk population (1 to 2 risk factors) was 57.1 months. Accordingly, 52% of all subjects achieved OS ≥ 30 months and 33.3% of subjects were still alive at 48 months after registration. Five of the original 21 (23% of the study population) have exceeded, or are currently nearing the five-year plus survival mark. The absolute change in CD8+CD28+ memory T cells (the proposed MOA for AGS-003) directly and significantly correlated to prolonged OS, PFS, and best tumor response. **Conclusions:** When compared to historical estimates of PFS and OS for unfavorable risk patients (time from diagnosis to treatment of less than one year), the addition of AGS-003 to sunitinib resulted in a 50% increase in median PFS, doubling of expected median OS, more than 50% of patients surviving long-term (OS ≥ 30 months) and 33% of patients surviving for at least 54 months. Updated survival and corresponding CD8+CD28+ memory T cell expansion in long-term survivors will be presented. Currently the combination of AGS-003 plus sunitinib is being compared to sunitinib alone in a large phase III study (ADAPT). Clinical trial information: NCT00678119.

**4525 Poster Highlights Session (Board #17), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A randomized phase II study of GDC-0980 versus everolimus in metastatic renal cell carcinoma (mRCC) patients (pts) after VEGF-targeted therapy (VEGF-TT).** *Presenting Author: Thomas Powles, St. Bartholomew's Hospital, London, United Kingdom*

**Background:** GDC-0980 (G) is a potent oral dual pan-PI3K and mTOR (TORC1/2) inhibitor that has been evaluated in multiple solid tumors in Phase I and II. Everolimus (E) inhibits TORC1 and is active in mRCC post VEGF-TT. This study is the first to dirctly test if a PI3K/mTOR inhibitor may improve efficacy over a TORC1 inhibitor. **Methods:** Clear cell mRCC pts who progressed on or after VEGF-TT were randomized (1:1) to G (40 mg QD) or E (10 mg QD), stratified by MSKCC score and time to progression on first VEGF-TT ($\leq$ or $>$ 6 months). The primary endpoint was progression-free survival (PFS); secondary endpoints included safety, overall survival (OS), objective response rate (ORR); and pharmacokinetic (PK) and biomarker correlation with safety and efficacy were exploratory. **Results:** Eighty-five pts were randomized (G 42:E 43). After 62 events (G 32:E 30), stratified analysis revealed the median PFS was significantly shorter for G than E (3.7 vs. 6.1 mo: HR 2.04 [95%CI: 1.18-3.54; $p<0.01$]) and did not favor G for any stratification subgroup. Median OS was not significantly different but trended in favor of E (11.9 vs. 14.6 mo: HR 1.73 [95%CI: 0.87-3.43; $p=0.12$]). ORR was 7.1% for G and 11.6% for E. Patients treated with G had greater incidence of Grade 3-4 adverse events (AEs) and were more likely to discontinue treatment because of an AE (G 31%:E 12%). G was associated with substantially more high-grade hyperglycemia (G 40%:E 7%) and rash (G 24%:E 5%). PK analyses of G suggest a relationship between exposure and safety (rash and hyperglycemia), but no clear exposure-efficacy relationship. Retrospective biomarker analyses from archived tissue revealed a relationship between VHL mutation status (by NGS) and outcome with E but not G. High HIF1A protein expression was associated with better outcome in both arms. **Conclusions:** This study was unable to demonstrate that inhibition of PI3K/TORC1/TORC2 with GDC-0980 provides any benefit over inhibition of TORC1 alone with everolimus. This may be due to the high rate of AEs associated with potent pathway inhibition. VHL mutation and HIF1A expression may be predictive of mTOR inhibitor benefit, though future prospective validation is required. Clinical trial information: NCT01442090.

**4526 Poster Highlights Session (Board #18), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**PD-L1 expression in non-clear cell renal cell carcinoma and benign kidney tumors.** *Presenting Author: Andre Poisl Fay, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Programmed death-1 (PD-1) receptor negatively regulates T cell-mediated responses.PD-1 ligand (PD-L1) is aberrantly expressed in clear cell renal cell carcinoma (ccRCC) and is associated with worse prognosis. PD-L1 expression and its association with clinicopathological features/clinical outcome are unknown in non-ccRCC and benign kidney tumors (BKT). **Methods:** Formalin-fixed paraffin embedded (FFPE) specimens were obtained from 124 patients (pts) with chromophobe RCC (CHR), papillary RCC (PAP), translocation Xp11.2 RCC (TrL), collecting duct carcinoma (CDC), oncocytoma (ONC), and angiomyolipoma (AML). PD-L1 expression was evaluated by immunohistochemistry using a mouse monoclonal anti-PD-L1 antibody (405.9A11). The assay was validated using FFPE cell line controls known to be positive or negative for PD-L1 expression by flow cytometry. PD-L1 positivity (PD-L1+) was defined as $\geq$5% tumor cell membrane staining. For immune cells, a combined score based on the extent of infiltrate and percentage of positive cells was used. Baseline characteristics including stage/grade and outcome data [time to recurrence (TTR) and survival (OS)] were also collected. **Results:** Among 124 pts, 17 (13.7%) were considered PD-L1+ in tumor cells: 2/36 (5%) of CHR, 5/50 (10%) of PAP, 4/11 (36%) of TrL, 1/5 (20%) of CDC, 5/15 (33%) of ONC and 0/7 (0%) of AML. In non-ccRCC, PD-L1+ in tumor cells was significantly associated with higher stage ($p=0.025$) and grade ($p=0.03$), as well as lower OS on univariate analysis ($p<0.001$). On the other hand, PD-L1+ by immune cells was observed in 73 (58.8%) pts: 13/36 (36%) of CHR, 30/50 (60%) of PAP, 10/11 (91%) of TrL, 5/5 (100%) of CDC, 8/15 (53%) of ONC and 7/7 (100%) of AML. PD-L1+ in immune cells did not correlate with stage ($p=0.3$) or grade ($p=0.1$). In non-ccRCC, a trend for lower OS was observed in pts with PD-L1+ in immune cells ($p=0.08$). PD-L1+ in tumor cell membrane and immune cells were associated with lower TTR ($p=0.009$ and $p=0.019$, respectively) **Conclusions:** PD-L1 expression is variable in non-ccRCC and BKT and depends on histology. PD-L1+ on tumors cells, but not immune cells was associated with aggressive features. In non-ccRCC, PD-L1+ pts (by either tumor or immune cells) appear to present worse TTR and OS.

**4527 Poster Highlights Session (Board #19), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**CGH array and matching gene expression profiling for identification of distinct molecular variants among type II papillary renal cell carcinomas.** *Presenting Author: Laurence Albiges, Institut Gustave Roussy, Villejuif, France*

**Background:** Type II papillary renal cell carcinoma (pRCC) is a heterogeneous entity with poor prognosis. Limited biological data are available to date. **Methods:** 220 frozen pRCC were collected through French RCC Network, quality controlled for percentage of malignant cells >70% and subsequently RNA and DNA extraction were performed. Gene expression data generated with human whole genome Agilent 8x60K arrays was assessed on 98 pRCC, including, 45 type II pRCC. Copy number alterations were analysed using Agilent Human 2x400K or 4x180 on 37 type II pRCC. **Results:** Using gene expression profiling (GEP), we identified two distinct subgroups of type II pRCC that were associated with distinct pathological features: group A included tumors with higher grade, higher stage and more lymph nodes involvement ($p<0.05$) pRCC than group B harboring more favorable features. CGH array analysis of tumors clustering in GEP groups A vs B identified distinct patterns of copy number alterations (Group A: -1p, -11, +12, -15, Group B: +2, +5, +20). More interestingly, CDKN2A/2B (9p) loss was more likely to be observed in group A tumors 19% vs. 8% in group B tumors, in line with previous report of 9p loss to be associated with a dismal prognosis in pRCC (Klatte 2009). Four cases out of 37 (11%) presented chromothripsis (catastrophic genome rearrangements). This incidence is higher than in other solid tumors reports (<2%). Chromothripsis previously reported in neuroblastoma, melanoma, myeloma and acute myeloid leukaemia has been strongly linked to poor survival and therefore its diagnosis has potential to aid prognosis and stratification in pRCC. **Conclusions:** We report the first cohort of type II pRCC assessed by copy number analysis and matching gene expression profiling in type II pRCC. Gene expression profiling identifies two subgroups among type II pRCC. CDKN2A/2B loss as well as chromothripsis events appear as recurrent mechanism in the biology of type II pRCC.

**4528 Poster Highlights Session (Board #20), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Genotype correlations with blood pressure and efficacy outcomes from the randomized phase III AXIS trial of second-line axitinib versus sorafenib in metastatic renal cell carcinoma.** *Presenting Author: Bernard J. Escudier, Institut Gustave Roussy, Villejuif, France*

**Background:** In the AXIS trial, axitinib significantly increased progression-free survival (PFS) vs sorafenib in patients with previously treated metastatic renal cell carcinoma (mRCC). Final analyses of association between select germline single nucleotide polymorphisms (SNPs) and outcomes in AXIS are reported. **Methods:** DNA samples from blood were genotyped by TaqMan allelic discrimination. Logistic/Cox regression analyses evaluated association between 15 SNPs in 4 genes (*VEGF-A*, *VEGFR1*, *VEGFR2*, *HIF1α*) and blood pressure (BP; grade $\geq$3 hypertension, diastolic BP >90 mmHg or increase $\geq$15 mmHg from baseline) and efficacy (overall survival [OS], independently-assessed objective response rate [ORR] and PFS) endpoints. Kaplan-Meier PFS/OS estimates were compared with 2-sided unstratified log-rank tests. Multivariate analyses assessed SNPs and baseline characteristics as potential predictors of PFS/OS. **Results:** Genotype samples were available for 305/714 (43%) patients: 159 received axitinib, 146 sorafenib. After Bonferroni correction for multiple comparisons, no association was found for SNPs with BP endpoints. In the axitinib arm, *HIF1α* rs11549465 (C/T vs C/C) was associated with shorter PFS (2.8 vs 8.3 mo; HR 1.93; $P_{unadj}=0.006$; $P_{adj}=0.09$) and OS (13.3 vs 22.6 mo; HR 1.88; $P_{unadj}=0.007$; $P_{adj}=0.11$), and *VEGF-A* rs699947 (A/A vs C/C) and rs833061 (C/C vs T/T) with longer OS (27.0 vs 13.4 mo; HR 0.39; $P_{unadj}=0.001$; $P_{adj}=0.015$). In the sorafenib arm, *VEGFR2* rs2071559 (G/G vs A/A) was associated with higher ORR (21% vs 0%; $P_{unadj}=0.005$; $P_{adj}=0.075$), and longer PFS (4.7 vs 2.9 mo; HR 0.49; $P_{unadj}=0.01$; $P_{adj}=0.15$) and OS (26.8 vs 13.8 mo; HR 0.41; $P_{unadj}=0.002$; $P_{adj}=0.03$). In multivariate analyses, no SNP predicted axitinib efficacy; *VEGFR2* rs2071559 predicted PFS ($P=0.0053$) and OS ($P=0.0027$) for sorafenib. Sensitivity/specificity of *VEGFR2*rs2071559 for OS was <80%. **Conclusions:** No SNP predicted axitinib outcomes, whereas *VEGFR2* rs2071559 may have predicted sorafenib efficacy in patients with mRCC. Sensitivity/specificity limitations, however, preclude the use of this SNP for selecting sorafenib in individual patients. Clinical trial information: NCT00678392.

**4529 Poster Highlights Session (Board #21), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Loss of BAP1 and PBRM1 expression in non-clear cell renal cell carcinomas compared to clear cell renal cell carcinomas.** *Presenting Author: Thai Huu Ho, Mayo Clinic Arizona, Scottsdale, AZ*

**Background:** Loss of function mutations in *PBRM1* (41-50%) and *BAP1*(5-15%) are associated with poor outcomes for patients with clear cell renal cell carcinoma (ccRCC) tumors. However, there are no data regarding the prevalence of these mutations in other RCC subtypes (non-ccRCC). We evaluated loss of PBRM1 and BAP1 expression in ccRCC and non-ccRCC tumors using an IHC assay for which negative staining correlates with loss of function mutations. **Methods:** From our Registry database, we identified 311 and 105 patients treated surgically for ccRCC and non-ccRCC. We performed *IHC assays to evaluate PBRM1 and BAP1 protein expression.* We classified tumors as BAP1 or PBRM1 negative when tumor cells showed diffuse absence of nuclear staining. We compared loss of expression of these two proteins between ccRCC and non-ccRCC using Fisher's exact tests. **Results:** Of the total cohort of 416 patients, we successfully stained BAP1 in 406 (97.5%) and PBRM1 in 372 (89.4%). Of those with successful staining, we further excluded samples with focal negative or weak positive expression of BAP1 (n=59) or PBRM1 (n=55). Thus, we were left with 186 ccRCC and 79 non-ccRCC patient samples that had both BAP1 and PBRM1 available for analysis. We observed BAP1 loss of expression in 9% (17/186) of the ccRCC tumors but only 1% (1/79) of the non-ccRCC tumors (p=0.016). Similarly, we noted loss of expression of PBRM1 in 43% (80/186) of the ccRCC tumors but only 4% (3/79) of the non-ccRCC tumors (p=0.0001). Of note, within the non-ccRCC group, we observed 0% (0/61) papillary tumors and 5% (1/18) chromophobe tumors with loss of BAP1. By comparison, 3% (2/61) of papillary tumors and 1/18 (5%) of chromophobe tumors showed loss of PBRM1 expression. **Conclusions:** Our data are the first to suggest that loss of function mutations in *PBRM1* and *BAP1* are less common in non-ccRCC tumors compared to ccRCC. If these findings are independently confirmed, they suggest that while loss of PBRM1 and BAP1 are key events in ccRCC, disruption of other pathways may support tumorigenesis in non-ccRCC subtypes.

**Association of loss of BAP1 expression in cell renal cell carcinomas with PDL1 expression.** *Presenting Author: Richard Wayne Joseph, Mayo Clinic Cancer Center, Jacksonville, FL*

**Background**: A subset (10-20%) of clear cell renal cell carcinoma (ccRCC) tumors evades the immune system through expression of programmed death ligand 1 (PDL1), and these tumors are associated with a more aggressive clinical course. Related to this, loss of PBRM1 or BAP1 expression in ccRCC is also associated with poor outcomes. Herein, we evaluate whether loss of PBRM1 or BAP1 expression is associated with PDL1 expression in ccRCC tumors. **Methods**: From the Mayo Clinic Renal Tumor Registry we identified 1,010 patients undergoing nephrectomy for localized ccRCC from 1990-2004 who had immunohistochemistry (IHC) for PDL1, BAP1, and PBRM1 as part of previous investigations. A pathologist (PK) classified PBRM1 and BAP1 as either positive or negative and excluded those with heterogeneous or weak staining. A separate pathologist (JCC) defined PDL1+ tumors as those with ≥5% on IHC. We examined the association of PDL1 expression with PBRM1 and BAP1 separately and in combination using two-sided p-values from Fisher exact tests. **Results:** Among the 1,010 patients, 126 (12%) were excluded for unclear PBRM1/BAP1 expression leaving a total of 884 (88%) for evaluation. The distribution of each marker is as follows: 87 (10%) BAP1 negative, 458 (52%) PBRM1 negative, and 81 (9%) PDL1 positive (see Table). BAP1-negative tumors were more likely to be PDL1 positive than BAP1-positive tumors (17% vs 8%, p=0.0102)); however, the absolute difference was small (9%). In contrast, PDL1 expression did not differ by PBRM1 status (10% vs 9%, p=0.56). In a combined analysis grouping tumors by both PBRM1 and BAP1 expression, there remained a significant association with PDL1 positivity (p=0.015). **Conclusions**: In this study, BAP1 negative tumors were more likely to be positive for PDL1; however, the majority of BAP1 negative tumors are PDL1 negative. PBRM1 expression was not associated with PDL1 positivity.

**Identification and validation of predictive biomarkers (BM) for everolimus (EVE) in metastatic renal cell carcinoma: Analysis of 442 patients on RECORD-3.** *Presenting Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** RECORD-3 is a phase 2 trial that compared 1st-line EVE then sunitinib (SUT) with first-line SUT then EVE at progression (1:1 randomization). The study did not meet its primary endpoint (median progression free survival (mPFS) non-inferiority) in unselected treatment-naïve mRCC pts. This work investigated BMs predictive of EVE efficacy (PFS in first-line). **Methods:** 121 cancer-related BMs were analyzed by multiplex ELISA on baseline plasma samples collected from 94% of the trial subjects. The subjects were divided into training (327) and validation (115) cohorts. Kaplan-Meier estimates of mPFS for individual BM (low vs high, relative to an optimal cut-point for each BM), hazard ratios (HR) from Cox proportional hazards model and log-rank test p-values for differences in PFS between treatments in BM subgroups were computed. **Results:** Three BM levels were predictive for mPFS with EVE in the training set (table). Similar mPFS between the treatments was seen in the low BM subgroups, while mPFS remained significantly shorter for EVE vs SUT in the high BM subgroups. mPFS for EVE was longer in low than in high BM patients, but independent of the BM levels in SUT treated patients. Some results were supported by the validation set. **Conclusions:** EVE and SUT efficacies were comparable for mRCC patients with low plasma levels of three novel BMs in the first-line setting. The correlation of these BMs with EVE efficacy may be due to their interactions with pathways associated with mTOR inhibitor resistance, such as activation of PI3K and MAPK pathways by RTK-AXL. Clinical trial information: NCT00903175.

**Prognostic and predictive tumor-based biomarkers in patients (pts) with advanced renal cell carcinoma (RCC) treated with interferon alpha (IFN) with or without bevacizumab (Bev): Results from CALGB (Alliance) 90206.** *Presenting Author: Harriet M. Kluger, Yale University, New Haven, CT*

**Background:** In CALGB 90206, a phase III trial of IFN +/- Bev, the addition of Bev was associated with an improved progression-free survival (PFS) in RCC pts. Previously, we assessed a panel of soluble cytokines and angiogenic factors and demonstrated that IL-6 and HGF were predictive of overall survival (OS) from Bev. The objective was to evaluate the prognostic importance of tissue expression levels of cytokines and angiogenic factors in pre-treatment specimens from CALGB 90206 pts and to test whether they interacted with the treatment arm in predicting OS and PFS. **Methods:** Tissue microarrays were constructed using 3 cores from pretreatment specimens from 220 patients and stained for VEGFR1-3, VEGF A, B, C and D, HGF, c-Met, IL-6, IL-6R and STAT3 using a method of quantitative immunofluorescence. Vessel density was quantified by area of CD-34 staining. The proportional hazards model was used to test for the prognostic importance of marker levels (prognostic factors) and whether they interacted with the treatment arm (predictive factors) in predicting OS and PFS using prior nephrectomy and Motzer risk groups as stratification factors. No adjustment for multiplicity was performed. **Results:** On multivariable analysis, the onlymarker predictive of PFS independent of treatment was HGF, while IL-6 had an interaction with treatment (p-value for interaction = 0.02). None of the markers tested were predictive or prognostic of OS. **Conclusions:** Expression of HGF in pre-treatment specimens was prognostic for PFS in RCC patients and IL-6 was predictive of PFS in Bev treated patients, consistent with our findings in plasma. If validated, these data suggest that IL-6 may help guide use of anti-VEGF based therapies.

**VEGF and VEGFRs polymorphisms analysis in advanced renal cell carcinoma tissues: Is heterogeneity ever the answer?** *Presenting Author: Maristella Bianconi, Department of Medical Oncology, Università Politecnica delle Marche, Ancona, Italy*

**Background:** Metastatic renal cell carcinoma (mRCC) ever represented a challenge in patients' treatment, even with the new generation drugs. In fact there is a wide variability in the amount and duration of response among patients. Sunitinib a drug mainly targeting the angiogenic pathway, is commonly used in mRCC treatment. We previously reported how VEGF and VEGFRs SNPs could predict response to treatment with either sunitinib or pazopanib. Tumour heterogeinity and its possible correlation with response is matter of debate in mRCC. The aim of our study is to assess the expression of VEGF and VEGFRs polymorphisms in tumour, metastatic and normal renal tissues. **Methods:** We enrolled 123 patients treated at our Institution. We collected histologic samples of tumour, metastatic and normal renal tissue of 84 patients with mRCC treated with first-line sunitinib. For 61 patients samples of tumour, metastatic and normal renal tissue were available. Histologic samples were tested for VEGF-A, VEGF-C and VEGFR-1,2,3 single nucleotide polymorphisms (SNPs). Polymorphisms were correlated with PFS and OS. We then analysed concordance in SPNs expression among tissues. **Results:** The VEGF A rs833061 resulted significant in PFS (C>T, 17 vs 4 months; p<0.0001) and OS (C>T, 38 vs 10 months; p<0.0001). The VEGF A rs699947 was significant for PFS (A>C, 18 vs 4 months; p=0.0001) and OS (A>C, 37 vs 16 months; p<0.0001). The VEGF A rs2010963 was significant in PFS (G>C, 18 2 months; p=0.0001) and OS (G>C, 36 vs 9 months; p=0.0045). The VEGR3 rs6877011 was significant in PFS (C>G, 12 vs 4 months; p=0.0075) and OS (C>G, 36 vs 17 months; p=0.0001).59 out of 61 patients presented concordance between tumour, metastatic and normal renal tissue (97%). **Conclusions:** Preliminary data fromour analysis show how angiogenic polymorphisms are significantly correlated with either PFS and OS. These polymorphisms genotypes are preserved between tumour, its metastatic sites and the normal renal tissue. Further analyses will be presented at the Meeting.

**4534 General Poster Session (Board #102), Mon, 1:15 PM-5:00 PM**

**Feasibility and activity of two vinflunine (VFL)-based combinations as first-line chemotherapy (CT) in CDDP-unfit patients (pts) with advanced urothelial carcinoma (UC): VFL-gemcitabine (GEM) or VFL-CBDCA in a randomized international phase II trial (JASINT).** *Presenting Author: Maria De Santis, LBI-ACR Vienna and KFJ-Hospital, Vienna, Austria*

**Background:** There is no standard 1st line CT for advanced or metastatic UC in patients (pts) unfit for a CDDP-based regimen. CBDCA-GEM doublet or single agents are frequently used. VFL, a novel EMA approved agent in the post-platinum setting has shown to be safe in pts with renal impairment. The aim of this study is to provide data of the benefit/risk ratio of 2 VFL-based CT regimens in UC. **Methods:** Pts with a creatinine clearance (CrCl) <60mL/min but ≥30, PS 0/1, no prior systemic CT (except neoadjuvant or adjuvant CT if relapse occurred ≥6 months (mo) after last dose) were randomized. Based on the CrCl, <40 or ≥40mL/min, pts received q 21 days (D) VFL 250 or 280mg/m$^2$, plus GEM (Arm A) 750mg/m$^2$ D1&8 escalated to 1000 in cycle 2 (if no toxicity Grade (G) ≥2) or plus CBDCA AUC 4.5 D1 (Arm B). The primary endpoint was the disease control rate (DCR = CR + PR + SD, RECIST 1.1). With H0=41%, H1=63%, $\alpha$ =5% and $\beta$ =20%, 31 evaluable pts/arm were to be included to detect in each arm an improvement of 22% compared to H0. **Results:** 69 pts (34 arm A, 35 arm B) were enrolled 2011-2012: median follow-up 20.4 mo. Median (med) age was 70yrs, PS 0 in 42% and PS 1 in 58%; primary sites: 52% bladder and 46% upper tract; 16% had received prior CT. Pts characteristics were similar in both groups; 71% of pts had multiple comorbidities, cardiac in 23%. Med CrCl was 46mL/min (<40 in 19%). Med number of cycles was 5 [1–17] in arm A and 4 [1–11] in arm B. More haematological G3/4 adverse events (AE) were reported in arm B: neutropenia in 68% (vs 38%) and febrile neutropenia in 14% (vs 3%) of pts. Most common non-haematological G3/4 AE were fatigue (21.7%), infection (7.2%), and constipation (4.3%) without major difference between arms. DCR was similar in both groups: 76.5% (A) and 77.1% (B). ORR was confirmed in 44.1% vs 28.6%, med PFS was 5.9 vs 6.1 mo and med OS 13.9 vs 12.8 mo in arms A and B, respectively. **Conclusions:** This study confirms that both VFL doublets are feasible and can be administered for ≥4 cycles. The DCR was similar in both arms but haematological toxicity was more pronounced with VFL-CBDCA. Med OS warrants further study with VFL-GEM. Clinical trial information: NCT01599013.

**4535 General Poster Session (Board #103), Mon, 1:15 PM-5:00 PM**

**Stathmin-1 as a potential therapeutic target in urinary bladder cancer.** *Presenting Author: Ulrika Segersten, Department of Surgical Sciences, Uppsala University Hospital, Uppsala, Sweden*

**Background:** The oncoprotein-18/stathmin 1 (STMN1), involved in cell cycle progression and cell migration, has been reported to be expressed in several types of cancer, and is associated with clinical outcome in e.g. breast and liver cancer. The aims in this study were to investigate the clinical significance of STMN1 and to examine if STMN1 might be a possible therapeutic target in urinary bladder cancer. **Methods:** Immunohistochemical analyses of STMN1 protein expression were performed in three urinary bladder cancer cohorts; cohort I (115 Ta-, 115 T1-, 112 T2-4-tumors), a validation cohort II (236 T2-T4 tumors) based on randomized controlled trials and a metastatic primary tumor/matched metastasis-material (90 patients). In the urinary bladder cancer cell line, T24, the effect of STMN1 on cell proliferation and migration was evaluated by inhibiting the cellular expression of STMN1 using STMN1-siRNA. **Results:** Patients with T1- or muscle-invasive disease exhibiting high expressionof STMN1 had shorter overall survival (OS) and disease specific survival (DSS). In multivariate analysis, adjusting for stage, age and gender, the results were for T2-T4 patients: OS (HR=1.77 95% CI 1.02-3.07; p=0.04) and DSS (HR=2.04 95% CI 1.13-3.68; p=0.02); for T1-4 patients: DSS (HR=1.83 95% CI 1.09-3.08; p=0.02). The higher risk of cancer death within 2 years for T2-T4 patients with high STMN1-expressing tumors was validated in cohort II (HR= 1.76 95% CI 1.04 -2.99; p=0.03). In the metastatic bladder cancer material, 69% of the patients with one metastasis and 75% of the patients with several matched metastases were STMN1-positive in both the primary tumor and matched metastases. Moreover, the ability of the urinary bladder cancer cell line to grow or migrate was significantly reduced, (p<0.01 respectively p<0.0001) when transfecting the cells with a siRNA targeting STMN1. **Conclusions:** Our results suggest that STMN1 protein-expression has a potential both as a prognostic marker and a novel treatment target in urinary bladder cancer.

**4536 General Poster Session (Board #104), Mon, 1:15 PM-5:00 PM**

**A patient-derived xenograft (PDX) platform to optimize omics-driven precision medicine in bladder cancer.** *Presenting Author: Chong-xian Pan, Division of Hematology and Oncology, UC Davis Comprehensive Cancer Center, Sacramento, CA*

**Background:** Almost all cancers harbor multiple genetic alterations as determined by omics technologies, but most of these alterations are not driver ones critical for tumorigenesis. Hence, the efficacy of targeted therapy matching those alterations is still disappointing in most patients. We developed PDXs that share essentially the same genetic background as the parental cancers, and use this platform to optimize omics-drive precision medicine. **Methods:** PDXs were developed by direct implantation of fresh clinical cancer specimens in immunocompromised NSG mice (Jackson Laboratory, Sacramento, CA). Whole exome, transcriptome and microRNA sequencing was performed, followed by computational biological analysis to identify druggable genetic alterations that were further validated with immunofluorescence (IF) and immunohistochemical (IHC) staining. Efficacy tests together with mechanistic analysis were performed in NSG mice carrying PDXs. **Results:** So far, 21 PDXs have been established with an engraftment rate of 41 % (13/42) for invasive bladder cancer. The fidelity of PDXs was confirmed with cell morphology, tissue microarray IHC/IF staining and comparison of mutations in parental cancers and PDXs. Exome sequencing showed that 2 of the first 8 PDXs harbored PIK3CA mutations at the highly conserved helical and kinase domains. Transcriptome sequencing and IHC/IF staining revealed overexpression of several tyrosine kinase receptors. Of the first 8 PDXs, 5 had HER2/Neu overexpression (3+ by IHC), 5 fibroblast growth factor receptor 3 (FGFR3), and 4 EphB4 overexpression. Compared to the progression-free survival (PFS) of 9.5 days in the control arm, matched therapy with an FGFR3 inhibitor BGJ398 prolonged PFS to 18.5 days (p=2.61 X $10^{-6}$) in PDXs overexpressing FGFR3. Based on the miRNA profiling, a miRNA expression signature was identified that highly correlated with clinical response to chemotherapy (p=0.02) and accurately predicted response for defined responders (24/25 patients) or non-responders (11/11 patients). **Conclusions:** PDXs can potentially be used for efficacy assessment and mechanistic studies that can guide the design of precision cancer medicine.

**4537 General Poster Session (Board #105), Mon, 1:15 PM-5:00 PM**

**Delivery of peri-operative chemotherapy for muscle-invasive bladder cancer (MIBC) in routine clinical practice: Does regimen and timing matter?** *Presenting Author: Christopher M. Booth, Division of Cancer Care & Epidemiology, Cancer Research Institute, Queen's University, Kingston, ON, Canada*

**Background:** Few studies have documented regimens used and timing of peri-operative chemotherapy for MIBC in routine practice. In metastatic bladder cancer cisplatin has superior efficacy to carboplatin. Time to initiation of adjuvant chemotherapy (TTAC) from surgery is known to be associated with survival in other solid tumors. Here we describe regimens used and TTAC in the general population of Ontario, Canada. **Methods:** Treatment and physician billing records were linked to the Ontario Cancer Registry to describe use of neoadjuvant (NACT) and adjuvant (ACT) chemotherapy among all patients with MIBC treated with cystectomy in Ontario 1994-2008. Time to initiation of ACT (TTAC) was measured from cystectomy. Multivariate Cox regression was used to identify factors associated with overall (OS) and cancer-specific survival (CSS). **Results:** Of 2944 patients undergoing cystectomy, 4% (129/2944) and 19% (571/2944) were treated with NACT and ACT respectively. Five-year OS was 25% (95%CI 17-34%) for NACT, 29% (95%CI 25-33%) for ACT cases. Among patients with identifiable drug regimens, cisplatin was used in 82% (253/308) and carboplatin in 14% (43/308). The most common regimens were gemcitabine-cisplatin (54%, 166/308) and MVAC (21%, 66/308). Mean TTAC was 10 weeks; 23% of patients had TTAC >12 weeks. Advanced age (70+ years OR 3.86, 95%CI 1.25-11.9) and lower socioeconomic status (poorest quintile OR 2.38, 95%CI 1.13-5.02) were more likely to have TTAC > 12 weeks. Patients with node positive disease were less likely to have TTAC >12 compared to node negative (OR 0.58, 95%CI 0.34-0.99). TTAC greater than 12 weeks was associated with inferior OS (HR 1.28, 95%CI 1.00-1.62) and CSS (HR 1.30, 95%CI 1.00-1.69). In adjusted analyses, OS and CSS were lower among patients treated with carboplatin compared to those treated with cisplatin; OS HR 2.14 (95%CI 1.40-3.29) and CSS HR 2.06 (95% CI 1.26-3.37). **Conclusions:** Most patients with MIBC in the general population receive cisplatin and this may be associated with superior outcomes to carboplatin. Initiation of ACT beyond 12 weeks is associated with inferior survival. Patients should start ACT as soon as they are medically fit to do so.

**4538 General Poster Session (Board #106), Mon, 1:15 PM-5:00 PM**

**Next-generation sequencing to identify molecular alterations in DNA repair and chromatin maintenance genes associated with pathologic complete response (pT0) to neoadjuvant accelerated methotrexate, vinblastine, doxorubicin, and cisplatin (AMVAC) in muscle-invasive bladder cancer (MIBC).** *Presenting Author: Elizabeth R. Plimack, Fox Chase Cancer Center, Philadelphia, PA*

Background: Neoadjuvant cisplatin based chemotherapy prior to cystectomy is standard of care for MIBC, with 30-40% expected to achieve a pT0. Biomarkers predictive of pT0 are lacking. Methods: 36 MIBC pts treated on study with 3 cycles of neoadjuvant AMVAC were included. 14/36 were pT0. DNA from pre-treatment tumor tissue underwent sequencing of 287 cancer related genes and was analyzed for presence of base substitutions, indels, copy number alterations, and selected re-arrangements. The mean number of variants and variant status for each gene were correlated with pT0 using two-sample t-test and Fisher's exact tests. Variant data were used to create a classification tree to discriminate pts with and without pT0. Missense mutations were predicted to be deleterious/neutral using a support vector machine trained with sequence and protein structural features. Results: 747 alterations in 216 genes were detected. Pts with pT0 had more alterations (mean 25, range 11-39) than those with residual tumor (mean 18, range 8-32), p=0.01. All 13 pts with ≥ 1 variant in *ATM*, *RB1*, or *FANCC* achieved pT0 (positive predictive value=100%), while only 1/23 without a variant in 1 of these 3 genes achieved pT0 (negative predictive value=96%). This decision rule has a specificity of 100% and sensitivity of 93% for pT0. Permutation studies show the probability of this rule resulting in ≥ 97% accuracy by chance is ≤ 0.0001. Alterations in *ATM* and *RB1* remained independently associated with pT0 after correction for multiple testing. All but 1 of the alterations detected in *ATM*, *RB1* and *FANCC* were predicted to be deleterious. Conclusions: Alterations in ≥1 of *ATM*, *RB1* and *FANCC* predict pT0 to neoadjuvant AMVAC with high sensitivity and specificity. We hypothesize that defects in these genes, which are important for maintenance of chromatin structure and DNA repair, confer sensitivity to DNA damaging chemotherapy and that the accumulation of alterations seen among pts with pT0 reflect this phenotype. Independent validation of these findings is underway. Clinical trial information: NCT01031420.

**4539 General Poster Session (Board #107), Mon, 1:15 PM-5:00 PM**

**Assessing tumor response using CT density-volume trajectory in metastatic bladder cancer.** *Presenting Author: Les Folio, Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD*

**Background:** Automation advances in PACS provide efficient volumetric measurement capability not utilized by existing tumor criteria. We developed a combined density and volume assessment termed Automated Density and Volume Application (ADaVA) to quantify change in viable versus necrotic tumor volumes responding to anti-angiogenic therapy. Volume is not assessed in the Response Evaluation Criteria In Solid Tumors (RECIST) or other criteria such as MASS (Morphology, Attenuation, Size and Structure) and Choi. We compared overall survival (OS) predictive ability in ADaVA with existing and evolving criteria in metastatic bladder cancer. **Methods:** We assessed 141 lesions using RECIST, MASS, Choi, lesion volumes, and ADaVA at baseline and serial follow-up Contrast Enhanced CT exams (n=55) in 17 patients with metastatic bladder cancer treated with cabozantinib, a tyrosine kinase inhibitor. A semi-automated PACS tool (Carestream Health; Rochester, NY) segmented volumes for density thresholds representing viable (50-180 HU) or necrotic tissue (0-50 HU). RECIST response equivalents (partial response (PR), stable disease (SD) and progressive disease (PD)) were used. For each criterion, Kaplan-Meier curves and two-tailed log-rank test compared OS based on early response determination (PR+SD vs. PD); a Cox proportional hazards model assessed PR at any follow-up exam as a time-varying covariate for OS. **Results:** There was a statistical association between response determinations and OS (with binary tumor response) in total and low density-volume change in ADaVA (two-tailed, p=0.019); compared to other criteria that showed weak or no association. Low-density ADaVA change had the closest trend towards association (p=0.087; Hazard ratio=0.16; 95% CI on HR: 0.02 to 1.30) with time to developing PR. **Conclusions:** Our pilot study suggests that ADaVA incorporating lesion density and volume may predict OS as early as the first follow-up CT, potentially outperforming existing criteria. Combined density-volume criteria accurately reflect tumor burden and may predict outcomes earlier, improving therapeutic efficacy. Further study is warranted. Clinical trial information: 9236.

**4540 General Poster Session (Board #108), Mon, 1:15 PM-5:00 PM**

**High neutrophil to lymphocyte ratio persistent during first-line chemotherapy to predict clinical outcome in patients with advanced urothelial cancer.** *Presenting Author: Ugo De Giorgi, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) - IRCCS, Meldola, Italy*

**Background:** Increased neutrophil to lymphocyte ratio (NLR), an index of systemic inflammation, is associated with poor outcome for various types of cancers. We aimed to assess the role on outcome prediction of NLR at baseline and persistent during first-line chemotherapy in patients with advanced urothelial cancer (UC). **Methods:** We retrospectively reviewed 292 patients with unresectable or metastatic UC treated with first-line chemotherapy between January 2003 and December 2012. The cut-off values of NLR (>3 vs ≤3) were evaluated at pre-therapy and at day 1 of the second and third cycle (follow-up NLR). After univariate analysis, a multivariate analysis was carried out by Cox regression model and included the following variables: Eastern Cooperative Oncology Group (ECOG) performance status (≥2 vs 0-1), visceral disease (present vs absent), hemoglobin (<12 g/dL vs ≥12 g/dL), pre-therapy NLR (>3 vs ≤3) and follow-up NLR (>3 vs ≤3). **Results:** The median follow-up was 40.2 months (range, 0.5 to 100.4). The median progression-free survival (PFS) was 5.8 months (95% confidence interval (CI) 5.0-6.6) and the median overall survival (OS) was 10.9 months (95% CI 9.6-12.4). Patients with pre-therapy and follow-up NLR > 3 had a median PFS of 3.2 months and a median OS of 5.7 months. In multivariate analysis, visceral metastases, pre-therapy hemoglobin and follow-up NLR were significant predictors of PFS (HR 1.75, $p = 0.0001$; HR 1.57, $p = 0.0015$; HR 2.77, $p < 0.0001$, respectively), and of OS (HR 1.60, $p = 0.0023$; HR 1.59, $p = 0.0024$; HR 2.89, $p < 0.0001$, respectively); whereas pre-therapy NLR remained as predictor of OS only (HR 1.53, $p = 0.0101$). **Conclusions:** An increased NLR persistent during first-line chemotherapy is an independent predictive factor for patients with advanced UC.

**4541^ General Poster Session (Board #109), Mon, 1:15 PM-5:00 PM**

**Preliminary product parameter and safety results from NeuACT, a phase 2 randomized, open-label trial of DN24-02 in patients with surgically resected HER2+ urothelial cancer at high risk for recurrence.** *Presenting Author: Dean F. Bajorin, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** DN24-02 is an investigational HER2-targeted autologous cellular immunotherapy (ACI) based on the same manufacturing platform as sipuleucel-T, an ACI approved by the FDA and EMA for certain patients (pts) with asymptomatic or minimally symptomatic metastatic castration-resistant prostate cancer. DN24-02 consists of antigen presenting cells (APC) cultured with BA7072, a recombinant HER2-derived antigen (HER500) linked to GM-CSF. NeuACT (N10-1; NCT01353222) compares the efficacy and safety of adjuvant DN24-02 to surveillance in HER2+ urothelial cancer (UC) pts at high risk of relapse after resection. Preliminary product potency, immune response and safety data are reported. **Methods:** Pts randomized to DN24-02 received 3 infusions at 2 week intervals. Primary endpoint is overall survival. Secondary objectives include disease-free survival, antigen-specific immune response, product potency (measured by APC activation) and safety. **Results:** As of November 2013, 38 pts completed DN24-02 infusions and were assessed for product potency. APC activation was observed for each infusion and the profile was indicative of a prime boost effect, with a greater magnitude at infusions 2 (median 15.26; range: 6.42–23.97) and 3 (14.69; 7.38–30.86) than 1 (6.73; 3.47–14.34). T-cell associated cytokines were greater at infusions 2 and 3 than 1. Following treatment, significant increases were observed in peripheral immune responses ($p<0.01$), and were comparable in pts with and without neoadjuvant chemotherapy. Adverse events (AEs) occurring in >15% of 48 pts receiving ≥1 leukapheresis were fatigue (41.7%), chills (37.5), nausea (25.0), pyrexia (18.8) and headache (16.7). Three pts had treatment-related grade ≥3 AEs or SAEs. No clinically significant changes were reported in left ventricular ejection fraction. **Conclusions:** This preliminary analysis suggests a pattern of DN24-02 APC activation and T-cell cytokines consistent with immunological prime-boost similar to that of sipuleucel-T. DN24-02 appears well-tolerated in UC pts, and the most common AEs are similar to those reported with sipuleucel-T. Clinical trial information: NCT01353222.

**4542 General Poster Session (Board #110), Mon, 1:15 PM-5:00 PM**

**External validation of nomogram to predict progression-free survival at 6 months (PFS6) in patients receiving salvage therapy for advanced urothelial carcinoma (UC).** *Presenting Author: Guru Sonpavde, The University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

**Background:** A nomogram incorporating baseline prognostic factors has been reported to facilitate the evaluation of activity of salvage therapy for advanced UC (Pond GR, BJUI 2013). We performed an external validation in a phase III trial dataset. **Methods:** Data were obtained for patients randomized to vinflunine in the phase III trial comparing best supportive care +/- vinflunine. Progression-free survival at 6 months (PFS6) as well as the 4 prognostic factors: hemoglobin (Hb), performance status (PS), liver metastasis (LM) and time from prior chemotherapy (TFPC) were analyzed. Patients were grouped based on nomogram score and risk groups. Bootstrap analysis was performed and 95% bias-corrected and accelerated [BCa] CI were calculated. **Results:** Of 253 patients, 5 had missing TFPC and were excluded; thus, 248 were evaluable (Table). The number of nomogram points as a continuous variable was associated with PFS6 (odds ratio [OR]=1.10, 95% confidence interval [CI] = 1.05 to 1.15 / 10 point increase, c-index=0.680, $p<0.001$). Risk group was also significantly associated with PFS6 (OR=0.51, 95% CI=0.37 to 0.70 / increase in risk group, c-index=0.674, $p<0.001$). 95% BCa CI were calculated for the c-index (0.602 to 0.747) and for the estimated odds ratio (0.37 to 0.70). **Conclusions:** This external validation confirms the utility of the previously reported nomogram to predict PFS6 with salvage therapy in advanced UC. The nomogram is a useful tool to estimate the required minimal efficacy of agents in phase II trials to justify further investigation.

**4543 General Poster Session (Board #111), Mon, 1:15 PM-5:00 PM**

**Trans Tasman Radiation Oncology Group (TROG) 02.03 phase III trial: Concurrent weekly cisplatin and radiation therapy in localized muscle-invasive bladder cancer—Compliance, toxicity, QOL, and overall results.** *Presenting Author: Nirdosh Kumar Gogna, Princess Alexandra Hospital - Mater Radiation Oncology Centre, Brisbane, Australia*

**Background:** This phase III trial investigated the benefits and toxicities of a combination of weekly cisplatin and radiation therapy (Arm A) compared with radiation therapy (RT) alone (Arm B)in the definitive treatment of muscle-invasive bladder cancer (MIBC). **Methods:** Adult patients with localized Stage T2-T4a, bladder cancer of predominant transitional cell carcinoma histology with no contraindications to the use of pelvic radiation therapy or cisplatin chemotherapy were eligible. Othet exclusion criteria included extensive or multifocal carcinoma in situ and a contracted bladder. An initial maximal transurethral resection of the bladder tumour (TURBT) preceded randomisation. The primary outcome was local failure at 3 years. The secondary endpoints included complete response rate at3 months, overall and disease free survival, acute and late toxicity and QoL. The QoL of patients receiving organ preserving treatments for MIBC had not been previously investigated in a randomised Phase III setting. Intitial accrual target was set at 150 patients over 4 years. Slow accrual lead to early closure with Thirty eight patients were being randomised to arm A and 30 patients to arm B. **Results:** Compliance with RT in both arms was excellent. About 15% of patients in the chemoradiation arm required a significant reduction in cisplatin dose delivery mainly because of declining renal function. Acute and late toxicity was similar in the two arms, but in the short to medium term chemoradiation did affect QoL. Trends towards better local control, distant disease free and overall survival were noted in the chemoradiation arm. **Conclusions:** Overall weekly cisplatin and radiation therapy in MIBC are reasonably well tolerated. Treatment however in the short to medium term does affect Qol. Notwithstanding this negative impact, recovery does follow in the longer term. This is yet another study which suggests that chemoradiation does offer the prospect of improving local control and overall survival compared to radiation therapy alone. Clinical trial information: No NCT00330499.

**4544 General Poster Session (Board #112), Mon, 1:15 PM-5:00 PM**

**Updated analysis of circulating tumor cells (CTCs) in patients with urothelial cancer (UC) undergoing systemic treatment: Implications across the clinical stages.** *Presenting Author: Andrea Necchi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** CTCs from patients (pts) at different clinical stages were analyzed by a never explored experimental approach based on a combination of two techniques. Provision of this information may contribute to optimize tailored therapies. **Methods:** 3 cohorts of have been analyzed: pts with muscle-invasive bladder cancer receiving neoadjuvant (NA) sorafenib + chemotherapy (CT) (NCT01222676), and metastatic pts receiving first-line MVAC (M1), and second-line (M2) anti-TGF$\beta$ receptor ALK1 PF-03446962 in a phase 2 trial (NCT01620970). 5 ml of whole blood were filtered by ScreenCell Cyto devices and CTC status was assessed with centralized scoring by referral pathologists. Additional 5 ml of whole blood were processed by immunomagnetic beads (AdnaTestSelect® kit) and the expression level of a panel of markers (including *EPCAM* and *MUC1*) was studied using RT-multiplex PCR. The objective was the association with clinical endpoints (pathologic/clinical response, and relapse). **Results:** From 07/2012 to 1/2014, 65 pts (20 NA, 31 M1, and 14 M2) were enrolled. Rates of baseline CTC+ were: 92, 75, 91%, and 31, 50, 64% with the 2 techniques, respectively. NA setting: all pts had a stepwise reduction of CTC count/5 ml blood by ScreenCell (median baseline of 14 [0-40] to 0 [0-9] – end of treatment). Increase in circulating EPCAM±MUC1 levels by CTC was seen in accordance with the 3 disease progressions (PD). M1 setting: While there was a discrepancy between CTC signals and partial/complete response (PR/CR), a trend towards an increase in CTC levels was observed in 7/9 evaluable relapsers. Pts who relapsed had a median of 43 CTC/5 ml (IQR: 17-51.5) at the end of CT, while all the others had levels <13. EPCAM profile was not concordant in all cases (median 1.01 vs 1 ng/ul). Interestingly, an increase in both CTC signals anticipated relapse in 5/9 evaluable responders (CR+PR). M2 setting: an increase in CTC was documented by both methods in each case, in accordance with PD. **Conclusions:** This combined technique was endowed with promising utility to anticipate the detection of clinical relapse. Refining molecular characterization might help designing informed clinical trials.

**4545 General Poster Session (Board #113), Mon, 1:15 PM-5:00 PM**

**Engrailed-2 (EN2) protein expression and prognosis in bladder cancer following radical cystectomy (RC).** *Presenting Author: Simon J. Crabb, University of Southampton, Southampton, United Kingdom*

**Background:** Dysregulation of various developmental genes is associated with urological malignancies. In particular, HOXB13 overexpression is associated with aggressive invasive bladder cancer. Engrailed-2 (EN2), a member of the HOX gene family, was recently shown to be expressed and secreted by non-muscle invasive bladder cancer (NMIBC) leading to its development as a potential urinary diagnostic marker. However, the role of EN2 as a prognostic marker in muscle invasive advanced bladder cancer is unknown. **Methods:** We assessed EN2 protein expression in a tissue microarray of consecutive bladder cancer RC samples from a UK center. EN2 expression was prospectively dichotomised as positive (3+ nuclear and cytoplasmic staining) or negative. Univariate analyses of known prognostic factors and EN2 for survival outcomes from date of RC were by the Kaplan Meier method and log rank test. Statistically significant variables were then assessed by multivariate Cox regression. p values $<$ 0.05 were considered statistically significant. **Results:** 226 samples were eligible for inclusion (median age 72, range 33-87; 76.1% male, 90.3% pure/predominant transitional cell carcinoma). EN2 expression status was positive in 39 (17%) cases and negative in 160 (71%). No scoring was possible (mostly for missing cores) in 27 (12%) cases. Overall survival was reduced in patients with positive vs. negative EN2 staining (median survival 2.23 vs. 5.23 years, p=0.007) which was maintained in multivariate analysis (hazard ratio 1.61, 95% CI 1.05-2.48, p=0.03). Bladder cancer specific and relapse free survival were also reduced in EN2 positive cases in both univariate and multivariate analyses (multivariate analysis hazard ratios 2.00, 95% CI 1.21-3.30, p=0.007 and 2.17, 95% CI 1.35-3.49, p=0.001 respectively). Pathological complete response (pCR) rate following RC was inversely related to EN2 status (1 of 39 if EN2 positive vs. 23 of 160 if negative, $\chi 2=4.12$, df=1, p=0.04). **Conclusions:** EN2 protein expression is an independent poor prognostic factor following RC for bladder cancer and correlates with a reduced pCR rate. External validation is ongoing. If validated then EN2 expression might assist patient stratification strategies.

**4546 General Poster Session (Board #114), Mon, 1:15 PM-5:00 PM**

**Bladder cancer risk: Use of PLCO and NLST to identify a suitable screening cohort.** *Presenting Author: Laura-Maria Krabbe, University Hospital of Muenster, Muenster, Germany*

**Background:** Bladder cancer (BC) screening is not accepted in part due to low overall incidence. We utilized the PLCO and NLST to identify optimal high-risk populations most likely benefit from screening. **Methods:** Data were extracted from PLCO and NLST to stratify risk of BC by overall population, gender, race, age at inclusion and smoking status. Incidence rates between groups were compared using chi-square test. **Results:** BC was identified in 1430/154,898 in PLCO and 439/53,173 in NLST. BCs were grades III/IV in 36.8% and 41.3%, respectively. Incidence rates were significantly higher in men than women (PLCO: 1.4 vs. 0.31/1000 person-years, NLST: 1.84 vs. 0.6/1000 person-years, both p$<$0.0001). In proportional hazards models, male sex, higher age, duration and intensity of smoking were associated with higher risk of BC (all p$<$0.0001). In men $>$70 with smoking exposure of 30 pack years (PY) and more, incidence rates were as high as 11.92 (PLCO) and 5.23 (NLST) (per 1000 person-years). In current high intensity smokers ($\geq$50 PY) the gender disparity in incidence persists in both trials (0.78 vs. 2.99 per 1000 person-years in PLCO and 1.12 vs. 2.65 per 1000 person years in NLST). **Conclusions:** Men over 60 years with a smoking history of $>$30 PY generate incidence rates over 2/1000 person-years, which could serve as an excellent population for screening trials. Gender differences in BC incidence cannot be readily explained by differences in exposure to tobacco, since in PLCO and NLST the gender disparity persisted regardless of smoking intensity.

**4547 General Poster Session (Board #115), Mon, 1:15 PM-5:00 PM**

**Immunohistochemistry (IHC) to enhance the prognostic allocation of locally advanced and metastatic urothelial cancer (UC) undergoing first-line chemotherapy (CT).** *Presenting Author: Patrizia Giannatempo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** Knowledge of the expression of molecular drivers and potentially druggable targets may enhance prognostic classification of metastatic UC. We aimed at assessing the expression of multiple key molecular biomarkers (BMK) by IHC and their potential to enhance prognostic allocation of patients (pts) with UC. **Methods:** We analyzed formalin-fixed paraffin embedded tumor from pts with UC undergoing first-line CT with MVAC for locally-advanced unresectable (LA, T3-4$\pm$N+) and metastatic (M) disease between the years 2000 and 2013. The expression of the following panel of BMKs by IHC were evaluated using conventional protocols: ERCC1, EGFR, HER2, VEGFR-3, PDGFR$\alpha$, p53, p63. Expression levels were dichotomized as positive (2+,3+) or negative ($\leq$1+). Fisher exact test was used to evaluate the association with response and setting (LA vs M). Cox regression multivariate (MVA) models evaluated the association with PFS and OS of each biomarker, adjusted for recognized prognostic variables (setting [LA vs M], Bajorin score [0 vs 1-2], primary site). **Results:** Since 06/2009, tissues of 88 pts (27 LA, 61 M) underwent IHC. Samples were from primary tumor (N=67) or metastases (N=21). Rates of positive IHC/number evaluable were as follows: ERCC1: 30/66 (45%); HER2: 24/52 (46%); EGFR: 31/54 (57%); VEGFR-3: 50/66 (76%); PDGFR$\alpha$: 10/63 (16%); p53: 25/56 (45%); p63: 46/53 (87%). HER2 trended for a significant association with higher stage (p=0.079). Median follow up was 41 months (IQR, 15-64). On MVA, significant results were obtained for VEGFR-3 and PDGFR$\alpha$, in addition to Bajorin score (Table). The c-index was 0.68 for both PFS and OS. **Conclusions:** VEGFR-3 and PDGFR$\alpha$ expression appears to confer a divergent prognostic impact in pts receiving first-line cisplatin-based CT for advanced UC. These data warrant external validation and underline the difficulties in defining the role of angiogenesis as a molecular driver and therapeutic target.

**Changes in conditional survival (CS) in de novo metastatic urothelial carcinoma (mUC): A Surveillance, Epidemiology, and End Results (SEER) database analysis.** *Presenting Author: Kara DeWalt, City of Hope Comprehensive Cancer Center, Duarte, CA*

**Background:** No agents have been approved by the US FDA for the 2$^{nd}$-line treatment of mUC. Still, many US patients receive treatment in this setting, calling upon phase II datasets emerging over the past decade for payor justification. While the cumulative disease-specific survival (DSS) for mUC may not change on account of this practice, assessment of CS may allow greater focus on patients who receive post-1$^{st}$-line therapies. **Methods:** The SEER database was queried to compare the DSS and CS of de novo mUC patients diagnosed from 1994-2000 (T1) and 2001-2009 (T2). The year 2000 was chosen as a cutoff due to multiple phase II datasets for 2$^{nd}$-line regimens published subsequent to this date. DSS in subgroups divided by time period were summarized using the Kaplan-Meier method and compared using the log-rank test. The chi-square test was used to compare the CS of subgroups divided time period at annual intervals up to 5 years. Multivariate analysis (MVA) was performed to determine the relationship between DSS and clinicopathologic/treatment-related variables. **Results:** Outcomes were assessed for a total of 4,465 pts, with 1,155 diagnosed during T1 and 3,310 diagnosed during T2. Mean age of the overall cohort was 70, and the majority of patients had poorly differentiated or undifferentiated tumors. For the overall cohort, 1-year DSS for T1 and T2 were 23% and 25% (P=NS). At landmark analyses at 1 yr, 2 yrs and 3 yrs following diagnosis, 1-yr CS in groups diagnosed during T1 and T2 were 46% and 39%, 71% and 68%, and 76% and 78%, respectively (P=NS for each comparison). On MVA, time period of diagnosis (T1 vs T2) was not a significant predictor of DSS. Instead, older age ($>$65) and undifferentiated histology were predictive of poorer DSS, while use of radiation or surgery were associated with improved DSS. **Conclusions:** Multiple published phase II studies emerging over the past decade have been used to justify use of post-1$^{st}$-line therapies for mUC to payors. Our assessment of CS should better account for the impact of these therapies as compared to cumulative DSS. The lack of improvement CS calls into question the impact post-1$^{st}$-line therapies have had on the natural history of mUC.

**4549 General Poster Session (Board #117), Mon, 1:15 PM-5:00 PM**

**Long-term results and prognostic factors for survival following adjuvant chemotherapy (AC) for muscle-invasive urothelial bladder cancer (UC): A French retrospective multicenter cohort.** *Presenting Author: Damien Pouessel, Department of Medical Oncolgy, Hopital Saint-Louis - APHP, Paris, France*

**Background:** Role of AC in patients (pts) with UC undergoing radical cystectomy (RC) is debated. **Methods:** We retrospectively analyzed survival of 226 consecutive pts treated with RC and AC for UC with muscle-invasion or lymph node (LN) involvement in 6 French academic hospitals between 2000 and 2009. Non-urothelial cases were excluded. Multivariate Cox proportional hazards regression adjusted for center was used to estimate adjusted hazard ratios with 95% confidence interval. **Results:** Median age was 62.4 [range: 35-82], 189 (84%) were male. ECOG performance status was 0-1 in 211 pts (93.3%). Stage were p<T2 (n=15), pT2 (n=31), or pT≥3 (n=180), pN0 (n=37), pN1 (n=54), pN≥2 (n=114) or pNx (n=21), M0. Mixed UC were 43 (19%). Median number of resected LN was 11.5 [1-36]; density (LND) 25% [3.1-100]. Median time between RC and AC was 61.5 days [18-162]. Gemcitabine-cisplatin (GC), gemcitabine-carboplatin (GCb), and methotrexate-vinblastine-doxorubicine-cisplatin (MVAC) regimen were delivered in 71.2%, 21.7% and 5.3% of pts. Median number of cycles was 4 [1-6]. Thirteen pts (5.7%) with LN metastases (LN+) received adjuvant pelvic radiotherapy (ART) after AC. Median follow-up was 4.2 years [0.38-11.0], 135 (59.7%) pts have relapsed, 99 (73.3%) received at least one chemotherapy regimen for metastasis. Also 133 pts (59.2%) died, most death (90.1%) were related to recurrence. Median overall survival (OS) and disease-free survival were 3.4 and 1.03 years. Five-year OS and cancer-related survival (CRS) rates were 40.7% and 42.6% respectively. In multivariate analysis, pT≥3 stage (HR: 2.31, 95%CI 1.27-4.19, p=0.006), < 4 cycles (1.99, 1.15-3.45, p=0.01), and LND > 50% (2.34, 1.23-4.46, p=0.01) were adverse prognostic factors for CRS. ART (0.33, 0.10-1.11, p=0.07) tend to provide survival benefit. **Conclusions:** In this large contemporary retrospective study reporting real-life survivals in pts receiving AC after RC with survival results consistent with published data, LND < 50% and ART in LN+ pts predict a more favorable prognosis after AC. Further studies are warranted to reveal the exact impact of ART in this subset of pts.

**4550 General Poster Session (Board #118), Mon, 1:15 PM-5:00 PM**

**Pathologic down-staging following standard (SD) MVAC (methotrexate-vinblastine-doxorubicine-cisplatin) or dose-dense MVAC (DD) neoadjuvant chemotherapy (NC) for muscle-invasive urothelial bladder cancer (UC): A retrospective multicenter cohort of the French Genitourinary Tumor Group (GETUG/AFU).** *Presenting Author: Damien Pouessel, Department of Medical Oncolgy, Hopital Saint-Louis - APHP, Paris, France*

**Background:** The benefit of NC on survival in UC has been shown with SD and is most evident in patients (pts) who achieve a pathological complete response (ypT0). In the last decade, physicians used SD or DD. **Methods:** We conducted a retrospective cohort study in 246 pts who received SD or DD for NC before a planned RC for cT2-T4, cN0 or cN+, M0 UC at 16 French centers from 2004 to 2012. The primary outcome was stage ypT0 at RC. Other PDS end points were no residual muscle-invasion (< ypT2), stage < ypT3, and nodal status. Toxicities, disease-free survival (DFS) and overall survival (OS) were also evaluated. **Results:** A total of 246 pts (182 cN0 and 64 cN+) were identified, 208 (84.5%) were male, 56 and 190 were treated with SD and DD, respectively. Median age was 62 [range: 56.3-67.4]. The median time from start of NC to RC was 101 days [80-122]. RC has been realized in 214 pts (87.0%), 48 (85.7%) and 166 (87.6%) after SD and DD respectively. In 17 unoperated pts, concomitant chemoradiotherapy was performed, 8 (14.28%) and 9 (4.7%) after SD and DD respectively. Mean follow−up from RC was 15 months [7-28.3]. Stage ypT0 were found in 18 (40%) and 58 (36.4%) pts after SD and DD respectively (p= 0.73). PDS were reported in 27 (61%) and 81 (55%) pts after SD and DD respectively (p=0.49). The following adverse events were observed with SD and DD respectively: grade 4 neutropenia (25% and 11%), grade 3/4 anemia (63% and 36%), grade 4 thrombopenia (0% and 4%), febrile neutropenia (9% and 7%), and grade 2 peripheral neuropathy (0% and 4%). Median DFS following RC was not reached (NR) and 50.9 months (95%CI 24.2-NR, p= 0.37) after SD and DD respectively, 31 (55.3%) and 103 (54.2%) pts were still disease-free. The median OS was NR in SD versus 55 months in DD (39.3-NR, p=0.85). **Conclusions:** The proportion of pts whose primary tumor were downstaged was not different according to the two regimen. Toxicity was confirmed to be higher in SD than in DD. The GETUG/AFU has launched a randomized trial assessing the DD and gemcitabine-cisplatin regimens in the perioperative setting.

**4551 General Poster Session (Board #119), Mon, 1:15 PM-5:00 PM**

**Met signaling in urothelial carcinoma of the bladder.** *Presenting Author: Donald P Bottaro, Urologic Oncology Branch, National Cancer Institute, Bethesda, MD*

**Background:** Mounting evidence of hepatocyte growth factor (HGF)/Met signaling in urothelial carcinoma (UC) suggests that pathway inhibition could have therapeutic benefit in some patients. The effects of two Met inhibitors, cabozantinib (which also targets VEGFR2), and crizotinib (which also targets ALK), on Met-driven UC cell growth, invasion and tumorigenicity were analyzed in biochemical, cell-based and animal models. **Methods:** The effects of cabozantinib or crizotinib on HGF signaling were assessed in 9 human UC-derived cell lines: RT4, TCC-SUP, T24M2, T24M3, J82, SW780, UMUC3, UMUC5, and 5637. Biochemical assays included total Met protein, phospho-Met (pMet), pAkt, total Akt, pErk and total Erk analysis. Cultured cell assays of invasion, proliferation and anchorage independent growth were performed in all 9 lines. The growth rates of SW780 xenografts in SCID and human HGF knock-in SCID (hHGF/SCID) mice treated daily with cabozantinib or vehicle alone, as well as tumor levels of Met and pMet, were determined. **Results:** Met content was low in RT4 and higher in T24M2, T24M3, TCC-SUP, J82, SW780 UMUC3, UMUC5, and 5637 cells. Basal pMet content in quiescent cells was universally low and significantly enhanced by added HGF, an effect that was reversed by treatment with cabozantinib or crizotinib. HGF-driven increases in pAkt/Akt and pErK/ErK in all 9 cell lines were also reversed by cabozantinib or crizotinib treatment, as were HGF-enhanced cell invasion, proliferation and anchorage independent growth. SW780 xenograft growth rate in hHGF/SCID mice was significantly higher than in SCID mice and significantly inhibited by cabozantinib treatment, as was tumor pMet content. **Conclusions:** Cultured UC cell Met content was higher in cell lines derived from higher stage disease. HGF stimulated the activation of Met and known effectors, and enhanced invasion, growth rate and anchorage-independent growth; treatment with cabozantinib or crizotinib effectively reversed these HGF-driven effects. Cabozantinib also significantly inhibited HGF-driven tumor xenograft growth and Met activation in SCID and, more dramatically, in hHGF/SCID mice. These preclinical studies support further investigation of Met inhibitors for the treatment of UC in human clinical trials.

**4552 General Poster Session (Board #120), Mon, 1:15 PM-5:00 PM**

**PD-L1 expression in mononuclear cells and not in tumor cells, correlated with prognosis in metastatic urothelial carcinoma.** *Presenting Author: Stephanie A. Mullane, Bladder Cancer Center, Dana Farber Cancer Institute/ Brigham and Women's Cancer Center, Boston, MA*

**Background:** Programmed death-1 (PD-1) receptor negatively regulates T cell-mediated responses.PD-1 ligand (PD-L1) is expressed in several malignancies and is associated with higher grade, 9p24 loss and worse clinical outcome. Its role as potential predictive biomarker for immunotherapy is of clinical relevance. The prognostic impact of PD-L1 expression in tumor cells versus its expression in mononuclear (MNC) infiltrates in urothelial carcinoma (UC) is unknown. **Methods:** Formalin-fixed paraffin embedded (FFPE) tumor samples from 160 clinically annotated UC patients were retrieved. PD-L1 expression was evaluated by immunohistochemistry using a mouse monoclonal anti-PD-L1 antibody (405.9A11). The assay was validated using FFPE cell line controls known to be positive or negative for PD-L1 expression by flow cytometry. PD-L1 tumor positivity (PD-L1+) was defined as ≥5% tumor cell membrane staining. For PD-L1 expression in MNC, a score based on the extent of infiltrate and percentage of positive cells was used. Fisher's exact test was used to assess the associations with clinical variables (smoking history, prior BCG treatment and stage at diagnosis) and 9p24 copy number variation (CNV). Log rank test was used to assess the association of PD-L1 expression with overall survival (OS). **Results:** Among 160 UC patients, PD-L1+ expression was seen in 32 (20%) of tumors cell membrane and in 58 (37%) of MNC. Smoking history did not correlate with expression of PD-L1 in tumor cells or in MNC. PD-L1+ in MNC was non significantly higher in stage III/IV versus stage I/II tumors at diagnosis (41.8% versus 30%; p=0.56). In the subgroup of patients that developed metastatic disease (89 patients), MNC PD-L1+ was significantly associated with a longer OS (p=0.04). In patients that developed metastatic disease, PD-L1+ was seen in 14% of tumor cells and did not correlate with OS (p=0.45). Correlation with prior BCG exposure and CNV of 9p24 will be presented. **Conclusions:** PD-L1 is widely expressed in tumor cell membrane and MNC in UC. PD-L1+ in MNC is significantly associated with survival in those patients that subsequently develop metastatic disease.

**4553 General Poster Session (Board #121), Mon, 1:15 PM-5:00 PM**

**Identification of potentially targetable kinases by concurrent high-throughput functional kinomics and RNA-sequencing (seq) of muscle-invasive bladder cancer (MIBC).** *Presenting Author: Christopher Douglas Willey, The University of Alabama at Birmingham, Birmingham, AL*

**Background:** Interrogation of kinases in tumor and matched normal tissue by concurrent kinomic activity profiling and RNA-seq might identify the most relevant kinases and inform the development of agents for MIBC. We report the first such analysis followed by supportive analysis of the TCGA (The Cancer Genome Atlas). **Methods:** We performed kinomic profiling and RNA-seq of frozen tumor samples and matched adjacent normal bladder from 6 pts with MIBC. Kinomic profiling was performed using the PamStation 12 high-content phosphopeptide substrate microarray system (PamGene International). Protein tyrosine and serine/threonine kinome PamChips were used to measure global kinase activity by detecting phosphorylation of peptide substrates through FITC-labeled antibodies. Upstream kinase prediction was determined by a scoring algorithm derived from the phosphonet database. RNA-seq libraries were prepared using standard techniques and were sequenced on the Illumina HiSeq2000 platform. RNA-seq of kinases from 59 pts with MIBC and complete pathologic staging information were compared with 16 normal bladder controls from TCGA. Pathway analysis was conducted for kinases with gene expression changes concordant between the TCGA dataset and the 6 UAB pts. **Results:** Kinomic activity profiling identified increased tumor (vs. matched normal) kinase activity corresponding to BRK, FAK, PYK2, ZAP70 and CTK target peptides. Interestingly, kinase gene expression showed no concordance with activity. Among 529 kinase genes, 124 genes were significantly altered in tumor v. matched normal, of which 28 overlapped with the TCGA dataset. The top 5 up-regulated tumor kinases from both sets were CIT, CDK4, PRKD2, IKBKE, and EPHB2. Pathway analysis revealed significant involvement of post-translational modification and survival signaling. **Conclusions:** Comprehensive kinase analyses of MIBC using kinomic activity profiling and RNA-seq identified multiple potential therapeutic targets. Preclinical validation of agents targeting these kinases and pathways is warranted and will facilitate integration of kinomic and transcriptomic data.

**4554 General Poster Session (Board #122), Mon, 1:15 PM-5:00 PM**

**Screening for carcinoma in situ (CIS) testis and occurrence of metachronous germ cell cancer (mGCC).** *Presenting Author: Maria Gry Gundgaard, Survivorship, Danish Cancer Society, Copenhagen, Denmark*

**Background:** CIS is present in the contralateral testicle in 5-6% of untreated patients with unilateral germ cell cancer (GCC). A Danish screening program for contralateral CIS was initiated in order to prevent mGCC. **Methods:** In total, 4,180 GCC patients diagnosed from 1984 through 2007 were offered a contralateral single-site biopsy in relation to orchiectomy (intention to screen, ITS). A non-screened group included 450 patients. Recommended treatment for CIS was radiotherapy (RT) in doses of 14 to 20 Gy, also in chemotherapy treated (CT) patients. CIS-negative (CISneg) patients who developed mGCC had the biopsy revised according to today's standard including immunohistochemical staining. Data was merged with national administrative registries, and information on second GCC and vital status was obtained for all patients up to December 2012. **Results:** Median observation time was 14.1 years (range 0.1-28.9). Contralateral CIS was found in 193 patients (4.6%). Seven CIS-positive (CISpos) patients developed mGCC (n=3 after 14 Gy and n=4 after CT without local RT). Out of 3,987 CISneg patients, 55 developed mGCC. Revision of 46 biopsies available showed CISpos in 17 and confirmed CISneg biopsies in 29 patients. Older age at diagnosis and treatment with CT were significantly correlated with decreased risk of mGCC (HR 0.93 per year, p<0.0001 and HR 0.34, p=0.006, respectively). **Conclusions:** The risk of mGCC in a screened population was significantly lower than in a non-screened group after re-evaluation of false-negative biopsies. Further efforts should concentrate on the improvement of screening to eliminate false-negative biopsies and on the definition of risk factors to avoid taking biopsies in low-risk groups.

**Cumulative incidence of mGCC (% [95% CI]).**

**Renal impairment and late toxicity in germ-cell cancer (GCC) survivors.** *Presenting Author: Jakob Lauritsen, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*

**Background:** Treatment with bleomycin-etoposide-cisplatin (BEP) decreases renal glomerular filtration rate (GFR) and confers a risk of later cardiovascular disease (CVD) and death. We investigated the influence of BEP on renal function and looked at associations between renal toxicity and late effects in a large cohort of GCC survivors. **Methods:** Patients were identified in the Danish DaTeCa database, housing GCC patients diagnosed 1984-2007. All patients (N=1,046) received BEP with measurements of GFR (51Cr-EDTA clearance) before and after treatment. GFR was repeatedly measured at 1, 3, and 5 years of follow-up. Late toxicity was identified by merging with national registers. Influence of covariates on renal toxicity was evaluated by a linear mixed model approach. Risk factors for late toxicity were estimated by a landmark analysis adjusting for covariates and the cohort was compared to the background population with standardized hospitalization/mortality rates (SHR/SMR). **Results:** After treatment, GFR decreased (ΔGFR) with median 13 ml/min/1.73m2. ΔGFR was inversely associated to GFR pre-treatment (P<0.0001) and associated to number of cycles (P<0.0001). Patients who received 3 or 4 cycles of BEP had significant rebound of renal function during follow-up, whereas patients treated with 5 cycles or more stayed reduced. Compared to the background population all patients, irrespective of renal function, had an increased risk of CVD and death. The risk of CVD and death depended significantly on chronic kidney disease (CKD) stage before treatment but not after treatment (Table). ΔGFR had no influence on risk of late toxicity (CVD: HR 1.08, P=0.34; Death: HR: 0.98, P=0.71). **Conclusions:** BEP decreases renal function, but the changes in GFR are partly reversible and have no impact on late effects or death.

**A contemporary population-based study of testicular sex cord stromal tumors: Presentation, treatment patterns, and predictors of outcome.** *Presenting Author: Lindsay M Yuh, University of California at Davis, Sacramento, CA*

**Background:** Testicular sex cord stromal tumors (SCST) - consisting of Leydig and Sertoli cell subtypes - are a rare adult malignancy. Contemporary clinical data are gathered only from anecdotal case reports or small case series. Therefore, few evidence-based guidelines have been developed regarding the optimal management and surveillance of such tumors. In order to define SCST demographics and patient outcomes and to identify prognostic features, we analyzed the California Cancer Registry, a large statewide database. **Methods:** All male patients over the age of 18 diagnosed with SCST in California between 1988 and 2010 were included. Baseline demographic variables included age, race, histology, tumor stage, primary treatment, and socioeconomic status. Primary outcome measures were cause-specific survival (CSS) and overall survival (OS). Bivariate and multivariate Cox proportional hazards models were employed to identify predictors of CSS and OS. **Results:** Of 19,792 patients with testicular tumors, a total of67 patients with SCST were identified, representing 0.3% of the total population. Of these patients, 45 (67%) had Leydig cell and 19 (28%) had Sertoli cell tumors. Median age at presentation was 40 years and the vast majority of patients (84%) presented with localized disease. Following orchiectomy, 9 patients (15%) underwent RPLND, whereas 54 patients (80%) had no further treatment. With a median follow-up time of 75 months, 2-year OS and CSS was 91% and 95% for those presenting with stage I disease. For those presenting with stage II disease, 2-year OS and CSS was 30%. Significant predictors of worse OS on multivariable analysis included age >60 (HR 5.64, p<0.01) and metastatic disease (HR 8.56, p<0.01). Presentation with metastatic disease was the only variable associated with worse CSS (HR 13.36, p<0.01). Histology was not found to be a significant predictor of either CSS or OS. **Conclusions:** We present the largest reported series to date for this rare tumor and provide contemporary epidemiologic and treatment data. The primary driver of prognosis in patients with SCST is disease stage, emphasizing the importance of early detection and intervention.

**4557 General Poster Session (Board #125), Mon, 1:15 PM-5:00 PM**

**A retrospective analysis of patients with poor-risk germ cell tumor (PRGCT) treated at Indiana University from 1990 to 2011.** *Presenting Author: Nabil Adra, Indiana University, Indianapolis, IN*

**Background:** Based on the International Germ Cell Cancer Collaborative Group (IGCCCG), PRGCT represents 14% of germ cell tumors with a 5-year survival of only 48% and 5-year PFS of 41%. PRGCT is defined by primary mediastinal non-seminomatous germ cell tumor (PMNSGCT), non-pulmonary visceral metastasis (NPVM), AFP $>$ 10,000 or hCG $>$ 50,000. This analysis attempts to identify subsets of patients with more or less favorable outcomes among the poor risk groups. **Methods:** Retrospective analysis of all patients with testicular cancer seen at Indiana University from 1990-2011. 411 patients with PRGCT identified of whom 211 received initial therapy at Indiana University. Median follow-up time was 35.3 months. We analyzed the following variables: primary site testis/retroperitoneal T/RP (169) vs. PMNSGCT (42), no NPVM (109) vs. NPVM (102), PMNSGCT with no metastasis (18) vs. PMNSGCT with distant metastasis (24), and single criterion (128) vs. multiple criteria (83) for PRGCT. **Results:** Mean age 29, mean AFP 9,449, mean hCG 169,087. 20% had PMNSGCT, 48% NPVM. Patients with NPVM had significantly worse PFS. Patients with PMNSGCT had significantly worse OS compared to patients with other primary sites. Multiple different criteria for poor risk disease carried significantly worse impact on PFS when compared to having a single criterion for poor risk disease. Patients with PMNSGCT with distant metastasis had worse PFS. **Conclusions:** Our results for patients with PRGCT treated at Indiana University from 1990-2011 are superior to the IGCCCG patients treated from 1975-1990. Patients with PRGCT treated after 1990 had better outcome compared to 1975-1990 with a 5-year survival of 74% and PFS of 54%. Our data indicate that patients with NPVM, PMNSGCT, more than one criteria for poor risk disease, or PMNSGCT with distant metastasis have a worse outcome compared to other PRGCT subgroups.

| | 5-yr PFS | 5-yr OS | P value |
|---|---|---|---|
| **All patients** | 54% | 74% | |
| **No NPVM vs NPVM** | 60% vs 49% | 78% vs 71% | PFS 0.06; OS 0.2 |
| **PMNSGCT vs T/RP** | 46% vs 56% | 57% vs 78% | PFS 0.69; OS 0.002 |
| **Single criterion vs multiple criteria for poor-risk disease** | 60% vs 45% | 78% vs 69% | PFS 0.03; OS 0.12 |
| **PMNSGCT vs PMNSGCT + metastasis** | 69% vs 36% | 78% vs 45% | PFS 0.06; OS 0.16 |

**4558 General Poster Session (Board #126), Mon, 1:15 PM-5:00 PM**

**Evolving patterns of care in the management of stage I non-seminomatous germ cell tumors: Data from the California Cancer Registry.** *Presenting Author: Stanley A Yap, University of California, Davis, Sacramento, CA*

**Background:** Standard options for the management of stage I non-seminomatous germ cell tumors (NSGCT) following radical orchiectomy include active surveillance, retroperitoneal lymph node dissection (RPLND), or adjuvant systemic chemotherapy. However, few studies have assessed population-level practice patterns and how these have evolved over time. Here, we assess the shifting practice patterns across a 20 year timespan in the management of stage I NSGCTs. **Methods:** Using the California Cancer Registry, we reviewed all patients diagnosed with stage I NSGCT in California between 1988 and 2010. We determined whether primary treatment consisted of RPLND, chemotherapy, or surveillance, and their overall rates across the years. Other analyzed variables included patient age, socioeconomic status, race, year of diagnosis, and region. Predictors of treatment selection were assessed using logistic regression analysis. **Results:** A total of3,961 patients with stage I NSGCT were identified. The most common primary treatment was surveillance (48%), followed by RPLND (26%) and chemotherapy (24%). Significant changes in the rate of various treatment strategies were noted across the study period ($p<0.01$). Rates of surveillance increased from 35% in 1988 to 61% in 2010, while rates of chemotherapy remained relatively stable. However, rates of RPLND decreased from 44% in 1988 to 10% in 2010. Significant predictors of undergoing surveillance on multivariable logistic regression included diagnosis after 2006 (OR 1.52, CI 1.25-1.84) and age at diagnosis $>$60 years old (OR 1.63, CI 1.19-5.82). With a median follow-up of 96 months, 5-year overall survival (OS) rate among those undergoing RPLND, chemotherapy, or surveillance was 98%, 92%, and 97%, respectively. **Conclusions:** Treatment patterns in the management of stage I NSGCT have shifted with an increased utilization of surveillance and a concurrent decrease in the use of RPLND. Treatment patterns have evolved over the past 2 decades, where active surveillance is now the dominant strategy, potentially reflecting changes in perception of the oncologic safety and morbidity profile of such an approach.

**4559 General Poster Session (Board #127), Mon, 1:15 PM-5:00 PM**

**Bone metastases in germ cell tumors: Results from an international data base.** *Presenting Author: Christoph Oing, Department of Oncology, Hematology and BMT with Section of Pneumology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

**Background:** Bone metastases (BM) are rare in germ cell tumor (GCT) patients (pts). Systematic data on risk factors, treatment and outcome are largely lacking. **Methods:** An international data base including 272 GCT pts with BM (140 at primary diagnosis, 132 with first BM occurrence at relapse) diagnosed between 1983 - 2013 from 23 centers was retrospectively analyzed. **Results:** BM at primary diagnosis mostly affected spine (71%) and pelvis (24%), 40% had a single and 60% multiple lesions. Pts had a primary gonadal / retroperitoneal / mediastinal GCT in 68% / 16% / 16% and seminoma / nonseminoma in 25% / 74%. Primary treatment was standard dose chemotherapy in 90% (SD-CTX) and dose intensified CTX in 10% (DI-CTX). Secondary resection (SR) / radiotherapy (RTX) of BM was performed in 10 pts (7%) / 20 pts (14%). Histology was necrosis / mature teratoma / vital tumor in 6 / 2 / 1 pts. 45% of pts relapsed, 79% again with BM. Median FU was 21 months (mos). Calculated median PFS and OS were 31 mos (range, 0-225) and 98 mos ($^{95\%}$CI, 14–182). No survival benefit was achieved by DI-CTX (PFS p=.29; OS p=.96) or SR of BMs (PFS p=.25; OS p=.99). 132 pts developed BM at relapse: Mostly in spine (67%) and pelvis (24%). 47% had a single, 53% multiple lesions. Median time from initial GCT diagnosis to detection of BM was 20 mos ($^{95\%}$CI, 16-24). Salvage treatment was SD-CTX / DI-CTX in 86% / 14%. SR / RTX of BM were performed in 14% / 42%. Histology was necrosis / mature teratoma / vital tumor in 1 / 2 / 14 pts. Overall, 52% of pts progressed during salvage CTX. After a median FU of 45 mos (range, 2-335), median OS was 13 mos ($^{95\%}$CI, 8 – 17). PFS and OS seem to be improved by DI-CTX (2yr-PFS 37% vs 14%, p=.006; 2yr-OS 47% vs 25%, p=.008) and / or SR of residual bone lesions (2yr-PFS 37% vs 14%, p=.016; 2yr-OS 74% vs 20%, p<.001). Additional RTX of BM did not impact survival in the salvage setting (PFS p=.73; OS p=.15). No other characteristics (tumor markers, non-bone metastases) were associated with the occurrence of BM in both cohorts. **Conclusions:** Pts with BM at primary diagnosis will achieve long-term survival (median OS 98 mos), but pts relapsing with BM have a dismal prognosis (median OS 13 mos). In patients relapsing with BM intensification of salvage therapy and resection of residual bone lesions may improve survival.

**4560 General Poster Session (Board #128), Mon, 1:15 PM-5:00 PM**

**Salvage chemotherapy for relapsed germ cell tumors: A phase II trial of gemcitabine, paclitaxel, ifosfamide, and cisplatin (Gem-TIP).** *Presenting Author: Matthew James Wheater, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom*

**Background:** Cure is possible for patients with relapsed germ cell tumours using further intensive cisplatin based combination chemotherapy. The Medical Research Council TIP trial reported a complete response (CR) rate of 19%, 1 year progression free survival (PFS) of 38% and overall survival (OS) 65% (Br J Cancer 2005;93:178). The previously reported phase I Gem-TIP trial demonstrated the feasibility of delivering full dose gemcitabine (Gem) in combination with TIP (J Clin Oncol 27, 2009 [suppl; abstr e16031]). We now report efficacy and safety data on an expanded cohort of patients treated within a phase II trial. **Methods:** Patients with germ cell cancers at first relapse following cisplatin based chemotherapy received a maximum of 4 cycles of Gem-TIP (Gem 1200mg/m$^2$ d1, paclitaxel 175mg/m$^2$ d1, ifosfamide 1g/m$^2$ d2-6, cisplatin 20mg/m$^2$d2-6) with pegfilgrastim 6mg d7 of a planned 21 day cycle. Subsequent cycles were started on adequate haematological recovery with no planned dose reductions. **Results:** 20 patients were treated, 19 male, 1 female, median age 32 years (range 20-61). Histology 6 seminoma, 14 non-seminoma. 6 patients had poor prognostic features using the Memorial criteria. The mean relative dose intensity (RDI) for TIP for patients treated with Gem-TIP was paclitaxel 95%, ifosfamide 91% and cisplatin 94% compared with 92%, 92% and 94% respectively in the MRC TIP trial. Response was CR 9 patients (45%), CR surgery 1 (5%), PR marker negative 6 (30%), incomplete response 3 (15%), 1 unevaluable. 1 year PFS was 57.9% (95% CI 33.2-76.3%), 1 year overall survival 84.2% (95% CI 58.7%-94.6%). Of the 16 patients with a favourable response this was sustained for 11 (69%) with a median overall follow up of 29 months. Toxicity was manageable and predominantly haematological. Grade 3/4 neutropaenia 60%, thrombocytopaenia 75% febrile neutropaenia 15%. There were no toxic deaths. **Conclusions:** The addition of gemcitabine to TIP chemotherapy is a feasible chemotherapy combination with no detrimental impact on RDI of TIP drugs and acceptable toxicity. Response rate and duration are improved on those reported in the MRC TIP trial and warrant further evaluation in a larger study. Clinical trial information: 37453564.

**4561 General Poster Session (Board #129), Mon, 1:15 PM-5:00 PM**

**Etoposide, methotrexate, and dactinomycin alternating with cyclophosphamide and vincristine (EMA/CO) for males with HCG-expressing, chemorefractory germ cell tumors (GCT): Long-term efficacy and safety outcomes.** *Presenting Author: Daniele Raggi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** Patients (pts) with GCT who fail to be cured following multiple chemotherapy (CT) courses (including high-dose CT) have an extremely poor prognosis. EMA/CO regimen has shown efficacy in high-risk gestational trophoblastic tumors. Since 1992 we introduced this regimen for human chorionic gonadotropin (HCG)-producing refractory GCT. **Methods:** We retrieved data of adult male pts who received methotrexate (MTX) 100 mg/m$^2$ followed by MTX 200 mg/m$^2$ over 12h d1, etoposide 100 mg/m$^2$ and dactinomycin 0.5 mg mg/m$^2$ d1-2, folinic acid 15 mg orally every 6h d2-3, followed by cyclophosphamide 600 mg/m$^2$ plus vincristine 1 mg/m$^2$ d8, every 21 days. Treatment was continued until marker normalization. Pts had a HCG+ GCT and had failed at least 2 CT regimens. Multivariable analysis (MVA) was undertaken to analyze candidate prognostic factors. ITT analysis was applied. **Results:** From 02/92 to 05/13, 41 pts were treated in 3$^{rd}$ (20, 49%) or >3$^{rd}$ line (21, 51%). 36 (88%) had a mixed GCT, 2 a pure seminoma and 3 a clinical diagnosis. 7 (17%) had an extragonadal primary, 17 (41%) had liver, bone, or brain (LBB) metastases, and 21 (51%) HCG>1000 IU/l. 16 (39%) had received HDCT. 33 pts (80.5%) had a response with marker reduction, including 5 complete (12.2%) and 7 (17.1%) partial responses (PR) with HCG normalization. After a median follow up of 98 months (IQR: 80-183), 6 pts did not relapsed and 6 were alive. Median progression-free survival was 3 months (95%CI, 2-4) and median overall survival was 8 months (95%CI, 6-10). On MVA, the line of treatment (>3$^{rd}$ vs 3$^{rd}$) was the only significant predictor of both PFS (HR: 2.50, 95%CI, 1.20-5.24, p=0.015) and OS (HR: 3.17, 95%CI: 1.46-6.89, p=0.004). Overall 16 pts (39%) had G3-4 hematologic and 1 pt mucositis and gastrointestinal toxicity each. No discontinuations for toxicity occurred. 1 toxic death (cerebral hemorrhage) occurred. **Conclusions:** EMA/CO is an active regimen with acceptable toxicity and could be considered an option for the subset of HCG+ chemoresistant GCT having failed multiple lines, including pts who are not candidate to salvage HDCT.

**4562 General Poster Session (Board #130), Mon, 1:15 PM-5:00 PM**

**Validation of a prognostic classification system for mediastinal nonseminomatous germ-cell tumors (MGCT).** *Presenting Author: Lance C. Pagliaro, Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The anterior mediastinum is the most common location for extra-gonadal germ-cell tumors. MGCT has poor prognosis (International Germ Cell Consensus Classification); overall survival (OS) is 45–50% with standard treatment. Based on a prior study (Urol Oncol 2012, 30:879-85) we hypothesized that men with MGCT have favorable (Fav), intermediate (Int) or very poor (VP) prognosis when grouped by number of risk factors (RF). **Methods:** To validate the RF scoring system, we applied it to a prospectively collected subset of 66 men with MGCT who were registered on the GETUG-13 phase III trial (ASCO 2013, abstr #LBA4500). Patients (pts) were registered 11/2003–5/2012 and received bleomycin/etoposide/cisplatin (BEP) in the first cycle. Pts with unfavorable marker decline in cycle 1 were randomized to BEP (N=28) or an intensified regimen (paclitaxel-BEP-oxaliplatin x2 cycles and cisplatin/ifosfamide/bleomycin x2 cycles; N=29); the other 9 pts remained on BEP. One point was assigned for each of 3 RF at diagnosis: hCG ≥ 1,000 mg/ml, histology other than yolk sac tumor, and extra-mediastinal dissemination. Pts were then scored as Fav (0 RF), Int (1 RF), or VP (2–3 RF). We performed Kaplan-Meier analysis of OS and progression-free survival (PFS) for these groups and prognostic analyses (univariate and multivariate) for each RF. **Results:** Median age was 28 (18–65). Biopsy results were available for 30 pts (45%) and 36 (55%) had been diagnosed clinically. 27 pts died; 34 progressed and/or died. Median OS and PFS were not reached in the Fav (N=26) and Int groups (N=24). By contrast, the VP group (N=16) had median OS and PFS of 13 months and 4 months, respectively (log-rank P=.03; P<.001). Hazard ratios (HR) for RF are shown in the table. **Conclusions:** RF score predicted OS and PFS in this validation cohort of men with MGCT. Histology alone was not a strong RF, but the data were incomplete because a biopsy was not always clinically indicated.

| | | HR (95% CI) | | | |
|---|---|---|---|---|---|
| | | Univariate | | Multivariate | |
| RF | N (%) | OS | PFS | OS | PFS |
| Metastasis | 26 (39) | 2.3* (1.1–4.9) | 2.8* (1.4–5.6) | 2.1 (0.9–4.5) | 2.5* (1.2–5.2) |
| hCG ≥ 1,000 | 12 (18) | 2.5* (1.1–6.1) | 3.3* (1.5–7.1) | 2.1 (0.9–5.2) | 2.7* (1.2–6.0) |
| Non-yolk sac | 21 (32) | 1.4 (0.6–3.1) | 1.2 (0.6–2.4) | 1.5 (0.7–3.3) | 1.2 (0.6–2.4) |

**4563 General Poster Session (Board #131), Mon, 1:15 PM-5:00 PM**

**Chemotherapy compared to surgery: Quality-of-life analysis of the German prospective multicenter trial in clinical stage I NSGCT (AUO AH 01/94).** *Presenting Author: Peter Albers, Department of Urology, Heinrich-Heine-University, Düsseldorf, Duesseldorf, Germany*

**Background:** Although the superiority of one course of BEP over RPLND and surveillance in terms of recurrence rate has been shown, studies providing validated prospective quality of life (QoL) data in patients (pts) with NSGCT I treated with only one cycle of BEP are lacking. Therefore, the objective of the present trial was to examine long-term QoL issues in pts with clinical stage I NSGCT randomized after orchiectomy to either RPLND or one cycle of PEB chemotherapy. **Methods:** Results of the EORTC QLQ C30 plus additional scales questionnaire (QLQ C30+) were reviewed in 382 pts included in a prospective trial, which have been randomly assigned to receive either RPLND (n=191) or one course of BEP (n=191) after orchidectomy [AH 01/94, JCO 2008]. Pts with completed QLQ C30 and available data on treatment response were eligible for analysis. Pts with recurrences or 2$^{nd}$ malignancies were excluded. Treatment related changes of QoL in the no-event population were evaluated for the first 5 years after the end of treatment. A difference of >= 17% on the global item about "strain by treatment and/or tumor" was considered a clinically relevant difference between both treatment arms. Statistical comparisons between groups were performed using the Mann–Whitney U-test for nonparametric unpaired data. **Results:** The hazard ratio to experience a tumour recurrence with surgery as opposed to chemotherapy was 7.937 (95% CI, 1.808 to 34.48), i.e. 15 versus 2 recurrences. QoL results of pts with no event after the 1$^{st}$year were available from 138 pts with BEP and 126 pts with RPLND. For year 5, still 83 BEP pts had QoL assessments compared to 72 pts in the RPLND group. No significant differences between treatment groups in any of the QoL domains occurred during 5 years, not even at the time of treatment. Neither physical, nor emotional or global domains revealed any difference between the two approaches. As expected, hair loss reflected the side effects of chemotherapy during years 1 and 2, but recovered fully thereafter. **Conclusions:** This large randomized trial was not able to detect significant short- or long-term differences in QoL scores between RPLND and PEB. Clinical trial information: Number 141 / AH 01/94.

**4564 General Poster Session (Board #132), Mon, 1:15 PM-5:00 PM**

**Fatigue in relation to treatment and gonadal function in a population-based sample of 796 testicular cancer survivors 12 and 19 years after treatment.** *Presenting Author: Mette Sprauten, OUS, The Norwegian Radium Hospital, Oslo, Norway*

**Background:** Chronic fatigue (CF) is more prevalent in Testicular Cancer Survivors (TCSs) 12 years after treatment than in the general population (16% versus 10%). CF-related symptoms of emotional, physical and/or cognitive tiredness may be associated with poor gonadal function (low testosterone (T) and/or high Luteinizing Hormone (LH)). In this longitudinal study we assessed the prevalence of CF median 12 (12y) and 19 years (19y) after treatment in relation to applied treatment, age and levels of T and LH. **Methods:** T and LH levels were retrieved from 796 TCSs who completed fatigue questionnaires median 12y and 19y after treatment and categorized according to quartile thresholds of healthy controls for decadal age groups. Treatment was categorized as surgery (S, n=162), radiotherapy (RT, n=339) or chemotherapy (CT, n= 295). CF was defined according to previously published cut-off levels. Associations between CF and hormone levels, age and treatment were assessed with logistic regression. **Results:** CF increased overall significantly from 16% at 12y to 27% at 19y. A total of 67% of those reporting CF at 12y had persistent CF at 19y. The proportion of TCSs with T and/or LH within the poorest quartile increased from 72% at 12y to 81% at 19y. There were no significant associations between CF and T, LH, age or treatment 12 years after therapy. 19y after treatment, CF was significantly associated with the lowest quartile of T (compared to the highest quartile, referent) and previous RT (compared with S, referent) (Odds Ratio 1.9 95%CI: 1.0- 3.5 and 1.7; 95%CI: 1.0- 2.6, respectively). **Conclusions:** The increase of CF from 12 to 19 years after treatment was remarkable and disturbing. A significant association between CF and RT and the lowest T quartile emerged first almost 20 years after treatment. The increasing proportion of TCSs with CF and decreasing T levels underline the importance of continued long-term assessments of TCSs. T substitution may be considered many years after treatment of TCSs in order to treat CF.

**4565 General Poster Session (Board #133), Mon, 1:15 PM-5:00 PM**

**Survival of good-risk germ cell tumor patients following post-chemotherapy retroperitoneal lymph node dissection: The effect of bleomycin during induction chemotherapy.** *Presenting Author: K. Clint Cary, Indiana University School of Medicine, Department of Urology, Indianapolis, IN*

**Background:** Patients presenting with metastatic International Germ Cell Cancer Collaborative Group (IGCCCG) good risk testicular cancer may receive either 4 cycles of etoposide and cisplatin (EP) or 3 cycles of bleomycin, etoposide, and cisplatin (BEP). Those with residual retroperitoneal masses following either of these induction chemotherapy regimens will require a post-chemotherapy retroperitoneal lymph node dissection (PC-RPLND). We sought to examine differences in survival following PC-RPLND between patients receiving EPx4 compared to BEPx3. **Methods:** The Indiana University Testis Cancer database was queried to identify IGCCCG good risk PC-RPLND patients who received either EPx4 or BEPx3 induction chemotherapy. The primary outcome was overall survival (OS). Kaplan-Meier plots were generated for the EPx4 and BEPx3 groups and compared using the log-rank test. Survival time was calculated from the date of surgery until date of death or the last date the social security death index was accessed. **Results:** A total of 226 patients met inclusion criteria between 1985 and 2011. Induction chemotherapy consisted of EPx4 in 47 (21%) patients and BEPx3 in 179 (79%). Most patients (78%) received their chemotherapy at outside institutions and were subsequently referred for PC-RPLND. Of the 12 patients who received adjuvant chemotherapy following PC-RPLND, 8 (66%) had received induction EPx4 while 4 (33%) had received BEPx3 (Fisher's exact $p=0.001$). Median follow-up was 126 months (IQR: 65-228) during which 16 deaths occurred. The 10-year OS for the EPx4 and BEPx3 groups were 87% and 98%, respectively (log-rank $p<0.01$). Of the 29 patients with active cancer in the PC-RPLND specimen, the 10-year OS for EPx4 was 50% compared to 83% in the BEPx3 group (log-rank $p=0.03$). **Conclusions:** Good risk testicular cancer patients who received BEPx3 may have a modest improvement in survival compared to those who received EPx4 as induction chemotherapy in this retrospective analysis. The overall burden of treatment may be higher with EPx4 as those patients also received more adjuvant chemotherapy compared to those who received induction BEPx3.

**4566 General Poster Session (Board #134), Mon, 1:15 PM-5:00 PM**

**A two-part phase 2 randomized study of dalantercept and axitinib versus placebo plus axitinib in advanced renal cell carcinoma: Results from the part 1 dose escalation cohorts.** *Presenting Author: Michael B. Atkins, Georgetown University Lombardi Comprehensive Cancer Center, Washington, DC*

**Background:** The activity of agents that target the vascular endothelial growth factor (VEGF) pathway in metastatic renal cell cancer (mRCC) may be enhanced in combination with agents that inhibit non-VEGF angiogenesis pathways and may lead to improved outcomes for pts. Activin receptor-like kinase 1 (ALK1) is a type I receptor of the TGF$\beta$ superfamily that is expressed on endothelial cells and is involved in blood vessel maturation. Dalantercept (Dal) is an ALK1 receptor-fusion protein that inhibits signaling through ALK1 and has demonstrated additive efficacy with a VEGF receptor (VEGFR) TKI in RCC models. **Methods:** Part 1 of this randomized 2-part phase 2 study assessed the safety and tolerability of Dal plus axitinib, a VEGFR TKI in pts. with mRCC who had up to 3 prior lines of therapy and determined the recommended phase 2 dose (RP2D). Cohorts of 3-6 pts. each received Dal (0.6, 0.9, or 1.2 mg/kg) SC Q3W and axitinib 5 mg PO BID. An expansion cohort at the RP2D will enroll an additional 10-20 pts. Eligibility criteria include 1 prior VEGFR TKI, $\leq 3$ prior tx., and ECOG $\leq 1$. **Results:** 13 pts. were enrolled in the three cohorts (n= 4, 4, 5) and there were no DLTs within 28 days of the first dose. Of the 13 pts., 46% had $\geq 2$ prior tx and 15% had 2 prior anti-VEGF tx. Common Dal-related AEs were grade 1-2 diarrhea, fatigue, anemia, arthralgia, creatinine rise, constipation, nausea, dysphonia, headache, muscle spasms. There have been no Dal associated SAEs. AEs associated with axitinib did not occur with higher than expected frequency or severity. 3 of 12 (25%) evaluable patients (2 at 0.6 mg/kg and 1 at 0.9 mg/kg) 2 of whom had three prior tx, achieved partial responses and were on study for $\geq 10$ cycles (7.5 mo). 6 of 11 (55%) evaluable pts. completed $\geq 6$ cycles (4.5 mo). Enrollment in the expansion cohort at 1.2mg/kg Dal is ongoing. **Conclusions:** In this pretreated mRCC population, the combination of Dal and axitinib is well tolerated and associated with clinical activity including disease control in the majority of pts.These data support 1.2 mg/kg as the RP2D of Dal in the randomized double-blind part 2 of this study in which pts. will be randomized to Dal + axitinib vs. placebo + axitinib. Clinical trial information: NCT01727336.

**4567 General Poster Session (Board #135), Mon, 1:15 PM-5:00 PM**

**Subgroup analyses of a randomized sequential open-label study (SWITCH) to evaluate efficacy and safety of sorafenib (SO)/sunitinib (SU) versus SU/SO in the treatment of metastatic renal cell cancer (mRCC).** *Presenting Author: Peter J. Goebell, AURONTE (Urologische Klinik und Klinik fuer Haematologie und Onkologie (Med5); Universitaetsklinikum Erlangen), Erlangen, Germany*

**Background:** Results of the sequential randomized phase III SWITCH study comparing SO/SU and SU/SO have been reported previously (ASCO GU 2014, abstract 393) showing no significant difference in the primary endpoint total PFS (T-PFS, Hazard Ratio [HR] 1.01) nor the secondary endpoints overall survival (OS, HR 1.0) and 1st-line PFS (HR 1.19). We here report results of SWITCH study subgroup analyses per endpoints T-PFS, OS, and 1st-line PFS. **Methods:** Pts with mRCC unsuitable for cytokines without prior systemic therapy, ECOG PS 0/1, MSKCC score low or intermediate, and $\geq 1$ measurable lesion were randomized to receive open-label SO/SU (arm A) or SU/SO (arm B) in standard dosage. Retrospective subgroup analyses according to age, sex, MSKCC score, and ECOG PS were performed to identify any subgroup that profits more from one sequence or the other by comparing both groups using Cox proportional hazard regression model and log-rank testing. **Results:** A total of 365 pts were enrolled: 182 arm A, 183 arm B.At time of final T-PFS analysis 220 events had occurred (A, n=117 [64%]; B, n=103 [56%]). The Table shows the subgroup analyses comparing group A vs group B including HR and p value of tests for difference. **Conclusions:** There was no significant difference in T-PFS, OS, and 1st-line PFS in the evaluated subgroups between the two sequential treatments apart from OS per age group in which different results have been found. Both drugs provided overall benefit regardless of sequence and subgroup. However, the analyses were exploratory and hypothesis-generating as they were retrospective and the significance analysis was not corrected for multiple testing. Clinical trial information: NCT00732914.

| Subgroup | T-PFS HR (p value) | OS HR (p value) | PFS in 1st-line HR (p value) |
|---|---|---|---|

**4568 General Poster Session (Board #136), Mon, 1:15 PM-5:00 PM**

**Overcoming mTOR resistance: Results of a phase I study of the mTOR inhibitor ridaforolimus and the HDAC inhibitor vorinostat.** *Presenting Author: Matthew R. Zibelman, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Elevation of pAKT levels has been shown to result from mTOR inhibition. We hypothesized that the HDAC inhibitor vorinostat (Vori) would abrogate ridaforolimus (Rida) resistance due to down-regulation of pAKT when used in combination in patients with renal cell carcinoma (RCC). **Methods:** The primary objective was to determine the maximum tolerated dose (MTD) for RCC patients (pts), thus while all solid tumors were allowed, prior cytotoxic chemotherapy was limited to 1 regimen. There was no limit to the number of prior targeted or immunotherapies. ECOG PS 0-1 and adequate organ and marrow function were required. A modified 3+3 dose escalation design tested 2 dose levels concurrently by escalating each drug in separate cohorts. Rida was dosed days 1-5 and Vori days 1-3, weekly. **Results:** 15 pts (10 clear cell RCC, 3 papillary RCC, 1 esophageal, 1 carcinoid) were treated at 1 of 3 dose levels: 1) Rida 20mg QD + Vori 100mg BID, 2) Rida 20 mg QD + Vori 200 mg BID, 3) Rida 40 mg QD + Vori 100 mg BID. Inability to complete 80% of doses during cycle 1 due to thrombocytopenia resulted in dose limiting toxicities (DLTs) in 2/6 pts at dose level 2. There were no other DLTs and no grade 4-5 toxicities. Related grade 3 toxicities were: hyperglycemia (1), anemia (2), fatigue (1), and mucositis (1). Grade 2 pneumonitis was seen in 2 pts. The MTD was Rida 20mg QD + Vori 100mg BID, however all 7 pts who received >2 cycles required dose reduction to Rida 10-20 mg QD + Vori 100 mg QD, 6 due to thrombocytopenia. Thus the recommended phase II dose (RP2D) to allow for chronic dosing is Rida 20mg QD + Vori 100mg QD. Stable disease for 19, 21, 46+ and 74+ weeks, respectively, was maintained in 4 pts with RCC. Of these, 3 had progressed on prior mTOR therapy, including 2 pts with papillary RCC and ongoing disease control at the time of data cutoff. **Conclusions:** Rida 20mg QD + Vori 100 mg QD is the RP2D for this combination. Prolonged, ongoing disease control was seen in 2 papillary RCC pts, both of whom had progressed on a prior mTOR inhibitor. Further study of combined mTOR and HDAC inhibition in RCC, with tumor sampling to assess for pharmacodynamics and proof of concept, is warranted to further define the toxicity, efficacy and mechanism of this combination. Clinical trial information: NCT01169532.

**4569 General Poster Session (Board #137), Mon, 1:15 PM-5:00 PM**

**Dovitinib in first-line metastatic renal cell carcinoma and correlation of efficacy with tumor gene status: A phase II clinical trial.** *Presenting Author: Reuben James Broom, Auckland City Hospital, Auckland, New Zealand*

**Background:** Dovitinib is an anti-VEGFR tyrosine kinase inhibitor which also inhibits FGFR-1,-2,-3 and PDGFR$\beta$. We studied its activity as 1st-line therapy in patients with metastatic clear-cell renal cell carcinoma (mCCRCC) and correlated genes related to its action mechanism with clinical outcomes. **Methods:** The 31 treatment naïve patients with mCCRCC enrolled in this single-arm, single-site, phase II study received dovitinib at 500mg 5 days on/2 days off until progression. An optional post-treatment biopsy was offered to study resistance mechanisms. The primary endpoint was progression free survival (PFS) using RECIST 1.1. Secondary endpoints included response rate and efficacy by gene status (FISH and DNA sequence). **Results:** Accrual occurred over 15 months from March 2012. Median patient age was 64 and 72% were male. ECOG performance status was 0 in 45% and 1 in 55%. Heng prognostic group was favorable risk in 38%, intermediate risk in 52% and poor risk in 10%. 38% had bone metastases. 4 patients stopped treatment due to toxicity and 1 patient withdrew. Median PFS was 6.2 months (inter quartile range: 3.3 to 8.2). Of 28 evaluable patients, best response was: PR (29%), SD (53%) and PD (18%). All-cause grade 3/4 adverse events (AE's) occurring in $\geq$5% of patients were: fatigue (16%), abdominal pain (13%), pancreatitis (10%), gout (7%), diarrhea (7%), bone pain (7%), hypercalcemia (7%), elevated lipase (7%) and pulmonary embolism (7%). Pre-treatment metastatic and primary tumor tissue was available from 93% and 54% of patients respectively. 6 patients donated post-progression tissue. Gene status (FISH) for FGFR-1,-2,-3, PDGF$\beta$ and PDGFR$\beta$ was available for 20 primary and 17 metastatic specimens. FGFR-1 showed a trend towards positive correlation between gene gain/amplification and response (Spearman's rho = 0.32, p = 0.17). FGFR-2, FGFR-3, PDGFR$\beta$ and PDGF$\beta$ showed no statistically significant associations. **Conclusions:** Dovitinib has activity in the first line setting of mCCRCC with a tolerable safety profile at the given dosing schedule. A non-significant correlation of this activity with FGFR-1 gene gain/amplification was seen and further study with a larger sample size is warranted. Clinical trial information: ACTRN12612000140853.

**4570 General Poster Session (Board #138), Mon, 1:15 PM-5:00 PM**

**A phase II study of bevacizumab (Bev) and temsirolimus (Tem) in VEGF-refractory metastatic renal cell carcinoma (mRCC).** *Presenting Author: Kathleen Margaret Mahoney, Beth Israel Deaconess Medical Center, Boston, MA*

**Background:** Inhibiting VEGF and mTOR pathways are standard treatment approaches for patients (pts) with mRCC. Combinations of these agents have potential to improve efficacy. Here we report the activity and safety of the Bev and Tem combination in pts with clear cell (cc) and non-clear cell (ncc) mRCC who had failed prior VEGF blockade. **Methods:** In this phase II investigator-initiated multicenter study pts received Bev (10 mg/kg) IV q2 weeks and Tem (25 mg) IV weekly until progression of disease (PD) or unacceptable toxicity. The primary endpoint was progression free survival (PFS). Secondary endpoints included overall response rate (ORR), median overall survival (OS), toxicity, and correlative studies. The design provided 88% power (10% alpha) to prove a progression free rate of 50% at 2 months. **Results:** Forty-one pts were enrolled and 40 were treated; 31 (77.5%) had good/intermediate risk per the IMDC criteria (Heng JCO 2009) and 13 (32.5%) had ncc histology. Thirteen (32.5%) had primary VEGF-refractory disease, in which best response on prior VEGF-targeted therapy was PD. Median prior therapies was 1 (75% sunitinib). Median PFS was 5.8 months. Median OS was 13.1 months as of 10/2013. There were no CR. Confirmed PR occurred in 7 pts (17.5%). Median PFS and ORR were 7.8 months and 15% (2/13) in pts with primary VEGF-refractory disease and 7.6 months and 7.6% (1/13) in pts with nccRCC. All grade and grade 3/4 toxicities, at least possibly attributable to Bev and Tem, were seen in 62% and 49%, respectively. Dose reduction occurred in 77.5% of pts and 27.5% were taken off study because of toxicity. Most frequent toxicities include fatigue, dyslipidemia, and proteinuria. The most serious toxicity included deep vein thrombosis (1), esophageal fistula (1), bowel perforation (1), cerebrovascular accident (1) and ventricular arrhythmia/cardiac arrest (1). **Conclusions:** Combining Bev and Tem in a VEGF-refractory mRCC population was possible with dose reductions, and resulted in longer than expected PFS in pts with primary VEGF-refractory disease and non clear cell histology, both 2 unmet needs in RCC. We are currently in the process of assaying pretreatment tumor samples for predictive biomarkers. Clinical trial information: NCT00782275.

**4571 General Poster Session (Board #139), Mon, 1:15 PM-5:00 PM**

**Characterization of the mTOR autophosphorylation site, S2481, as a novel biomarker in renal cell carcinoma (RCC).** *Presenting Author: Lauren Christine Harshman, Dana-Farber Cancer Institute, Boston, MA*

**Background:** mTOR inhibitors have clinical utility in VEGF-refractory RCC and may be useful in non-clear cell disease. In general, mTOR inhibition is inferior to targeting VEGF in the treatment-naïve setting. However, some patients clearly demonstrate mTOR-dependent disease. It is critical that new biomarkers are identified to optimize patient selection for mTOR-targeting therapeutics. One such potential marker, the mTOR autophosphorylation site, S2481, is a direct readout of mTOR activation. The objective of this pilot study was to analyze the levels of phospho-S2481 in different RCC subtypes. **Methods:** Utilizing standard immunohistochemistry methods, archived, formalin-fixed paraffin-embedded primary tumor samples from an existing tissue microarray of patients with clear cell (cc, n=203), chromophobe (n=21) and papillary RCC (n=38) were stained for the presence of phospho-S2481. Samples from transitional cell carcinoma cases (n=38) were included as a control. Mean scores from the four cancer subtypes were calculated, and the Kruskal-Wallis test was applied to demonstrate the statistical relevance of the mean scores. Covariates such as stage, grade, age, and tumor size were analyzed by logistic regression. **Results:** ccRCC patients were most likely to have high levels of phospho-S2481 staining (mean=2.08), while the TCC controls had the lowest amount (mean=1.11), with papillary and chromophobe falling in between (mean=1.41 and 1.38 respectively). The mean score difference among the four cancer subtypes was highly significant (Chi-square statistic: 54.51, p $<$.0001). Tumor size and cancer subtype were highly correlated with the score (p$<$.01). Comparison of the odds ratios for the three RCC subtypes demonstrated that ccRCC cases were three times more likely to have high levels of phospho-S2481 and four times more likely than papillary RCC (p$<$.05). **Conclusions:** Phospho-S2481 may have the ability to classify RCC patients of different subtypes. Exploration of phospho-S2481's ability to predict patient response to mTOR inhibitors is under way.

**4572 General Poster Session (Board #140), Mon, 1:15 PM-5:00 PM**

**Comprehensive functional kinase profiling to classify clear cell (cc)-renal cell carcinoma (RCC).** *Presenting Author: Amitkumar N. Mehta, The University of Alabama at Birmingham, Birmigham, AL*

**Background:** Comprehensive high throughput functional kinase activity in localized cc-RCC tumors may assist in devising a classification system and help identify therapeutic targets. **Methods:** Kinomic profiling of fresh frozen cc-RCC tumor lysates was performed using the PamStation12(PamGene Intl). The protein tyrosine kinome (PTK) and serine/threonine kinome (STK) PamChips were used to measure global kinase activity. Advanced network modeling of altered phospho-peptides was performed using MetaCore (Thompson Reuters) while upstream kinase prediction scoring was based off of phosphonet (www.phosphonet.ca). Patients with localized tumors with minimum clinical follow-up of 18 months (mo) were studied to perform a supervised analysis of kinomics guided by objective tumor recurrence. Unsupervised cluster analyses were performed to classify tumors based on kinomics. **Results:** Tumor was available from 41 pts with localized tumors undergoing surgery and a minimum follow-up of 18 mo. The median age was 61 and baseline pathologic stage was 1, 2, 3 and 4 in 19, 1, 20 and 1 patients, respectively. Unsupervised clustering analyses showed 3 major kinomic groups A, B, C. Potential driver kinases implicated include PFTAIRE (PFTK1), PKG1 and SRC, which were identified in groups A, B, and C, respectively. Network modeling of these kinase groupings identified many Process Mappings including, but not limited to Inflammation pathways (A), translation initiation (B) and immune response and cell adhesion pathways(C).Five of the 9 patients who progressed were classified as Group C, 1 progressor was in Group B, and 3 were in Group A. Supervised analysis showed decreased CDK1, RSK1-4, ERK1-2, PKG2 and AKT2 kinase activity in those who progressed. Twelve tumors exhibited increased PIM1 and MAPKAPK3, and decreased JNK2 and CDK1 compared to normal. **Conclusions:** Comprehensive kinase profiling of cc-RCC tumors from patients with localized disease was used to classify tumors based on an unsupervised clustering, which appeared to confer differential long-term outcomes while supervised analysis also identified potential pathways related to outcome. Significant heterogeneity of kinases was found with no single dominant kinase.

**4573 General Poster Session (Board #141), Mon, 1:15 PM-5:00 PM**

**Pre-existing hypertension is an independent prognostic factor in metastatic renal cell carcinoma (mRCC) patients treated with sunitinib (SU).** *Presenting Author: Lisa Derosa, Department of Medical Oncology, Institut Gustave Roussy, Villejuif, France*

**Background:** Hypertension (HTN), one of the most frequent side effects of VEGF inhibitors, has been related with outcome in mRCC. We aimed to investigate the prognostic value of history of pre-existing HTN (HTN-PRE) and pre-existing medications with angiotensin system inhibitors (ASI-PRE). **Methods:** mRCC patients (pts) treated with SU as first line therapy at Gustave Roussy from April 2004 to January 2014 with available data about HTN-PRE and pre-existing concomitant medications were included. Overall survival (OS) and progression free-survival (PFS) were compared with the log rank test and hazard ratios (HR) and 95% confidence interval (CI) estimated through a multivariable Cox model adjusted on age, gender, histology and IMDC prognostic groups. **Results:** 213 pts with a 44 (95%CI=31-60) months median follow-up received SU as first line treatment. Most pts were male (78%), 59 years median age (28-86), had clear-cell histology (87%) and intermediate IMDC risk (61%). 84 pts (39%) had HTN-PRE including 54 (64%) receiving ASI-PRE. Pts with HTN-PRE received ASI-PRE more often than pts without (64% vs 6%, p<0.001). The total number of deaths and PFS events was 59% and 85%. Pts with HTN-PRE had a longer OS (median: 32 vs 23 months, p=0.03) and longer PFS (median: 12 vs 9 months, p<0.02) with respectively HR of 0.59 [0.39-0.89], p=0.01 for OS and HR of 0.66 [0.48-0.91], p=0.01 for PFS. In HTN-PRE subgroup, pts with ASI-PRE had a better OS but similar PFS than pts without ASI-PRE with HR of 0.45 [0.23-0.89], p=0.02 and HR of 0.72 [0.41-1.26], p=0.24, respectively. **Conclusions:** HTN-PRE is an independent prognostic factor in pts with mRCC treated with SU. The mechanism of action of ASI in SU treated pts deserves further evaluation.

**4574 General Poster Session (Board #142), Mon, 1:15 PM-5:00 PM**

**Association of CpG island methylator phenotype with clear-cell renal cell carcinoma aggressiveness.** *Presenting Author: Gabriel Malouf, Department of Medical Oncology, Groupe Hospitalier Pitié-Salpêtrière, University Pierre and Marie Curie (Paris VI), Institut Universitaire de cancérologie, AP-HP, Paris, France*

**Background:** The key roles of epigenetic dysregulation of chromatin remodeling genes in clear-cell renal cell carcinoma (ccRCC) have been recently discovered through exome-sequencing which showed frequent mutations of PBRM1, SETD2 and UTX genes. However, the contribution and the prognosis impact of DNA methylation aberrations in ccRCC remain limited. **Methods:** We herein analyzed DNA methylation of 298 primary ccRCC samples, fully annotated for clinico-pathological features and profiled by the cancer genome atlas (TCGA) project using infinium 450K arrays. Furthermore, we established DNA methylation subtypes based on distinct signatures, and correlated them with clinico-pathological tumor features and copy-number alterations. **Results:** Unsupervised hierarchical clustering based on DNA methylation of promoters located in CpG islands (CGI) revealed three clusters of ccRCC. Cluster C1 (n=65) displays a CpG island methylator phenotype (CIMP+), while cluster C2 (n=53) and C3 (n=153) correspond to CIMP-low and CIMP negative subgroups, respectively. Tumors belonging to CIMP+ subgroup were more aggressive with higher pathological Fuhrman grade (p<0.00001), higher TNM stage (p<0.0001) and poorest overall survival (p=5.4e-9). After adjusting for classical clinico-pathological prognostic factors using multivariate analysis, CIMP+ was not found to be independently associated with poor overall survival, suggesting that aberration DNA methylation might be acquired during tumor progression. Integration of DNA methylation with copy-number changes identified frequent gain of chr8q24.22 (p=0.0007) in CIMP+ subgroup, as well as losses of 9p23 (p=5.7E-09) and 9p21.3 (p=4.6E-07) regions. GSEA analysis reveals that promoters that gain DNA methylation in CIMP+ tumors were enriched for polycomb targets, and this was consistent with EZH2 increase (Fold change=1.5; p=0.05). **Conclusions:** Our study defines a novel genetically distinct CIMP subgroup in ccRCC associated with ccRCC aggressiveness and patient outcome. Furthermore, it provides evidence about the involvement of polycomb deregulation in ccRCC progression.

**4575 General Poster Session (Board #143), Mon, 1:15 PM-5:00 PM**

**105 cases of renal tumors in patients age 15 to 35: A specific entity? Experience of the Gustave Roussy Institute.** *Presenting Author: Charles Dariane, Gustave Roussy Institute, Villejuif, France*

**Background:** To describe the specific features of malignant renal tumors occurring in young adults. **Methods:** Medical charts of all 15-35 yo pts diagnosed with a primary renal malignant tumor from1990 to date and treated at Gustave Roussy were retrieved. **Results:** Overall, 105 pts were analyzed with a median follow up of 21.1 months (IQR 5.53-47.2). First pathological entity was Renal Cell Carcinoma (RCC) (n= 89) and second one was nephroblastoma (n=9). Median age at diagnosis was 28.7(24-32) : 31.1 (27.8-33.6) for RCC and 23.6 (22.2-25.8) for nephroblastoma. Only 24% pts underwent a tumor biopsy as first procedure while others had nephrectomy or tumorectomy front line. Among nephroblastoma, only 2 had first biopsy and received neo-adjuvant chemotherapy. Four had synchronous metastasis, 3 remained localized and received adjuvant chemotherapy and 2 developed peritoneal immediate recurrence after surgery requiring additional chemotherapy and radiation therapy. Regarding ccRCC (37pts), 87% of pts presented with symptoms; 76% presented metastasis at diagnosis or during follow up. Prognosis groups of mRCC (83pts), according to IMDC, were good/intermediate and poor in 44/34/5 respectively. One out of 9 pts with nephroblastoma has died. **Conclusions:** We report a large cohort of 15-35 yo patients with malignant renal tumors, highlighting (i) the issue of highly aggressive RCC disease in young adults and (ii) the challenge of differential diagnosis of nephroblastoma. Interestingly, nephroblastoma were diagnosed in pts aged up to 31 and diagnosis procedure did not comply with required pediatric guidelines. This report suggests the need of standardized guidelines in young adult renal tumors management.

**The impact of body mass index (BMI) on treatment outcome of targeted therapy in metastatic renal cell carcinoma (mRCC): Results from the International Metastatic Renal Cell Cancer Database Consortium.** *Presenting Author: Laurence Albiges, Dana-Farber Cancer Center Institute, Boston, MA*

**Background:** Obesity increases risk for RCC, yet recent report suggest that tumors developing in an obesogenic environment may be more indolent. We investigated the effect of BMI on treatment outcome in patients (pts) treated with targeted therapy (TT) for mRCC. **Methods:** Baseline characteristics and outcomes on 1975 pts from 19 centers of the IMDC were analyzed to study the impact of BMI on survival and treatment outcome of first and second line TT. Toxicity profile in relation to BMI was also assessed. **Results:** Median follow-up was 21.1 months. Median time to treatment failure on first-line TT was 7.2 months and median overall survival (mOS) was 21.5 months [95%CI: 20.1-23.3]. At therapy initiation, 785(40%) pts were considered underweight or normal weight (BMI<25 kg/m$^2$), 663(33.5%) overweight (BMI 25-<30 kg/m$^2$) and 527 (26.5%) obese (BMI≥30 kg/m$^2$). Overweight/obese pts had a longer mOS (25.6 vs. 17.1 months) than underweight/normal weight pts (p<0.0001). After adjusting for the IMDC prognostic risk factors, the mOS difference persisted in favor of the overweight/obese pts group (HR=0.84, (95%CI: 0.73-0.95), p=0.008). In addition, pts with higher BMI indices (overweight/obese) had improved time on therapy in both first-line (8.1 vs. 5.7 months, p<0.0001) and second-line (4.2 vs. 3.0 months, p=0.0006), and the difference remained after adjustment for the IMDC prognostic risk factors (p<0.01). Estimates of the cumulative incidence of treatment failure because of toxicity did not differ between the underweight/normal and overweight/obese groups (p=0.936), but the cumulative incidence of treatment failure because of progression/death favored the overweight/obese group after adjustment for the IMDC risk groups (p<0.002). **Conclusions:** We found that being overweight or obese is independently associated with an improved outcome in mRCC pts treated with TT. Increased toxicity was ruled out as a potential bias for treatment discontinuation or dose reduction in normal/underweight pts. Biological investigation in tissues collected from the IMDC cohort is in process to better characterize the obesity paradox in mRCC.

**4577 General Poster Session (Board #145), Mon, 1:15 PM-5:00 PM**

**Correlation of stable disease (SD) as best response with survival outcomes in patients (pts) with clear cell (cc) metastatic renal cell carcinoma (mRCC) treated with high-dose interleukin-2 (HD IL-2).** *Presenting Author: Joseph Merriman, University of Utah Huntsman Cancer Institute, Salt Lake City, UT*

**Background:** HD IL-2 is a standard of care for selected pts with mRCC. Generally objective responses (OR), i.e. complete response (CR) + partial response (PR), of 16-20% are discussed with pts, and not SD. Recent data suggest that cancer immunotherapy may improve survival without inducing OR. Thus, HD IL-2 may provide survival benefit to an additional group of pts not experiencing OR, but only SD as the best response. **Methods:** All sequential cc mRCC pts treated with HD IL-2 at the University of Utah (1988-2012) were included. Two practitioners independently assessed responses. Best responses were correlated with survival outcomes using Kaplan-Meier analysis. **Results:** A total of 176 pts (79% male; median age 55 yrs, range 13-76) were included and belonged to the following MSKCC risk categories: 51 (29%) good, 115 (65%) intermediate, and 10 (6%) poor. A CR was identified in 16 (9%), PR in 11 (6%), SD in 52 (30%), progressive disease (PD) in 68 (39%), and not evaluable for response (NE) in 29 (16%) pts. Median overall survival (OS) by risk category for the favorable, intermediate and poor groups was 47.6 ($p=0.0005$ vs intermediate), 18.0 ($p<0.0001$ vs poor), and 5.4 ($p<0.0001$ vs favorable) months (mo), respectively. Table shows correlation of best response with survival outcomes. **Conclusions:** A clinical benefit of HD IL-2 wasachieved in nearly half of all cc mRCC pts. SD was associated with clinically relevant survival outcomes. There was no statistical difference in outcomes between pts achieving a PR or SD. SD is an important response criterion for treatment with HD IL-2, and may be discussed with pts.

**Correlation of best responses with survival outcomes in mRCC pts treated with HD IL-2 .**

| | PFS, mos | OS, mos |
|---|---|---|
| **Overall** | 5.6 | 19.9 |
| **CR vs PR** | 113.8 vs 14.8 (HR 0.34, CI 0.12-0.95) | 182.0 vs 37.8 (HR 0.23, CI 0.06-0.74) |
| **CR vs SD** | 113.8 vs 11.0 (HR 0.22, CI 0.09-0.47) | 182.0 vs 29.2 (HR 0.16, CI 0.04-0.41) |
| **SD vs (PD and NE)** | 11.0 vs 2.6 (HR 0.40, CI 0.28-0.58) | 29.2 vs 9.7 (HR 0.42, CI 0.28-0.61) |

**4578 General Poster Session (Board #146), Mon, 1:15 PM-5:00 PM**

**Comparison of stem cell signaling pathways in long-term responders (LR) versus primary refractory (PR) patients with metastatic clear-cell renal cell carcinoma (ccRCC) under sunitinib (SU) treatment (SULONG study).** *Presenting Author: Javier Puente, Hospital Clinico Universitario San Carlos, Madrid, Spain*

**Background:** Deregulation of stem cell signaling pathways, such as Notch and Sonic Hedgehog (SHH) seems necessary for tumor initiation, maintenance and progression. Preclinical evidence supports that they may play an oncogenic or tumor suppressor role depending on the tumor type. **Methods:** Retrospective, observational and multicenter study of patients (pts) treated with SU under clinical practice aimed to compare clinical and molecular characteristics in two groups of pts: Metastatic ccRCC pts who achieved progression free survival ≥ 22 months (LR), and pts who showed progressive disease at first radiological evaluation (PR). Tumour expression of different Notch (Jagged-1, Notch-1, nuclear N1ICD) and SHH (SFU-SHH suppressor and GLI-1) signalling components was evaluated by immunohistochemistry and correlated with treatment outcome. This study was approved by the Regulatory Authorities. **Results:** From a total of 123 pts, 97 were identified as LR and 26 as PR. Pts with higher Fuhrman grade, metastasis at diagnosis, shorter time from primary to metastatic diagnosis, no nephrectomy and brain, lung and hepatic metastasis were significantly higher in the PR cohort. So far, 47 tumor samples have been analyzed, 36 of LR and 15 of PR. Expression of Jagged-1 ($p<0.001$) and SFU ($p<0.001$) was significantly correlated with PR; as well as the join expression of Jagged-1/Notch-1+ and Jagged-1/N1ICD+ ($p<0.001$) confirming the activation of the pathway in this group. Jagged-1 expression was also significantly correlated to Furhman G4 ($p<0.05$) in the PR group, metastasis at diagnosis ($p<0.001$) in LR and poor risk group by Heng's criteria ($p<0.05$) in the overall population. The ongoing molecular analysis of the remaining tumour samples and their correlation with PFS and OS in the LR group is warranted to confirm their predictive value under SU treatment. **Conclusions:** These preliminary results suggest that Notch signaling activation predicts poor outcome in metastatic ccRCC. By contrast, SHH seems to be activated in the LR group suggesting an opposite role for both pathways in this tumor.

**4579 General Poster Session (Board #147), Mon, 1:15 PM-5:00 PM**

**Molecular subtypes of clear cell renal cell carcinoma: Impact of diabetes mellitus, metformin, and immunotherapy on patient outcomes.** *Presenting Author: Scott Mattox Haake, Medical Oncology Fellowship, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** A 34-gene subtype classifier was previously developed to define clear cell renal cell carcinoma (ccRCC) tumors as either clear cell A (ccA) or B (ccB). The objective of this study was to investigate clinical factors and immunotherapies in the context of these subtypes. **Methods:** In this retrospective analysis, the Total Cancer Care (TCC) database at Moffitt Cancer Center was queried and 255 patients with ccRCC were identified with primary tumor gene expression analyses. The TCC database and medical record were queried to define patient characteristics, treatments, and outcomes. **Results:** The classifier identified tumors as ccA (206) and ccB (49). Prognostic outcomes including overall survival (OS) in all patients ($p<0.01$), stage IV patients ($p=0.01$), and recurrence free survival ($p<0.01$) were confirmed. The superior prognostic group, ccA, had higher BMI (29.7 vs. 27.8 kg/m$^2$, $p=0.03$). There was a trend towards a higher rate of DM2 in ccA patients (26% vs. 12%, $p=0.058$). Thus, we analyzed the impact of metformin on survival in ccA patients. The nondiabetic ccA patients had a similar outcome to diabetic ccA patients treated with metformin but diabetic ccA patients not treated with metformin had decreased survival ($p=0.02$). For the 37 stage IV patients treated with cytoreductive nephrectomy (CRN), ccA patients demonstrated superior OS (median survival 39 vs. 15 months, $p=0.02$) and remained significant in multivariate analysis that included age, gender, nuclear grade, and tumor size. Among 12 patients treated with interleukin-2 (IL2), the six ccA patients had a nonsignificant ($p=0.12$) better outcome. **Conclusions:** The ccA patients have a higher BMI and a trend towards higher frequency of DM2. When compared to nondiabetic ccA patients, ccA diabetic patients have decreased survival that is improved in those treated with metformin. The ccB patients have a worse prognosis and decreased survival when treated with CRN or IL2. Overall, ccA and ccB patients represent distinct populations that may have differential responses to therapies.

**4580 General Poster Session (Board #148), Mon, 1:15 PM-5:00 PM**

**Association of hand-foot syndrome (HFS), treatment dose reductions (TDRs), and outcomes in patients (pts) with metastatic renal cell carcinoma (mRCC) treated with vascular endothelial growth factor (VEGF) tyrosine kinase inhibitors (TKIs).** *Presenting Author: Erin B. Bailey, University of Utah Huntsman Cancer Institute, Salt Lake City, UT*

**Background:** HFS is a common toxicity of VEGF TKIs, often requiring TDRs. Correlation between HFS, in the context of TDRs, with survival outcomes has not been reported in mRCC. **Methods:** From a single-institutional database (2004-2013), incidence of HFS and TDRs (for any reason) in mRCC pts receiving VEGF TKIs were recorded and correlated with survival outcomes. Univariate and multivariate analyses were performed using Kaplan-Meier method and COX Proportional Hazard model. **Results:** Of 123 pts (median age 60 yrs, males 71%), the majority had clear cell histology (71.5%) and were in the MSKCC (71%) and Heng (55%) intermediate-risk groups. Pts received the following TKIs: sunitinib (77.2%), sorafenib (14.6%), pazopanib (7.3%), and axitinib (0.8%). HFS (G1 20.3%, G2 8.9%, G3 9.8%) occurred in 39% of pts. The most common reasons for TDRs were mucositis (38.8%), HFS (29.9%), and fatigue (17.9%). The median progression free survival (PFS) and overall survival (OS) were significantly longer in pts with HFS (Table). The median OS was improved in those who had TDRs for HFS as compared with those who had TDRs for other reasons (Table). Two multivariate analyses were conducted. The first included age, sex, HFS, TSH > 10 mIU/L while on VEGF TKI, and risk criteria. HFS remained significant for improvements in PFS and OS (PFS: HR 0.38, CI 0.19-0.76, $p=0.0060$; OS: HR 0.37, CI 0.15-0.83, $p=0.0157$). In the second multivariate analysis, development of HFS was substituted for TDRs for HFS and it was not an independent predictor of survival (PFS: HR 0.58, CI 0.25-1.23, $p=0.1601$; OS: HR 0.46, CI 0.16-1.14, $p=0.0981$). **Conclusions:** HFS in mRCC pts treated with VEGF TKIs predicts improved survival despite TDRs. Thus, VEGF TKI dose reductions for the management of HFS are not expected to negatively impact survival outcomes.

**Outcomes with HFS and TDRs.**

| | n | PFS, months | OS, months |
|---|---|---|---|
| **HFS vs no HFS** | 123 | 14.1 vs 6 (HR 0.51, CI 0.32-0.79, p=0.0021) | 42.8 vs 10.8 (HR 0.39, CI 0.23-0.63, p<0.0001) |
| **TDRs for HFS vs TDRs for other reasons** | 67 | 21.9 vs 8.5 (HR 0.55, CI 0.28-1.02, p=0.0582) | 45.1 vs 13.9 (HR 0.37, CI 0.16-0.76, p=0.0061) |

**4581 General Poster Session (Board #149), Mon, 1:15 PM-5:00 PM**

**Q-TWiST analysis of patients with metastatic renal cell carcinoma (mRCC) randomized to pazopanib (PAZ) or sunitinib (SUN).** *Presenting Author: Jennifer L Beaumont, Northwestern University Feinberg School of Medicine, Chicago, IL*

**Background:** In a phase 3, randomized, open-label trial (NCT00720941), PAZ demonstrated non-inferiority for progression-free survival vs SUN in mRCC patients with no prior therapy (NEJM 2013; 369: 722). Overall treatment differences were evaluated in a post-hoc analysis using the quality-adjusted time without symptoms of progression or toxicity of treatment (Q-TWiST). **Methods:** Each patient's overall survival (OS) was partitioned into 3 health states: grade 3 or 4 toxicity (TOX), time without symptoms of progression or toxicity (TWiST), and time after progression or relapse (REL). The time spent in each state was then weighted by a health-state utility associated with that state and summed to calculate the Q-TWiST. A threshold utility analysis was used, applying utilities across the range of 0 (similar to death) to 1 (perfect health). **Results:** A total of 1,110 patients were enrolled (557 PAZ, 553 SUN). The mean number of days spent with TOX was 31 days (95% CI: 13, 49) higher for SUN compared to PAZ. In the threshold utility analysis the difference in Q-TWiST ranged from 3 days (utility TOX=1, REL=0) to 38 days (TOX=0, REL=1), always in favor of PAZ across all analyses. Differences were statistically significant in roughly half of the utility combinations examined, typically when the utility for TOX was ≤ the utility weight for REL. A subset of these results are in the Table. For instance, when TOX is weighted at 0.75 relative to TWiST and REL is weighted somewhat worse than TOX at 0.50, the Q-TWiST difference between arms is 13 days (95% CI: –7, 32), in favor of PAZ. **Conclusions:** Patients randomized to PAZ had slightly longer Q-TWiST compared to SUN patients, primarily due to a reduced length of time spent with grade 3/4 toxicities. This difference (3 to 38 days, depending on utility combination) is less than 10% of OS (median: 28 months).

| Utility weights | | | PAZ vs SUN Q-TWiST difference, days (95% CI) |
|---|---|---|---|
| TOX | TWiST | REL | |

**4582 General Poster Session (Board #150), Mon, 1:15 PM-5:00 PM**

**Osteopontin (OPN), TIMP-1, and interleukin (IL)-6 as prognostic (prog) for overall survival (OS) and independent from clinical criteria in patients (pts) with metastatic renal cell carcinoma (mRCC).** *Presenting Author: Amado J. Zurita, MD Anderson Cancer Center, Houston, TX*

**Background:** No biomarker has been incorporated into clinically based prog algorithms for mRCC. In previous work in pts with ECOG PS ≤1 treated in a randomized placebo-controlled phase III trial of pazopanib (paz, veg105192), we identified for progression-free survival (PFS), IL-6 as predictive (pred) of paz benefit (Tran, Lancet 2012) and OPN and IL-6 as prog, independent of established criteria (Zurita, ESMO 2012). Here, we evaluate cytokines and angiogenic factors (CAFs) relative to clinical prog variables (varbs) for OS. **Methods:** Seven baseline plasma CAFs (IL-6, IL-8, OPN, VEGF, HGF, TIMP1, E-Selectin) were measured (Searchlight, Aushon), and 10 prognosis varbs (ECOG PS, time from diagnosis to treatment [TDT], hemoglobin, calcium, neutrophils, platelets, LDH, sum of the longest diameters [SLD], bone metastasis (meta), and number of meta sites) were correlated with OS ($n$=343: n=225 paz/n=118 placebo [plb]; $n$=310 including TDT: n=202 paz/n=108 plb) using uni- and multivariable Cox (multiCox) proportional hazard and stepwise models (stm) based on the randomization assignment. **Results:** Median OS for all pts was 22.7 months (mo) (95% CI 20.2-25.5), 22.9 mo (95% CI 20.2-25.4) for those treated with paz and 20.9 mo (95% CI 15.6-28.8) for plb. Neutrophilia (NEUT), anemia, high LDH, PS 1 ($v$0) and SLD (plus TDT instead of LDH in $n$=310) were significantly associated with poor prognosis in multiCox regression and stm that only considered clinical criteria (and treatment as a variable). When the 7 CAFs were incorporated into the stm, OPN, TIMP-1 and IL-6 were identified as independently prog [Table, $n$=343, minus IL-6 and treatment in $n$=310]. **Conclusions:** Circulating OPN, TIMP-1 and IL-6 are prog for OS independent of established clinical criteria in mRCC pts with good PS. These CAFs should be incorporated into prog and pred models for validation in mRCC trials.

**4583 General Poster Session (Board #151), Mon, 1:15 PM-5:00 PM**

**The effect of *SETD2* mutation (mts) on histone 3 lysine 36 tri-methylation (H3K36me3) and correlation with clinical outcome in patients (pts) with metastatic clear cell renal cell carcinoma (ccRCC) enrolled in COMPARZ.** *Presenting Author: Thai Huu Ho, Mayo Clinic Arizona, Scottsdale, AZ*

**Background:** Systematic sequencing studies of ccRCC identified loss of function mts in histone modifying enzymes such as *SETD2 (15%)*. *A*ll *SETD2* mts identified in pts disrupt expression of the SET domain, a conserved motif responsible for H3K36 tri-methyltransferase activity. In this study, we hypothesized that *SETD2*mts are associated with decreased H3K36me3 in ccRCC and we also investigate this association in relation with clinical outcome. **Methods:** Tumor samples were collected from consented subjects enrolled in a phase III trial of pazopanib vs. sunitinib (Motzer, NEJM 2013). Immunohistochemistry (IHC) for H3K36me3 was optimized with corresponding isotype controls. The Aperio platform was used to scan the slides for analysis of nuclear H3K36me3 levels using the CellMap image algorithm by Flagship Biosciences on 46 subjects with known *SETD2* gene status by next generation sequencing. H3K36me3 signal was scored according to an H-score. **Results:** IHC shows a decrease in H3K36me3 staining in the tumor cells of SETD2 mutant (insertion/Deletion/Stop) while adjacent matched uninvolved kidney tissue retains H3K36me3 expression. Some SETD2 wild-type tumors also had decreased H3K36me3 staining, while the majority of these tumors displayed relatively robust, uniform staining for H3K36me3. Using an H-score cutoff of H≤29 (n=24) or >29 (n=22), we also observed significant differences in overall survival between patients with higher and lower H3K36me3 staining regardless of SETD2 mutation status (P=0.0454, Log-Rank). **Conclusions:** Loss of function *SETD2* mts are associated with decreased H3K36me3 IHC. Loss of H3K36me3 staining in SETD2 wild-type RCC may reflect tumor heterogeneity or other post-translational mechanisms that promote dysregulation of SETD2 methyltransferase activity. Future studies will also examine the correlation of H3K36me3 with treatment response to contemporary therapy.

**4584 General Poster Session (Board #152), Mon, 1:15 PM-5:00 PM**

**Impact of angiotensin system inhibitors (ASI) on outcome in sunitinib (SU)-treated patients for metastatic renal cell carcinoma (mRCC): Gustave Roussy experience.** *Presenting Author: Lisa Derosa, Department of Medical Oncology, Institut Gustave Roussy, Villejuif, France*

**Background:** ASIs are widely used for hypertension (HTN) and proteinuria. Limited data for their anti-angiogenic effect exists in combinations with targeted therapy. We aimed to evaluate the role of ASI on outcome in mRCC. **Methods:** Patients (pts) treated with SU as first line at Gustave Roussy from 04/04 to 11/13 with available data about the use of ASI before, or during treatment (defined as during first month) were included. Overall survival (OS) and progression free-survival (PFS) were compared with log-rank test and hazard ratios (HR) and 95% confidence interval (CI) through a multivariable Cox model adjusted on age, gender, histology, IMDC risk groups and history of HTN. **Results:** N=213 pts with a 44 month median follow-up received SU as first line. Median age was 59, most pts were male (78%), with clear-cell histology (86%), intermediate IMDC risk group (61%). N=102 (48%) pts were ASI-users either before SU (n=61, 29%) or during SU (n= 41, 19%). ASI use was associated with improved OS and PFS when compared to ASI nonuser pts. Among ASI users, OS and PFS were not significantly different. **Conclusions:** Use of ASI in mRCC pts receiving SU significantly improves outcome (PFS and OS). There is no difference between pts who receive ASI before starting SU or those who received ASI within one month of SU.

**ASI users compared to nonusers.**

| | OS median (months) | PFS median (months) |
|---|---|---|
| **ASI nonusers (n=109)** | 18 [12, 23] | 7 [5, 8] |
| **ASI users (n=102)** | 44 [30, 55] | 15 [12, 17] |
| **Log rank test** | p<0.0001 | p<0.0001 |
| **HR user / non user [95%CI]** | 0.32 [0.21, 0.49] | 0.45 [0.32, 0.63] |
| **ASI users (n=102)** | | |
| **ASI users during SU only (n=41)** | 51 [38, 92] | 15 [10, 20] |
| **ASI users before SU (n=61)** | 37 [27,55] | 15 [11, 17] |
| **Log rank test** | p=0.30 | p=0.41 |
| **HR user / non user [95%CI]** | 0.91 [0.39, 2.11] | 1.12 [0.62, 2.02] |

**PD-L1 expression in primary clear cell renal cell carcinomas (ccRCCs) and their metastases.** *Presenting Author: Marcella Callea, Brigham and Women's Hospital, Boston, MA*

**Background:** Clinical trials evaluating anti-PD-1 and anti-PD-L1 antibodies (Abs) in ccRCC have shown tumor responses in a subset of patients. Tumor PD-L1 expression increases the likelihood of benefit with anti-PD-1 Ab, but fails to identify all responders. One explanation for these results is that predictive biomarkers are usually evaluated in the primary tumors, which may not accurately reflect expression in the metastases (mets) that are targeted by therapy. In this study, we compared PD-L1 expression in a series of ccRCCs and their mets. **Methods:** Paraffin tissue blocks from 33 primary ccRCCs and corresponding lymph node or distant mets (excisional biopsies) were retrieved. Multiple areas of the primary tumors (e.g. areas of predominant and highest Fuhrman nuclear grade (FNG)) were selected for analysis. Slides were immunostained with a validated mouse monoclonal anti-PD-L1 Ab (405.9A11). Membranous expression in tumor cells was quantified using an H-score. A case was considered positive when any tumor cell positivity was detected. For expression in intratumoral immune cells, a combined score based on the extent of inflammatory infiltrate and percentage of positive cells was used. **Results:** PD-L1 expression in tumor cells of primary tumors and their mets is summarized in Table 1. The pattern of PD-L1 staining was highly heterogeneous in the primary tumors and was restricted to areas of highest FNG. The staining was more homogeneous in the mets. In 12/33 (36%) cases with positive primary tumors and/or mets, PD-L1 expression in tumor cells tended to be higher in the mets (median average H-score=4.5) compared to the primary tumors (median average H-score=1.3) (p=0.13). No significant difference was found in PD-L1 expression in immune cells between primary tumors and their mets (p>0.5). **Conclusions:** Discordant expression of PD-L1 between the primary tumor and their mets was detected in 5/33 (15%) of cases suggesting that accurate assessment of predictive biomarkers for PD-1 blockade in ccRCC may require analysis of multiple areas of primary tumors and/or mets. Analysis of a larger patient cohort is ongoing to confirm these findings.

| | | Metastases | | Total |
|---|---|---|---|---|

**4586 General Poster Session (Board #154), Mon, 1:15 PM-5:00 PM**

**Molecular characterization of renal medullary carcinoma (RMC).** *Presenting Author: Jianjun Gao, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** RMC is a rare and highly aggressive malignancy that affects primarily young individuals with sickle cell trait. RMC usually presents at advanced stages and is universally fatal with a median survival of <12 months despite chemotherapy and targeted therapy. Molecular insights of RMC are needed for identification of potential therapeutic targets. **Methods:** We performed whole-exome sequencing using the Illumina platform on RMC tumor tissues from 11 patients for somatic mutational analysis. We also performed Affymetrix microarray and Ingenuity pathway analyses to identify genes that are differentially expressed. In addition, reverse phase protein arrays (RPPA) were carried out to identify differentially expressed proteins. Molecular changes were compared and correlated at DNA, RNA, and protein levels to identify genes and signaling pathways that may play important roles in RMC pathogenesis and serve as potential therapeutic targets in RMC. **Results:** Exome sequencing identified 981 genes that were mutated in 1 tumor; 87 genes mutated in 2 tumors; 10 genes mutated in 3 tumors; 1 gene mutated in 4 tumors; 4 genes mutated in 5 tumors; and 1 gene mutated in 6 tumors. Microarray analysis indicated mRNA expression levels of a total of 2166 genes were changed ≥ 2 fold with p-value <0.05 in RMC tumors. RPPA data showed that protein expression levels of a total of 60 genes were changed ≥1.4 fold with p<0.05. Further correlation analyses demonstrated genes involved in signaling pathways such as PI3 kinase (PIK3C2G), cell cycle control (CDC25D and CDC73), and histone synthesis (HIST2H3D) are significantly changed at DNA, mRNA, and protein levels. **Conclusions:** Our data suggest that genes in at least 3 signaling pathways may be important for RMC pathogenesis and may have therapeutic relevance for future targeting.

**4587 General Poster Session (Board #155), Mon, 1:15 PM-5:00 PM**

**Impact of perioperative chemotherapy on survival in patients with advanced primary urethral cancer: Results of the international collaboration on primary urethral carcinoma.** *Presenting Author: Georgios Gakis, Department of Urology, University of Tuebingen, Tuebingen, Germany*

**Background:** The present analysis aims to investigate the prognostic benefit of perioperative chemotherapy in patients undergoing surgery for primary urethral carcinoma. **Methods:** A total of 124 patients (86 men, 38 women) who were diagnosed with primary urethral carcinoma in ten tertiary international academic centers between 1993 and 2012, underwent surgery for primary treatment. Platinum-based neoadjuvant and adjuvant chemotherapy was administered in 18 (15%) and 21 (17%) patients, respectively. Kaplan-Meier analysis with log-rank testing was used to investigate the impact of perioperative chemotherapy on progression-free (PFS) and overall survival (OS). The median follow-up was 20 months (mean: 32 months; IQR: 4-48). **Results:** Median age at surgery was 67 years (IQR: 53-74). Receipt of neoadjuvant chemotherapy was associated with clinically node-positive tumor stage (cN+; p=0.009). Conversely, delivery of adjuvant chemotherapy was associated with locally advanced primary tumors (≥cT3; p=0.003). No further significant associations were found between perioperative chemotherapy and age, gender, tumor location (proximal vs. distal), underlying histology, tumor grade and use of palliative therapy. The 3-year PFS/3-year OS for patients with cN+-stage disease who underwent neoadjuvant chemotherapy was 40%/100%, compared to 0%/29% for no neoadjuvant chemotherapy (p=0.043 and p=0.034, respectively). By contrast, the 3-year PFS/3-year OS for patients with ≥cT3-stage disease who received adjuvant chemotherapy was 23%/46%, versus 20%/53% for no adjuvant chemotherapy (p=0.44 and p=0.20, respectively). The 3-year OS for patients with ≥cT3 and/or cN+ stage disease who received neoadjuvant chemotherapy was 100%, compared to 20% for adjuvant chemotherapy (p=0.031). **Conclusions:** In this series, patients who received neoadjuvant platinum-based chemotherapy for locally advanced primary urethral carcinoma exhibited improved survival compared to those who underwent immediate surgery and adjuvant chemotherapy.

**4588 General Poster Session (Board #156), Mon, 1:15 PM-5:00 PM**

**Phase II study of dovitinib in first line metastatic or (non resectable primary) adrenocortical carcinoma (ACC): SOGUG study 2011-03.** *Presenting Author: Jesús García-Donas, Centro Integral Oncológico Clara Campal, Madrid, Spain*

**Background:** Dovitinib is a novel targeted therapy that inhibits the fibroblast growth factor receptor (FGFR). Preclinical studies have pointed to a major role of this pathway in adrenocortical carcinoma (ACC) thus we aimed to test its clinical activity in this tumor. **Methods:** A phase II proof of concept trial was designed. Based on a two-stage Gehan model 15 patients needed to be included to show a treatment efficacy of at least 15% (probability of Type I error $\alpha = 0.05$, power $[1 - \beta] = 0.8$). Main inclusion criteria was advanced non-resectable ACC, histologically confirmed, with no prior therapy other than mitotane. Primary endpoint was response rate (RR) by RECIST 1.1 centrally assessed. Dovitinib was administered at 500mg daily dose 5 days on 2 days off for 6 months. Continuation of therapy was permitted at physician criteria. A translational substudy looking for biomarkers of efficacy was also scheduled. **Results:** From January 2012 to August 2012, 17 patients (5 male and 12 female) were included. Median age was 53 years (range 26–72); ECOG was 0–1 in 15 patients, 2 in one patient and N/A in one patient. Grade 3–4 adverse events deemed as related to the drug were: rash (6%), asthenia (12%), diarrhea (6%), GGT elevation (18%), nausea (6%),hypertriglyceridemia (6%), hypertension (6%), hyperkalemia (6%). No toxic death was reported. After a median follow-up of 5.2 months (range 2.27–21) one partial response has been observed. Median PFS was 1.8 months (95%CI [1.35–2.25]), however clinical benefit has been achieved in 30% of patients with long lasting stable disease (>6 months) in 23%. One patient remains on dovitinib 21 months after initiating therapy. We sequenced 409 tumor suppressor genes and oncogenes frequently mutated in cancer (Ion AmpliSeq Comprehensive Cancer Panel) in 9 FFPE tumor samples. Putative variants are currently being validated by Sanger sequencing and will presented at the meeting. **Conclusions:** Though primary endpoint was not reached, dovitinib showed activity in a subpopulation of ACC patients. The ongoing molecular identification of such subpopulation will be key in order to prompt further investigation. Clinical trial information: NCT01514526.

**TPS4589 General Poster Session (Board #157A), Mon, 1:15 PM-5:00 PM**

**Pazopanib versus paclitaxel in relapsed urothelial tumors: A randomized phase II study investigating pazopanib versus weekly paclitaxel in relapsed or progressive transitional cell carcinoma of the urothelium (PLUTO).** *Presenting Author: Robert J. Jones, University of Glasgow, Glasgow, United Kingdom*

**Background:** Urothelial cancer (UC) is a chemosensitive disease. There is a clear role for first line, platinum-based chemotherapy in advanced disease, response rates being around 40-50%. However, responses are usually brief and the role of subsequent therapy remains unclear. There are currently no approved second line therapies in North America, although vinflunine is approved in some countries. Nevertheless, a variety of second line therapies are widely used on the basis of modest response rates observed in small, non-randomized phase II trials. In the UK, the most commonly used second line therapy is paclitaxel. Two non-randomized phase II trials with the vascular endothelial growth factor (VEGF) receptor targeted tyrosine kinase inhibitor pazopanib suggest clinical activity in this setting. **Methods:** 140 patients with progressive advanced UC who have failed a single prior line of chemotherapy which must have contained platinum will be randomized to receive either pazopanib 800mg once daily until progression or paclitaxel 80mg/m$^2$ days 1, 8, 15 of a 28 day cycle for up to 24 weeks. The primary endpoint of the study is overall survival. Secondary endpoints include progression free survival, response rate, safety and tolerability. Archival tissue, blood and urine samples will be collected prospectively from patients, in order to explore molecular and genomic predictors of benefit for both drugs. The trial is designed to detect a 50% improvement in overall survival (paclitaxel 8 months; pazopanib 12 months) with power 90% and 1-sided significance level of 20%. If positive, a randomized phase III trial will be required to confirm efficacy of pazopanib in this population. On 1 Feb 2014, 70 patients had been recruited. Clinical trial information: 73030316.

**TPS4590 General Poster Session (Board #157B), Mon, 1:15 PM-5:00 PM**

**A randomized, prospective, phase II study to determine the efficacy of BCG given in combination with panvac versus BCG alone in adults with high grade non-muscle invasive bladder cancer who failed at least one induction course of BCG.** *Presenting Author: Sam Joseph Brancato, National Institutes of Health, Bethesda, MD*

**Background:** High grade non-muscle invasive bladder cancer (NMIBC) has a 70% recurrence rate and rate of 15-30% progression. The standard of care is an induction course of bacillus Calmette-Guerin (BCG). A second induction course can be used in patients who fail the initial course, however only 35% of patients will experience a 12 month disease free survival. For those patients failing a second induction course, radical cystectomy is the gold standard treatment, although the morbidity rate is high. Therefore there is an unmet need for localized treatment for patients who fail an initial induction course of BCG. Recently, a pox viral vector-based vaccine, PANVAC, has been shown to induce a CD4 and CD8 antigen-specific immune response against the tumor-associated antigens, carcinoembryonic antigen (CEA) and mucin-1 (MUC-1). This vaccine also contains transgenes for three human T cell co-stimulatory molecules that can potentially augment an immune response. We hypothesize that the combined administration of BCG and PANVAC may augment the BCG-induced cytotoxic T lymphocyte response against bladder cancer cells expressing MUC-1 and/or CEA and potentially reverse BCG failure. MUC-1 is overexpressed in 93% and CEA is over-expressed in 76% of high grade bladder tumors and therefore PANVAC may enhance BCG response. **Methods:** This is a randomized, prospective Phase II study in subjects with NMIBC who have failed at least one induction course of intravesical BCG. Patients will be randomized to one of the following arms: BCG + PANVAC or BCG alone. All subjects will receive intravesical BCG as per usual standard of care once weekly for a total of 6 weeks. The combination arm will receive the pox viral vaccines (rV-PANVAC and rFPANVAC) that contain the transgenes for CEA and MUC-1 as well as 3 human T-cell costimulatory molecules. We will test the hypothesis that subjects in the BCG + PANVAC arm have a better disease-free survival at 12 months than subjects in the BCG alone arm. Secondary endpoints include disease progression, treatment-related toxicities, and immunologic correlates. Clinical trial information: NCT02015104.

**TPS4591 General Poster Session (Board #158A), Mon, 1:15 PM-5:00 PM**

**A randomized trial comparing two different retention periods of intravesical pirarubicin instillation for intermediate risk non-muscule-invasive bladder cancer after transurethral resection.** *Presenting Author: Yoshiaki Kawano, Department of Urology, Kumamoto University Faculty of Life Sciences, Kumamoto, Japan*

**Background:** Anthracyclines are recommended reagents for one immediate intravesical instillation after transurethral resection (TUR) and additional adjuvant instillation in intermediate risk non-muscule invasive bladder cancer (NMIBC) to reduce the risk of recurrence. Pirarubicin (THP), an anthracycline analogue, is widely used reagent for intravesical instillation chemotherapy. Several studies have showed that THP can rapidly penetrate tumor tissue after intravesical instillation. Therefore long instillation time (e.g. 120 min) may not be required for its prophylactic effect against recurrence since it may reduce the risk of adverse events such as cystitis and hematuria without compromising its efficacy. However, there is no high level evidence regarding optimized intravesical THP instillation time in terms of both toxicity and efficacy. **Methods:** This randomized, prospective, open-label trial intends to enroll 160 pts with primary non-muscle invasive bladder cancer (NMIBC) with intermediate risk based on EORTC criteria. All pts receive initial THP instillation within 24 hr after TUR-Bt followed by weekly repetitive THP instillation for a total of 9 treatments. Pts are randomized into two groups with different intravesical THP retention times, (a) 30 min versus (b) 120 min. Eligibility criteria include pts with pathological diagnosis of urotherial carcinoma, with complete tumor resection by TUR-Bt, and with ECOG-PS 0-2. Exclusion criteria include pts who had previously treated with therapeutic BCG intravesical instillation or prophylactic maintenance intravesical instillation of anti-cancer drug, with coexisting cancer, and with history or coexistence of upper urinary tract urothelial cancer. Follow-up period is 3 years. Primary endpoint is change from baseline in quality of life (assessed by SF36, OABSS and I-PSS), which will be evaluated every 3 months until 2 years after TUR, then half-yearly for another year. Secondary endpoint is recurrence-free survival rates at 1, 2 and 3 years, and safety. Currently 82 pts have enrolled. Clinical trial information: UMIN000006861.

**TPS4592 General Poster Session (Board #158B), Mon, 1:15 PM-5:00 PM**

**Development of a phase 2 study of the aurora kinase-A inhibitor alisertib (MLN8237) in pretreated patients (pts) with urothelial cancer (UC).** *Presenting Author: Andrea Necchi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** Progress in developing new effective therapies in advanced and relapsing urothelial cancer has been stagnant in the last few decades and a paradigm shift is desperately needed. Aurora kinase-A overexpression has been previously described in bladder cancer and spindle checkpoint dysregulation is a common feature of human UC. Alisertib (Millennium Inc.) is an orally available, selective small molecule inhibitor of Aurora A kinase. Single agent and combination treatment of MLN8237 with either paclitaxel (TXL) or gemcitabine synergistically reduced UC cell viability compared with either drug alone. Hence, sequential application of MLN8237 and TXL warrants clinical investigation. Phase 1 trials of both single agent and the combination with TXL defined the recommended doses for phase 2 trials. **Methods:** A multistep approach will be adopted for this Phase 2 trial. A single-group run-in phase will be conducted first with Alisertib 50 mg orally BID for 7 days, followed by 14d rest until disease progression. In case of activity, a confirmatory randomized (1:1) trial of weekly TXL plus either Alisertib or Placebo will follow, incorporating efficacy and futility boundaries for early stopping. In a single-blind design, TXL will be given on days 1,8,15 q4wks at the dose of 60 mg/m2 with alisertib and 80 mg/m2 with placebo. Alisertib dose will be 40 mg BID days 1-3, 8-10 and 15-17, q4wks. In the single-arm phase, primary endpoint (EP) will be RECIST 1.1 response-rate. 20 pts will be accrued, $\geq$3 responses will be required (10% type I and 20% type II error costraints). An accrual of 110 pts is foreseen in the randomized phase. Primary EP: progression-free survival (PFS), assuming an improvement in PFS from a median of 2.5 months ($H_0$) to a median of 4.5 months ($H_1$) (44% hazard rate reduction, 10% drop out rate). Eligibility will include diagnosis of metastatic UC and failure of 1-2 CT regimens (single-arm) or 1 prior CT only (randomized phase). A relapse within 6 months of a peri-operative CT will be counted as 1 line. Computed tomography and PET will be done every 2 cycles (2 months). Additional pharmacodynamic and translational analyses are planned on pre- post- blood and tissue samples. Clinical trial information: 2014-000557-36.

**TPS4593^ General Poster Session (Board #159A), Mon, 1:15 PM-5:00 PM**

**The Borealis-2 clinical trial: A randomized phase 2 study of OGX-427 (apatorsen) plus docetaxel versus docetaxel alone in relapsed/refractory metastatic urothelial cancer.** *Presenting Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Heat shock protein 27 (Hsp27) is over-expressed in many cancers including bladder, lung, prostate, and breast. Increased Hsp27 has been associated with inhibition of chemotherapy-induced apoptosis, increased tumor cytoprotection, and development of treatment resistance. OGX-427 (Apatorsen) is an antisense oligonucleotide designed to bind Hsp27 mRNA, inhibiting production of the Hsp27 protein. Inhibition of Hsp27 has been shown to increase apoptosis, inhibit tumor growth, and sensitize tumor cells to chemotherapy in a variety of malignancies, including urothelial cancer. Results of preclinical and phase 1 studies suggest that addition of apatorsen to chemotherapy is well tolerated and may improve treatment efficacy. Borealis-2 is a randomized, multicenter, phase 2 study of apatorsen in combination with docetaxel (DOC) vs. DOC alone in locally advanced/metastatic bladder cancer patients who received at least one line of prior platinum-based therapy. The primary objective is to evaluate overall survival. Secondary objectives include comparisons of safety and tolerability, disease response, and serum levels of Hsp27 and other pathway-related proteins. Associations between clinical outcomes, levels of Hsp27 and other proteins, and circulating tumor cells will be evaluated. **Methods:** Patients (N=200) are randomized in a 1:1 ratio following stratification (time from prior systemic chemotherapy; Bellmunt criteria). Up to 2 prior systemic therapies are allowed. Treatment-arm patients receive three loading doses of apatorsen (600 mg) followed by up to ten 21-day treatment cycles (apatorsen 600 mg on Days 1, 8, and 15 and DOC 75 mg/M$^2$ IV on Day 1). Control-arm patients receive DOC 75 mg/M$^2$ IV on Day 1 of each cycle. Treatment may continue until disease progression, unacceptable toxicity, completion of ten cycles, or patient withdrawal. Patients who discontinue DOC due to toxicity after ≥2 cycles and do not have disease progression may receive maintenance therapy with apatorsen. One interim futility analysis will be performed. The trial will not be stopped early based on efficacy. Clinical trial information: NCT01780545.

**TPS4594 General Poster Session (Board #159B), Mon, 1:15 PM-5:00 PM**

**Phase II study of fosaprepitant plus 5HT3 receptor antagonists plus dexamethasone in patients with germ cell tumors undergoing 5-day cisplatin-based chemotherapy: Hoosier Oncology Group QL12-153.** *Presenting Author: Costantine Albany, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

**Background:** Germ cell tumors (GCT) account for 1% of malignancies of American males. Cisplatin combination chemotherapy is the cornerstone for curative therapy in metastatic GCT. Cisplatin is administered for 5 consecutive days, and it is appropriately categorized as highly emetogenic chemotherapy (HEC). Clinical and basic research over the past 25 years has led to steady improvements in the control of chemotherapy-induced nausea and vomiting (CINV). All of the guidelines (ASCO, MASCC and NCCN) unanimously suggest a combination of a 5-HT3RA, dexamethasone, and aprepitant for the prevention of acute and delayed CINV with single day HEC. However, there is paucity of studies and no clear guidelines evaluating multiday cisplatin-induced nausea and vomiting compared to single day cisplatin. We have published a randomized double-blind phase III trial testing whether the addition of aprepitant to standard 5HT3RA plus dexamethasone would provide additional protection in this patient population. Aprepitant was given for 5 consecutive days, starting on day 3 of chemotherapy; aprepitant 125mg PO (or matched placebo) was given on day 3, then 80mg PO on days 4-7. The complete response rate (CR) was 42% in the aprepitant arm vs. 13% in the placebo arm ($p<0.0001$), 80% of patients experienced no emetic episodes on days 1-5 on the aprepitant arm vs. just 52% on the placebo arm ($p<0.0001$).(*J Clin Oncol. 2012 Nov 10;30(32):3998-4003. doi: 10.1200/JCO.2011.39.5558.)* **Methods:** The current study is a single arm phase II study to evaluate the efficacy of combining fosaprepitant with a 5HT3RA + dexamethasone. This is the first clinical trial evaluating fosaprepitant in patients receiving multiday cisplatin. The primary objective is the Complete Response (CR) rate (no emetic episodes or use of rescue medications). Secondary objectives are the incidence of vomiting or retching via patient log and the patient's self-reported assessment of nausea Days 1-8 using a 0-100mm visual analog scale (VAS). Clinical trial information: NCT01736917.

**TPS4595^ General Poster Session (Board #160A), Mon, 1:15 PM-5:00 PM**

**ATLAS study: A randomized double-blind phase 3 study of adjuvant axitinib versus placebo in subjects at high risk of recurrent renal cell carcinoma (RCC).** *Presenting Author: Kwon Tae Gyun, Kyungpook National University Medical Center, Daegu, South Korea*

**Background:** Kidney cancer is diagnosed in approximately 270,000 people each year worldwide, and results in 120,000 deaths, with RCC as the most common form. Up to 30% of patients treated by nephrectomy for localized disease will relapse. 5-year survival rates for TNM stage II, III and IV are 65-80%, 40-60% and 0-20%, respectively. RCC is a high VEGF- and PDGF-expressing tumor. Axitinib, an oral, potent and selective inhibitor of vascular endothelial growth factor (VEGF) receptors 1, 2, and 3, is approved for the treatment of advanced RCC after failure of one prior systemic therapy. Preclinical data indicate higher potency and selectivity against the VEGFR family for axitinib compared to some other antiangiogenic agents. This phase 3 study tests the hypothesis that prevention of micro-metastases and tumor growth by anti-VEGF treatment with axitinib can prolong disease free interval after nephrectomy for patients with high risk of recurrent RCC. **Methods:** 692 patients, ECOG PS 0-1, with histologically confirmed preponderant clear cell RCC; treatment naïve and no residual or metastatic disease after nephrectomy will be randomized 1:1 to axitinib or placebo, 5mg PO BID for up to 3 years in a global, randomized, double blind placebo controlled trial. Patient will be stratified according their country and their stage of disease (any Fuhrman grade allowed): 1) pT2, pN0 or pNx, M0; 2) pT3, pN0 or pNx, M0; 3) pT4, pN0 or pNx, M0; or 4) any pT, pN1, M0; and ECOG PS 0-1. Primary objective is disease free survival as assessed by independent review committee. Key secondary objectives are overall survival as well as safety and tolerability of treatment. Efficacy analysis will be performed on the intention-to-treat population. This is a global, multi-center study with sites in Asia, US and Europe. As of January 2014, 167 subjects have been randomized and last patient enrollment is expected at the end of 2014. Clinical trial information: NCT01599754.

**TPS4596 General Poster Session (Board #160B), Mon, 1:15 PM-5:00 PM**

**Phase Ib study of axitinib in combination with crizotinib in patients with advanced solid tumors.** *Presenting Author: Dale Randall Shepard, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

**Background:** Antiangiogenic therapy is proven to be effective in the treatment of multiple advanced solid tumors, including renal cell carcinoma (RCC), colorectal cancer, and non-small cell lung cancer. However, the majority of patients treated with vascular endothelial growth factor (VEGF)-pathway inhibitors ultimately develop resistance to such treatments. Overexpression of mesenchymal-epithelial transition factor (c-MET), with or without upregulation of its ligand hepatocyte growth factor, has been implicated in tumor resistance to VEGF-pathway inhibitors. Results from preclinical models suggest that combining c-MET and VEGF receptor (VEGFR) inhibition provides added benefit compared with VEGF-pathway inhibition alone (Ciamporcero et al, AACR 2013:Abstr 1618). This study is evaluating axitinib (highly specific tyrosine kinase inhibitor of VEGFRs 1–3) in combination with crizotinib (c-MET/anaplastic lymphoma kinase [ALK] inhibitor). **Methods:** This ongoing, multicenter, phase Ib study (NCT01999972) employs a dose escalation phase exploring oral administration of axitinib (starting dose 3 mg twice daily [BID]; range 2–5 mg BID) plus crizotinib (starting dose 200 mg BID; range 250 mg once daily–250 mg BID) on a continuous schedule to ~25 patients with advanced solid tumors resistant to standard therapy or for which no standard therapy is available. Dose escalation/de-escalation decisions are based on the modified toxicity probability interval (mTPI) design. Following determination of the maximum tolerated dose (MTD) of the combination treatment, patients with advanced clear cell RCC will be enrolled in two cohorts of ~20 patients each (cohort 1: no prior systemic therapy; cohort 2: 1–2 prior systemic therapies) in a dose expansion phase. The primary study objective is to assess the tolerability of the combination treatment in order to determine the MTD and select the recommended phase II dose. Other objectives include characterization of pharmacokinetics and antitumor activity. Correlative biomarker studies on blood and tumor tissue (archival tissue and de novo biopsies) will be performed and will include evaluation of c-MET expression. Enrollment in the dose escalation phase began in Jan 2014. Clinical trial information: NCT01999972.

**TPS4597 General Poster Session (Board #161A), Mon, 1:15 PM-5:00 PM**

**A-PREDICT: A phase II study of axitinib in patients with metastatic renal cell cancer unsuitable for nephrectomy (CRUKE/11/061).** *Presenting Author: Rosalie A. Fisher, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

**Background:** Patients presenting with metastatic renal cell carcinoma (mRCC) who cannot have palliative nephrectomy constitute a poor prognosis group. The vascular endothelial growth factor receptor (VEGFR) inhibitor axitinib has demonstrated a high response rate in mRCC, but its efficacy has not been evaluated in this patient group. Sustained disease control and predicting sensitivity to VEGFR inhibitors may be difficult to achieve in mRCC because of intra-tumour heterogeneity (ITH) and branched, subclonal tumour evolution. **Methods:** A-PREDICT is a single group phase II trial of axitinib in patients with newly diagnosed mRCC not considered suitable for immediate nephrectomy. The primary objective is to assess clinical activity of axitinib in this patient group. The study includes longitudinal sampling of tumour tissue during therapy to investigate the extent of ITH and track evolution of somatic mutational and copy number events. Key inclusion criteria are: clear cell histology and unsuitability for nephrectomy due to locally advanced primary tumour, high burden of metastatic disease or lack of fitness for surgery. Five core biopsies of the primary tumour are taken before the patient starts axitinib (starting dose 5 mg twice daily). After 8 weeks' treatment, multiple biopsies of the kidney tumour are repeated. Axitinib is continued for as long as the patient benefits. At treatment cessation, the progressing site is biopsied. Nephrectomy is offered to any patient who becomes suitable during the course of the trial and resected specimens are sampled. The primary endpoint is the proportion of participants free from disease progression 6 months from treatment start. The proportion of patients who become operable as a consequence of axitinib will be measured. To end 2013, 17 patients from 7 UK sites were recruited. The target accrual of 99 patients has 90% power to discount an 'ineffective' rate of freedom from progression at 6 months of 25% in favour of a rate of at least 40%. Serial tumour & blood samples will be evaluated by a functional genomics approach. Dynamic changes in expression of putative biomarkers during therapy will be compared between patients who respond to axitinib and those who are resistant. Clinical trial information: ISRCTN72679844.

**TPS4598 General Poster Session (Board #161B), Mon, 1:15 PM-5:00 PM**

**Dose adjustment of axitinib based on AUC monitoring in sunitinib-refractory advanced renal cell carcinoma.** *Presenting Author: Yuji Miura, Department of Medical Oncology, Toranomon Hospital, Tokyo, Japan*

**Background:** Axitinib is a standard second-line treatment after sunitinib in patients (pts) with metastatic or advanced renal cell carcinoma (RCC). The previous results of pharmacokinetic (PK) and pharmacodynamic (PD) analysis of axitinib showed that higher exposure and diastolic blood pressure (dBP) were independently associated with longer progression free survival (PFS) and overall survival in metastatic RCC pts (Rini et al., J Clin Pharmacol, 2013). These findings support that axitinib dose titration to increase plasma exposure in pts who tolerate axitinib, and also demonstrate dBP as a potential marker of efficacy. In clinical practice, axitinib dose titration based on dBP is recommended; however, it has limitations because underlying hypertension and anti-hypertensive agents usually affect daily dBP. Therefore, we hypothesize that the dose adjustment of axitinib based on its exposure is more adequate than that based on dBP. **Methods:** A prospective single arm trial is conducted at 6 institutions in Japan. The starting dose of axitinib is 5mg BID and blood samples are taken at 2h, 4h, 8h, and 12h after the first administration to assay axitinib levels and calculate the area under concentration-time curve from 0 to 12 hours ($AUC_{0\text{-}12}$) on day 1. We target $AUC_{0\text{-}12}$ value at the steady state over 150 ng*hr/mL, and suggest a sufficient dose to reach the 150 ng*hr/mL for each patient. After day 15, dose adjustment of axitinib to keep over the target value is performed according to adverse drug reaction for each patient. The primary endpoint is 6-month PFS rate based on axitinib AUC monitoring, and secondary endpoints include toxicity and objective response rate. The target $AUC_{0\text{-}12}$ value in sunitinib-refractory pts is also investigated, because the value of 150 ng*hr/mL is referred from the previous PK/PD analysis in which the first-line treatments were not only sunitinib. Major eligibility criteria include (1) metastatic or advanced clear cell RCC or RCC with clear cell component; (2) previously treated with sunitinib; and (3) disease progression on sunitinib or within 6 months of last dose of sunitinib. Prior treatment with cytokines is permitted. Twelve of planned 32 pts have been enrolled as of February 2014. Clinical trial information: UMIN000009579.

**TPS4599^ General Poster Session (Board #162A), Mon, 1:15 PM-5:00 PM**

**Enrollment insights in the synchronous mRCC population: An update from the ongoing ADAPT* phase 3 study experience.** *Presenting Author: Robert A. Figlin, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA*

**Background:** AGS-003 is an autologous immunotherapy designed to induce a T-cell response specific to a patient's tumor antigens. Sunitinib is a TKI and first-line therapy for mRCC that also reverses the immune suppression observed in these patients. In a single arm phase 2 study, AGS-003 plus sunitinib was safe and yielded a median overall survival (OS) of over 30 months in newly diagnosed mRCC patients. **Methods:** The ADAPT study is a randomized (2:1) international phase 3 study comparing standard targeted therapy plus AGS-003 to standard therapy alone. The primary objective is to compare the median OS between treatment arms. The study is enrolling adults with synchronous, metastatic, clear cell RCC who are good candidates for surgery and standard targeted therapy (initiating with, but not limited to, sunitinib), KPS $\geq$ 70%, life expectancy of at least 6 months, between 1-4 Heng risk factors, and adequate end organ function. Initial enrollment patterns were investigated in order to gain insight on the features of mRCC patients that are candidates for cytoreductive nephrectomy. More than 105 sites in North America and other select countries have been activated and >200 patients have been consented and tumor samples collected. Approximately 50% of these patients have been excluded from participation in the treatment phase of the ADAPT study after surgery with about half of these being excluded because of non-clear cell histology. Other major reasons include ineligibility for sunitinib and lack of measurable metastatic disease after nephrectomy. Clinical trial information: NCT 1582672.

**TPS4600^ General Poster Session (Board #162B), Mon, 1:15 PM-5:00 PM**

**Principal: A prospective observational study of real-world treatment patterns and treatment outcomes in patients with advanced or metastatic renal cell carcinoma (mRCC) receiving pazopanib.** *Presenting Author: Aristotelis Bamias, University of Athens Medical School, Athens, Greece*

**Background:** Pazopanib is an oral, selective, multikinase inhibitor of VEGF receptors 1/2/3, PDGF receptors $\alpha$/ß, and stem cell factor receptor (c-Kit) that is approved for first-line treatment of patients with advanced renal cell carcinoma (RCC) and for patients who received prior cytokine therapy. The COMPARZ study of pazopanib versus sunitinib as first-line treatment demonstrated noninferiority of pazopanib for progression-free survival (PFS) in the intention-to-treat population, and pazopanib statistically favored health-related quality of life (HRQoL) in 11 of the 14 domains measured (NEJM 2013;369:722-31). The PISCES patient preference study demonstrated that significantly more patients preferred pazopanib over sunitinib due to overall better HRQoL and less fatigue (JCO 2012;30 suppl 15:CRA4502). The purpose of the PRINCIPAL study is to evaluate the real-world effectiveness and safety of pazopanib in patients with advanced or mRCC. **Methods:** This is a global, multicenter, prospective, observational study (VEG115232, NCT01649778) designed to enrol up to 700 patients. Primary endpoints include PFS, overall response rate, overall survival, relative dose intensity data, HRQoL data, and safety data. Additional treatment strategies for RCC will be obtained post-progression. Key inclusion criteria include a clinical decision to initiate treatment with pazopanib (before enrolment in the study), no prior systemic therapy for advanced or mRCC, and no participation in an interventional trial. The study has enroled 339 patients to date and is currently recruiting in 15 countries, including Europe, Asia, Latin America, and the United States. This study will determine patient outcomes with pazopanib in a real-world setting in terms of efficacy, safety, and patient compliance outside the normal parameters of a controlled trial. PRINCIPAL will also provide further data in patient groups that were under-represented in the controlled clinical trials to date, such as the elderly and patients with co-morbidities. Clinical trial information: NCT01649778.

**TPS4601 General Poster Session (Board #163A), Mon, 1:15 PM-5:00 PM**

**Phase 3 randomized study of cabozantinib (XL184) versus everolimus in subjects with clear cell renal cell carcinoma (METEOR).** *Presenting Author: Toni K. Choueiri, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

**Background:** Cabozantinib is an oral receptor tyrosine kinase inhibitor (TKI) with potent activity against MET and VEGFR2. Cabozantinib has demonstrated clinical activity in multiple solid tumor types, including heavily pretreated subjects with clear cell renal cell carcinoma (ccRCC) (Choueiri et al.; ASCO 2012, abstract 4504). In ccRCC, VHL tumor suppressor gene dysfunction results in impaired HIF degradation and consequent activation of MET and VEGF pathways. Moreover, MET has been implicated in adaptive resistance to VEGF-pathway targeted agents. Based on the clinical activity seen to date and the scientific rationale, there is strong interest in the evaluation of cabozantinib in ccRCC. **Methods:** This Phase 3, open-label, multicenter study evaluates the efficacy and safety of cabozantinib compared with everolimus in subjects with ccRCC (NCT01865747).The primary endpoint is progression-free survival (PFS) as evaluated by an independent radiology review committee (IRC). Secondary endpoints are overall survival (OS) and response rate. Exploratory endpoints are safety, tolerability, tumor MET status, circulating tumor cells, serum bone markers and plasma biomarkers, skeletal-related events (SRE), and health-related quality of life (HRQoL). Enrollment started in August 2013. Target recruitment is 650 subjects with ccRCC, which will provide power for both PFS and OS endpoints. Eligible subjects must have progressed after 1 or more prior VEGFR TKI therapy. Subjects are randomized 1:1 to receive either cabozantinib or everolimus. Stratification factors are the number of prior VEGFR TKI therapy and MSKCC prognostic criteria (Motzer et al.; J Clin Oncol 22:454-463, 2004). Radiographic assessments include CT/MRI and bone scintigraphy. PFS and response are determined by IRC using RECIST criteria version 1.1. SREs are defined as radiation therapy to bone, pathological fracture, spinal cord compression, and surgery to bone. The NCCN-Functional Assessment of Cancer Therapy (FACT) Kidney Symptom Index (FKSI-19) questionnaire and the EuroQol Health questionnaire (EQ-5D-5L) are being used to measure HRQoL. Subjects are being followed for survival. Clinical trial information: NCT01865747.

**TPS4602 General Poster Session (Board #163B), Mon, 1:15 PM-5:00 PM**

**Qualitative study of social and working life aspects of patients with metastatic renal cell carcinoma (mRCC) on palliative therapy.** *Presenting Author: Sandra Meyer-Moock, University Medicine Greifswald, Greifswald, Germany*

**Background:** The backbone of medical treatment of metastatic renal cell carcinoma (mRCC) consists of targeted agents. Inhibitors of VEGFR or mTOR with chronic exposure have led to the recent improvement in mRCC therapy. To assess health-related quality of life (HRQoL) of patients with mRCC, several generic and disease-specific instruments are available (eg. EQ-5D or the FKSI). Yet, little is known about the impact of mRCC on social and working life aspects as well as treatment-related decisions of patients on a palliative treatment. The aim of this study is to identify relevant dimensions as well as to develop and validate an instrument to close this gap. **Methods:** The study consists of three parts with qualitative and quantitative methods. In part I (development), we conducted 2 focus group interviews with 15 patients in patients support groups in Germany. In a pretest (part II), patients were asked to complete a draft questionnaire and to comment on it briefly during an interview. Qualitative data analysis (focus groups, field testing) consisted of content analysis methods (qualitative content analysis); software for qualitative data analysis (MAXQDA) was used. In part III (validation), the questionnaire will be validated by testing the psychometric properties in a sample of 100 patients with mRCC. Psychometric methods used will include factor analysis, assessment of distributional properties, floor and ceiling effects, percentage of missing values and subgroup analysis.

**TPS4604^ General Poster Session (Board #164B), Mon, 1:15 PM-5:00 PM**

**A phase I/II study to assess the safety and efficacy of pazopanib and MK-3475 in subjects with advanced renal cell carcinoma.** *Presenting Author: David F. McDermott, Beth Israel Deaconess Medical Center, Boston, MA*

**Background:** Pazopanib is an angiogenesis inhibitor targeting VEGFR-1, -2, and -3; PDGFR-$\alpha$ and -$\beta$; and the receptor c-Kit, and is indicated for the treatment of subjects with advanced RCC and advanced soft tissue sarcoma. MK-3475 (Merck) is a potent and highly-selective humanized mAb of the IgG4/kappa isotype designed to block directly the interaction between PD-1 and its ligands, PD-L1 and PD-L2. Proangiogenic factors suppress various immune functions whereas antiangiogenic agents have potential to modulate the tumor microenvironment and improve immunotherapy. High expression of PD-L1 on tumor cells, and to a lesser extent of PD-L2, has been found to correlate with poor prognosis and survival in various cancer types including RCC [Thompson 2007]. An analysis of patients with RCC treated with paz demonstrated that elevated expression of PD-L1 correlates with shorter PFS [Figueroa 2013]. Additionally an objective response rate of 27% in RCC patients was reported in an early phase study with another antibody to PD-1 forall doses tested[Topalian 2012]. These findings suggest that MK-3475 may potentiate the activity of paz in patients with RCC. This Phase I/II trial has been undertaken to test the safety and tolerability of paz in combination with MK-3475 in advanced RCC, and assess the efficacy of the combination as compared with paz or MK-3475 alone. **Methods:** This is an open-label, 2-part multi-center study of paz and/or MK-3475 in treatment-naïve subjects with advanced predominantly clear cell RCC. Part 1 is Phase I dose escalation using a modified 3+3 design, with combination dosing starting at 800mg/day paz + 2mg/kgQ2W MK-3475, followed by an expansion cohort to confirm the maximum tolerated regimen and the recommended Phase 2 dose. Part 2 is a randomized 3-arm (1:1:1) Phase II study to evaluate the clinical efficacy and safety of paz + MK-3475 as compared to paz or MK-3475 alone. The primary endpoint in Part 2 is PFS by RECIST v1.1. Secondary endpoints are PFS rate at 18 months, PFS by modified RECIST criteria, overall response, stable disease $\geq$6 months, time to response, duration of response, overall survival, safety and tolerability. Part 1 has opened to enrollment. Clinical trial information: NCT02014636.

**TPS4605 General Poster Session (Board #165A), Mon, 1:15 PM-5:00 PM**

**A multicenter, open-label, single-arm, phase 2 study of the S1P inhibitor sonepcizumab (LT1009) in patients with previously treated metastatic renal cell carcinoma (mRCC).** *Presenting Author: Rupal Satish Bhatt, Beth Israel Deaconess Medical Center, Boston, MA*

**Background:** Sphingosine-1-phosphate (S1P), a key component of the sphingolipid signaling cascade, is a pleiotropic tumorigenic growth factor. S1P promotes tumor growth by stimulating cell proliferation, metastasis and cell survival while promoting tumor-associated angiogenesis by supporting the migration and survival of endothelial cells needed to form new blood vessels. Cancer cells promote conditions that favor the production of S1P through upregulation of sphingosine kinase (SphK) which appears responsible for release of S1P into the extracellular compartment. Data thus far implicate the type 1 isoform of SphK in chemoresistance and in the enhanced tumorigenicity adaptations to hypoxia, all of which correlate with poor patient outcomes in several cancer types. Sonepcizumab (LT1009) is a humanized murine-derived monoclonal antibody directed at S1P. Sonepcizumab slowed the progression of several orthotopic and subcutaneous human tumors in nude mice, including sunitinib-resistant renal tumors. Sonepcizumab was safe and well tolerated in a completed phase 1 study in 28 pts with advanced solid tumors up to 24 mg/kg weekly. Based on these data, we hypothesize that sonepcizumab may be effective in pts with advanced mRCC who failed previous therapies. **Methods:** A two-part, multi-center, open label phase 2 study is in progress to evaluate safety, tolerability, efficacy, and the pharmacokinetics (PK) and pharmacodynamics (PD) of sonepcizumab as a single agent when given at the dose of 24 mg/kg weekly in pts with previously treated mRCC. Two cohorts will be enrolled and dosed at the phase 1 maximum tolerated dose (MTD) of 24 mg/kg. If at least 12 out of the first 22 pts are progression-free at 2 months, then a second cohort will be enrolled for a total of approximately 60 pts. Key eligibility criteria include prior therapy with a VEGF/VEGFR targeted therapy (an mTOR inhibitor and/or prior immunotherapy are also permitted for a total of no more than 3 prior therapies); The primary endpoint is PFS. Secondary endpoints include response rate and serum PD biomarkers, including S1P. Clinical trial information: NCT01762033.

**TPS4606 General Poster Session (Board #165B), Mon, 1:15 PM-5:00 PM**

**Phase II efficacy trial of pazopanib in non-clear cell metastatic renal cell carcinoma (PINCR trial).** *Presenting Author: Brian Addis Costello, Mayo Clinic, Rochester, MN*

**Background:** Seven treatments for metastatic renal cell carcinoma (mRCC) have been FDA approved since December, 2005. Most of the trials evaluating these agents excluded non-clear cell histologies and therefore the efficacy of these agents remains unclear in patients with metastatic non-clear cell RCC. One such agent is pazopanib, an oral tyrosine kinase inhibitor; its effects are being studied in patients with metastatic non-clear cell RCC in this trial. The primary endpoint is to determine the overall survival rate at 12 months in patients with metastatic non-clear cell RCC. Secondary endpoints are to determine best tumor response rates after two cycles, progression free survival and toxicity profile. **Methods:** Main eligibility criteria include: (1) age ³ 18 years old; (2) histologic confirmation of non-clear cell renal cancer; (3) ECOG Performance Status (PS) 0, 1, or 2; (4) up to one prior treatment for metastatic non-clear cell renal cell carcinoma is allowed as long as the agent was not pazopanib; (5) measurable or nonmeasurable metastatic disease as defined by RECIST criteria. This is a single arm Phase II study designed to determine the efficacy of pazopanib in metastatic non-clear cell RCC. Treatment is pazopanib 800 mg by mouth daily until progression or intolerability of treatment. Dose reductions are allowed for toxicity with dose level -1 being 600 mg daily and dose level -2, 400 mg daily. Cycles are 28 days. Routine evaluation includes history, examination, adverse events assessment, serum studies, and ECG with every cycle. Research blood and urine specimens are being collected for future correlative studies. All eligible patients will be followed until death or for a minimum of two years. The sample size will be 35 evaluable patients with accrual of 4 additional patients to account for ineligibility or other reasons. Full accrual is anticipated to take 24 months. Final analysis will begin approximately 36 months after the trial begins which is the time point at which the last patient enrolled can be observed for at least 12 months. The Mayo Clinic Cancer Center Data Safety Monitoring Board is responsible for reviewing accrual and safety data. Supported in part by GSK. Clinical trial information: NCT01767636.

**TPS4607 General Poster Session (Board #166A), Mon, 1:15 PM-5:00 PM**

**Phase 1 study of ATR-101 in adrenocortical carcinoma (ACC): ATR-101-001.** *Presenting Author: Aung Naing, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** ATR-101 (Atterocor, Inc., Ann Arbor, MI, USA) is in clinical development for the treatment of adrenocortical carcinoma (ACC). ATR-101 is a selective inhibitor of ACAT1 (acyl coenzyme A:cholesterol acyltransferase). ACAT1 catalyzes cholesterol ester formation and, in the adrenals, is particularly important in creating a reservoir of substrate for steroid biosynthesis. ATR-101 is uniquely distributed to adrenal tissues and inhibition of adrenal ACAT1 by ATR-101 disrupts steroidogenesis and leads to selective apoptosis of steroid producing adrenocortical-derived cells. Similar effects have been seen in the human ACC cell line, H295R. ATR-101 has shown pre-clinical efficacy in H295R xenograft mouse models. ACC is an ultra-rare malignancy, occurring in about 2 per million population annually. ACC is frequently discovered in Stage 4 and the overall disease survival is approximately 17 months. Tumors often overproduce steroids normally produced in the adrenal cortex. Current therapies are toxic, difficult to administer, and poorly effective. **Methods:** ATR-101-001 is a phase 1, dose escalation "3+3" design study of ATR-101 in advanced ACC patients who have failed or declined standard therapy. The primary objectives are the safety and tolerability of once a day, orally administered ATR-101. Secondary objectives include the determination of MTD and pharmacokinetics, anti-tumor efficacy by RECIST, and evaluation of pharmacodynamic biomarkers, including steroid hormones and steroid intermediate production rates. Initial safety evaluation is after 28 days of therapy; subjects who appear to be deriving benefit may continue on ATR-101 indefinitely. The study is open at two centers in the United States to patients age 18 and over with advanced ACC. Patient's mitotane level must be 5 ng/ml or less; the QTcF 470 ms or less; and if present, CNS metastases must be treated and inactive. Clinical trial information: NCT01898715.

**5000 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Enzalutamide (ENZA) in combination with abiraterone acetate (AA) in bone metastatic castration resistant prostate cancer (mCRPC).** *Presenting Author: Eleni Efstathiou, Alexandra General Hospital of Athens, Oncology Department, Department of Clinical Therapeutics, Medical School, University of Athens, Athens, Greece*

**Background:** Co-targeting the androgen receptor (AR) and paracrine androgen biosynthesis in mCRPC may be more effective than either alone. This study aims to evaluate safety, pharmacokinetic (PK) drug-drug interactions (DDI), androgen signaling and steroid metabolome modulation and efficacy of ENZA with AA in mCRPC **Methods:** We enrolled patients (pts) with progressive bone mCRPC, castrate level serum testosterone (≤ 50 ng/dl) consenting to bone marrow (BM) biopsy. Pts were treated with ENZA 160 mg QD and AA 1g QD + prednisone 5 mg bid and monitored every 4-week with CBC, chemistry, physical exams. mCRPC was assessed clinically by PSA, ALP and imaging. Tumor was characterized by IHC and LC mass spectrometry (blood and BM). $C_{trough}$plasma concentrations of AA were measured on days 4 & 29, and ENZA and its active metabolite M2 on d29 in pt subset. **Results:** We enrolled (07/12-09/13) 60 pts with median age 66 yrs (range 40-82), PS-ECOG 1 (range 0-2) and PSA 20.8 ng/ml (range1-670). Gleason Score (GS) at diagnosis ≥ 8 in 38/53 (72%), [GS ≥ 9 29/53 (55%)/7 unknown]. Thirty (50%) had > 20 bone lesions, 19/60 (32%) lymph node lesions and 2/60 (3%) visceral metastases. Interim data on evaluable pts: PSA changes for 49 pts: maximum PSA decline ≥ 50% (37/49 [76%]), ≥ 90% (22/49 [45%]), PSA ≤ 0.1ng/ml (5/49 [10%]) and PSA progression (6 [12%]). Grade 3 adverse events: ALT rise (5), hypertension (5), ALP rise (4 ), arthralgia (3), bone pain (2). No Grade 4 AEs reported. At ENZA steady state (d29), $C_{trough}$ of AA was ~23% lower than d4 (pt n=14; LS means ratio 77.67 %; 90% CI 47.51-126.98) and $C_{trough}$for ENZA, M2, and the sum of both (pt n=15) were comparable to those reported previously. Following 8 weeks treatment, serum and BM testosterone were undetectable (<1pg/ml) in 29/39 (74%) and 31/36 (86%) evaluated pts respectively, and androstenedione in all pts. Nuclear AR expression was reduced following treatment in 5/6 of evaluable paired tumor specimens. **Conclusions:** ENZA+ AA combination has a favorable safety profile, without clinically meaningful PK DDI. Feedback mechanisms observed by either agent are dissipated. These promising findings are indicative of more efficacious androgen signaling inhibition in men with mCRPC. Clinical trial information: NCT01650194.

**5001 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Androgen receptor splice variant, AR-V7, and resistance to enzalutamide and abiraterone in men with metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Emmanuel S. Antonarakis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Androgen receptor splice variant-7 (AR-V7) is a truncated form of the androgen receptor that lacks the ligand-binding domain, the target of enzalutamide and abiraterone, but remains constitutively active as a transcription factor. We hypothesized that detection of AR-V7 in circulating tumor cells (CTCs) from men with mCRPC may be associated with primary resistance to enzalutamide and abiraterone. **Methods:** We used quantitative reverse-transcription PCR (qRT-PCR) to interrogate CTCs for the presence or absence of AR-V7 from prospectively enrolled patients with mCRPC initiating treatment with enzalutamide or abiraterone. We examined associations between AR-V7 status and PSA response rates, PSA progression-free survival (PSA-PFS), and clinical/radiographic progression-free survival (PFS). Multivariable Cox regression analyses were performed to determine the independent effect of AR-V7 status on these clinical outcomes. 30 men (per cohort) were required to detect a difference in PSA response rates from 10% (in AR-V7–positive men) to 60% (in AR-V7–negative men), using a 2-sided $\alpha$=0.10 and $\beta$=0.15. **Results:** 31 enzalutamide-treated patients and 31 abiraterone-treated patients were enrolled, of which 38.7% and 19.4% had detectable AR-V7 from CTCs, respectively. Among men receiving enzalutamide, AR-V7–positive patients had inferior PSA response rates (0% *vs* 52.6%, *P*=0.004), PSA-PFS (median 1.4 *vs* 5.9 months, *P*<0.001), and PFS (median 2.1 *vs* 6.1 months, *P*<0.001) compared to AR-V7–negative patients. Similarly, among men receiving abiraterone, AR-V7–positive patients had inferior PSA response rates (0% *vs* 68.0%, *P*=0.004), PSA-PFS (median 1.3 months *vs* not reached, *P*<0.001), and PFS (median 2.3 months *vs* not reached, *P*<0.001). The negative prognostic impact of AR-V7 was maintained after adjusting for full-length AR expression levels. **Conclusions:** Detection of AR-V7 in CTCs from men with mCRPC is associated with resistance to enzalutamide and abiraterone. AR-V7 status may be used as a biomarker to predict resistance to AR-targeting agents, facilitate treatment selection, and fuel the development AR N-terminal domain inhibitors.

**5002 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**The site of visceral metastases (mets) to predict overall survival (OS) in castration-resistant prostate cancer (CRPC) patients (pts): A meta-analysis of five phase III trials.** *Presenting Author: Susan Halabi, Duke University Medical Center, Durham, NC*

**Background:** Recent studies have shown that metastatic site is an important predictor of overall survival, but the reports were based on small sample sizes and as such the estimates were unstable. We sought to test two hypotheses: 1) CRPC pts with lung mets have worse survival than pts with non-visceral mets; and 2) pts with liver mets have worse survival than pts with lung mets. **Methods:** We combined individual patient data from 3,993 chemotherapy-naive mets CRPC pts randomized to receive docetaxel (D) based therapy on 5 phase III trials: CALGB 90401 (D +/- Bevacizumab): SWOG 0421(D +/-atrasentan),ENTHUSE 33 (D +/- zibotentan), TAX327 (D 3 wks, D weekly) and SWOG 9916 (D + estramustine). Site of mets at baseline was categorized as: lymph node (LN) only, bone +/- LN with no visceral mets, any lung mets (but no liver), any liver mets, and other visceral. We used fixed-effects meta-analysis to estimate the pooled hazard ratios (pHR) and 95% confidence intervals (CI) for comparing pts with lung mets vs. non-visceral mets and liver mets vs. lung mets. **Results:** The pHR for death for pts with lung mets compared to pts with non-visceral mets was 1.3 (95% CI= 1.1-1.5, p<0.001) and the pHR for pts with any liver mets compared with pts with lung mets was 1.4 (1.2-1.7, p<0.001). The median overall survival by site of mets is presented in table below. f mets at baseline was categorized as: lymph node (LN) only, bone +/- LN with no visceral mets, any lung mets (but no liver), any liver mets, and other visceral. **Conclusions:** As anticipated, CRPC patients with liver mets had the worst OS (12.1 m). While pts with lung mets had better OS (16.5 months) compared to liver mets pts, they had significantly worse survival than pts with non-visceral bone mets (20 months). These data may help in treatment decisions and in the design of future clinical trials in mCRPC pts. Clinical trial information: NCT00110214.

| Metastatic Site | N (%) | Median OS in months (95% CI) |
|---|---|---|
| LN only | 187 (5) | 27.0 (24.7-32.4) |
| Bone/Bone with LN | 3334 (83) | 20.3 (19.7-21.0) |
| Lung (+/- bone), no liver | 300 (7) | 16.5 (14.8-18.4) |
| Liver (LM) (+/- bone) | 280 (7) | 12.1 (10.1-13.5) |
| Other Visceral (adrenal, brain) | 55 (1) | 14.4 (12.6-19.1) |

**5003 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Immediate versus deferred initiation of androgen deprivation therapy in prostate cancer patients with PSA-only relapse.** *Presenting Author: Xabier Garcia-Albeniz, Harvard School of Public Health, Boston, MA*

**Background:** The optimal timing to start androgen deprivation therapy (ADT) in patients with rising PSA as the only sign of relapse is unknown. ASCO guidelines state "the critical issue is to determine whether there is benefit and how large it is for starting ADT while patients are asymptomatic." **Methods:** We studied 2,022 men in the Cancer of the Prostate Strategic Urologic Research Endeavor (CaPSURE), a national prospective registry, staged < cT3aN0M0, treated with radical prostatectomy (RP) or radiotherapy (RT) and had a PSA relapse (> 0.2 ng/mL [RP] or three rising determinations one month apart [RT]). Exclusion criteria included ADT in the 12 months before inclusion, metastatic disease by CT scan or bone scan, and symptoms. We assigned patients to the "immediate" strategy if they initiated ADT within 3 months (grace period) of PSA relapse and to the "deferred" strategy if they initiated ADT 2 or more years after PSA relapse or when they presented with metastasis, symptoms or a short PSA doubling time. We did not allow a treatment other than ADT for PSA relapse (e.g., rescue RT). We censored patients when they deviated from the assigned strategy and adjusted for this censoring via inverse probability weighting where the weights are a function of time-varying confounders: PSA, Karnofsky, weight loss, and bone pain. **Results:** Of the 2,022 patients analyzed, median age was 69 (range 63 to 74) years, 33.8% had a Gleason score >7, 31.8% received radiotherapy as primary treatment, and median time from primary treatment to PSA relapse was 27 (range 14 to 51) months. After relapse, patients were followed a median of 53.2 months. All cause mortality HR for "immediate ADT" vs. "deferred ADT" was 1.06 (95% CI: 0.59 to 1.89), corresponding to a survival difference at 5 years of -5.5% (95% CI: -15.1 % to 4.2%). The prostate-cancer specific mortality HR was 1.48 (95% CI 0.69-3.16), corresponding to a 5-year survival difference of -5.6% (95% CI: -12.5% to 1.3%). **Conclusions:** Our study suggests little or no survival benefit of immediate ADT initiation for immediate ADT initiation compared with deferred ADT initiation (at clinical progression or at least two years after PSA relapse) among prostate cancer patients with PSA-only relapse.

**5004 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Main oncologic endpoints of the TROG 03.04 (RADAR) Trial for men with locally advanced prostate cancer** *Presenting Author: James William Denham, Calvary Mater Newcastle, University of Newcastle, Newcastle, Australia*

**Background:** To determine whether 18 months androgen suppression (AS) plus radiotherapy (RT) ± 18 months zoledronate (Z) is more efficacious than 6 months AS plus RT ± 18 months Z, and is associated with a widely acceptable morbidity profile in men with locally advanced prostate cancer (PC). **Methods:** Between 2003 and 2007 1071 men with locally advanced PC were randomly allocated in a 2X2 factorial trial design in a 1:1:1:1 ratio to short-term (6 months) neo-adjuvant AS using leuprolide (22.5mg i.m. every 3 months) and radiation (STAS) either alone, or followed by intermediate term (12 months) AS (ITAS) (22.5mg i.m. every 3 months), or accompanied by 18 months of zoledronate (4mg i.v. every 3 months) (STAS+Z), or by both (ITAS+Z). Eligibility included T2a-4, N0, M0 adenocarcinoma of the prostate, with PSA ≥10 and Gleason score (GS) ≥7 in T2a cases. The primary endpoint is time to prostate cancer specific mortality (PCSM). Secondary endpoints include time to PSA, all distant and bony progressions (PSAP, DP and BP), time to starting secondary therapeutic intervention (STI) and all-cause mortality (ACM). Analysis was by intention-to-treat. All endpoints were assessed using competing risks methodology (unadjusted Fine and Gray models) except ACM where the log-rank test was used. **RESULTS:** Median follow-up was 7.4 years IQR [6.5-8.4]. Important bi-directional interactions were identified. Compared to STAS, STAS+Z significantly increased BP SHR 1.85 [1.11-3.10] p=0.02. Compared to STAS, ITAS+Z significantly reduced PSAP SHR 0.71 [0.53-0.95] p=0.02 and STI SHR 0.67 [0.48-0.94] p=0.02, and further still in subjects with GS>7 tumours: PSAP SHR 0.59 [0.37-0.94] p=0.03 and STI SHR 0.49 [0.29-0.83] p=0.01 respectively. ITAS was superior to STAS only in subjects with GS≤7 tumours; PSAP SHR 0.65 [0.43-0.98] p=0.04, STI SHR 0.49 [0.29-0.84] p=0.01. Corresponding reductions in DP, PCSM and ACM did not reach significance. Apart from two mandibular osteonecroses, no increases in morbidity or adverse patient reported outcomes were attributable to 18 months AS or Z. **CONCLUSIONS:** Ten year data is required to confirm and quantify reductions in DP, PCSM and ACM from the use of ITAS and ITAS+Z. STAS+Z cannot be recommended. Clinical trial information: NCT00193856.

**5005 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Docetaxel-estramustine in localized high-risk prostate cancer: Results of the French Genitourinary Tumor Group GETUG 12 phase III trial.** *Presenting Author: Karim Fizazi, Department of Cancer Medicine, Gustave Roussy, University of Paris Sud, Cancer Campus, Grand Paris, Villejuif, France*

**Background:** Docetaxel-estramustine improves survival in patients (pts) with castrate-resistant prostate cancer (CaP). This phase III trial assessed docetaxel-estramustine in pts with high-risk localized CaP. **Methods:** Eligibility included non-pretreated high-risk localized CaP, defined as ≥1 of the following criteria: T3-T4, Gleason score (GS)≥8, PSA≥ 20 ng/mL, pN+ (stratification factors). All pts had a staging pelvic lymph node dissection. Pts were randomly assigned to either goserelin 10.8 mg every 3 months for 3 years and 4 cycles of docetaxel 70 mg/m$^2$ q3w + estramustine 10 mg/kg/d d1-5 (ADT+DE arm) or goserelin alone (ADT arm). Local therapy was administered at 3 months. The primary endpoint is progression-free survival (PFS); events=PSA relapse, radiographic relapse, death. The planned number of pts was 400, to detect a 12% difference at 4 years with a power of 80% and a type I error of 0.05 (two-sided Logrank test). Preliminary results indicated a better PSA response rate (PSA ≤ 0.2 ng/mL: 34% in the ADT+DE arm vs 15% in the ADT arm [p< 0.0001]), neutropenic fever in 2%, and no negative impact on QoL at 1 year in the ADT+DE arm (Fizazi, Eur J Cancer 2012; 48:209-17). Here we report PFS results. **Results:** 413 pts were accrued. With a median follow-up of 7.6 years, PFS was marginally improved in the ADT+DE arm: 8-year PFS rate: 62% [55–69] in the ADT+DE arm vs 53% [45–60] in the ADT arm (adjusted HR: 0.75 [0.55-1.01], p=0.06). In pts with a GS<8, the 8-year PFS rate was 69% [60-78] (ADT+DE) and 51% [41-61] (ADT) (HR: 0.55 [0.36-0.84], interaction test =0.06 for GS). A non-significant trend favoring ADT+DE was found for clinical PFS (HR: 0.79 [0.55-1.13]). No long-term toxicity signal was detected, with no toxic death. The 8-year cumulative incidence of second cancers (11% vs 10%) was similar in the two arms. The 8-year OS rate is 83% [77–89] with no difference between treatment arms (HR: 0.94 [0.60-1.49]). In pts with a GS<8, the 8-year OS rate was 94% [89-98] (ADT+DE) and 85% [78-92] (ADT) (HR: 0.40 [0.17-0.91], interaction test: p=0.02). **Conclusions:** Docetaxel-estramustine is associated with a borderline significant reduction in the risk of relapse or death in high-risk prostate cancer. Clinical trial information: NCT00055731.

**5006 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**SWOG S0925: A randomized phase 2 study of androgen deprivation combined with cixutumumab versus androgen deprivation alone in patients with new metastatic hormone-sensitive prostate cancer.** *Presenting Author: Evan Y. Yu, University of Washington/Seattle Cancer Care Alliance, Seattle, WA*

**Background:** Cixutumumab (CIX), formerly IMC-A12, is a fully recombinant human monoclonal IgG$_1$ antibody that specifically targets insulin-like growth factor 1 receptor (IGF-IR). Pre-clinical studies have shown interaction between IGF-IR and the androgen receptor, with greatest anti-tumor activity in castration-sensitive xenografts. **Methods:** Patients with new metastatic prostate cancer were randomized within 30 days of initiation of LHRH agonist plus bicalutamide (AD) to CIX with AD versus AD alone. With 180 eligible patients randomized and one-sided alpha=0.10 there would be 90% power to detect an absolute difference of 20% in the primary endpoint, undetectable PSA (≤0.2 ng/mL) rate at 28 weeks (relative risk (RR)=1.44) using an intent-to-treat analysis; this endpoint was previously shown to be strongly correlated with survival. Secondary endpoints included the proportion of patients with 0.3 ≤ PSA ≤4.0 ng/mL, safety and tolerability, circulating tumor cell levels (CTCs) and multiple plasma IGF biomarkers. Fisher's exact test was used for the primary endpoint, and extended MH chi-square was used for 3 PSA response categories. **Results:** The trial accrued 210 eligible patients (105 randomized to each arm). Patient characteristics were similar in both arms. The undetectable PSA rate was 42/105 (40.0%) for CIX with AD and 34/105 (32.3%) for AD alone (RR=1.24, one-sided p=0.16). When separating out the PSA ≤4.0 ng/mL rate (see Table), there was no significant difference in PSA response rates between arms (p=0.17). CTCs were obtained at baseline prior to AD for 39 patients. Lower CTC (<5 vs. ≥ 5/7.5 mL whole blood) levels were associated with higher rate of PSA response (3 categories) (p=0.03). IGF-associated biomarkers will be reported at the meeting. **Conclusions:** CIX with AD did not significantly increase the proportion of men with an undetectable PSA in men with new metastatic hormone-sensitive prostate cancer. CTCs at baseline may carry prognostic value for this population. Clinical trial information: NCT01120236.

**5007 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Primary, secondary, and quality-of-life endpoint results from PREVAIL, a phase 3 study of enzalutamide in men with metastatic castration resistant prostate cancer (mCRPC).** *Presenting Author: Andrew J. Armstrong, Duke University, Durham, NC*

**Background:** Enzalutamide (ENZ), an androgen receptor inhibitor, improved overall survival (OS) in men with mCRPC who had received prior docetaxel therapy (Scher, N Engl J Med 2012;367:13). The PREVAIL study examined whether ENZ could prolong OS and radiographic progression-free survival (rPFS) in men with mCRPC who had progressed on androgen deprivation therapy (ADT). **Methods:** In this randomized double-blind, placebo-controlled, multinational study (NCT01212991), asymptomatic or mildly symptomatic patients were randomized 1:1 to ENZ 160 mg/day or placebo (PBO). OS and rPFS were co-primary endpoints and analyzed for the intent-to-treat population. Key prespecified secondary and exploratory endpoints are noted in the table below. **Results:** 872 men were randomized to ENZ and 845 to PBO, with respective median treatment durations of 16.6 and 4.6 months. Based on a planned interim analysis at 540 deaths the Data Monitoring Committee recommended stopping the study and crossing PBO patients to ENZ. Efficacy results are shown in the Table. The most common adverse events with a higher incidence in the ENZ arm than PBO were fatigue (35.6% vs 25.8%), back pain (27.0% vs 22.2%), constipation (22.2% vs 17.2%), and arthralgia (20.3% vs 16.0%). Seizure was reported in 1 patient in each treatment arm (0.1%). **Conclusions:** In men with mCRPC who progress on ADT, treatment with enzalutamide has a favorable safety profile and significantly improves OS, rPFS, and secondary measures of disease response and progression. Clinical trial information: NCT01212991.

**5008 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Phase 3, randomized, placebo-controlled trial of orteronel (TAK-700) plus prednisone in patients (pts) with chemotherapy-naïve metastatic castration-resistant prostate cancer (mCRPC) (ELM-PC 4 trial)** *Presenting Author: Ronald De Wit, Erasmus University Medical Center, Rotterdam, Netherlands*

**Background:** Orteronel, an investigational, non-steroidal, selective 17,20-lyase inhibitor, demonstrated improved radiographic PFS (rPFS) but not OS in men with mCRPC post-docetaxel (Dreicer et al, ASCO GU 2014, Abstract 7). The double-blind ELM-PC 4 trial (NCT01193244) evaluated orteronel in pts with chemotherapy-naïve mCRPC. **Methods:** Men with progressive mCRPC (rising PSA and/or radiographic evidence) and testosterone $<$ 50 ng/dL (post-orchiectomy or with maintained GnRH suppression) were randomized 1:1 to orteronel 400 mg twice daily (BID) + prednisone 5 mg BID (O+P) or placebo + prednisone (P), stratified by region and radiographic progressive disease at baseline. Co-primary endpoints were OS and rPFS. Based on 90% power to test OS ($>$ 90% for rPFS), an initial HR of 1.25 in favor of orteronel was anticipated with 1454 pts and 900 deaths (pre-assigned alpha: OS 0.045, rPFS 0.005). The final analysis for rPFS was conducted at an interim analysis (IA) for OS; the final analysis for OS was conducted at 600 deaths, with 78% power. **Results:** 1560 pts were randomized. The study met the co-primary endpoint of rPFS; at the IA (final for rPFS), median rPFS with O+P *v* P was 11 *v* 8.3 months (HR 0.7; 95% CI: 0.5–0.8; $P < .001$). At the final analysis for OS the updated median rPFS benefit with O+P *v* P had increased to 5.1 months (median 13.8 *v* 8.7 mo; HR 0.7; 95% CI: 0.6–0.8; $P < .00001$). The co-primary endpoint of OS was not met. Median OS with O+P *v* P was 31.4 *v* 29.5 months (HR 0.9; 95% CI: 0.8–1.1; $P = .314$), with no notable differences across regions. More pts had a $\geq$ 50% PSA decrease (43% *v* 25%, $P < .00001$) and a favorable circulating tumor cell count (15% *v* 9%, $P = .00016$) at 12 weeks with O+P *v* P. Common all-grade adverse events with O+P *v* P included nausea (36% *v* 15%), fatigue (34% *v* 20%), constipation (33% *v* 15%), and diarrhea (28% *v* 14%); 30% *v* 18% of pts discontinued due to AEs. In O+P *v* P groups, 45% *v* 51% of pts received subsequent therapy, including docetaxel/abiraterone/enzalutamide in 31%/14%/6% *v*33%/20%/6%. **Conclusion:** O+P demonstrated a significant improvement in rPFS but no statistically significant improvement in OS *v* P in chemotherapy-naive mCRPC. Clinical trial information: NCT01193244.

**5009 Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

**Nivolumab for metastatic renal cell carcinoma (mRCC): Results of a randomized, dose-ranging phase II trial.** *Presenting Author: Robert J. Motzer, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** Nivolumab, a fully human IgG4 programmed death-1 immune checkpoint inhibitor antibody, restores T-cell immune activity and showed objective responses in mRCC in a phase I trial (*NEJM* 366:2443). This phase II trial (NCT01354431) assesses three nivolumab doses in mRCC patients (pts) pretreated with agents targeting the VEGF pathway. **Methods:** Pts with clear-cell mRCC ($\geq$1 agent targeting VEGF pathway; $\leq$3 prior systemic therapies) were randomized (blinded 1:1:1) to nivolumab 0.3, 2 or 10 mg/kg IV Q3W until progression or toxicity. The primary objective was to evaluate the dose-response relationship measured by progression-free survival (PFS). Secondary objectives included overall survival (OS), objective response rate (ORR) and safety assessment. **Results:** All pts (N=168) received prior systemic therapy (70% received $\geq$2) including VEGFR TKIs (98%), mTOR inhibitors (38%) and immunotherapy (24%). 25% were MSKCC poor risk. All had $>$16 months of follow-up. No dose-response relationship was noted for PFS (stratified trend test, $P$=0.9). PFS and ORR were similar across doses (Table). For 0.3 mg/kg, median duration of response was 15.7 months and median OS was 18.2 months; for other doses medians were not reached. Across doses 19/35 responders (54%) had objective responses lasting $>$12–20+ months. Rates of grade 3–4 related adverse events (AEs) were $\leq$17% for all doses (Table). There was no grade 3–4 pneumonitis. For 0.3, 2 and 10 mg/kg, 1 (2%), 6 (11%) and 4 (7%) pts, respectively, had treatment-related AEs that led to discontinuation. **Conclusions:** Antitumor activity was observed with nivolumab in this pretreated mRCC population including objective responses of long duration. No dose-response relationship for PFS was noted and the safety profile was acceptable. Median OS was 18.2 months for the 0.3 mg/kg dose and was not reached for 2 or 10 mg/kg; updated OS will be presented. Clinical trial information: NCT01354431.

**Nivolumab (anti-PD-1; BMS-936558, ONO-4538) in combination with sunitinib or pazopanib in patients (pts) with metastatic renal cell carcinoma (mRCC).** *Presenting Author: Asim Amin, Levine Cancer Institute, Charlotte, NC*

**Background:** Antiangiogenic agents sunitinib (S) and pazopanib (P) are SOC for mRCC, but new therapies are needed as pts advance through therapy with limited survival benefit. We report preliminary results of a phase I trial of nivolumab, a fully human IgG4 PD-1 immune checkpoint inhibitor antibody, in combination with S or P in pts with mRCC. **Methods:** mRCC patients ($\geq$1 prior systemic therapy) received nivolumab in combination with S (50 mg, 4 wks on, 2 wks off; arm S) or P (800 mg daily; arm P), until progression/unacceptable toxicity. Starting dose of nivolumab was 2 mg/kg IV Q3W (N2), with planned escalation to 5mg/kg IV Q3W (N5). Based on tolerability, arm S N5 cohort was expanded to treatment-naïve pts. Primary objectives were safety/tolerability and determination of maximum tolerated dose (MTD) for the combinations; secondary objective was antitumor activity (objective response rate [ORR] and duration of response [DOR]). **Results**: 7 pts were assigned to each of arms S N2 and N5. No dose-limiting toxicities (DLTs) were observed and MTD was not reached thus N5 was expanded with 19 additional pts (total n=33). Arm P enrolled 20 pts at N2; 4 DLTs (elevated ALT/AST [n=3], fatigue [n=1]) were observed, leading to closure of this arm. Grade 3–4 related AEs were observed in 24/33 pts (73%) in arm S and 12/20 pts (60%) in arm P. Most common related grade 3–4 AEs included elevated ALT (18%), hypertension and hyponatremia (15% each) in arm S and elevated ALT/ AST (20% each) and fatigue (15%) in arm P. Hepatotoxicities were manageable using treatment algorithms. Grade 3 pneumonitis occurred in 1 pt (arm S, N5). Grade 3–4 related AEs led to therapy discontinuation in 8/33 pts (24%; 1 N2, 7 N5) in arm S and 4/20 pts (20%) in arm P. ORR was 52% (17/33) in arm S and 45% (9/20) in arm P. Responses occurred by first assessment (6 wks) in 41% (arm S) and 56% (arm P) of responding pts and were durable (range: arm S: 12.1+ to 54 wks; arm P: 12.1 to 69.1+ wks). Stable disease rate was 33% (n=11) in arm S and 35% (n=7) in arm P. PFS rate at 24 wks was 78% for arm S and 55% for arm P. **Conclusions:** Nivolumab plus S or P showed encouraging antitumor activity and a manageable safety profile in pts with mRCC. Additional follow up will be presented. Clinical trial information: NCT01472081.

**5011 Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

**Inhibition of PD-L1 by MPDL3280A and clinical activity in pts with metastatic urothelial bladder cancer (UBC).** *Presenting Author: Thomas Powles, Barts Cancer Institute, Queen Mary University Hospital of London, London, United Kingdom*

**Background:** Metastatic UBC is associated with a poor prognosis and limited treatment options. PD-L1 expression is prevalent in this disease and may protect cancer cells from immune-mediated destruction by binding to its receptors PD-1 and B7.1. MPDL3280A is a human anti-PD-L1 mAb with an engineered Fc-domain designed for optimized efficacy and safety. **Methods:** In a Ph I study, UBC pts received MPDL3280A 15 mg/kg IV q3w for up to 1 y. Objective response rate (ORR; including unconfirmed responses) was assessed by RECIST v1.1. In parallel, tumor and circulating biomarkers were evaluated to study MPDL3280A immune correlates. **Results:** As of Sep 19, 2013, 31 UBC pts were treated with MPDL3280A. Pts were 84% male, had a median age of 66 y (42-86), 57% were ECOG PS 1 and 68% had visceral metastases. 71% received $\geq$ 2 prior therapies; 97% received prior platinum-based chemotherapy. Pts had received MPDL3280A for a median duration of 43 d (1-153); the majority remained on treatment as of the data cutoff. The G1-4 treatment-related AEs occurring in $\geq$ 2 pts were pyrexia, anemia, decreased appetite, fatigue and nausea. Related G3-4 AEs occurred in 3.2% of pts. There were no immune-related AEs. 20 PD-L1+ pts were evaluable for efficacy at time of analysis with a median follow up of 2.8 m (1.4-5). The ORR was 50% (1 CR and 9 PRs) with a median time to response of 43 d (39-82), corresponding to the first radiographic assessment. Responders included pts with visceral metastases at baseline. All responders were still responding at the time of clinical cutoff. Treatment resulted in transient increases in circulating CD8+Ki-67+ T cells and plasma proteins (eg, IL-18) upstream of IFN$\gamma$ signaling, representing pharmacodynamic biomarkers of activity. Gene expression data from pretreatment tumors showed that pts who progressed had a proportionally higher myeloid gene signature (eg, IL8, CCL2). Updated data will be presented, including data from PD-L1–neg pts. **Conclusions:** MPDL3280A was well tolerated in this pretreated UBC population. 50% of pts treated responded to treatment. Responses were rapid and on-going. Biomarker analysis revealed pharmacodynamic markers, as well as markers of potential mechanisms of resistance to therapy. Clinical trial information: NCT01375842.

**5012 Clinical Science Symposium, Sat, 3:00 PM-4:30 PM**

**Immunomodulatory activity of nivolumab in previously treated and untreated metastatic renal cell carcinoma (mRCC): Biomarker-based results from a randomized clinical trial.** *Presenting Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Nivolumab, a fully human IgG4 programmed death-1 (PD-1) inhibitor antibody, has shown encouraging activity in mRCC. This trial assessed the immunomodulatory and clinical activity, and safety of nivolumab in patients (pts) with mRCC. **Methods:** Ninety-one pts received nivolumab IV Q3W: pretreated pts (1–3 prior therapies; ≥1 anti-angiogenic agent) received 0.3 (n=22), 2 (n=22), or 10 mg/kg (n=23); 24 treatment-naïve pts received 10 mg/kg. Fresh biopsies and serum were obtained at baseline (BL) and nivolumab cycle 2 day 8 (C2D8; biopsy) and cycle 4 day 1 (C4D1; serum). Primary objective was to assess the immunomodulatory activity of nivolumab on serum chemokines (CXCL9, CXCL10) and tumor T cell infiltrates from BL to post treatment. Secondary/exploratory objectives included safety and tolerability, antitumor activity (ORR; RECIST 1.1), BL and treatment-induced changes in PD-1 ligand (PD-L1) expression (Dako immunohistochemistry assay; PD-L1 positivity: >5% tumor membrane staining at any intensity) and association of clinical activity with BL PD-L1 expression. **Results:** Mean increase from BL to C4D1 was 191% for CXCL9 and 90% for CXCL10. T cell infiltrates increased by a median of 70% (CD3+; range 53–220%) and 88% (CD8+; 61–257%) from BL to C2D8. Of 56 evaluable fresh pretreatment biopsies, 18 (32%) were PD-L1+. ORR was 22% (4/18) for PD-L1+ pts vs 8% (3/38) for PD-L1–. In 5/27 (19%) matched biopsy pairs PD-L1 expression increased >5% by C2D8. For evaluable pts ORR was 16% (14/90); 16% in previously treated pts, 13% in untreated pts. Median duration of response was 15 months; 6 (43%) responses are ongoing. 14/91 (15%) pts had grade 3–4 related AEs, most commonly colitis and elevated AST (n=2 each), diarrhea and pneumonitis (n=1 each), all grade 3. **Conclusions:** In this prospective biomarker-based study, nivolumab showed clinical activity and manageable safety in pts with previously treated and untreated mRCC. Responses were numerically higher in PD-L1+ pts but also seen in PD-L1– pts. Changes in biomarkers were consistent with PD-1 inhibition and provided evidence of immunomodulatory effects in serum and in the tumor microenvironment. Clinical trial information: NCT01358721.

**5013 Poster Highlights Session (Board #27), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Validation of a prognostic model for metastatic castrate-resistant prostate cancer (mCRPC) patients receiving abiraterone acetate (AA).** *Presenting Author: Praful Kumar Ravi, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

**Background**: A prognostic model based on clinical parameters has been derived from the population of the COU-AA-301 Phase 3 trial for mCRPC patients treated with AA after docetaxel. It relies on the presence of six clinical parameters: ECOG-PS=2, presence of liver metastases, time from start of initial LHRH agonist therapy to AA therapy ≤36mths, low albumin, high alkaline phosphatase and high LDH (1 point per parameter) to stratify patients into 3 risk groups. We sought to validate this model in an independent cohort of patients treated with AA post-docetaxel, and to explore its utility in patients treated with AA in the pre-chemotherapy setting. **Methods**: We reviewed all mCRPC patients who received AA between January 2006 and June 2013 at our centre who either received AA post-docetaxel outside of a clinical trial (group A, validation set) or were treated with AA prior to chemotherapy (group B, exploratory analysis). Clinical data at the time of starting treatment with AA and outcome was collected from electronic patient records. Patients were assigned into 'good' (0-1), 'intermediate' (2-3), and 'poor' (4-6) prognostic groups as per the published model (Chi KN et al, J Clin Oncol 2013;abstr 5013). Differences in median overall survival (mOS) were assessed using the log-rank test. **Results**: A total of 158 patients were eligible for this analysis (group A: n=94, group B: n=64). Median duration of AA therapy and mOS were 4.7mths and 13.3mths (group A), and 15.3mths and 40.4mths (group B) respectively. When considering the validation set of patients post-docetaxel, mOS was significantly different across the three prognostic groups (good: n=39, mOS=21.8mths; intermediate: n=44, mOS=10.6mths; poor: n=7, mOS=6.8mths; p=0.0001). Analysis of group B confirmed the ability of the model to prognosticate for OS in the pre-chemotherapy setting: (good: n=44, mOS=45.6mths; intermediate or poor: n=20, mOS=34.5mths; p=0.042). **Conclusions**: These results serve to validate the prognostic model in an independent, unselected population treated with AA post-docetaxel and support clinical implementation of the score. Additionally, the model remains valid in the pre-chemotherapy setting.

**5014 Poster Highlights Session (Board #28), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Circulating tumor cells (CTCs) and LDH as prognostic factors in patients with metastatic castration-resistant prostate cancer (mCRPC) progressing during or following docetaxel treated in the orteronel phase 3 ELM-PC 5 trial.** *Presenting Author: Howard I. Scher, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Results from a global phase 3 study demonstrated that orteronel 400 mg BID /prednisone 5 mg (O+P), vs placebo/prednisone alone (P), improved radiographic progression (rPFS) and increased PSA50 response but resulted in no overall survival (OS) benefit (HR 0.89) (Dreicer et al., ASCO GU 2014). **Methods:** Whole blood samples for CTC enumeration (Veridex Cell Search, Esoterix) were obtained from 1,038 pts at baseline and 635 at end of wk 12 (primary CTC endpoint). Results were reported as number counted CD45-/EpCam+ cells/7.5 mL whole blood. **Results:** Baseline distribution of favorable (< 5 cells/7.5 mL) to unfavorable (≥ 5 CTCs/7.5 mL) were balanced in the two groups (40% favorable in each). In cross sectional analysis, the percent favorable remained unchanged with P at wk 12 (96/214) (45%) but increased to 62% (262/421) with O+P. Patient shift analysis showed that 99 of 231 (43%) of pts on O+P converted to favorable vs. 17 of 113 (15%) on P. A trichotomous surrogate biomarker panel (Scher et al, ESMO 2013) based on 12-wk data categorized patients as low-risk (CTC ≤ 4), intermediate-risk (CTC ≥ 5, LDH ≤ 225 U/L) or high-risk (CTC ≥ 5, LDH > 225 U/L). Distribution of risk at 12 wks by treatment was for O+P vs. P: low, 262 (36%) vs. 96 (26%); intermediate, 63 (9%) vs. 54 (15%); and high, 93 (13%) vs. 59 (16%). At 12 wks, the overall survival (OS) HRs for the three risk categories adjusted for treatment and other baseline characteristics are shown in the table. Addition of treatment effect to the K-M estimates for risk groups did not give additional predictive value at that 12-wk timepoint. Results with a dichomotous CTC-only model were similar: OS % at 1 and 2 yrs was 87 and 61 vs. 51 and 15 for ≤ 4 vs. ≥ 5 respectively (P < 0.0001). **Conclusions:** O+P resulted in a more favorable risk redistribution of CTCs at 12 wks and the risk categories were strongly predictive of OS. The findings support the therapeutic impact of O+P relative to P as well as the prognostic potential for CTC at 12 wks. Clinical trial information: NCT01193257.

| Risk at 12 wks | HR | CI | P-value |
|---|---|---|---|
| Intermediate- vs. low-risk | 2.596 | (1.742, 3.870) | < 0.0001 |
| High- vs. low-risk | 6.218 | (4.329, 8.931) | < 0.0001 |

**5015^ Poster Highlights Session (Board #29), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Association of serum (SR) and tissue (TX) abiraterone (ABI) levels with intraprostatic steroids and pathologic outcomes in men with high-risk localized prostate cancer (PCa).** *Presenting Author: Elahe A. Mostaghel, Fred Hutchinson Cancer Research Center, Seattle, WA*

**Background:** Factors influencing efficacy of ABI in suppressing SR and TX androgens and inhibiting tumor growth in PCa are unknown. We examined the relationship of SR and TX ABI levels with SR and TX steroid levels and pathologic responses. **Methods:** Steroid and ABI levels were measured by mass spectrometry in SR and TX from 58 men with localized PCa in a clinical trial of castration with 3 or 6 months (mo) of ABI prior to prostatectomy. **Results:** Median ABI levels in SR and TX were 31 ng/ml (range 2.8-414) and 18 pg/mg (1.3-265) respectively. SR and TX ABI levels were positively correlated with SR and TX steroids upstream of CYP17A (pregnenolone [Preg], progesterone [Prog]) and inversely correlated with downstream steroids (17OH Preg, DHEA, all p<0.05). Two men at 3 mo and six at 6 mo had undetectable ABI in SR and TX, and did not show changes in steroids up or downstream of CYP17A. In men with undetectable vs detectable TX ABI levels, there was a trend toward higher cross-sectional tumor dimension, TX cellularity, tumor PSA staining and SR PSA (all p<0.10). TX ABI levels were significantly lower at 6 vs 3 mo (7.8 vs 62 pg/mg, p<0.001) while SR ABI levels were similar. At 3 mo 0/25 men had TX dihydrotestosterone (DHT) levels >1 (range 0.08-0.57 pg/mg), while at 6 mo 22% (10/46) had TX DHT >1 (1-17 pg/ml). At 3 mo TX Preg was strongly correlated with TX DHEA, while DHT was correlated with androstenedione (AED) and testosterone (T) (r>0.5, all p<0.01). At 6 mo the intraprostatic correlations of up- and downstream steroids were markedly increased (r>0.5 for TX Preg with downstream DHEA, AED, T and DHT; and for TX DHT with upstream T, AED, DHEA and Preg, all p<0.01). **Conclusions:** Prostate TX ABI levels are associated with TX steroids and pathologic responses in localized PCa. At 6 mo TX ABI levels decreased nearly 10-fold vs 3 mo (despite stable SR ABI levels), DHT levels markedly increased in >20% of samples, and intraprostatic correlations of DHT with steroids upstream of CYP17A inhibition became highly significant. These findings suggest that potential mechanisms of ABI resistance are induction of drug export or metabolism, and intraprostatic conversion of upstream precursors to DHT. Clinical trial information: NCT00924469.

**5016 Poster Highlights Session (Board #30), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Pathologic correlation of 18F-16β-fluoro-5α-dihydrotestosterone (FDHT) and FDG PET in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Jarett Lawrence Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** We have demonstrated the feasibility, pharmacokinetic properties, tumor targeting, and the preliminary prognostic value of FDHT as a PET tracer for prostate cancer (PCa). As part of an imaging trial, we performed biopsies (bx) to assess the tumor-detection rate of FDHT and compared it with FDG PET. **Methods:** Pts with progressive mCRPC identified on standard imaging (CT, MRI, and bone scintigraphy) from 2007 to 2013 underwent FDHT and FDG PET/CT. Bx locations were selected by a consensus panel prioritized on the basis of: FDHT & FDG positivity, FDHT & FDG mismatch, and standard imaging positivity & any PET mismatch. Bx were considered positive (pos) if PCa was identified and negative (neg) if benign tissue or a secondary malignancy was sampled. **Results:** A total of 64 bx (28 soft tissue, 36 bone) were obtained from 54 pts of which 62 were evaluable (2 were non-diagnostic). 53/62 (85%) bx were pos and 9/62 (15%) were neg for PCa. FDHT and pathology correlated (pos/pos or neg/neg) in 56/62 (90%). FDG and pathology correlated in 57/62 (92%). All 47 FDHT pos lesions were pos for PCa. Notable mismatches were: FDHT neg/biopsy pos appeared in 6/53 (11%) cases of which 3 displayed neuroendocrine (NE) features and 2 were poorly-differentiated (PD) adenocarcinoma. FDG pos/bx neg for PCa appeared in 5/62 (8%) cases; 3 were secondary malignancies. The histopathologic correlation is provided in the table below. **Conclusions:** FDHT is highly effective at identifying adenocarcinoma of the prostate as demonstrated by pathology. A subset of lesions that are not detected on FDHT, but present on FDG imaging, represent neuroendocrine/poorly-differentiated PCa; these require further investigation in regards to prognosis and response to treatment. Clinical trial information: NCT00588185.

**Biopsy correlation of evaluable lesions with imaging findings (N=62).**

| Imaging results | | | Biopsy pos for PCa | | Biopsy neg for PCa | | Total lesions (# of pts[a]) |

**5017 Poster Highlights Session (Board #31), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Comparison of plasma microRNAs with CTCs and PSA in patients treated on SWOG S0925, a randomized phase II study of androgen deprivation combined with cixutumumab versus androgen deprivation alone for patients with new metastatic hormone-sensitive prostate cancer.** *Presenting Author: Heather H. Cheng, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

**Background:** Circulating, blood-based microRNAs (miRNAs), like circulating tumor cells (CTCs), are promising prostate cancer biomarker candidates. However, circulating miRNAs have yet to be examined in prospective clinical trials. Here, we examine the correlation between baseline plasma miRNAs and CTCs with 7-month PSA (previously shown to be strongly correlated with overall survival in SWOG 9346) in patients from SWOG 0925. **Methods:** Plasma and CTCs were collected prior to initiation of androgen deprivation (AD) from patients on SWOG 0925. miRNA was extracted and measured from plasma using miRCURY RNA Isolation kit and miRNA Ready-to-Use PCR, Human panel I, V1.M qRT-PCR arrays (Exiqon). CTC measurements were performed using the CellSearch® platform (Veridex). **Results:** Correlation between miRNA cycle threshold and CTCs are shown (Table). Baseline plasma miR-375 levels were associated with stratified 7-month PSA response (≤0.2, 0.2 to ≤4.0, or >4.0, P=0.0071, Friedman test). Using ROC curve analysis, there was no significant difference between baseline miR-375 and baseline CTC in predicting 7-month PSA response (≤0.2 vs. >0.2). **Conclusions:** Baseline plasma miR-141, miR-200a, miR-200c and miR-375 levels were significantly correlated with baseline CTC count. Baseline plasma miR-375 was similar to baseline CTCs in ability to predict 7-month PSA in a prospective, multi-center clinical trial.

**Correlation of baseline miRNA (cycle threshold) and CTC counts.**

| MicroRNA | N | Spearman correlation | 95% CI | p-value |
|---|---|---|---|---|
| **miR-141** | 35 | -0.60 | -0.78 to -0.34 | 0.0001 |

**Effect of HOXB13 and FOXA1 on the AR cistrome during prostate tumorigenesis in primary human tissue.** *Presenting Author: Mark M Pomerantz, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The androgen receptor (AR) is central to prostate carcinogenesis and cancer progression. Current understanding of the prostate AR cistrome - the genome-wide set of AR binding sites (ARBS) - is driven largely by tumor model systems. The role of the AR cistrome in prostate tumorigenesis in human tissue is unknown. We map the AR cistrome in 20 normal and tumor human prostate samples using chromatin immunoprecipitation followed by high-throughput sequencing (ChIP-seq). **Methods:** Chromatin was extracted from 13 tumor and 7 matched histologically normal foci (>70% enrichment) from fresh-frozen radical prostatectomy specimens. Tissue was pulverized, fixed and sonicated then immunoprecipitated with antibody to AR; DNA was isolated; libraries were constructed for the Illumina platform; sequencing reads were aligned to the human genome using MACS (false discovery rate 0.01) **Results:** Median 19,602 ARBS were called per sample. In unsupervised pairwise analysis of each AR cistrome, specimens clustered distinctly into tumor and normal groups. 9,181 ARBS were consistently enriched in tumor relative to normal (T-ARBS) and 2,690 were enriched in normal relative to tumor (N-ARBS). DNA binding motif analysis showed that AR itself is the most significantly enriched motif in N-ARBS, while FOXA1, and HOXB13 and AR were most significantly enriched in T-ARBS (z-score < -15). HOXB13 ChIP and FOXA1 ChIP in VCaP cell line showed substantial overlap with T-ARBS (68% and 76% of T-ARBS, respectively) and their knockdown via shRNA adversely affects prostate cell line survival. We identified genes within 1 megabase of T-ARBS or N-ARBS that are differentially expressed in tumor and normal. Expression levels of these genes in large clinically annotated patient cohorts are highly associated with multiple clinical parameters, including tumor grade and development of metastasis. **Conclusions:** We performed the most comprehensive study of the AR cistrome in human tumor and normal prostate tissue. We demonstrate that the AR cistrome is dynamic and implicate HOXB13 and FOXA1 as factors that reprogram the AR during transformation. These findings attest to the power of performing epigenetic analysis in both normal and tumor human tissue.

**5019 Poster Highlights Session (Board #33), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Concordance of ETS fusion status of matched metastatic castration-resistant prostate cancer and primary prostate cancer: Data from NCI 9012, a randomized ETS fusion-stratified phase II trial.** *Presenting Author: Lakshmi Priya Kunju, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

**Background:** Fusions of androgen-regulated genes with ETS transcription family members have been reported in 50% of localized pPCa patients (pts), with *TMPRSS2-ERG* fusions being the most common. ETS fusion products functionally depend upon Poly (ADP-ribose) polymerase 1 (PARP1), and its inhibition is preferentially cytotoxic to ETS translocation positive disease in preclinical models. We hypothesized that targeting ETS gene fusions will improve response rate in pts with these molecular subtypes and in pts with ETS fusion positive tumors, targeting the promoter and transcription factor of ETS fusion is more effective than targeting a single aspect of the fusion. **Methods:** Eligible mCRPC pts undergo a metastatic site biopsy to determine ETS fusion status by immunohistochemistry (ERG), fluorescent in-situ hybridization and/or RNA in-situ hybridization (ETV1) and sequencing (ETV4). Pts are stratified by ETS status and randomized to abiraterone (ABI) +/- the PARP inhibitor veliparib. Soft tissue biopsies are done using 18-gauge needle: 1-cm core (≥ 6 specimens), 2-cm core (≥4 specimens). For bone biopsy: 2-8 cores. We report interim results on rates of positive biopsy, ETS status/type and concordance between primary PCa and metastasis. **Results:** To date, 86 pts (Caucasians: 80%, African Americans 14%) with a median age 70 years and a median PSA 36.3 ng/ml have been enrolled. Of the 86 pts, 1 had an unreachable bone lesion, 36 had soft tissue and 49 had bone biopsies; all soft tissue and 36/49 (73%) bone biopsies were evaluable for analysis (13 had no tumor), ETS fusion status is positive in 36% pts: ERG positive (31%), ETV1 positive (4%), ETV4 positive (1%). Concordance of ETS status between primary PCa and metastatic site was found in 30/31 pts (97 % [95% CI: 83-99.9%]. **Conclusions:** This trial represents one of the first prospective predictive biomarker-driven trials in mCRPC. Results indicate feasibility of real time biopsy (adequate tissue yield including from bone) and biomarker determination, and demonstrates significant concordance of ETS status between primary PCa and metastasis in the subset analyzed to date. Clinical trial information: NCT01576172.

**5020 Poster Highlights Session (Board #34), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Androgen receptor (AR) amplification in patients with metastatic castration-resistant prostate cancer (mCRPC) refractory to therapy with abiraterone acetate or enzalutamide: Preliminary results from the SU2C/PCF/AACR West Coast Prostate Cancer Dream Team (WCDT).** *Presenting Author: Eric Jay Small, University of California, San Francisco, San Francisco, CA*

**Background:** The mechanisms of resistance to androgen signaling inhibitors such as Abiraterone (Abi) or Enzalutamide (Enz) are poorly understood. AR amplification (AR+) has been observed in Abi/Enz naive mCRPC patients (pts), but its role in Abi/Enz resistant pts is not known. Progressive mCRPC has historically been challenging to biopsy and characterize on a molecular basis because of its bone tropism. As part of the WCDT project which aims to identify genetic pathways underlying primary and acquired resistance to Abi and Enz, AR+ was assessed in mCRPC biopsies. **Methods:** Following central radiologic review, eligible mCRPC pts underwent biopsy at one of 5 WCDT clinical sites, using a uniform biopsy protocol. Tissue was both frozen, and formalin fixed/paraffin embedded (FFPE). FFPE tissue underwent a CLIA-certified assessment of a mutational panel, IHC for PTEN, and fluorescence in situ hybridization (FISH) for AR+. **Results:** 60 of 300 planned mCRPC pts have undergone a metastasis biopsy. To date, 33 pts have had biopsies successfully evaluated by AR FISH, including 12 from bone, 11 from lymph nodes, 8 from liver and 2 from other soft tissues. Of 16 Abi and Enz naive pts, 13 (81%) were AR+. By contrast, only 1/11 Abi resistant pts (9%) was AR+. 4/6 Enz resistant pts (67%) were AR+. Of 6 AR+ patients that went on to receive Abi or Enz, 3 (50%) had a response (PCWG2 criteria), whereas of 5 pts without AR+ who went on to receive Abi/Enz, just 1 (20%) had a response. **Conclusions:** AR amplification can be evaluated by FISH in small biopsies of mCRPC, including bone, and it was observed in 18/33 samples (55%). AR+ was common in mCRPC patients prior to therapy with Abi or Enz (81%). However, once resistance developed, Abi resistant pts had a far lower likelihood of AR+ (9%) than Enz resistant pts (67%). These data support the hypothesis that treatment with Abiraterone selects for non-AR amplified cells, whereas Enzalutamide does not. In this relatively small cohort, mCRPC pts with AR+ are more likely to respond to subsequent AR targeted therapeutics than pts without AR+.

**5021 Poster Highlights Session (Board #35), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Genomic analysis of circulating tumor DNA (ctDNA) in plasma of metastatic castration-resistant prostate cancer (mCRPC) patients (pts) treated with abiraterone acetate (abi) and enzalutamide (enza).** *Presenting Author: Arun Azad, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** CollectingctDNA represents a promising and minimally invasive approach for profiling the cancer genome of mCRPC pts, which may reveal key resistance mechanisms to agents such as abi and enza. **Methods:** Plasma was collected from 51 mCRPC pts at cessation of abi (n=26), enza (n=17) or other agents (n=8) due to any of biochemical, objective or clinical progression. DNA was extracted and subjected to array Comparative Genomic Hybridization (aCGH) for chromosome copy number analysis and next generation sequencing of exon 8 of the androgen receptor (AR) ligand-binding domain (LBD). **Results:** Sufficient DNA was available for aCGH in 48 of 51 pts (94%). 8p loss, 8q gain and AR gain were seen in 29% (14/48), 40% (19/48) and 54% (26/48) of pts respectively, with AR amplification status being concordant between ctDNA and fluorescence in situ hybridization (FISH) of concurrent metastatic tumour biopsies in 3 of 4 pts. Other copy number changes detected included high CCND1 and CCNE1 gain (4% each). Correlation of clinical and genomic data showed that AR amplification was significantly more frequent in pts progressing on enza compared to those progressing on abi (76% vs. 39%, p=0.027; Chi-square). In 26 pts switched onto enza after ceasing abi/other agents, those with AR amplification at initiation of enza were significantly more likely to have enza-refractory disease (i.e. no PSA decline on treatment) compared to pts without AR amplification (60% vs. 19%, p=0.046; Chi-square). AR sequencing in 29 pts detected several high frequency mutations including T877A and F876L in 41% (12/29) and 10% (3/29) of pts respectively. The F876L mutation, linked with resistance to enza pre-clinically, was detected in two enza-naïve pts, both of whom progressed within 3 months on subsequent enza therapy. **Conclusions:** Genomic analysis of ctDNA from mCRPC pts identified key aberrations that may be associated with therapeutic resistance including AR amplification and the F876L AR mutation. Our data illustrate the potential utility of profiling ctDNA to characterize the genomic landscape of mCRPC.

**5022 Poster Highlights Session (Board #36), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A randomized, open label, multicenter, phase 3, 2-arm study of androgen deprivation with leuprolide (L), ± docetaxel (D) for clinically asymptomatic prostate cancer (PC) subjects with a rising PSA following definitive local therapy: Safety results.** *Presenting Author: Michael J. Morris, Sidney Kimmel Center for Prostate and Urologic Cancers, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** The optimal approach to PC patients (pts) who biochemically relapse following a radical prostatectomy (RP) is not known. Pts with a rapidly rising PSA are at high risk of early metastasis and death. We conducted a phase III study in such pts to determine the clinical benefit of adding chemotherapy to early hormonal therapy (ADT). All pts have been treated. Here we report the safety results. **Methods:** Pts with PC who underwent a RP ± salvage RT and developed a rising PSA with a doubling time ≤ 9 months (mo) and no evidence of metastasis were eligible. PSA ≥ 1 ng/mL and testosterone (T) ≥ 100 ng/dl were required. Prior ADT ≤ 6 mo was allowed. Pts were randomized (1:1) to receive L 22.5 mg q3 mo x 18 mo, bicalutamide 50 mg x 30 days, with (Arm A) or without (Arm B) D 75 mg/m2 q3 weeks x 10 cycles. The primary endpoint was PFS at 18 mo post treatment (tx), with T recovery > 50 ng/dl. A sample size of 412 was calculated to detect a HR of 1.6 with 90% power. **Results:** 400 pts received tx (Arm A = 196, Arm B = 204) and 352 pts completed tx (Arm A = 170, Arm B = 182). 87% of pts treated in Arm A and 89% of pts treated in Arm B completed tx. Pts in Arm A received a mean of 9 cycles of D (range: 1-10), with 79.1% receiving all cycles. Pt compliance for L and bicalutamide was 100%. A greater % of Arm A pts experienced tx-related adverse events (AEs) (93.9 vs. 66.7%), AEs ≥ Gr 3 (48 vs. 10.8%), and serious AEs (25 vs. 9.8%). Most common AEs in Arm A were alopecia (Gr 1-2), fatigue, hot flush, edema, and diarrhea (Gr 1-4), and in Arm B were hot flush (Gr 1-4) and fatigue (Gr 1-2). Most common Gr ≥ 3 AEs in Arm A were neutropenia (15.8%), febrile neutropenia (6.6%), fatigue (4.6%), hyperglycemia (2.6%), and peripheral neuropathy (2.0%). In Arm B, no AE of Gr ≥ 3 occurred in more than 1 pt. **Conclusions:** ADT for 18 mo ± D for 10 cycles is feasible when given to pre-metastatic castration-sensitive PC pts. As expected, tx in Arm A was concordant with the known D safety profile. Collection of data for analysis of the primary endpoint is ongoing. Clinical trial information: NCT01813370.

**5023 Poster Highlights Session (Board #37), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase 2 trial of prostate-specific membrane antigen antibody drug conjugate (PSMA ADC) in taxane-refractory metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Daniel Peter Petrylak, Yale University Medical Center, New Haven, CT*

**Background:** PSMA expression on prostate cancer cells provides a rationale for ADC therapy. PSMA is a clinically validated target. PSMA ADC is a fully human antibody to PSMA linked to the microtubule disrupting agent MMAE. It induces cell cycle arrest and apoptosis specifically in PSMA-positive cells. We have completed enrollment in a multicenter phase 2 trial of PSMA ADC in mCRPC pts progressing after taxane and antiandrogen. **Methods:** Pts with progressive mCRPC following taxane and abiraterone (ABI) and/or enzalutamide (ENZ) regimens and ECOG PS 0, 1 or 2 were eligible. PSMA ADC was administered Q3 wk IV for up to 8 cycles. Safety, tumor response by PSA, circulating tumor cells (CTC), imaging, biomarkers and clinical progression were assessed. Dosing was initiated at 2.5 mg/kg and adjusted for tolerability. **Results:** 34 pts received PSMA ADC at 2.5 mg/kg. Due to neutropenia, 49 pts subsequently received 2.3 mg/kg. 39% had both docetaxel and cabazitaxel (CAB); and 58% had both ABI and ENZ. 30% had visceral or soft tissue metastases. Duration of therapy on 2.3 mg/kg was longer than on 2.5 mg/kg. Any related adverse event (AE) grade ≥3 was 37% (2.3) and 59% (2.5 mg/kg). Related, grade 3/4 AEs occurring in ≥10% were fatigue, neutropenia and decreased electrolytes (16% vs 15%, 6% vs 18%, and 8% vs 21% at 2.3 and 2.5 mg/kg, respectively). 2 pts at 2.5 mg/kg died of sepsis. PSA decline of ≥30% was noted in 36% (2.3) and 16% (2.5 mg/kg), and CTC decline of ≥50% was noted in 74% pts in both 2.3 and 2.5 mg/kg. CTC conversion from ≥5 to <5 cells/7.5 ml blood occurred in 48% (2.3) and 50% (2.5 mg/kg). PSA and CTC responses were associated with higher PSMA+CTC and PSA responses with lower neuroendocrine markers. Stable disease was seen in 80% of RECIST evaluable pts (n=15). Pts with prior CAB had lower CTC responses. Responses in pts with prior ABI did not differ from pts with prior ENZ. **Conclusions:** PSMA ADC at 2.3 mg/kg was active and well tolerated in heavily pretreated mCRPC pts. Updated safety and secondary efficacy endpoints from the 2.3 and 2.5 mg/kg cohorts will be presented. These data warrant further evaluation in this population. A taxane-naïve cohort is ongoing. Clinical trial information: NCT02020135.

**5024 Poster Highlights Session (Board #38), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase I study of DSTP3086S, an antibody-drug conjugate (ADC) targeting STEAP-1, in patients (pts) with metastatic castration-resistant prostate cancer (CRPC).** *Presenting Author: Daniel Costin Danila, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

**Background:** Six-transmembrane epithelial antigen of the prostate-1 (STEAP1) protein is a cell-surface protein frequently overexpressed in prostate cancer. The ADC DSTP3086S contains the humanized IgG1 anti-STEAP1 monoclonal antibody linked to the potent anti-mitotic agent MMAE. **Methods:** This study evaluated safety and activity of DSTP3086S (0.3-2.8 mg/kg IV) given every 3 weeks (q3w) to pts with CRPC. A traditional 3+3 design was used to determine maximum-tolerated dose, followed by cohort expansion at the recommended Phase II dose (RP2D). Clinical activity was evaluated per PCWG2 criteria. **Results:** As of 18 Dec 2013, 59 pts were enrolled with a median age of 68 (43-87), all ECOG PS 0-1, and with a median of 6 prior systemic regimens (71% received prior taxanes). Pts received a median of 3 doses (range 1-14) of DSTP3086S, with 14 pts (24%) still ongoing. Two patients in dose escalation (1 at 2.25 mg/kg and 1 at 2.8 mg/kg) had dose limiting G3 transaminitis. Cohort expansion started at 2.8 mg/kg (n=10). Frequent dose reductions at 2.8mg/kg led to testing 2.4 mg/kg (n=22) which had increased tolerability. The most common related AEs (>10%) across all doses were fatigue, nausea, constipation, peripheral neuropathy, anorexia, vomiting, diarrhea, and abdominal pain. There were 9 treatment-related serious AEs in 6 pts, including DVT (G3) at 1.5 mg/kg, sepsis (G5) and GI hemorrhage (G3) at 2.25 mg/kg, bacteremia (G4), neutropenia (G3 and G4), presyncope (G2), and constipation (G2) at 2.4 mg/kg; and abdominal pain (G3) at 2.8 mg/kg. Approximately 60% of archival tumor tissues from Ph1 dose escalation patients were STEAP1 IHC high (2+/3+), while STEAP1 IHC high was required in the expansion cohort. PSA declines by >50% were obtained in 1/7 at 2.25 mg/kg, 3/21 at 2.4 mg/kg, and 5/16 at 2.8 mg/kg; 2 pts at 2.8 mg/kg also had RECIST responses. CTC conversions from unfavorable to favorable (<5) occurred in 1/5 at 2.25 mg/kg, 3/5 at 2.4 mg/kg, and 7/10 at 2.8 mg/kg. **Conclusions:** DSTP3086S at dose levels between 2.25 and 2.8 mg/kg demonstrated anti-tumor activity and the RP2D is 2.4 mg/kg q3w. Clinical trial information: NCT01283373.

**5025 Poster Highlights Session (Board #40), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase 1b study of abiraterone acetate (AA) and docetaxel (D) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Scott T. Tagawa, Weill Cornell Medical College, New York, NY*

**Background:** Coadministration of D and AA may be beneficial due to complementary mechanisms of action. A phase 1b safety and pharmacokinetic (PK) study assessed the safety and efficacy of D + AA. **Methods:** 3 cohorts (C) of chemo-naive mCRPC pts received escalating doses of D + AA. Primary end point: proportion of pts with dose-limiting toxicity (DLT) between Wks 2 and 7, defined as grade (Gr) ≥ 3 non-heme toxicity, Gr 4 neutropenia > 7 days (or febrile neutropenia), Gr 4 thrombocytopenia, or other intolerable toxicity. Pts could continue AA after discontinuing D. D + AA was deemed safe if ≤ 2 pts/C experienced DLT; the maximum tolerated dose (MTD) was the highest safe combination of D + AA. PSA changes and PK parameters were evaluated. **Results:** 22 pts were treated; 18 pts were evaluable for DLT assessment. The combination dose received by C3 (1 pt had DLT) was deemed the MTD. With treatment ongoing, 90% and 70% of pts had ≥ 50% and ≥ 90% PSA decline from baseline, respectively (Table). With median follow-up of 11.8 months, there were 5 PSA progression events. PK parameters were comparable for both abiraterone and D alone and in combination. **Conclusions:** D + AA was well tolerated at full doses of each drug. PK was comparable when D and AA were given alone and in combination. The efficacy signal may justify further study. Clinical trial information: NCT01400555.

**ARN-509 in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) with and without prior abiraterone acetate (AA) treatment.** *Presenting Author: Dana E. Rathkopf, Memorial Sloan-Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

**Background:** ARN-509 is a second-generation antiandrogen that selectively binds to the ligand-binding domain of the androgen receptor, blocks its nuclear translocation and impairs DNA binding to androgen response elements. ARN-509-001 is a phase 1/2 study evaluating ARN-509 activity in 3 cohorts: 1) nonmetastatic CRPC; 2) mCRPC; and 3) mCRPC post-abiraterone acetate (AA). Phase 2 results for the mCRPC cohorts as of July 2013 are presented. **Methods:** All pts with mCRPC had progressive disease based on rising prostate-specific antigen (PSA) and/or imaging. Prior chemotherapy for mCRPC was an exclusion. The post-AA cohort required treatment with AA for ≥ 6 mos. All pts received 240 mg/d ARN-509, the phase 2 recommended dose (Rathkopf et al. J Clin Oncol. 2013). The primary end point was PSA response at 12 wks, using Prostate Cancer Working Group 2 (PCWG2) criteria. Secondary end points were safety, time to PSA progression, objective response rate, and progression-free survival (PFS). PSA was assessed every 4 wks and tumor imaging was performed every 12 wks. **Results:** Enrolled pts included 25 mCRPC and 21 post-AA mCRPC pts with median age of 68 yrs (range 48-91). At baseline 57% had ECOG score 0; 52% had Gleason score ≥ 8; median PSA 14.7 (mCRPC) and 58.4 (post-AA) ng/mL. Median duration on ARN-509 treatment is 9.2 mos (range 1.8-25.8). 31 pts have discontinued the study due to disease progression (n = 18), adverse events (n = 5), consent withdrawal (n = 4), or other reasons (n = 4). The most common treatment-related adverse events were fatigue (n = 21), nausea (n = 13), diarrhea (n = 10) and abdominal pain (n = 8). **Conclusions:** ARN-509 is safe and well tolerated, with evidence of activity in chemo-naïve mCRPC, including in 24% of pts who have received prior AA. Clinical trial information: NCT01171898.

**5027^ Poster Highlights Session (Board #42), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase 1 dose-finding study of cabozantinib (cabo) plus abiraterone (abi) combination therapy in castration resistant prostate cancer (CRPC): An investigator-sponsored study.** *Presenting Author: Christopher Sweeney, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Abi (CYP17A1 and lyase inhibitor) and cabo (multi-tyrosine kinase inhibitor including MET and VEGFRs) have complementary mechanisms of action. Both have single agent activity in CRPC. Preclinical in vivo work with LAPC4-CR (castration and abi resistant cell line) has shown the combination has enhanced activity. **Methods:** A phase 1 dose escalation trial using a 3 + 3 design with a fixed dose of abi 1,000 mg daily and prednisone 5mg BID with escalating daily doses of cabo (20mg, 40mg, 60mg) in pts with progressive metastatic CRPC (pre or post chemo). Cycles were 28 days. The dose expansion cohorts alternated between the 20 and 40mg doses. **Results:** 21 patients were enrolled. Median age was 60 yrs. All had ECOG PS 0 or 1. 6 pts had prior docetaxel for CRPC. 3 patients were enrolled at each dose level. No DLTs were observed in the first 4 week cycle. The 60 mg cabo cohort had grd 2 adverse events (AEs) of myalgias (2), fatigue (2) and DVT (1) in cycles 2 and 3 necessitating a dose reduction to 40 mg (no change to abi). Due to a preferable tolerability profile over the 60mg dose, the 20mg and 40mg cohorts were expanded (9 pts each). See Table for key activity data. At time of report, 9 patients had >8 mos of combination therapy. The most common grd 1/2 AEs (n≥2) in the 20mg cohort were myalgias (5), nausea (2) , fatigue (3), edema (2), and hypertension (htn, 2). At the 40mg dose, grd 1/2 AEs (n≥2) included nausea (2), diarrhea (2), fatigue (4), mylagias (2), hand-foot syndrome (2), and htn (2). 6 pts had cabo-related grd 3 AEs (20mg: diarrhea, anemia, increased AST/ALT; 40mg: HTN, low phosphate, increased lipase). Five 40mg cohort pts required dose reductions but none were needed in the 20mg cohort. **Conclusions:** Cabo at either 20mg or 40 mg is tolerable when combined with standard dose abi/prednisone. The long term tolerability and preliminary efficacy data support the investigation of this combination for further clinical development in metastatic CRPC. A phase 2 study is underway. Clinical trial information: NCT01574937.

**Everolimus plus bicalutamide in men with castration-resistant prostate cancer (CRPC): Final results of a phase II trial.** *Presenting Author: Chong-xian Pan, VA Northern California Health Care System, Mather, CA*

**Background:** We previously reported that the mammalian target of rapamycin (mTOR) pathway was upregulated in CRPC, and that inhibition of mTOR was ineffective in killing prostate cancer cells likely due to its effect on upregulating the androgen receptor (AR) pathway (Wang et al. Oncogene. 2008; 27:7106). We hypothesized that simultaneous blockade of both AR and mTOR pathways would be effective against CRPC. **Methods:** Eligible patients (pts) must have progressive CRPC with serum testosterone <50 ng/dl. No prior bicalutamide (except to prevent flare) or everolimus was allowed. Treatment regimen included bicalutamide 50 mg and everolimus 10 mg po, both qd. Primary endpoint was prostate specific antigen (PSA) response (≥30% reduction). Sample size of 23 pts would have the power of 0.8 and $\alpha$ error of 0.05 (one-sided) if the combination had a PSA response rate of 50% vs. a historical rate of 25% with bicalutamide alone. Molecular correlative studies were performed. **Results:** Twenty four pts were enrolled. Mean age was 71.1 years (range: 53.0-87.0). Mean PSA at the study entry was 43.4 ng/dl (2.5-556.9). Mean number of treatment cycles was 7.9 (1.0-23.0). Of 24 pts, 18 had a PSA response (75%, 95% CI: 0.53-0.90). Of these, 15 had a PSA decrease of ≥ 50% (62.5%, 95% CI 0.41-0.81). Median overall survival was 28 months (95% CI 14.1-42.7). Fourteen pts (54%, 95% CI 0.37, 0.78) developed Grade 3 (13 pts) or Grade 4 (1 pt with sepsis) adverse events attributable to the treatment. Serum ErbB3 increased by 5.16 folds in non-responders vs a 60% decrease in responders ($p<0.001$). **Conclusions:** The combination of bicalutamide and everolimus has very encouraging efficacy in men with bicalutamide-naïve CRPC. These results are contrary to the results of a similar phase II trial that predominantly enrolled pts previously treated with bicalutamide, and reported limited efficacy for this doublet (Nakabyashi, BJU Intl 2012; 110:1729). A substantial number of pts experienced everolimus-related toxicity. ERBB3 appears to be a candidate marker of response to therapy and deserves further study. A randomized Phase III trial of bicalutamide +/- everolimus in bicalutamide-naïve CRPC is warranted. Clinical trial information: NCT00814788.

**5029 Poster Highlights Session (Board #44), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Galeterone in men with CRPC: Results in four distinct patient populations from the ARMOR2 study.** *Presenting Author: Robert B. Montgomery, University of Washington, Seattle, WA*

**Background:** Galeterone is a 1st in class oral small molecule that disrupts androgen receptor (AR) signaling via multi-targeted mechanism of action (1) selective inhibition of CYP17 lyase; (2) competitive antagonism of androgen binding to AR; and (3) degrading of AR protein. CYP17 enzyme inhibition (abiraterone) and AR antagonism (enzalutamide) separately have shown significant activity in metastatic castrate resistant prostate cancer (mCRPC) and considered standard treatment for these pts. Galeterone is a single molecule that has the potential advantage to target both mechanisms. **Methods:** ARMOR2 (*NCT# 01709734*) is a 2 Pt Phase 2 study designed to confirm dose of reformulated galeterone (spray dry dispersion; SDD) (Pt 1) and assess the safety and efficacy of the dose, 2550 mg QD for 12 wks, in 4 distinct CRPC pt cohorts; non-metastatic tx naïve (M0 TN, n= 7, median PSA=15.6 ng/dL, median PSA DT=2.30 mo), metastatic tx naïve (M1 TN, n=24, median PSA = 22.9 ng/dL, median PSA DT=2.3 mo), abiraterone refractory (Abi-R, n=11, median PSA=35.8 ng/dL, median PSA DT=1.57 mo) and enzalutamide refractory (Enza-R, n=2, median PSA = 72.85 ng/dL, median PSA DT=1.97 mo). This abstract presents interim results of the 2550 mg dose for pts treated in both Pt 1 and 2. **Results:** Response was seen at 2550 mg in all tx groups, including decreases in PSA. In the most mature dataset of 24 M1 TN pts, PSA decreases of 30% (92%), and 50% (83%) were reached. Data on the M1 group showed encouraging preliminary objective responses (ORR) in 7 of 8 (86%) evaluable pts at 3 months. Safety: Drug was well tolerated by all tx groups. 94% of all adverse events (AE) were gr1 or 2 in severity. Most common < gr 2 AEs were GI (nausea, diarrhea), fatigue and pruritis with no mineralocorticoid excess (ME) or seizures. **Conclusions:** SDD Galeterone has shown significant biochemical activity and preliminary clinical activity and is well tolerated with no ME or seizures. These data support continued testing of this unique compound in pts with prostate cancer. Clinical trial information: NCT01709734.

**5030 Poster Highlights Session (Board #45), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Primary outcomes of the placebo-controlled phase 2 study PERSEUS (NCT01360840) investigating two dose regimens of abituzumab (DI17E6, EMD 525797) in the treatment of chemotherapy-naive patients (pts) with asymptomatic or mildly symptomatic metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Maha Hussain, University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI*

**Background:** The humanized monoclonal IgG2 antibody abituzumab inhibits $\alpha$v integrins expressed on CRPC cells, tumor vessels, and osteoclasts involved in bone (B) metastasis. It showed antitumor effects in in vivo CRPC models and was well tolerated in a phase 1 study in mCRPC pts previously treated with docetaxel. **Methods:** PERSEUS is an exploratory double-blind trial with 180 pts randomized 1:1:1 to placebo, abituzumab 750, or 1,500 mg i.v. given every 3 weeks in addition to standard of care. Eligible pts had radiologic disease progression (rPD) of B lesions <28 days prior to randomization. Pts were treated until rPD in either B or soft tissue (ST) lesions, skeletal event, death, or unacceptable toxicity. Primary endpoint was progression-free survival (PFS). In addition, overall response (OR, RECIST 1.0) and safety were assessed. **Results:** Baseline characteristics were balanced across arms. In pts treated with placebo, abituzumab 750, and 1500 mg, median PFS (ITT) was 3.3 (95% CI: 2.8, 4.8), 3.4 (95% CI: 2.8, 5.6; HR = 0.89 [95% CI: 0.57, 1.39]), and 4.3 months (95% CI: 2.8, 6.6; HR = 0.81 [95% CI: 0.52, 1.26]), respectively. Progression occurred in 72, 68, and 65% of pts, respectively, incl. B lesion progression observed in 42% of pts in the control arm and in 23% of pts in each abituzumab arm. Of 74 OR-evaluable pts with confirmed ST lesions at baseline, 2 achieved partial responses (placebo: 1/28 pts; abituzumab 1500 mg: 1/24 pts). Treatment-emergent adverse events (TEAEs) occurred in 92, 85, and 88% of pts in the placebo, abituzumab 750, and 1500 mg arms, respectively, incl. serious TEAEs in 27, 22, and 23% and TEAEs with fatal outcomes in 3, 3, and 5% (treatment-related AE: 1 pt in the placebo arm). **Conclusions:** Median PFS with abituzumab 1500 mg was above the duration observed with 750 mg or placebo. Compared with placebo, pts receiving abituzumab experienced B progression less frequently. Considering these favorable trends, further investigation of abituzumab efficacy is needed. Its previously observed safety profile was confirmed. Clinical trial information: NCT01360840.

**5031 Poster Highlights Session (Board #46), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Adjuvant radiation, androgen deprivation, and docetaxel for high-risk prostate cancer post-prostatectomy: Results of RTOG 0621.** *Presenting Author: Mark Hurwitz, Department of Radiation Oncology, Jefferson Medical College of Thomas Jefferson University, Philadelphia, PA*

**Background:** Phase III trials have shown benefit in progression-free survival and in some cases overall survival with adjuvant radiation therapy (ART) in men with adverse pathologic findings at radical prostatectomy (RP). Despite ART, a high-risk group of patients has been defined with 50% risk of progression at 3 years, a risk factor for prostate cancer specific mortality. RTOG 0621 is a single-arm phase II trial that assessed whether addition of androgen deprivation (ADT) and docetaxel to ART would increase freedom from progression (FFP) at 3 years from 50% to ≥ 70% in these high-risk patients. **Methods:** Eligible subjects had prostatic adenocarcinoma who underwent RP with PSA nadir > 0.2 and Gleason score ≥ 7 or PSA nadir ≤ 0.2 with Gleason score ≥ 8 and ≥ pT3. Subjects received 6 months of ADT + RT to the pelvis with prostatic fossa boost to 66.6 Gy followed in one month with 6 cycles of docetaxel 75 mg/m$^2$ every 21 days. The primary objective was to assess whether addition of ADT and docetaxel to ART results in FFP of ≥70% as defined as PSA < 0.4 ng/ml, and no clinical failure or death from any cause at 3 years. Multivariate logistic regression was used to model association of factors with the occurrence of FFP. Odds ratios and respective 95% confidence intervals were computed. **Results:** 76 patients with median age 62 meeting eligibility criteria were enrolled on the study. 3 year FFP was 71%, (95% CI:61-81%), p-value<0.001. In univariate and multivariate models, only post-RP PSA was statistically significantly associated with FFP. Two deaths occurred of which only 1 was related to prostate cancer. The most common significant chemotherapy side effects were peripheral neuropathy (12 grade 2 and 1 grade 3) and febrile neutropenia in 3 patients. Six subjects (8%) experienced late grade 3-4 treatment related toxicities. **Conclusions:** Addition of ADT and docetaxel to ART for men as high risk of failure despite ART alone following prostatectomy resulted in a significant improvement in FFP as compared to historical controls. Phase III trials assessing chemotherapy in this high-risk population are warranted. This work was supported by RTOG grant U10 CA21661 and CCOP grant U10 CA37422 from the NCI and Sanofi-Aventis. Clinical trial information: NCT00528866.

**First double-blind placebo-controlled, multicenter, randomized trial of stabilized natural sulforaphane in men with rising PSA following radical prostatectomy.** *Presenting Author: Bernard G Cipolla, CH Privé Saint Grégoire, Saint Gregoire, France*

**Background:** Sulforaphane (SF) is a natural compound present in cruciferous vegetables. It has demonstrated molecular targets. Its main problem is its instability in its free form. We have assessed the efficacy of a natural, stabilized SF in recurrent prostate cancer patients (pts) after radical prostatectomy (RP) ± adjuvant or salvage external radiotherapy (RT). **Methods:** In this multicenter trial, 81 pts, mean age 69 ± 6 years with a rising prostate-specific antigen (PSA) >0.2 ng/ml (and <5 ng/ml) after RP ± RT, without metastasis, a Gleason score ≤7, a PSA doubling time (PSADT) >5 and <36 months (M) participated in a double-blind, randomized, placebo (P) controlled study. Treatment consisted in 60 mg daily SF during six-months (M0-M6). A two months washout period (M6 to M8) followed. Clinical and biological assessments were performed at M0, M1, M3, M6 and M8. The study was designed to detect a 0.012 log(ng/ml)/month decrease in Log PSA slope in the SF arm compared to P. **Results:** Baseline parameters did not differ between the 2 groups considering pathological stage and Gleason score, PSA, PSADT, Log PSA slope and serum testosterone. Three non-complying pts were excluded. The ITT population was 78 patients (40 P and 38 SF). Log PSA slope in the SF group (0.0298±0.0096) was significantly lower between M0 and M6 (p=0.036, 0.0285 log(ng/ml)/month =-49%) than in the P group (0.0583±0.0093) and most particularly (-83%) between M3 and M6 (p=0.011). The difference in PSA levels observed at M6 between the two groups was preserved during the washout period. A 78 % PSA DT increase was observed in the SF group (21.9 vs 12.1 months) compared to P. The mean change in PSA levels between M6 and M0 was significantly lower in the SF group compared to P (0.099±0.341 vs 0.620±1.417 ng/ml; p=0.03). Testosterone levels did not differ between the two groups. Observance was excellent (96% in each group). Safety was very good with a few more GI tract side effects in the SF arm (17 vs 10). **Conclusions:** The stabilized SF used in this study was shown to significantly delay PSA progression after RP ± RT. These encouraging results both on efficacy and safety indicate more extensive studies of this SF. Clinical trial information: ID-RCB: 2011- A00347-34.

**5033 Poster Highlights Session (Board #48), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**15-year survival outcomes following primary androgen deprivation therapy for localized prostate cancer.** *Presenting Author: Grace L. Lu-Yao, Rutgers Cancer Institute of New Jersey, Robert Wood Johnson Medical School, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

**Background:** Primary androgen deprivation therapy (ADT) for early stage prostate cancer has been widely utilized for localized prostate cancer, especially among older patients, despite a lack of data supporting its use. This study presents long-term survival outcomes following primary ADT in older men with localized (T1/T2) prostate cancer as a follow up to our prior study. **Methods:** Instrumental variable analysis was used to assess the impact of primary ADT in a population-based cohort consisting of residents in areas covered by the Surveillance, Epidemiology, and End Results (SEER) Program. **Results:** The cohort consisted of 66,717 patients aged ≥66 years diagnosed in 1992-2009 who received no definitive local therapy within 180 days of prostate cancer diagnosis. After a median follow-up of 9.2 years, primary ADT was not associated with improved 15-year overall or prostate cancer-specific survival. Among patients with moderately differentiated cancers, 15-year overall survival was 20.0% in high-use regions vs. 20.8% in low-use regions (difference 95% CI -2.2% to 0.4%), and 15-year prostate cancer survival was 90.6% in both high- and low- use regions (difference 95% CI -1.1% to 1.2%). Among patients with poorly differentiated cancers, the 15-year cancer-specific survival was 78.6% in high-use regions versus 78.5%, in low-use regions (difference 95% CI -1.8% to 2.4%), and 15-year overall survival was 8.6% in high-use regions vs. 9.2% in low-use regions (difference 95% CI -1.5% to 0.4%). **Conclusions:** Primary ADT is not associated with improved long-term overall or disease-specific survival for localized prostate cancer.

**5034 Poster Highlights Session (Board #49), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**The risk of second malignancies after treatment for localized prostate cancer.** *Presenting Author: Elizabeth J. Davis, University of Michigan Medical School, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

**Background:** Prostate cancer has an excellent prognosis with a 10-year relative survival of 99.7%. The long survival for this common cancer raises questions about the risk of second primary malignancies after initial therapy for localized disease. **Methods:** A population-based cohort of 441,504 men diagnosed with prostate cancer between 1992 and 2010 was identified from Surveillance, Epidemiology and End Results Program data (SEER13). Standardized incidence ratios (SIR) were calculated as an estimate of the risk of a second primary malignancy based on the incidence in the general population according to whether or not men received radiation therapy (external beam radiation therapy or EBRT) as their initial treatment for prostate cancer. Only new primary cancers that arose 10 years or more after prostate cancer treatment were considered. **Results:** Compared to men who were not treated with radiation, men treated with EBRT were significantly more likely than the general population to be diagnosed with rectal ($SIR_{radiation}$=1.70 versus $SIR_{noradiation}$=0.74, p <0.0001) and bladder cancer ($SIR_{radiation}$=1.42 versus $SIR_{noradiation}$=0.76; p<0.0001). Both groups were at reduced risk of second primary malignancy and second solid tumors overall, but the magnitude of the reduction was less among men who received radiation (e.g., for solid tumors SIR=0.72; 95% CI=0.69,0.76 for those treated with EBRT compared to SIR=0.51; 95% CI=0.49,0.52 for those not exposed to radiation). **Conclusions:** Men who receive ERBT for localized prostate cancer have a significantly increased risk of later diagnoses of bladder and rectal cancer. Although the absolute risk of developing these cancers is small, physicians should discuss this information with patients before decisions are made on primary treatment for localized prostate cancer.

**5036 Poster Highlights Session (Board #51), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**The natural history of progression to PSA recurrence and metastasis among at risk men following radical prostatectomy.** *Presenting Author: Ashley E. Ross, Brady Urological Institute, John Hopkins Medical Institute, Baltimore, MD*

**Background:** Active surveillance for low risk disease has been gaining acceptance with the aim of preferentially treating men with NCCN intermediate and high risk prostate cancer. Currently used outcome estimates however, were developed using cohorts, which included a high proportion of men with low or very low- risk disease. Here we describe the natural history of intermediate and high-risk prostate cancer treated only by radical prostatectomy (RP). **Methods:** Men who underwent RP in the PSA era, initially had undetectable PSAs after surgery, and received no post-RP therapy prior to metastasis were included (1,739 men). Biochemical recurrence (BCR) was defined by a PSA of ≥0.2 ng/ml and metastasis was diagnosed by axial imaging or bone scan. **Results:** Median follow up was 10 years and 17% developed BCR with a median time to BCR of 3 years (range 1-18). Of men with BCR, 41% developed metastasis (median time 3 years (range 0-11) after BCR). Median time from metastasis to death was 4 years (range 0-11). Men with metastasis had higher median CAPRA-S and Stephenson scores than those without metastatic progression (6 vs. 2 and 0.28 vs. 0.04, respectively, p<0.001 for both) but the range of scores was broad (1-12 vs. 0-10 and 0.02-0.95 vs. 0.01-0.71 respectively). Following BCR, the cumulative incidence of metastasis among intermediate and high-risk men was similar (p=0.57) as was the cumulative incidence of death after metastasis (p=0.69). The AUC for predicting metastasis after BCR was 0.67 for the Stephenson and 0.55 for CAPRA-S scores. **Conclusions:** As practice patterns shift towards the treatment of higher risk localized disease, point estimates for the time to BCR, metastatic progression, and death shorten accordingly. In addition, the predictive ability of clinicopathologic variables and nomograms is significantly diminished. This highlights the need for additional information (i.e. molecular markers) to help guide treatment decisions among at risk men following radical prostatectomy.

**5037 Poster Highlights Session (Board #52), Sat, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A multicenter yearlong randomized controlled trial of different exercise modalities in prostate cancer survivors on androgen deprivation therapy.** *Presenting Author: Daniel Abido Galvao, Edith Cowan University, Perth, Australia*

**Background:** It is well recognized that androgen deprivation therapy (ADT) for prostate cancer is associated with a number of substantial adverse effects including a reduction in muscle mass and strength, increased fat mass and poorer physical function. Recently, undertaking purposeful physical exercise has been proposed as an effective strategy to counter many of these ADT-related adverse effects. The purpose of this multi-centre, year-long randomized controlled trial was to extend these findings by assessing the effects of two varying exercise regimens, one targeting the musculoskeletal system (impact loading + resistance training; ILRT) and the other the cardiovascular and muscular systems (aerobic + resistance training; ART), on body composition, lower body muscle strength and physical function in men currently undertaking ADT. **Methods:** One hundred and sixty three men aged 42-90 years with a BMI of 24.8 kg/m$^2$ completed baseline testing and were randomized to ILRT (n=58), ART (n=54) or delayed exercise (CON, n=51) for 12 months. Training was undertaken for ~1 hour twice weekly under supervision at a moderate-to-high intensity. Lean and fat mass were determined by DXA, muscle strength by the 1-RM test, and lower body physical function by a battery of tests (6-m walk, 6-m backwards walk, 400-m walk, chair rise, stair climb). **Results:** There were no differences among the groups for any variable at baseline. Between pre and post-intervention, lean mass increased in ILRT by 1.4 kg ($p<0.001$) and 0.6 kg ($p=0.030$) in ART with no change in CON. Fat mass also increased in ILRT and CON by1.1 kg ($p<0.001$) with no significant change in ART (0.6 kg, $p=0.156$). Upper and lower body muscle strength increased by 17-45% in ILRT which was greater than that in ART and CON ($p<0.001$). Compared to pre-intervention, ILRT and ART generally improved in most physical function tasks ($p<0.050$). **Conclusions:** The combination of impact loading and resistance training produced superior gains in lean mass and muscle strength compared to aerobic plus resistance exercise in prostate cancer survivors on ADT. Strategies to implement this novel training protocol are warranted. Clinical trial information: ACTRN12609000200280.

**5038 General Poster Session (Board #167), Mon, 1:15 PM-5:00 PM**

**Long-term versus short-term androgen deprivation combined with high-dose radiotherapy for intermediate and high-risk prostate cancer: A randomized controlled trial (DART01/05).** *Presenting Author: Almudena Zapatero, Department of Radiation Oncology, Hospital Universitario de la Princesa, Madrid, Spain*

**Background:** Androgen deprivation (AD) combined with radiotherapy (RT) is an established treatment for locally advanced prostate cancer (PCa). However, the timing and optimal duration of AD associated with dose escalation RT remains controversial. This trial was designed to determine whether long-term AD (LTAD) is superior to short-term AD (STAD) when combined with high-dose radiotherapy (HDRT). **Methods:** Between 2006 and 2010, 362 assessable patients were enrolled. Eligible patients had cT1c-T3aN0M0 adenocarcinoma of prostate with intermediate risk (IR) and high risk (HR) factors according to 2005 NCCN criteria and PSA less than 100 ng/ml. All patients received 4 months of neoadjuvant and concomitant AD (STAD) + HDRT (median RT dose 78 Gy) before randomization to adjuvant gosereline for two years (LTAD). Stratification was performed according to risk group (IR versus HR). Study endpoints included biochemical-disease free survival (bDFS), metastasis free survival (MFS) and overall survival (OS). **Results:** Three hundred and fifty two patients (STAD =177, LTAD=175) were eligible with 57 months median follow-up.There were188 HR patients (STAD = 97, LTAD = 91) and 164 IR patients (STAD = 80, LTAD = 84) ($p=0.669$). Twenty-three patients in the STAD group and 7 patients in the LTAD group had biochemical failure according to Phoenix Consensus definition ($p=0.003$). Median OS has not been reached. At 5 years bDFS was significantly improved in the LTAD group (95.4%, 95% CI: 93.2-97.6), compared to the STAD group (86.1%, 95% CI: 83.5-88.7). Five-year MFS was 85.5% (95% CI: 82.9-88.1) for STAD and 93.2% (95% CI: 91.0-95.4) for LTAD, and OS was 88.8% (95% CI: 86.3-91.3) for STAD and 94.0% (95% CI: 91.9-96.1) for LTAD. **Conclusions:** The results of the present study indicate that the combination of HDRT with LTAD is superior to HDRT plus STAD in terms of bDFS. Further follow-up is needed to confirm these data and to assess the effect on MFS, OS and CSS. Clinical trial information: 2005-000417-36.

**5039 General Poster Session (Board #168), Mon, 1:15 PM-5:00 PM**

**Activity of abiraterone acetate (AA) in metastatic castration-resistant prostate cancer (mCRPC) patients (pts) previously treated with ketoconazole (keto): A prospective phase II study from the Prostate Cancer Clinical Trials Consortium.** *Presenting Author: Won Kim, University of California, San Francisco, San Francisco, CA*

**Background:** AA, like keto, inhibits CYP17, the rate-limiting enzyme in androgen synthesis. Since pts with prior keto were excluded from the pivotal phase III AA trials, the utility of AA following keto is not well understood. This prospective study evaluated the efficacy of AA in pts previously treated with keto. **Methods:** Pts with progressive mCRPC, prior keto ≥28 days, and normal baseline organ function were treated with AA 1000mg PO daily and prednisone 5mg PO BID. Pts with prior chemotherapy were excluded. Serum androgen levels, including dehydroepiandrosterone (DHEA), were measured by liquid chromatography/mass spectrometry (LC/MS) at baseline and during treatment for exploratory analyses. Radiographic progression-free survival (rPFS) was defined as freedom from death, radiographic progression, or unequivocal clinical progression. **Results:** 42 pts were enrolled. Median duration of prior keto was 38 weeks (wks). 40 pts discontinued keto due to disease progression, and 2 due to toxicities. AA resulted in ≥30% PSA decline at 12 wks in 20 pts (48%, 95% CI 32-63%), and ≥50% PSA decline at 12 wks in 16 pts (38%, 95% CI 24-54%). Median time on prior keto was significantly shorter in pts who had ≥30% PSA decline compared to those who had <30% decline (20 vs. 58 wks, $p=0.003$). Median time to PSA progression (TPP) was 16 wks (range, 4-64). Median rPFS was 24 wks (range, 1-88). Baseline serum DHEA levels were measured in 40 pts. 9 pts had DHEA < limit of quantitation (LOQ, 0.250ng/mL), and 31 pts had DHEA ≥LOQ. 1 pt with DHEA <LOQ (1/9, 11%) had PSA decline ≥30% at 12 wks, compared to 17 pts (17/31, 55%) with DHEA ≥LOQ ($p=0.027$). Median TPP was 6 wks (range, 4-32) for pts with DHEA <LOQ, compared to 16 wks (range 4-64) for pts with DHEA ≥LOQ ($p=0.017$). Median rPFS was 12 wks (range, 4-36) for pts with DHEA <LOQ, compared to 31.5 wks (range, 1-88) for pts with DHEA ≥LOQ ($p=0.0009$). 4 pts remain on AA. **Conclusions:** AA retains clinical activity in a significant proportion of pts previously treated with keto. DHEA levels via LC/MS merits further study as a biomarker in pts treated with androgen synthesis inhibitors.

**5040 General Poster Session (Board #169), Mon, 1:15 PM-5:00 PM**

**Time to chemotherapy following treatment with sipuleucel-T: Data from PROCEED.** *Presenting Author: Christopher Michael Pieczonka, Associated Medical Professionals, Syracuse, NY*

**Background:** Sipuleucel-T (sip-T) is an autologous cellular immunotherapy that targets prostatic acid phosphatase and is approved by the US FDA and EMA for the treatment of certain patients (pts) with asymptomatic or minimally symptomatic metastatic castration-resistant prostate cancer. PROCEED is an ongoing multicenter Phase 4 registry in the US that enrolled pts treated with commercial sip-T. PROCEED is collecting information on chemotherapy treatments (C) after sip-T treatment; these data will allow us to assess C predictability and determine characteristics associated with time to C after sip-T treatment. **Methods:** PROCEED enrolled >1,900 mCRPC pts who were treated with sip-T within the prior 6 months. Demographics, disease characteristics, and prior and ongoing prostate cancer treatments were recorded at baseline. We further characterized data from patients who received C after sip-T and used statistical modeling to identify predictors of time to first C. **Results:** As of May 2013, 1,254 enrolled pts had completed sip-T treatment. Time to first C ranged from 0.4 – 19.2 months. Median time to first C was shorter at oncology vs. urology practices (11.6 vs. 18.0 months, Kaplan-Meier method; HR= 2.154; $p<0.001$). A stepwise Cox model for time to C was developed from preliminary analysis of several baseline factors. **Conclusions:** The final stepwise Cox model indicates that pts who are younger, have lower baseline hemoglobin, have higher baseline PSA, or who received prior C, receive subsequent C sooner. Clinical trial information: NCT01306890.

**Predictors of time to C[1].**

| | | |
|---|---|---|
| Kaplan-Meier estimate of median time (95% CI[2]) to first C, months[3] | | 13.1 (12.2, 15.4) |
| Final Stepwise Cox model for time to first C | | |
| Baseline covariate[4] | Hazard ratio (95% CI[4]) | P value |

**5041 General Poster Session (Board #170), Mon, 1:15 PM-5:00 PM**

**A randomized phase 2 study evaluating optimal sequencing of sipuleucel-T (sip-T) and androgen deprivation therapy (ADT) in biochemically recurrent prostate cancer (BRPC): Preliminary clinical data.** *Presenting Author: Emmanuel S. Antonarakis, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Sip-T is an autologous cellular immunotherapy targeting prostatic acid phosphatase (PAP) that is approved by the FDA and EMA for the treatment of certain patients with asymptomatic/minimally symptomatic metastatic castration-resistant prostate cancer. The STAND trial (NCT01431391) evaluated optimal sequencing of sip-T and ADT in men with BRPC at high risk of developing metastases (PSA-DT ≤12 mos). **Methods:** Men (N=68) were randomized (1:1) to Arm 1: sip-T followed by ADT (2 wks after infusion 3) or Arm 2: ADT (3 mo lead-in) followed by sip-T. Men received 3 doses of sip-T and 12 mos of ADT (leuprolide). The primary endpoint was cellular immune response to target antigen (ELISPOT to PA2024). Secondary endpoints included humoral and cytokine responses, product parameters, clinical efficacy, and safety. Here we report preliminary clinical data and longer-term immune responses. **Results:** 65 men have been followed for ≥9 mos from last ADT injection: 10/32 (31.3%) in Arm 1 and 14/33 (42.4%) in Arm 2 achieved undetectable PSA (<0.02 ng/mL) and testosterone (T; <0.35 ng/mL) at 9 mos from last ADT injection; 4/65 men (6.2%) developed PSA progression (2 consecutive PSA measurements, 4 wks apart, ≥50% above nadir, >5ng/mL). In both arms, sip-T induced robust and prolonged immune responses to PA2024 and PAP (measured by T cell memory and ELISA antibody responses), although no significant differences have yet emerged between arms. There appear to be higher levels of serum cytokines in Arm 2 vs Arm 1, with a pattern suggesting a mixed $T_H1/T_H2$ cellular immune response; significant increases were seen in $T_H1$ (IFNg, IL-12), $T_H2$ (IL-4, IL-10, IL-13), and $T_H17$ (IL-17) subsets (P<0.05). **Conclusions:** These data suggest that tumor-specific T cell responses and broad-based immune responses are augmented in both arms, and cytokine responses may be superior when sipuleucel-T is given after (rather than before) ADT initiation. In addition, augmented PA2024- and PAP-specific humoral responses have persisted for at least 12 mos, and are equally robust in both groups. Longer-term T cell responses and cytokine responses will be presented. Clinical trial information: NCT01431391.

**5042 General Poster Session (Board #171), Mon, 1:15 PM-5:00 PM**

**Regional differences observed in the phase 3 trial (ELM-PC 5) with orteronel (TAK-700) plus prednisone in patients with metastatic castration-resistant prostate cancer (mCRPC) that has progressed during or following docetaxel.** *Presenting Author: Karim Fizazi, Institut Gustave Roussy, University of Paris Sud, Villejuif, France*

**Background:** Orteronel is an investigational, nonsteroidal, selective 17,20-lyase inhibitor. ELM-PC 5 (NCT01193257) did not meet the primary endpoint of OS (P = 0.1898) despite improvement in radiographic PFS (rPFS; P = 0.00038) (Dreicer, ASCO GU 2014, Abstract #7). Here we analyze baseline characteristics and outcomes across study regions (Europe [E], North America [NA], and non-E/NA). **Methods:** Men with progressive mCRPC who had received prior docetaxel but not orteronel, abiraterone or ketoconazole were randomized 2:1 to orteronel 400 mg BID plus prednisone 5 mg BID (O+P) or placebo plus prednisone (P). Enrollment (N = 1099) was stratified by region (E, n = 590; non-E/NA, n = 397; NA, n = 112). The primary endpoint was OS; other key endpoints were rPFS, ≥50% prostate-specific antigen (PSA50) decrease and pain response. **Results:** Baseline characteristics were generally balanced, except for pain score, ≥2 prior chemotherapies, PSA and lacate dehydrogenase (LDH). Substantial regional differences were noted in OS, rPFS and PSA50 rates.Regional data are summarized below (Table). **Conclusions:** Substantial differences in efficacy were seen across regions, with differences in OS possibly being related to subsequent therapies. Clinical trial information: NCT01193257.

**The impact of baseline serum testosterone and duration of first-line androgen deprivation therapy on the efficacy of docetaxel in patients with metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Robert J. van Soest, Erasmus University Medical Center, Rotterdam, Netherlands*

**Background:** The TAX 327 study was conducted in 1,006 men with mCRPC who were randomized to receive 3-weekly docetaxel (D3), weekly docetaxel, or 3-weekly mitoxantrone (M), each with prednisone. Survival and symptom control were superior following D3 as compared to M. In this post hoc analysis, we aimed to identify factors that could characterize subgroups of patients who obtain the greatest benefit from the use of D3. **Methods:** Using a Cox model, we investigated the OS benefit obtained from D3 as compared to M in subgroups of baseline testosterone (T) ≥ median and < median, and in subgroups of duration of first-line ADT ≥ median and < median. Duration of first-line ADT was defined as the time from start date of first-line ADT to the start date of subsequent treatment. **Results:** Baseline characteristics known to predict OS including visceral metastases and Karnofsky performance score were well balanced between patient groups. The analysis demonstrated that D3 was superior to M irrespective of baseline T and the duration of first-line ADT, but demonstrated greater and statistically significant OS benefit in patients with a baseline T ≥ median (14.5 ng/dl) (p=0.035, see table) and in patients with a duration of first-line ADT <median (15 months) (p=0.022). **Conclusions:** In conclusion, docetaxel is effective in patients with mCRPC irrespective of baseline T and duration of first-line ADT, but demonstrated superior OS benefit in patients with high baseline T and in patients with a short duration of first-line ADT. These results will be further investigated in the dataset of the VENICE study, and require validation in a prospectively designed fashion.

**Changes in androgen deprivation therapy overuse: Reimbursement response and characteristics of persistent overusers.** *Presenting Author: Shellie D. Ellis, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Reimbursement cuts driven by the Medicare Modernization Act of 2003 are associated with declining androgen deprivation therapy (ADT) overuse in prostate cancer; yet, 25.7% of men for whom ADT was not recommended still received it in 2005. We examined physician-level prescribing changes and characteristics of persistent overusers among urologists. Understanding characteristics of urologists who persistently overuse ADT can improve quality of care and inform current efforts to limit reimbursement. **Methods:** We conducted a population-based, retrospective study of 2,138 urologists treating 12,943 men with early stage and lower grade prostate cancer diagnosed between 2000 and 2007. SEER-Medicare data was matched to American Medical Association physician data. Mixed effects regression modeling controlled for patient and provider characteristics. **Results:** We observed 3 distinct patterns of overuse. Static users (69%) had low levels of ADT overuse in 2000 and maintained infrequent overuse. Decreasing users (18%) had the highest levels of ADT overuse in 2000, but overuse decreased sharply in 2004, matching levels of use of static users by 2008. Increasing users (13%),increased ADT overuse in 2004 adopting levels higher than any user in 2000. Urologists' time in practice was not associated with ADT overuse (OR 0.89; 95% CI 0.75-1.05). However, solo practice type (OR 1.65; 95% CI 1.34-2.02), lack of medical school affiliation (OR 1.35; 95% CI 1.23-1.45), and patient race were. Compared to non-Hispanic whites, non-Hispanic blacks (OR 1.76; 95% CI 1.37-2.27), Hispanics (OR 1.41; 95% CI 1.12-1.79) and men of "other" race (OR 1.44; 95% CI 1.04-1.99) had greater odds of receiving unnecessary ADT. **Conclusions:** ADT overuse remains high among some urologists who may be professionally isolated and difficult to reach by usual means. These urologists may treat more vulnerable populations, which may contribute to health disparities in prostate cancer treatment quality. Finally, efforts to limit reimbursement may not have uniform effects, warranting careful assessment of subsequent quality and potential disparate impact.

**5045 General Poster Session (Board #174), Mon, 1:15 PM-5:00 PM**

**Obesity and the odds of weight gain following androgen deprivation therapy for prostate cancer: Toward a risk adapted approach for ADT use.** *Presenting Author: Lior Zvi Braunstein, Harvard Radiation Oncology Program, Boston, MA*

**Background:** Increasing BMI is associated with an increased risk of mortality; however, quantifying weight gain in men undergoing ADT for prostate cancer (PC) as stratified by baseline BMI remains unexplored and was the subject of the current study. **Methods:** Between 1995 and 2001, 206 men with unfavorable-risk prostate cancer were enrolled on a randomized trial evaluating the impact on survival of adding 6-months of ADT to radiotherapy (RT). BMI, both at baseline and after therapy, was available in 171 men who formed the study cohort. The primary endpoint was weight gain of ≥10 lbs by the 6-month follow-up. Logistic regression multivariable analysis was performed to assess whether baseline BMI or treatment-received was associated with this endpoint adjusting for comorbidity and known PC prognostic factors. **Results:** By the 6 month follow-up, 12 men were observed to have gained ≥10 lbs of which 10 (83%) were treated with RT and ADT and, of these, 7 (70%) were obese at randomization. As shown in the table, men treated with RT as compared to RT and ADT were significantly less likely to experience a weight gain of ≥ 10 pounds (adjusted odds ratio (AOR): 0.18 [95% confidence interval (CI) 0.04 - 0.89]; p = 0.04); whereas this risk was significantly increased with increasing BMI (AOR: 1.15 [ 95% CI 1.01 – 1.31]; p = 0.04). Moreover, weight gain persisted at 2 years for the obese men who gained ≥ 10 lbs after treatment with RT and ADT (median: 13.0 lbs; range: 9.0 to 21.0). **Conclusions:** Consideration should be given to avoiding ADT use in obese men with low or favorable-intermediate risk PC where improved cancer control has not been observed, but a shortened life expectancy from weight gain is expected. Clinical trial information: NCT00116220.

**The in vivo efficacy of docetaxel and cabazitaxel in a cell-line based xenograft of castration-resistant prostate cancer (CRPC) previously treated with enzalutamide.** *Presenting Author: Robert J. van Soest, Erasmus University Medical Center, Rotterdam, Netherlands*

**Background:** With the rapid evolvement of treatment options for metastatic CRPC, it has become of critical importance to determine the optimal sequencing of therapies. We recently reported in vitro cross-resistance between the taxanes docetaxel and cabazitaxel, and the AR targeting agents abiraterone and enzalutamide (Eur J Cancer 2013;49(18):3821-30). In the present study, we investigated the efficacy of docetaxel and cabazitaxel in an in vivo model of CRPC previously treated with enzalutamide. **Methods:** The enzalutamide-resistant prostate cancer cell line PC346Enza was derived by continuous culturing of PC346C cells in the presence of enzalutamide (1 $\mu$M). PC346Enza cells were subcutaneously inoculated in nude mice. Castrated mice were treated with a single intraperitoneal dose of docetaxel 33 mg/kg, cabazitaxel 33 mg/kg, or placebo when a tumor volume of 300 mm$^3$ was reached. Uncastrated male mice received oral enzalutamide 60 mg/kg daily or placebo. Mean tumor volumes at the time of analysis were calculated after 46 and 25 days of follow-up and compared using an unpaired 2 sample t-test. **Results:** Cabazitaxel demonstrated a greater antitumor effect as compared to docetaxel in the PC346Enza xenograft. Mean tumor volumes after 46 days of treatment were 61 mm$^3$ (95% CI 24-98) for cabazitaxel versus 258 mm$^3$ (95% CI 95-421) for docetaxel (p=0.01). The mean tumor volume of the placebo treated mice was 743 mm$^3$(95% CI 345-1142). Although the PC346Enza cell line demonstrated complete resistance to enzalutamide in vitro, xenografts still responded to high dose enzalutamide in vivo (60mg/kg). **Conclusions:** Our in vivo data demonstrated that cabazitaxel was more effective as compared to docetaxel in a model of CRPC previously treated with enzalutamide. Our current findings provide the rationale for a clinical study investigating the efficacy of cabazitaxel versus docetaxel, given as first-line chemotherapy in patients previously treated with enzalutamide. These data and are concordant with clinical studies demonstrating that cabazitaxel retains activity as second-line chemotherapy, even after prior AR-targeted treatment in metastatic CRPC.

**5047 General Poster Session (Board #176), Mon, 1:15 PM-5:00 PM**

**Prognostic role of derived neutrophil to lymphocyte ratio (dNLR) in men with metastatic castration resistant prostate cancer (mCRPC) treated in a phase 3 trial (VENICE).** *Presenting Author: Arnoud J. Templeton, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** We evaluated retrospectively the prognostic impact of derived neutrophil to lymphocyte ratio (dNLR), a marker of host inflammation, in men with progressive metastatic castration-resistant prostate cancer (mCRPC) treated in VENICE, a phase 3, multicenter, trial of aflibercept versus placebo in combination with docetaxel and prednisone funded by Sanofi and Regeneron (Tannock et al. Lancet Oncology 2013). **Methods:** The arms were combined for analysis, since no difference was observed in the primary endpoint of overall survival (OS). dNLR was calculated as the absolute count of neutrophils divided by the absolute white cell count minus the absolute count of neutrophils. A logarithmic transformation was applied to non-normal factors. The Kaplan-Meier method was used for OS estimation. To adjust for baseline patient and tumor characteristics we used Cox proportional hazards regression with backward stepwise selection, stratifying for ECOG PS (0 vs. 1-2) and treatment group. **Results:** Complete data for construction of a prognostic model were available in 876 men. Patients with a dNLR greater than the median (2.0) had significantly worse survival (2y OS: 38% vs. 54%, log-rank $P$<0.001; HR (univariate) 1.48 [95% CI 1.29 - 1.69], $P$for stratified Cox model <0.001). The factors that remained individually significant for OS in multivariable analysis are shown in the Table. **Conclusions:** High dNLR was associated with worse survival in men with mCRPC treated with docetaxel. These data warrant external validation.

**The potential of peripheral blood HERV-K expression as a biomarker for diagnosis with prostate cancer in older men.** *Presenting Author: Sharon A. Glynn, Prostate Cancer Institute, National University of Ireland Galway, Galway, Ireland*

**Background:** Aberrant expression of human endogenous retrovirus-k (HERV-K) has been observed in prostate cancer (PCa). HERV-K is unique as it encodes sequences in the human genome containing open reading frames for near intact retroviruses. We hypothesized that HERV-K reactivation could serve as a non-invasive early disease detection marker. **Methods:** We evaluated HERV-K *gag* mRNA expression in PBMCs of African-American (AA) and European-American (EA) men via qRT-PCR (294 PCa cases and 135 male controls). We examined HERV-K env protein expression in PCa by immunohistochemistry. Fisher's exact test and logistic regression were used to analyze continuous and dichotomized data and calculate odds ratios (ORs). Multivariable models adjusted for age at diagnosis and race/ethnicity. Mann-Whitney test was used to compare HERV-K $C_t$-based expression values between groups. **Results:** HERV-K *gag* expression in PBMCs was significantly higher in PCa cases than controls (Table). Men with *gag* in the highest quartile had > 12-fold increased odds [OR = 12.87 (95% CI 6.3-26.25)] of PCa than those in the lowest quartile. Additionally, HERV-K may perform better in older than younger men (sensitivity of PSA testing decreases with age). HERV-K envelope protein was up-regulated in PCa, with the most abundant expression observed in AA patients (61% versus 40%, $P < 0.01$). **Conclusions:** Combining non-invasive HERV-K testing with PSA testing may improve the efficacy of PCa detection specifically among older men.

**Association between HERV-K *gag* mRNA levels in PBMC and a PCa diagnosis.**

**The effect of change in PSA velocity on overall survival (OS) in men with biochemically recurrent prostate cancer (BRPC) treated with nonhormonal agents: Combined analysis of four phase 2 trials.** *Presenting Author: Daniel L. Suzman, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Multiple phase 2 trials in men with BRPC have assessed the impact of non-hormonal agents on PSA kinetics. We have previously demonstrated that changes in PSA kinetics are correlated with metastasis-free survival; however, it is unknown whether these changes may also correlate with overall survival (OS). **Methods:** We performed a combined retrospective analysis of 146 men with BRPC treated on phase 2 trials using one of four investigational drugs: lenalidomide (n=60), marimastat (n=39), ATN-224 (n=22), and imatinib (n=25). We examined factors influencing OS, including within-subject changes in PSA kinetics (PSA slope, PSA doubling time, and PSA velocity) before and 6 months after treatment initiation. **Results:** After median follow up of 137 months, 48 men had died. In univariate Cox regression analysis, four factors were associated with OS: prior androgen deprivation therapy (ADT), prior local radiotherapy, baseline PSA velocity, and change in PSA velocity after therapy. In a landmark multivariable model, stratified by study, which also controlled for age and Gleason score (<7 vs ≥7): prior radiotherapy, baseline PSA velocity, and increase in PSA velocity remained independent predictors of OS (Table). Median OS for men with an increase in PSA velocity on treatment was 9.4 years vs not-yet-reached for men with a decrease in PSA velocity (HR 2.2; 95% CI 1.10-4.39; *P*=0.03). **Conclusions:** This hypothesis-generating study suggests that within-subject changes in PSA velocity after initiation of non-hormonal therapy may correlate with OS in men with BRPC. If validated in prospective trials using OS as the primary endpoint, change in PSA velocity may represent a reasonable intermediate endpoint for screening new agents in these patients.

**Safety results of the enzalutamide expanded access program in the United States and Canada for patients with metastatic castration-resistant prostate cancer (mCRPC) previously treated with docetaxel.** *Presenting Author: Anthony M. Joshua, Princess Margaret Hospital, University Health Network, Toronto, ON, Canada*

**Background:** In the Phase 3 AFFIRM trial, the androgen receptor inhibitor enzalutamide improved overall survival compared with placebo in patients (pts) with mCRPC who had received prior docetaxel. The aim of this open-label single-arm study was to monitor safety and provide access to enzalutamide for mCRPC pts pending marketing approval in the U.S. and Canada. **Methods:** 507 pts with mCRPC were treated at 54 sites. Pts received enzalutamide 160 mg/d in the study until disease progression, intolerable adverse event (AE), or commercial availability. AEs, serious AEs (SAEs), vital signs, and laboratory measurements were assessed on day 1, wk 4 and 12, and every 12 wks thereafter. No efficacy data were collected. **Results:** Median age was 71 yr (range 43-97). Baseline ECOG PS was 0, 1 and 2 in 27.8%, 56.1%, and 15.9% of pts, respectively. Prior treatments for prostate cancer included abiraterone (76.0%), and cabazitaxel (28.6%); 24.8% of pts received both prior abiraterone and cabazitaxel. Median enzalutamide treatment duration in the study was 2.6 mo (range 0.03-9.07); data following transition to commercial drug was not collected. Common AEs (≥10%) included fatigue (39.1%), nausea (22.7%), anorexia (14.8%), anemia (11.8%), peripheral edema (11.4%), back pain (10.3%), vomiting (10.3%), and arthralgia (10.1%). SAEs reported in ≥1% of pts were disease progression (7.9%), pneumonia (2.0%), asthenia (1.8%), anemia (1.6%), and back pain (1.4%). Drug-related AEs leading to permanent discontinuation occurred in 3.7% of pts. Grade ≥3 drug-related AEs were reported in 14.2 % of pts and drug-related AEs leading to death occurred in 4 pts: 1 cerebrovascular accident, 2 myocardial infarctions and 1 death not otherwise specified. Seizure was reported in 4 (0.8%) pts, of whom 3 had brain metastases. **Conclusions:** In this expanded access population of pts with progressive mCRPC who had previously received docetaxel, enzalutamide was well tolerated. The safety profile was consistent with that seen in the AFFIRM trial. Median treatment duration was shorter than in AFFIRM (2.6 vs 8.3 mo); duration on subsequent commercial drug was not collected. Clinical trial information: NCT01606982.

**5052 General Poster Session (Board #181), Mon, 1:15 PM-5:00 PM**

**A pilot study of supraphysiologic testosterone (T) and oral etoposide (E) in men with castrate-resistant prostate cancer (CRPC).** *Presenting Author: Michael Thomas Schweizer, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** Prostate cancer (PC) cells become resistant to chronic castration via an adaptive increase in androgen receptor (AR) expression, a liability that can be exploited therapeutically. Mechanistically, supraphysiologic androgens can induce PC cell death through topoisomerase 2 (topo2) mediated double-strand DNA breaks and disruption of DNA relicensing due to persistence of AR at origins of replication during the cell cycle. **Methods:** We evaluated parenteral T in combination with the topo2 inhibitor E in men with CRPC and low metastatic burden (≤5 bone and <10 soft tissue metastases). To rapidly cycle from supraphysiologic (>1500 ng/dL) to near castrate T levels, men received intramuscular T cypionate 400 mg on day (D) 1 and oral E 100 mg D 1-14 of a 28 D cycle. After 3 cycles, men with declining PSA could continue T alone every 28 D. The primary endpoint was PSA response, defined as a PSA below baseline, after cycle 3. Secondary endpoints included objective response rates and safety. **Results:** Sixteen men enrolled of which 14 completed 3 cycles of T+E and were evaluable for response. 7/14 went on the T-only expansion stage. After 3 cycles, 6/14 men had a PSA response. 7 (50%) had a PSA response at any timepoint [4 (29%) had PSA declines ≥50%] (Table). In men with RECIST-evaluable disease, 2 had progressive and 3 had stable disease (SD), 4 had partial (PR) and 1 had a complete response (CR). Median response duration was 343 D (95% CI, 91 to 434 D). Post T, 12/12 men had a PSA decline to subsequent androgen ablative therapies. Most adverse events (AEs) were ≤grade 2 and considered effects of E. One man died from neutropenic sepsis before completing the 1st cycle. AEs possibly related to T included lower extremity edema (n=1), priapism (n=1) and asymptomatic pulmonary embolism (n=2). No one developed new pain on T. **Conclusions:** T with or without E demonstrated preliminary efficacy in patients with CRPC as manifested by PSA and objective responses. This regimen is generally safe. Cyclic T-based therapies warrant further study. Clinical trial information: NCT01084759.

**5053 General Poster Session (Board #182), Mon, 1:15 PM-5:00 PM**

**15-year outcomes following conservative management among patients with screen-detected localized prostate cancer.** *Presenting Author: Grace L. Lu-Yao, Rutgers Cancer Institute of New Jersey, Robert Wood Johnson Medical School, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

**Background:** An understanding of the natural history of screen-detected prostate cancer is essential for making appropriate treatment decisions; however, such data are few and far between **Methods:** We assembled a population-based cohort consisting of 12,271 men aged >65 years diagnosed with screened detected (T1c) localized prostate cancer during 1992 - 2009 who did not receive surgery, radiotherapy, or androgen deprivation therapy (ADT) within 6 months of diagnosis. Competing risk analyses were used to assess cancer-specific mortality and use of cancer-related interventions. **Results:** Compared to outcomes of pre-PSA era patients, 15-year survival has improved considerably for conservatively managed patients diagnosed in the PSA era. The 15-year risk of prostate cancer specific mortality for men aged 66-74 diagnosed with T1C Gleason 5-7 prostate cancer was 6.1% (95% CI 3.6-8.8% ) compared to 17 - 23% among men diagnosed in the pre-PSA era. Similarly, substantial improvement was observed for patients with T1c Gleason 8-10 prostate cancer: 15-year prostate cancer mortality was 21.4% (95% CI 11.9 – 44.2%) compared to 56-65% in the pre-PSA era. The 15-year prostate cancer mortality for patients aged 75+ was 9.8% (95% CI 7.7-12.1%) for Gleason 5-7 and 25.2% (95% CI 18.4-33.2%) for Gleason 8-10. Among patients aged 66-74 with T1c Gleason 5-7 cancer, 53.6% (95% CI 50.6 – 56.9%) received cancer therapy (42.3% attempted curative therapy, 22.5% ADT, 6.6% palliative therapy) within 15 years of cancer diagnosis. Among those who received attempted curative cancer therapy, the majority did so within the first 3 years of follow-up. **Conclusions:** To our knowledge, this is the largest US population-based long-term study on screen-detected prostate cancer initially treated with conservative management. Fifteen-year disease-specific mortality following conservative management among men with screen-detected cancer has decreased by more than 60% as compared with results from the pre-PSA era. The risk of death due to prostate cancer for men diagnosed with T1c Gleason 5-7 disease in the PSA era is low.

**5054 General Poster Session (Board #183), Mon, 1:15 PM-5:00 PM**

**Sensitivity analyses for radiographic progression-free survival (rPFS): Results from the phase 3 PREVAIL trial comparing enzalutamide to placebo.** *Presenting Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

**Background:** In the PREVAIL trial, enzalutamide (ENZ), an androgen receptor inhibitor, significantly improved overall survival (HR: 071, $P<0.0001$) and rPFS (HR: 0.19, $P<0.0001$) compared with placebo in asymptomatic/mildly symptomatic chemotherapy-naive men with mCRPC (Beer, ASCO GUCS 2014, LBA1). Sensitivity analyses (SA) were performed to assess the impact of different sources of progression on the prespecified rPFS analysis. We also analyzed concordance between central and local reviewers. **Methods:** In this double-blind, placebo-controlled, multinational study (NCT01212991), 1,717 patients were randomized 1:1 to ENZ 160 mg/day (n=872) or placebo (n=845). rPFS was a co-primary endpoint defined as time from randomization to the earliest objective evidence of radiographic progression by central review or death within 169 days of treatment discontinuation. Radiographic progression was defined by PCWG2 guidelines for bone disease or by RECIST 1.1 for soft tissue disease; bone progression was captured using a validated bone scan data capture assay. The primary rPFS analysis was event driven (at least 410 events). Characteristics of representative SA are reported in the Table. **Results:** Concordance between central and local assessment of progression was 87.6%. Results of the SA were statistically significant in favor of ENZ (see Table). **Conclusions:** rPFS sensitivity analyses in PREVAIL demonstrated a consistent and robust treatment benefit with ENZ. Central and local assessment showed good concordance using a quantitative definition of radiographic progression and validated bone scan data assay. Clinical trial information: NCT01212991.

| Analysis | Modifications from primary analysis | Total events | Hazard ratio* (95% CI) |

**Comparison of prostate health index and PCA3 values in patients with clinical or biologic suspicion of prostate cancer.** *Presenting Author: Pierre-Jean Lamy, Institut Régional du Cancer Montpellier, Montpellier, France*

**Background:** The Prostate Health Index (PHI) and the Prostate CAncer gene 3 (PCA3) have shown to have predictive values for early detection of PCa. The aim of this prospective observational study was to compare the values of the both markers in patients consulting for a suspicion of PCa **Methods:** Samples of 573 consecutive patients presenting a suspicion of PCa were included in a biobank between 2010 and 2012. Total PSA (tPSA),Free PSA (fPSA) and -2proPSA (Beckman Coulter) were performed on serum to calculate the PHI ([-2proPSA/fPSA] X [tPSA]$^{1/2}$). Urine samples were collected after digital rectal examination (DRE) by an urologist in order to calculate the PCA3 score ([PCA3 mRNA]/[PSA mRNA] X 1,000). Prostate biopsies were performed for 235 men according usual clinical practice. Correlation between PSA, PHI, PCA3 score and clinico-pathological factors were studied with the Kruskall-Wallis tests. ROC–derived area under the curve (AUC) was used to quantify the predictive accuracy of the tests predicting pathologic findings in biopsies specimens. **Results:** PCA3 score was only correlated with age (Spearman's rho = 0.21; p=0.001) and PHI was only correlated with tPSA (Spearman's rho = 0.35; p<0.0001). PHI and PCA3 were slightly correlated (Spearman's rho = 0.16; p=0.01). Comparing biomarkers values in patients with positive (P+; n=60, 25.5%) and negative biopsy (P-; n=175, 74.5%), PHI and PCA 3 were statistically different according to patients status. **Conclusions:** In this large series of patients consulting for a suspicion of PCa, tPSA is hardly more effective than a coin toss to predict PCa. PHI, an independent biological marker, presented a higher predictive value for positive biopsy prediction than PCA3, a marker slightly correlated with age.

**5056 General Poster Session (Board #185), Mon, 1:15 PM-5:00 PM**

**Development and validation of a prognostic index for fracture risk in older men undergoing prostate cancer treatment.** *Presenting Author: Tisheeka Graham-Steed, Yale School of Medicine, New Haven, CT*

**Background:** Although men treated with androgen deprivation therapy (ADT) or radiation therapy (RT) for prostate cancer are at an increased risk for fractures, it is unclear whether specific factors can be used to identify men at increased risk. We therefore developed a prognostic index for risk of fracture in this population. **Methods:** We used the Surveillance, Epidemiology, and End Results-Medicare database to identify men diagnosed with -localized prostate cancer in 2007-2009 who received ADT or RT. Potential risk factors for fracture included age, comorbidity (including osteoporosis), medication use, and functional status. Cox proportional hazards models tested the association of potential risk factors on fracture. In a derivation group (n=2,912), hazard ratios were used to assign points for factors independently related to fracture. The prognostic index was then applied to a validation group (n=2,912). **Results:** The sample of 5,824 men had a mean age of 74.2 years; 82.9% were white and 8.6 % had a fracture within 2 years of treatment for prostate cancer. The Cox model identified 8 variables (age, race, hormone treatment, Elixhauser score, anxiety, Parkinson's, fall-inducing medications, disability score) independently associated with fracture; data not shown. Fractures in the derivation cohort included 4.3% in the low-risk group, 8.9% in the intermediate group, and 19.2% in the high-risk group (C statistic, 0.749). The incidence of fractures in the validation cohort ranged from 6.2% in the lowest-risk, 10.6% in the intermediate-risk, and 16.5% in the high-risk group (C statistic, 0.782). **Conclusions:** These data underscore the importance of identifying risk factors for fracture, given the substantial variation in fracture risk in men treated with ADT or RT. The prognostic index can help to inform treatment decisions (e.g., identifying patients at increased risk for fracture).

**5057 General Poster Session (Board #186), Mon, 1:15 PM-5:00 PM**

**Longitudinal assessment of general health-related QOL in patients undergoing active surveillance (AS) for low-risk prostate cancer: Interim results of the PRIAS-JAPAN cohorts.** *Presenting Author: Mikio Sugimoto, Department of Urology, Kagawa University Faculty of Medicine, Kagawa, Japan*

**Background:** Japan is participating in the Prostate cancer Research International: Active Surveillance (PRIAS) study as PRIAS-JAPAN since 2010. QOL has been assessed annually as an independent side study of PRIAS-JAPAN. The objective of this study is to measure the base-line QOL and the longitudinal changes in QOL status of Japanese AS cohorts. **Methods:** PRIAS-JAPAN study was launched since January 2010. Until July 2013, 354 patients were enrolled into the study from 33 institutions. Participants' general health related QOL (HRQOL) have been assessed using SF-8 at enrollment and annually thereafter. QOL subscales and summary scores were compared with norm-based scoring (general population) and also between each evaluation points over time. A paired t-test served to compare the data, and $p< 0.05$ was considered to indicate statistical significance. **Results:** Of the 354, 325 could be able to follow in PRIAS protocol. Median age of participants was 68 (45-87 yr.), median PSA was 5.27ng/ml (1.5-9.93). 220 patients were remained on the AS program with median observation period of 15 months. Of the 325 patients, QOL was evaluable in 315, 183, 48 and 18 patients at enrollment, 1-year, 2-year and 3-year after, respectively. Almost all domains of QOL at enrollment revealed better QOL than that of general population. At 1 and 2-year after starting of AS, there was no significant QOL deterioration and favorable QOL was maintained. When it stratified by median baseline QOL score, the physical and mental component summary score in favorable baseline QOL group were deteriorated over time ($p<0.01$ and $p<0.05$ respectively). On the other hand, those of unfavorable baseline QOL group revealed significant improvements over time ($p<0.05$ and $p<0.01$ respectively). **Conclusions:** QOL of the Japanese patients who choose AS as initial treatment is relatively better than that in general population and it has been maintained at 2-year after AS. However, there is a possibility of QOL deterioration with time, especially for better QOL patients at baseline. Clinical trial information: UMIN000009876.

**5058 General Poster Session (Board #187), Mon, 1:15 PM-5:00 PM**

**Predicting response to abiraterone acetate (AA): mRNA biomarker analysis of study COU-AA-302.** *Presenting Author: Deborah Sokol Ricci, Janssen Research and Development, Raritan, NJ*

**Background:** AA is metabolized to abiraterone, a CYP17 inhibitor that blocks testicular, adrenal, and tumoral androgen biosynthesis. AA is approved for the treatment of metastatic castration-resistant prostate cancer (mCRPC). We examined the predictive value of mRNA biomarkers in determining clinical response to AA therapy in chemo-naive pts with mCRPC. **Methods:** 1,088 pts were randomized 1:1 to AA 1000 mg + prednisone (P) 5 mg po BID vs placebo + P and stratified by Eastern Cooperative Oncology Group (ECOG) score 0 or 1. Co-primary end points: radiographic progression-free survival (rPFS) and overall survival (OS). 329 pts provided optional consent for biomarker analysis of pretreatment FFPE tumor samples. Of these, 110 pts were evaluable for mRNA analysis using Taqman array microfluidic cards. We tested 94 biomarkers relevant to androgen receptor (AR) signaling, steroidogenesis, and AA response or resistance. Association analysis of single biomarkers or predetermined biomarker groups with rPFS (independent review) and OS was done by Cox regression within each treatment group and stratified by ECOG score. **Results:** Six biomarkers (SF1, HSD17B10, SRD5A1, UBE2C, NUSAP1, ANLN) were significantly associated with rPFS in the AA ($p < 0.05$) but not the P ($p \geq 0.2$) group; none were significant based on false discovery rate (FDR) $\geq 0.15$. Higher AR expression was significantly associated with longer rPFS in the AA group, HR (95% CI): 0.80 (0.65-0.98), $p = 0.03$, FDR = 0.2. Androgen-regulated genes and CYP17 cofactors were associated with longer rPFS and OS in the biomarker group analysis (Table). **Conclusions:** This exploratory analysis shows that gene expression of androgen-regulated genes and CYP17 cofactors at the time of diagnosis may be predictive of outcome to AA therapy. The current study is limited by sample size and lack of independent validation datasets and requires confirmation in planned additional studies. Clinical trial information: NCT00887198.

**Validation of an RNA cell cycle progression (CCP) score for predicting prostate cancer death in a conservatively managed needle biopsy cohort.** *Presenting Author: Jack M. Cuzick, Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, London, United Kingdom*

**Background:** The natural history of prostate cancer is highly variable and difficult to predict accurately. Better markers are needed to guide management and avoid unnecessary treatment. To validate the predictive value of a cell cycle progression (CCP) score and a pre-specified linear combination of the CCP score with standard clinical variables (CAPRA) to form a combined clinical cell cycle risk (CCR) score for predicting prostate cancer death in a cohort of conservatively managed patients diagnosed by needle biopsy. **Methods:** A retrospective cohort study of 585 men diagnosed by needle biopsy in the UK from 1990-2003 using UK cancer registry data - supplemented by hospital records and histopathology review of diagnostic needle biopsies. The primary endpoint was prostate cancer death. Clinical variables consisted of centrally reviewed Gleason score, baseline PSA, age, clinical stage, and extent of disease. These were combined into a single predefined risk assessment (CAPRA) score. **Results:** In univariate analysis, the CCP score hazard ratio (HR) was 2.08 (95% CI (1.76, 2.46), $P < 10^{-13}$) for a one unit change of the score and in a bivariate analysis including CAPRA, the CCP score HR was only marginally decreased (HR=1.76, 95% CI (1.44, 2.14)), and remained highly significant ($P < 10^{-6}$). The predefined CCR score combining CCP and CAPRA was highly predictive (HR = 2.17; 95% CI (1.8, 2.6), $\chi^2 = 89.0$, $P < 10^{-20}$) and captured all available prognostic information. The predictive value of the CCP score was maintained for 10 years, and there was no significant interaction with other prognostic factors. CAPRA identified 80 men (13.7%) in the low risk group (0-2) and they had a 10y prostate cancer mortality of 4.3%. CCR indicated 19 (3.2%) of these men had a higher risk, but identified a further 31 (5.3%) men with CAPRA $> 2$, but with a risk $<$ 4.3% using the combined score. **Conclusions:** The CCP score provides substantially more significant pre-treatment prognostic information than available from clinical variables and is useful for determining which patients can be safely managed by a conservative policy avoiding radical treatment.

**5060 General Poster Session (Board #189), Mon, 1:15 PM-5:00 PM**

**Phase I trial of docetaxel (D), prednisone, and pasireotide (P) (SOM230) in metastatic castrate-resistant prostate cancer (mCRPC).** *Presenting Author: Hema M. Vankayala, John D. Dingell VA Medical Center, Detroit, MI*

**Background:** Neuroendocrine (N) differentiation is a resistance mechanism to chemotherapy in mCRPC. Somatostatin (sst) receptor analogs demonstrate efficacy in N tumors. P is a multitargeted sst -receptor analog with affinity to sst 1, 2, 3 and 5, and the potential to overcome chemoresistance. A phase I trial of D+P was conducted to establish the maximum tolerated dose (MTD) and the recommended Phase II dose (RP2D). **Methods:** Chemotherapy naïve mCRPC patients (pts) with performance status (PS) 0-2 and adequate renal and hepatic function were enrolled. D was administered at a dose of 75 mg/m$^2$ intravenously every 21 days and P was administered intramuscularly (IM) every 28 days at escalating dose levels of 40, 60, and 80 mg. A 3 + 3 study design was utilized. Correlative studies included circulating tumor cell counts (CTC), IGF-1, neuron specific enolase (NSE), and chromogranin A (ChA) levels pre and post therapy. **Results:** Phase I portion of the study is complete. 12 pts were enrolled with a median age of 65 years (range 54-74) and PS of 1. Gleason score was $> 8$ in 8 pts. 4 pts had visceral metastases. Pre-study regimens included, enzalutamide (2pts); abiraterone (2 pts); and clinical trial agents (4 pts). Dose limiting toxicity noted at 80 mg of P were, grade 4 hyperglycemia unresponsive to therapy and 1 with grade 4 neutropenia lasting for $> 7$ days. The RP2D of P is 60 mg every 28 days in combination with D 75 mg/m$^2$ every 21 days. 4 of 6 pts at 60 mg of P had grade 3 hyperglycemia. No cholelithiasis, severe liver toxicity, or treatment related deaths were noted. 8 pts had grade 1-2 diarrhea, and 1 had grade 3 diarrhea. A median of 6.5 (range 2-14) cycles of D and 5 cycles (1-13) of P were administered. To date, 9 pts have progressed with median time to progression of 8.3 months (range 1.4 - 10.4) which compares favorably with docetaxel therapy alone (median 6.3 months). 3 of 6 pts with pretreatment CTC $> 5$ converted to CTC $< 5$ post therapy. Of the markers, only IGF-1 levels revealed a median 51% decrease with therapy. **Conclusions:** The addition of P to D is clinically feasible at a dose of 60 mg IM every 28 days. Clinical efficacy is encouraging and warrants study in the phase II setting. Supported in part by Novartis Inc. Clinical trial information: NCT01468532.

**5061 General Poster Session (Board #190), Mon, 1:15 PM-5:00 PM**

**Final analysis of a large, open-label global early access protocol (EAP) with abiraterone acetate (AA) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) progressing after chemotherapy.** *Presenting Author: Cora N. Sternberg, Hospital San Camillo-Forlanini, Rome, Italy*

**Background:** A global EAP was conducted to provide broader access to pts with mCRPC post-chemotherapy and to generate additional clinical efficacy and safety data for AA after registrational study COU-AA-301 had completed enrollment. In COU-AA-301, a phase 3 randomized trial of 1195 pts, AA + prednisone (P) significantly prolonged median overall survival by 4.6 months with a 26% reduction (HR = 0.74 [95% CI, 0.64-0.86]; $p < 0.0001$) in the risk of death vs placebo + P. **Methods:** 2314 pts with mCRPC who progressed after a taxane and possibly 1 additional chemotherapy entered an open-label EAP. Pts received AA (1000 mg po/d) + P (5 mg BID) in 28-day cycles. Ongoing pts were to be transitioned to marketed product upon regulatory and marketing approval in individual countries. Efficacy measures, collected to guide treatment decisions, were prostate-specific antigen progression (PSAP) and clinical progression (CP). Safety assessments included treatment-emergent adverse events (AEs). The final results are presented. **Results:** Pts were enrolled from 253 sites in 23 countries in Europe (51%), N. America (23%), Asia-Pacific (20%), and Latin America (6%). Baseline pt characteristics were similar to COU-AA-301, with median age 70 years (range 44-98) and bone metastases present in 91%. Median therapy duration was 4.9 months (74% received $\geq 4$ cycles). Median time to PSAP (683 events) and CP (721 events) was 8.5 months (95% CI, 8.3-9.7) and 12.7 months (95% CI, 11.8-13.8), respectively. Median time to PSAP was identical to the AA + P arm of COU-AA-301 (ie, 8.5 months; CP not measured). No new safety signals were detected. Grade 3/4 AEs of special interest were infrequent: any liver function test abnormalities (8.0%), hypertension (4.3%), cardiac disorders (2.2%), hypokalemia (1.2%), fluid retention/edema (1.0%). Discontinuations due to AEs or death were 7.4% each. **Conclusions:** These final EAP results demonstrate that the clinical safety and efficacy of AA + P are reproducible across a broader global distribution of sites than COU-AA-301, and reveal no additional safety concerns. Clinical trial information: NCT01217697.

**5062^ General Poster Session (Board #191), Mon, 1:15 PM-5:00 PM**

**Efficacy and quality of life (QoL) of cabazitaxel/prednisone (Cbz) in Canadian metastatic castration resistant prostate cancer (mCRPC) patients (pts) with or without prior abiraterone acetate (Abi).** *Presenting Author: Fred Saad, University of Montréal Hospital Center, CRCHUM, Montréal, QC, Canada*

**Background:** In the TROPIC study, Cbz was shown to improve overall survival in mCRPC pts post-docetaxel, however none of these pts had prior exposure to Abi. To better understand the impact of prior Abi treatment on Cbz efficacy and QoL, we evaluated Canadian pts enrolled in the International Phase IIIb/IV single arm Cbz study. **Methods:** In total 61 pts were enrolled from 9 centers (May 2011 to February 2012). Cbz efficacy (PSA Response Rate (RR, decline ≥50%)) and impact on QoL were analyzed as a function of prior Abi use. **Results:** Baseline and disease characteristics were similar between NoPriorAbi (n=35, 57%) and PriorAbi (n=26, 43%) groups, except for age and time between last docetaxel dose and progression (Table). Pts received a median of 9 cycles of prior docetaxel. 92% of pts were ECOG 0/1, with 88% having bone metastases and 25% visceral metastases. 31% of pts received prophylactic G-CSF. Median number of Cbz cycles received was similar between groups (NoPriorAbi= 6, PriorAbi= 7) as were PSA RR (NoPriorAbi= 42.4%, PriorAbi= 47.6%, p=0.78). QoL and pain were improved in Cbz pts with no significant difference observed based on prior Abi use (Table). Overall, treatment discontinuation was mainly due to progression (45.9%) and adverse events (32.8%). Most frequent grade 3/4 toxicities were anemia and fatigue (9.8%), with diarrhea, neutropenia and febrile neutropenia each observed in 8.2% of pts. **Conclusions:** Cbz efficacy and impact on QoL were not affected by prior Abi use. In routine clinical practice, toxicity rates observed were similar to the TROPIC study. Clinical trial information: NCT01254279.

**5063 General Poster Session (Board #192), Mon, 1:15 PM-5:00 PM**

**A study of ERG, PTEN, and ki-67 in a phase III trial assessing docetaxel and estramustine in high-risk localized prostate cancer (GETUG 12).** *Presenting Author: Shanna Rajpar, Institut Gustave Roussy, Villejuif, France*

**Background:** High-risk localized prostate cancer (CaP) is a heterogeneous disease and only a minority of patients (pts) ultimately die of their cancer. GETUG 12 is a phase III trial assessing androgen deprivation therapy (ADT) with or without docetaxel-estramustine (DE) in pts with high-risk localized CaP (Eur J Cancer 2012; 48:209-17). Progression free survival (PFS) data will be reported at the ASCO 2014 meeting. The aim of this study was to investigate the prognostic and predictive value of Ki-67, PTEN, and ERG expression in GETUG 12. **Methods:** Pre-treatment prostate core biopsies were collected from 255 of the 413 pts (62%) who were enrolled in GETUG 12. Immunohistochemistry analysis was performed for Ki-67, PTEN and ERG. PTEN and ERG expression were defined as positive if there was a staining (1+ or 2+) in any core. Ki-67 was characterized as low and high according to the cut-off based on the observed median value (1%). PFS differences were compared using the Logrank test and multivariate analysis was conducted with established prognostic factors using the Cox model. **Results:** In the overall population, the median age was 63 (46-77) years. 72/174 pts (41%) had Ki-67 >1%, 106/178 pts (60%) were negative for PTEN and 103/191 pts (54%) were negative for ERG. ERG negative expression (p=0.03) and high Ki-67 (p=0.02) predicted for unfavorable PFS. In multivariate analysis, pN+ (p<0.0001), ERG negative expression (0.0003) and PTEN negative expression (p=0.05) were independent prognostic factors of poor PFS. DE improved PFS in pts with a ERG positive expression (HR=0.56 [0.28-1.15]) but not in pts without ERG expression (HR=1.12 [0.65-1.91]), interaction test: p=0.02. In contrast no PFS benefit was associated with DE in subgroups defined according to Ki-67 and PTEN expression. **Conclusions:** Docetaxel-estramustine is associated with an improved PFS in pts treated for a high-risk localized CaP with ERG expression.

**5064 General Poster Session (Board #193), Mon, 1:15 PM-5:00 PM**

**Phase I trial of docetaxel/prednisone plus fractionated dose radiolabeled anti-prostate-specific membrane antigen (PSMA) monoclonal antibody $^{177}$lu-J591 in patients with metastatic, castration-resistant prostate cancer (mCRPC).** *Presenting Author: Scott T. Tagawa, Weill Cornell Medical College, New York, NY*

**Background:** Docetaxel remains a standard agent for mCRPC and has radiosensitizing properties. $^{177}$Lu-J591 delivered with fractionated dosing leads to less myelosuppression while maintaining efficacy in mCRPC. This study was designed to determine the safety, dose limiting toxicity (DLT) and maximum tolerated dose (MTD) of fractionated $^{177}$Lu-J591 administered concurrently with standard docetaxel. **Methods:** Men with progressivem-CRPC received docetaxel 75 mg/m$^2$ every 3 weeks with escalating 2 fractionated doses of $^{177}$Lu-J591 (initial dose 20 mCi/m$^2$ x2 up to max of 40 mCi/m$^2$ x2) with cycle 3. Cycle 4 of docetaxel was planned 6 weeks after cycle 3 to allow for recovery from $^{177}$Lu-J591-associated hematologic toxicity. DLT was defined as delay in docetaxel >3 weeks, prolonged myelosuppression or need for >2 platelet (plt) transfusions, febrile neutropenia, or grade >2 non-heme toxicity following $^{177}$Lu-J591. PSA was assessed prior to each cycle and CTC count (CellSearch) was assessed at baseline and after $^{177}$Lu-J591. **Results:** 15 men with median age 67.3 (range 49.2-80.8), PSA 84.3 (17-776), 73.3% with elevated LDH, 71.4% unfavorable CTC counts received up to the highest anticipated dose (40 mCi/m$^2$ x2). No DLT was seen at any dose level. Significant toxicity was limited to reversible myelosuppression. Gr 4 neutropenia without fever occurred in 3 (20%) and Gr 4 plts in 2 (13.3%), with 2 receiving prophylactic plt transfusion. No Gr >2 non-heme toxicity was observed. 13 had PSA decline, with 11 (73.3%) and 12 (80%) having >50% and >30% PSA decline respectively. All 14 evaluable men had decline (85.7%) or persistently undetectable (14.3%) CTC counts, with 78.6% having CTC counts decline by >50% and 78.6% having favorable counts after $^{177}$Lu-J591. Of 10 analyzed to date, all had targeting of known sites of disease by planar $^{177}$Lu-J591 imaging. **Conclusions:** The combination offractionated dose $^{177}$Lu-J591 and docetaxel/prednisone is well tolerated in patients with mCRPC. Without pre-selection, accurate targeting of known sites of disease and a strong preliminary efficacy signal was observed. Clinical trial information: NCT00916123.

**Management trends in the United States for low-, intermediate-, and high-risk prostate cancer.** *Presenting Author: Kamran A. Ahmed, H. Lee Moffitt Cancer Center & Research Institute, Department of Radiation Oncology, Tampa, FL*

**Background:** The purpose of this study is to determine recent trends in the United States regarding management of clinically localized prostate cancer. **Methods:** A population-based analysis was conducted of 216,785 men with low (29%), intermediate (49%), or high (22%) recurrence risk prostate cancer, as defined by the National Comprehensive Cancer Network (NCCN). Annual rates of utilization of surgery, external beam radiation therapy, brachytherapy, external beam radiotherapy and brachytherapy, and no treatment between 2004 and 2010 were determined using the Surveillance, Epidemiology and End Results (SEER) database. **Results:** White patients were more likely than African American patients to undergo surgery (44.0% vs. 33.3%, respectively; p<.0001), and African American patients were more likely than White patients to undergo radiotherapy (28.1% vs. 22.6%, respectively; p<.0001) or no treatment (20.3% vs. 16.0%, respectively; p<.0001). There was an annual increase of 1.38% (95% confidence interval (CI) 1.06% to 1.70%) in surgery utilization corresponding to a 7.6% increase in utilization over the period of analysis. Using multivariate analysis, patients were more likely to receive no treatment if they were single (odds ratio (OR) 1.65; 95% CI 1.60-1.70), diagnosed in 2010 (vs. 2009 or earlier, OR = 1.18; 95% CI 1.14 -1.22), had low risk disease (vs. high risk, OR = 2.14; 95% CI 2.07-2.21), African American (vs. White, OR=1.42; 95% CI 1.37-1.47), resided in a county with a low education level (vs. high educational level, OR=1.30; 95% CI 1.26-1.35), or were >65 (vs. ≤ 65, OR = 2.25; 95% CI 2.19-2.31). For low risk prostate cancer, there was an annual decrease of 2.29% (95% CI -2.77% to -1.81%) in utilization of brachytherapy corresponding to a 14.3% decrease over the period of analysis and an annual increase of 2.57% (95% CI 1.79% to 3.36%) in patients receiving no treatment corresponding to a 15.7% increase. **Conclusions:** In patients with low risk prostate cancer, there was decreasing utilization of brachytherapy and increasing utilization of no treatment. Patients were less likely to receive treatment if they had low risk disease or were >65, African American, single, or resided in a county with a low educational level.

**5066 General Poster Session (Board #195), Mon, 1:15 PM-5:00 PM**

**Recent trends in the management of localized prostate cancer: Results from the National Cancer Data Base.** *Presenting Author: Phillip John Gray, Harvard Radiation Oncology Program, Boston, MA*

**Background:** The management of localized prostate cancer (PC) is evolving. Using a large national database, we sought to analyze recent trends in practice patterns for this common disease in the United States. **Methods:** Data on all patients presenting with a new diagnosis of PC between 2004 and 2011 were extracted from the National Cancer Data Base. Patients with nodal or distant metastases were excluded. Patients were categorized as low risk (LR), intermediate risk (IR) or high risk (HR) according to the National Comprehensive Cancer Network's (NCCN) guidelines. P-values correspond to trend tests for the described treatment modality. **Results:** 823,977 patients met the study criteria, with 38.5% of these patients classified as LR, 42.7% as IR and 18.9% as HR. For LR patients, rates of observation after diagnosis between 2004 and 2011 increased from 12.4% to 18.5% while receipt of prostatectomy increased from 40.3% to 54.4% (p both <.001). In contrast, receipt of brachytherapy fell from 24.4% to 11.4% and receipt of external beam radiation monotherapy fell from 18.2% to 13.4% (p both <.001). For IR patients, rates of observation increased from 6.1% to 7.3%, prostatectomy increased from 48.1% to 58.5% (p both <.001), brachytherapy fell from 12.1% to 6.4% (p <.001), receipt of external beam monotherapy remained relatively unchanged (~15%) while external beam radiation plus androgen deprivation therapy (ADT) fell from 14.7% to 8.7%. For HR patients, receipt of observation and external beam monotherapy were unchanged (~8% and ~10% respectively) while receipt of surgery increased from 30.6% to 41.3% (p< .001). In contrast, receipt of external beam therapy plus ADT fell from 30.4% to 28.0%, receipt of brachytherapy fell from 8.7% to 4.1% while receipt of ADT alone dropped from 7.2% to 5.8% (p all <.001). **Conclusions:** Utilization of prostatectomy for patients with localized PC increased significantly across risk groups from 2004 to 2011 while utilization of radiotherapy (especially brachytherapy) decreased. Rates of observation have increased in LR disease while rates of combined ADT and radiotherapy in IR and HR PC are declining. Further work is needed to elucidate the causes and appropriateness of these trends.

**5067 General Poster Session (Board #196), Mon, 1:15 PM-5:00 PM**

**Bone density in men receiving androgen deprivation therapy for prostate cancer: A randomized comparison between transdermal estrogen and luteinising hormone-releasing hormone agonists.** *Presenting Author: Ruth E Langley, Medical Research Council, Clinical Trials Unit at University College London, London, United Kingdom*

**Background:** Androgen deprivation therapy (ADT) for prostate cancer with luteinising hormone-releasing hormone agonists (LHRH) reduces bone mineral density (BMD), as testosterone suppression also causes estrogen deficiency in men. Transdermal estrogen is a compelling alternative to LHRH as it achieves similar castrate levels of testosterone but mitigates the cardiovascular toxicity associated with oral estrogen (Langley et al. Lancet Oncology 2013;14:306-16) and may avoid estrogen depletion related toxicities including osteoporosis. **Methods:** PATCH (Prostate Adenocarcinoma: TransCutaneous Hormones,PR09) is a randomised trial (n=686) comparing estrogen patches (EP; FemSeven 100 $\mu$g/24 hr, 4 patches changed twice-weekly reducing to 3 after 4 weeks) versus LHRH for locally advanced or metastatic prostate cancer (allocation ratio 2:1 before 21/2/2011, 1:1 after). In a bone-sub-study, dual-energy x-ray absorptiometry (DXA) scans were performed at baseline, 1 and 2 years. Primary outcome was change in lumbar spine (LS) BMD (mean L1-L4) at 1 year, compared between arms based on intention-to-treat using analysis of covariance, adjusting for baseline values. **Results:** 85 patients were enrolled from October 2007 to September 2012 from 7 centres (31 LHRH, 54 EP), of whom 8 were excluded (2 withdrew, 6 not eligible as they had osteoporosis on baseline scan). LS BMD data were available for 60 patients (21 LHRH, 39 EP). Median age was 77 years (IQR 73-80), 24 (40%) had bone metastases. At 1 year, mean LS BMD change was -0.03 g/cm$^3$ (95% CI -0.06, -0.003) in LHRH vs 0.08 g/cm$^3$(0.04, 0.11) EP arm (p<0.001); corresponding mean percentage change was -2.11% vs +6.43%, respectively. In patients without bone metastases, the difference was -3.74% LHRH vs +5.04% EP (p=0.001). At 2 years, LS BMD decreased further in LHRH patients (-6.09% from baseline, n=10) while the increase was maintained in those on EP (+4.58%, n=20); p<0.001 comparing arms. **Conclusions:** Transdermal estrogen, used for achieving androgen deprivation in prostate cancer, protects against bone mineral density loss, confirming the need to continue evaluation of its clinical efficacy. Clinical trial information: ISRCTN70406718.

**5068 General Poster Session (Board #197), Mon, 1:15 PM-5:00 PM**

**Enzalutamide monotherapy: One-year extended follow-up of a phase 2 study in hormone-naive prostate cancer patients.** *Presenting Author: Bertrand Tombal, Service d'Urologie, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

**Background:** The efficacy and safety of enzalutamide monotherapy was assessed in men with any-stage hormone-naive prostate cancer eligible for androgen-deprivation therapy (ADT). The primary endpoint of PSA response rate (≥80% PSA decrease between baseline and week 25) was 92.5% (Smith M et al, ASCO 2013). The median (range) maximum PSA decline from baseline to week 25 was –99.6% (–100, –86.5). 1-year extended follow-up data are presented. **Methods:** In an open-label, single-arm Phase 2 study (NCT01302041), men ≥18 years with histologically confirmed prostate cancer requiring ADT, non-castrate testosterone (≥8 nmol/L), PSA ≥2 ng/mL at screening, and a life expectancy of ≥12 months, received 160 mg enzalutamide once daily until disease progression or unacceptable toxicity. Other endpoints included changes in hormone levels, metabolic parameters, BMD, safety, and quality of life (QoL). **Results:** 67 men were enrolled. Median (range) age was 73 years (48–86); 38.8% had metastases; 35.8% and 23.9% had undergone prior prostatectomy and radiotherapy, respectively. 54 men (80.6%) completed 1 year of treatment with a PSA response rate of 100% and 53 (98.1%) had ≥90% PSA decrease from baseline. The median (range) maximum decline in PSA was –100% (–100, –86.5) from baseline to 1 year. Luteinizing hormone and testosterone were increased from baseline by 215.2% and 101.7%, respectively. Mean changes from baseline for fasting metabolic variables were: +5.0% total cholesterol, +8.9% triglycerides, –3.5% HbA1c, and +19.7% insulin resistance (HOMA-IR). Total body BMD was maintained (–0.3% from baseline). The most frequently reported treatment-emergent AEs were gynecomastia (47.8%) and fatigue (38.8%). Seven non-drug-related serious AEs were reported. QoL scores at 1 year demonstrate maintenance of global health status and a decrease in sexual activity and sexual functioning. **Conclusions:** Extended follow-up of hormone-naive patients demonstrated sustained PSA reductions up to 1 year of enzalutamide monotherapy. Endocrine and metabolic changes, and AEs were consistent with potent AR inhibition and similar to results reported at 25 weeks. Clinical trial information: NCT01302041.

**5069 General Poster Session (Board #198), Mon, 1:15 PM-5:00 PM**

**Patient-reported quality of life (QOL) analysis of radium-223 dichloride (Ra-223) evaluating pain relief from the phase 3 ALSYMPCA study.** *Presenting Author: Sten Nilsson, Karolinska University Hospital, Stockholm, Sweden*

**Background:** Ra-223, a first-in-class $\alpha$-emitter, significantly improved overall survival vs placebo (pbo) and was well tolerated (Parker. *NEJM* 2013; ALSYMPCA). Ra-223 had a positive impact on pain, significantly delaying time to external beam radiotherapy and reducing pain and opioid use (Nilsson. ASCO GU 2013). This post hoc analysis assessed Ra-223 treatment (tx) effects on QOL Functional Assessment of Cancer Therapy-Prostate (FACT-P) pain-related score (PRS), with subgroup assessments by prior docetaxel use (pD) and baseline number of bone mets. **Methods:** Pain was assessed at baseline and wk 16 and 24 with FACT-P; PRS was derived from 4 pain-related questions. In responders, baseline PRS increased 2 points (improved pain). Nonresponders had neutral response (baseline PRS change -1, 0, +1) and failure (2-point baseline PRS decrease [worse pain], including pts starting opioids during tx). Chi-square tests calculated *P* values of responder rates between tx groups. Logistic regression determined odds ratios (ORs) (Ra-223 vs pbo) adjusted for stratification factors (pD, baseline total ALP, concurrent bisphosphonate) and baseline PRS as covariates. **Results:** Of 921 pts (Ra-223, n = 614; pbo, n = 307), analysis included pts with recorded PRS at each assessment visit (wk 16; Ra-223, n = 405; pbo, n = 175, wk 24, Ra-223, n = 305; pbo, n = 118, wk 16 and 24, Ra-223, n= 283; pbo, n = 109). Significantly more Ra-223 vs pbo pts were responders; pain improved at each visit (wk 16, $P = 0.028$; wk 24, $P = 0.007$) and across visits (improved for wk 16 and 24, $P = 0.013$). Ra-223 tx significantly increased odds of improved pain vs pbo at wk 16 (OR, 1.70; 95% CI, 1.08-2.70; $P = 0.023$) and wk 24 (OR, 2.18; 95% CI, 1.17-4.06; $P$= 0.014); Table shows increased odds for wk 16 and 24. For all assessed subgroups and time points, a nominally higher % of Ra-223 pts had improved pain vs pbo pts. **Conclusions:** Ra-223 was associated with greater odds of pain relief vs pbo based on FACT-P PRS. Clinical trial information: NCT00699751.

**1.5-year post-treatment follow-up of radium-223 dichloride (Ra-223) safety in patients with castration-resistant prostate cancer (CRPC) and symptomatic bone metastases from the phase 3 ALSYMPCA study.** *Presenting Author: Chris Parker, The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, Sutton, United Kingdom*

**Background:** Ra-223, an alpha-emitting pharmaceutical, significantly improved overall survival and was well tolerated in ALSYMPCA (Parker, *NEJM*2013). Long-term safety monitoring of Ra-223 is essential to build a complete safety profile and identify any association with secondary malignancies. Here we report adverse events (AEs) from ALSYMPCA patients (pts) ~1.5 y after last pt's final injection (inj). **Methods:** All ALSYMPCA pts were to enter designated follow-up starting 4 wk after each pt's last inj to 3 y after first inj. Only treatment (tx)-related AEs and specific diseases (acute myelogenous leukemia [AML], myelodysplastic syndrome [MDS], aplastic anemia [AA], primary bone cancer, primary cancer in other organs) were reported. **Results:** Of 921 pts (Ra-223, n = 614; pbo, n = 307), 574 entered designated ALSYMPCA follow-up (Ra-223, n = 406; pbo, n = 168). 335/406 (83%) Ra-223 pts and 119/168 (71%) pbo pts had 6 inj. Median follow-up time was 10.4 mo for Ra-223 pts and 7.6 mo for pbo pts. In the safety population, 25/404 (6%) Ra-223 pts and 8/167 (5%) pbo pts had 37 tx-related AEs (Table). Overall, myelosuppression incidence was ≤3%. No pts had AML, MDS, or primary bone cancer; 1 Ra-223 pt had AA, and 2 Ra-223 pts and 3 pbo pts had primary cancer in other organs (Table). **Conclusions:** Long-term follow-up of ~1.5 y after last pt's final inj showed no new safety concerns or secondary malignancies related to Ra-223. Clinical trial information: NCT00699751.

**Evaluation of the prostate health index (PHI) as a novel biomarker in active surveillance of prostate cancer.** *Presenting Author: Andrew Eichholz, University College London Hospitals NHS Foundation Trust, London, United Kingdom*

**Background:** PHI is calculated from serum PSA, free/total (f/t) PSA and [-2]proPSA using the Beckman Coulter assay kit, and has been approved for use in patient selection for diagnostic prostate biopsy. We hypothesized that phi might also predict outcome of active surveillance. **Methods:** From 2002, we have done a prospective cohort study of active surveillance for men with T1/2, Gleason <= 3+4, PSA < 15ng/ml prostate cancer. Serum was banked at baseline. Monitoring included 6 monthly PSA and 2-yearly repeat biopsy. Treatment was indicated for PSA velocity > 1ng/ml/yr or Gleason >= 4+3 on repeat biopsy. We analyzed baseline phi with respect to time to treatment. A multivariate model was fitted using total PSA, PSA velocity, PSA density, Gleason score, % biopsy cores positive, T stage, and maximum % cancer in any biopsy core. The fit of this model was then compared with the addition of % f/t PSA and PHI. **Results:** 370 patients were evaluable with a median follow-up of 5 years. The table shows the association between baseline PHI and time to treatment. On multivariate analysis, the model with % f/t PSA was a significant improvement over base model (change in fit 41.1, p<0.001), and the model with % f/t PSA and phi was a significantly better fit than % f/t PSA alone (change in fit 11.1, p=0.001). **Conclusions:** In men with favorable risk prostate cancer, PHI at diagnosis was a significant predictor of the outcome of active surveillance. The data require validation, but suggest that active surveillance is particularly attractive to men with a low PHI.

**A safety study of cabozantinib (C) plus docetaxel (D) and prednisone (P) in metastatic castrate-resistant prostate cancer (mCRPC).** *Presenting Author: Fatima Karzai, National Cancer Institute, Bethesda, MD*

**Background:** Two landmark trials demonstrate docetaxel improves overall survival in metastatic castrate-resistant prostate cancer (mCRPC). Benefits remain short-lived requiring evaluation of other treatment options, including docetaxel (D) combinations. Combining D with other agents, such as cabozantinib (C) could target different cellular signaling pathways producing either additive or synergistic activities without overlapping toxicities. C is a multikinase inhibitor of c-Met, vascular endothelial growth factor receptor 2, and RET, which has shown activity in mCRPC. **Methods:** Patients (pts) with no prior history of D, receive D at 75 mg/m2 IV on day 1 of a 21 day cycle, and prednisone (P) at 5 mg po q12 hours, with C at three dose levels: 20 mg, 40 mg, or 60 mg po daily. Three-six pts are treated at each dose level until the maximum tolerated dose (MTD) has been defined. **Results:** Fifteen pts have been accrued; 4 at 20 mg C, 6 at 40 mg C, and 5 at 60 mg C. Median age is 67 (45-84 yrs). Median baseline PSA is 69.46 (0.01-521.5 ng/mL). Median Gleason score is 9 (7-10). Four pts have ECOG PS of 0 and 11 pts have a PS of 1. Six pts have bone only disease and 8 pts have bone and soft tissue/visceral disease (STD). Median number of cycles is 9 (1-23). Most common Grade 2 and 3 adverse events (AE's), possibly related to C are: anemia (2/14), diarrhea (2/14), hand/foot syndrome (3/14), fatigue (3/14), hypophosphatemia (4/14), and oral mucositis (4/14). Of 13 evaluable pts, PSA declines are seen in 7 pts (4 declines at 40 mg C, 3 declines at 60 mg C). Two pts with bone only disease have resolution of some lesions on bone scan (BS) and both pts had PSA declines >30%. 4 pts with bone only disease have stable BS, and of these, 2 pts had PSA declines >20%. Two pts with bone and STD have PSA declines >30% and stable imaging results. Of 15 pts, six month PFS is 83.9% (95% CI: 56.3% to 95.5%) and 9 month PFS is 59.9%. **Conclusions:** The addition of C to D and P has shown to have a tolerable side effect profile. An expansion cohort will be enrolled at the MTD to further characterize safety, toxicity, and to obtain additional information on the efficacy of the combination treatment. Clinical trial information: NCT01683994.

**5073 General Poster Session (Board #202), Mon, 1:15 PM-5:00 PM**

**An open-label phase II clinical trial of the RXR agonist IRX4204 in taxane-resistant, castration-resistant metastatic prostate cancer (CRPC).** *Presenting Author: Fairooz F. Kabbinavar, University of California, Los Angeles, Los Angeles, CA*

**Background:** IRX4204 is a potent, selective, oral small compound agonist of RXR nuclear receptor pathways. In preclinical studies IRX4204 synergizes with insulin-like growth factor binding protein-3, to induce apoptosis in human prostate cancer cells and was effective in reducing human prostate tumor burden in a murine xenograft model. The only prostate cancer patient in a phase I trial of IRX4204 trial manifested a sustained >90% PSA reduction and a PR lasting over 7 months. These findings led to the current open label phase II trial of IRX4204 to evaluate safety and activity or futility, for treatment of advanced CRPC. **Methods:** The trial enrolled 23 men with metastatic CRPC, who had failed a taxane or declined chemotherapy, with ECOG 0-2 with evidence of biochemical or radiographic progression on bone scan, CT and/or MRI. Patients continued with androgen blockade and had to have adequate organ function. Patients were deemed to have demonstrated benefit of IRX4204 treatment if they had PFS >56 days, and/or a 50% PSA decrease, and/or PR or CR by RECIST. Futility defined as 4 or fewer patients demonstrating benefit in the planned enrollment of 37 patients. Patients received IRX4204 (20 mg/orally daily) . PSA was checked Q 4 weeks & radiographic assessments Q8 weeks. Radiographic not PSA progression was used to determine progression. **Results:** IRX4204 was well tolerated for up to 11 months. No drug related SAE have occurred. Manageable decreases in TSH and increases in triglycerides, both known adverse effects of RXR agonists, have been observed. Protocoldefined patient benefit was observed in 13/23 (57%) patients. PFS >56 days observed in 13/23 (57%). PFS >112 days observed in 9/23 (39%), range 113 to 330 days. PSA 50% response occurred in 3/23 (13%), including one additional PSA 90% response. No objective responses have occurred. **Conclusions:** This study demonstrates that IRX4204 treatment of taxane-resistant CRPC is well tolerated, & provides an activity signal warranting further evaluation of IRX4204as a treatment for chemo-refractory CRPC. Funding: Supported by Io Therapeutics, Inc. 1805 East Garry Ave., Suite 110, Santa Ana, 92705. Clinical trial information: NCT01540071.

**5074 General Poster Session (Board #203), Mon, 1:15 PM-5:00 PM**

**A safety study of trebananib (AMG 386) and abiraterone in metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Michelle A. Ojemuyiwa, Walter Reed National Military Medical Center, Bethesda, MD*

**Background:** Trebananib is an angiopeptide angiopoietin1/2 peptibody antagonist . Androgens stimulate expression of VEGF via activation of hypoxia inducible factor-a (HIFa). Androgen deprivation therapy (ADT) is associated with lower HIF1a gene expression in prostate cancer tissue. Dual targeting of the androgen and angiogenic axis represents a potential synergistic anti-angiogenic therapeutic approach in mCRPC. In this preliminary safety study we hypothesize that trebananib in combination with abiraterone will have a favorable tolerability and efficacy profile. **Methods:** Patients(pts) with mCRPC were treated with abiraterone 1000mg daily and prednisone 5 mg twice daily. Trebananib was administered intravenously every week, in escalating doses from 15mg/kg to 30mg/kg on days 1, 8, 15 and 22 every 28-days. **Results:** A total of 9 pts were enrolled. Three of nine pts had prior chemotherapy. The median age was 63.8 (63-71yrs). No dose limiting toxicities were observed. The most common grade ≥2 toxicities included limb edema (3/9), hyperglycemia (1/9), gastrointestinal (2/9), fatigue (2/9), hypertension (1/9), confusion (1/9), weight gain (1/9) and insomnia (2/9). 5/9 of pts had an overall PSA decline of >30%. 8/9 pts were evaluable for response. Pts previously treated with chemotherapy were on study for 1and 3 months, respectively. Chemotherapy-naïve pts were treated for 1, 6, 9, 10, 10, and 21 months, respectively. **Conclusions:** Trebananib in combination with abiraterone is well tolerated and displayed an acceptable safety profile in pts with mCRPC. Based on this safety data a randomized phase II study randomizing chemotherapy-naïve mCRPC pts to either abiraterone/prednisone plus AMG 386 at 30mg/kg or abiraterone/prednisone is currently accruing at the NCI. Clinical trial information: NCT01553188.

**5075 General Poster Session (Board #204), Mon, 1:15 PM-5:00 PM**

**Symptomatic skeletal events (SSE) in patients with advanced prostate cancer: Results from a phase III trial of denosumab for the prevention of skeletal-related events.** *Presenting Author: Laurence Klotz, University of Toronto, Toronto, ON, Canada*

**Background:** In a randomized controlled trial of men with castration-resistant prostate cancer (CRPC) and bone metastases, denosumab was superior to zoledronic acid (ZA) for reducing skeletal-related events (SRE, defined as pathological fracture, surgery or radiation to bone [including the use of radioisotopes], or spinal cord compression) (Fizazi, et al. Lancet 2011;377:813-822.). Recently, the composite endpoint of symptomatic skeletal event (SSE, defined as symptomatic fracture, surgery or radiation to bone, or spinal cord compression) was introduced as an alternative term/clinical trial endpoint to describe skeletal morbidity. **Methods:** Men with CRPC, ≥ 1 bone metastasis, and no prior IV bisphosphonate use received either SC denosumab 120 mg or IV ZA 4 mg (adjusted for creatinine clearance) in a blinded fashion every 4 weeks. Oral calcium and vitamin D supplements were recommended. SSEs included pathologic fractures considered symptomatic by the investigator, spinal cord compression and surgery and radiation to bone. **Results:** As previously reported, fewer men who received denosumab than ZA had confirmed first SREs, and experienced multiple SREs (Table). Similarly, fewer patients in the denosumab group than the ZA group had confirmed first SSE and multiple SSEs. The median (95% CI) estimate of time to first SSE (superiority analysis) for denosumab was not reached (28.8 mo, not estimable), and for ZA it was 24.2 (20.7, 30.2) mo (HR = 0.78 [0.66, 0.93], $P < 0.01$). **Conclusions:** Denosumab reduced the risk of skeletal events in men with CRPC regardless of endpoint definition as SRE or SSE. The risk of developing SSEs was reduced by up to 22% when comparing denosumab with ZA. Clinical trial information: NCT00321620.

| Number of confirmed skeletal events, n (%) | Denosumab (N = 950) | ZA (N = 951) | Hazard or rate ratio (95% CI) |
|---|---|---|---|
| First SSE | 241 (25.4%) | 289 (30.4%) | HR = 0.78 (0.66, 0.93) $P < 0.01$ |
| First SRE | 341 (35.9%) | 386 (40.6%) | HR = 0.82 (0.71, 0.95) $P < 0.01$ |
| Multiple SSEs | 329 | 409 | RR = 0.78 (0.65, 0.92) $P < 0.01$ |
| Multiple SREs | 494 | 584 | RR =0.82 (0.71, 0.94) $P < 0.01$ |

**5076 General Poster Session (Board #205), Mon, 1:15 PM-5:00 PM**

**Genetic variant in fragile histidine triad gene (*FHIT*) and mortality in prostate and breast cancers: Results from the Prostate, Lung, Colon, Ovarian Cancer Screening Trial (PLCO) and Women's Health Initiative (WHI).** *Presenting Author: Yan Ding, City of Hope, Duarte, CA*

**Background:** Prostate and breast cancers combined account for over 10% of all cancer deaths each year in the U.S. Previous studies detected familial concordance in prostate and breast cancer-specific mortality, suggesting shared genetic component associated with poor survival in the two cancers. We previously identified a genetic locus associated with prostate cancer in a 28.5 kb intronic region of *FHIT*, a triphosphatase that promotes apoptosis in response to DNA damage in epithelial cell.To evaluate its association with mortality, a prostate cancer cohort nested in the PLCO (n=1239) and a breast cancer cohort nested in the WHI (n = 682) were studied. **Methods:** We obtained data on genotypes, tumor characteristics, and outcomes from dbGaP and PLCO, and imputed genotypes for genetic variants within the 28.5 kb region. Multivariable-adjusted Cox proportional hazard regression was used to calculate hazard ratio (HR) of genotypes on mortality due to prostate cancer, breast cancer, or due to all causes, with 95% confidence intervals (CI). Other variables included in the models were age at diagnosis, PSA, Gleason score, stage, and primary treatment for prostate cancer and age at diagnosis for breast cancer. **Results:** We identified a common genetic variant in the *FHIT* locus associated with mortality due to prostate cancer (GG or AG vs. AA, HR = 2.96, 95% CI, 1.05 – 8.27, p = 0.04) or due to breast cancer (HR = 3.76, 95% CI, 1.4 – 10.2, p = 0.01). Furthermore, the variant was associated with all cause mortality in patients who had prostate (HR = 1.98, 95% CI, 1.3 – 3.1, p = 0.003) or breast (HR = 2.00, 95% CI, 1.00 – 1.05, p = 0.017) cancer. The association was stronger in patients who were diagnosed at younger ages or had family history in first degree relatives. We also detected interaction between the *FHIT* variant and treatments with radical prostatectomy or radiation therapy on prostate-cancer specific mortality ($P_{interaction}$ = 0.0045). **Conclusions:** The significant effect of the *FHIT* variant on mortality in both prostate and breast cancers suggests a role for the *FHIT* region on cancer outcomes, justifying further investigation.

**5077 General Poster Session (Board #206), Mon, 1:15 PM-5:00 PM**

**Low-dose abiraterone (abi) with food in men with metastatic castration-resistant prostate cancer (mCRPC): The Princess Margaret Cancer Centre experience.** *Presenting Author: Raya Leibowitz-Amit, Division of Medical Oncology, Princess Margaret Hospital/University of Toronto, Toronto, ON, Canada*

**Background:** Abiraterone (abi) prolongs survival in men with mCRPC [de Bono et al. NEJM 2011; 364:1995.]. Initial studies showed that abi plasma concentrations are higher when administered with a high-fat meal vs the fasting state, and similar maximal plasma drug concentrations and areas under the curve were reported after administration of 250 or 500 mg of abi in the fed-state ('low dose') as after 1000 mg in the fasting state ('full dose') [Attard. JCO 2008; 26:4563. Ryan. JCO 2010; 28:1481.]. Two phase III trials assessed full-dose abi [de Bono et al. NEJM 2011; 364:1995., Ryan. NEJM 2012; 368:138.], and this dose was approved for both pre- and post-chemotherapy. At the Princess Margaret (PM) Cancer Centre, low-dose abi in the fed-state is sometimes prescribed to men who otherwise cannot access the drug due to funding constraints, particularly in the pre-chemotherapy setting. **Methods:** All men treated with abi at PM until Mar-2013 were reviewed. Associations between dose (full vs. low) and PSA response rate (PSA-RR), progression free survival (PFS), and overall survival (OS) were assessed using chi-square and log rank tests, respectively. PSA-RR was defined as a confirmed PSA decrease ≥50%, PFS was from start of abi to PSA progression, clinical progression, drug cessation, or death, and OS from start of treatment to death. **Results:** 90 and 21 men were treated with full or low dose abi, respectively. PSA-RR was non-significantly lower in chemo-naive men treated with low doses compared to full doses (p=0.09), but there were no significant differences in PFS or OS for both the entire cohort and the chemo-naïve cohort (table). **Conclusions:** Administration of low dose abi after a high-fat meal is not associated with shorter PFS or OS despite a trend to lower PSA-RR. These results may be relevant in resource-limited settings and warrant further prospective clinical research.

| | Dose | N | PSA-RR % (95% CI) | *P* value | median PFS, months (95% CI) | *P* value | Median OS, months (95% CI) | *P* value |
|---|---|---|---|---|---|---|---|---|
| All men | Full | 90 | 43 (32-54) | 0.36 | 4.4 (2.8-5.7) | 0.3 | 18.7 (14.8-22.1) | 0.25 |
| | Low | 21 | 32 (13-57) | | 5.6 (2.1-8.0) | | 16.6 (13.4- nr) | |
| Chemo-naive | Full | 34 | 53 (35-71) | 0.09 | 5.5 (4.4-6.5) | 0.9 | 18.8 (14.8-32.1) | 0.49 |
| | Low | 16 | 27 (8-55) | | 4.6 (2.0-8.0) | | nr (15.3-nr) | |

**5078 General Poster Session (Board #207), Mon, 1:15 PM-5:00 PM**

**Population-based analysis of a novel prognostic model for metastatic castration-resistant prostate cancer (mCRPC) patients (pts) treated with abiraterone acetate (AA).** *Presenting Author: Arun Azad, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** A prognostic model for predicting overall survival (OS) in mCRPC pts commencing AA was recently developed from a post-hoc analysis of the COU-AA-301 trial. The model consists of 6 pre-treatment risk factors (RF): ECOG performance status (PS) ≥2, presence of visceral metastases, time from start of androgen deprivation therapy (ADT) to start of AA ≤36 months (mos), low albumin (≤40g/L), high ALP (>160 IU/L) and high LDH (>250 IU/L). Our aim was to evaluate this model in a population-based cohort. **Methods:** Three Canadian cancer registries were used to identify mCRPC pts treated with AA. OS was estimated by the Kaplan-Meier method and compared by log-rank. Multivariate analysis was performed with the Cox proportional hazard regression model. **Results:** In post-docetaxel pts (n=286), 21%, 50% and 28% were classified into good (0-1 RF), intermediate (2-3 RF) and poor (4-6 RF) prognosis (prog) groups respectively based on the COU-AA-301 model. Median OS was significantly longer for good prog pts (23.9 mos) compared to intermediate (16.2 mos) and poor prog pts (8.0 mos) (Table). ECOG PS (p<0.001), LDH (p=0.040), albumin (p=0.003), visceral metastases (p<0.001) and time from start of ADT to start of AA (p=0.037) were confirmed as independent prognostic factors. In docetaxel-naïve pts (n=138), 31%, 50% and 19% were classified into good, intermediate and poor prog groups respectively. Median OS was significantly longer for good prog pts (36.9 mos) compared to intermediate (13.3 mos) and poor prog pts (7.3 mos) (Table). **Conclusions:** In a population-based setting, our data validate the COU-AA-301 model as a tool for prognostic stratification of both docetaxel-experienced and –naïve mCRPC pts treated with AA. This model can be used to predict outcomes for individual pts and to assist in selection of pts for clinical trials based on expected prognosis.

*Versus good prog group.

**5079^ General Poster Session (Board #208), Mon, 1:15 PM-5:00 PM**

**Long-term efficacy and safety of androgen receptor inhibitor ODM-201 in ARADES phase I/II trial.** *Presenting Author: Christophe Massard, Gustave Roussy, University Paris Sud, Villejuif, France*

**Background:** ODM-201, is an novel oral androgen receptor (AR) inhibitor that has shown good preclinical efficacy, and has high antitumor activity in metastatic CRPC (mCRPC) patients (pts) (Fizazi et al. 2013). **Methods:** We report the long-term data in CYP17i-naïve progressive mCRPC pts in the ARADES phase I/II trial and the phase II extension study, in which pts were enrolled into dose levels of 100mg bid, 200mg bid or 700mg bid. Radiographic progression was evaluated either according to RECIST 1.1 for soft tissue or defined by at least 2 new lesions in bone compared to a prior scan. **Results:** 69 pts had progressive mCRPC; 37 pts were chemotherapy-naïve and 32 chemotherapy-pretreated. The median age was 69 yrs (53-83 yrs). 59 pts (86%) had bone metastases and 12 (17%) had visceral metastases. The median PSA was 99 ng/mL (3-1294) and the CTC count was 5 or more CTCs per 7.5ml in 42% of the pts. Forty-six (67%) pts continued drug over 12 weeks (wks). With a median follow-up of 38 wks the median time to PSA progression was 36 (95% CI: 24–74) wks for chemotherapy-naïve pts, and 21 (95%CI: 16–28) wks for chemotherapy-pretreated pts. The median time to radiographic progression was not reached for chemotherapy-naïve (95% CI: 24–not reached), and was 32 (95% CI: 12–not reached) wks for chemotherapy-pretreated pts. Treatment related AEs occurred in 22/69 (32%) pts. Most commonly reported treatment related AEs in the trial were asthenia/fatigue 6 (9%), decreased appetite 4 (6%), arthralgia 2 (3%), back pain 2 (3%), diarrhea 2 (3%), headache 2 (3%), hot flushes 2 (3%), and myalgia 2(3%), mostly mild to moderate. **Conclusions:** These data are in line with 12-wk efficacy and safety data reported previously, and show high anticancer activity and favorable tolerability of ODM-201. Clinical trial information: NTC01317641; NTC01429064.

**5080 General Poster Session (Board #209), Mon, 1:15 PM-5:00 PM**

**Role of serum lipids and glucose as biomarkers of prostate cancer severity.** *Presenting Author: Alejo Rodriguez-Vida, Medical Oncology department, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

**Background:** We have previously shown in a Swedish cohort study that high levels of triglycerides (TG) and glucose and low levels of high density lipoprotein (HDL) cholesterol and apolipoprotein A-I (apoA-I) are related to increased prostate cancer (PC) risk. The current study investigates serum lipids and glucose in relation to severity of localized PC, at time of diagnosis and at metastatic progression. **Methods:** Between 2001-2004, 203 consecutive patients with localized PC were recruited. Levels of total cholesterol (TC), HDL and low density lipoprotein (LDL) cholesterol, TG, apoA-I, apolipoprotein B (apoB), and glucose were assessed at baseline, with a second measure for 74 patients after a median time of 10 years. Correlation coefficients and multivariate logistic and Cox proportional hazards regression was used to assess associations between metabolic components and PC severity at time of diagnosis and at metastatic progression. **Results:** Median age at diagnosis was 65 years (range: 40-76), with a median follow up of 8.1 years (0.4-13.9). 66 men underwent radical radiotherapy (33%), 57 radical prostatectomy (28%), 27 active surveillance (13%) and 17 watchful waiting (8%). At baseline, we found a statistically significant inverse correlation between PSA and the apoB/apoA-I, LDL/HDL, and TC/HDL ratios (r=-0.18, r=-0.17, r=-0.18 respectively; P<0.05). Gleason score was positively associated with HDL and inversely with TC/HDL (r=0.15, r=-0.14; P<0.05). There was no association between the second lipid measurements and baseline PSA, but HDL remained positively associated with baseline Gleason and TG inversely associated (r=0.24, r=-0.30; P<0.05). Age-adjusted multivariate model including TG, HDL, glucose, and hypertension showed a statistically significant association between glucose and Gleason ≥7 versus <7 (OR 1.14, 95%CI: 1.00-1.29). A similar model for PSA ≥15 versus <15 did not show any statistically significant results, whereas an equivalent Cox model for progression to metastasis also showed a weak positive association with glucose (HR 1.13, 95%CI: 0.95-1.35). **Conclusions:** Our study supports the hypothesis that metabolic markers such as serum lipids and glucose may be a biomarker of prostate cancer severity.

**5081 General Poster Session (Board #210), Mon, 1:15 PM-5:00 PM**

**Improving the specificity of prostate cancer screening for early detection of lethal disease.** *Presenting Author: Hans Lilja, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** PSA is used to detect prostate cancer, but many men need to be screened, biopsied, and diagnosed to prevent one cancer death. We sought to increase the specificity of screening for lethal prostate cancer. **Methods:** We conducted a nested case-control study to determine the relationship between four kallikrein markers (kallikrein related peptidase 2, total, free, and intact PSA) and long-term risk of metastasis. Of the 40,379 men providing blood at age 40, 50, and 60 during 1986-2009 for the Västerbotten Intervention Project, 12,561 were followed for over 15 years. Using the Swedish Cancer Registry, 1,423 incident prostate cancer cases and 235 men with evidence of distant metastases were identified. Kallikrein markers were measured in cryopreserved blood from cases and controls. **Results:** Risk of prostate cancer metastasis at 20 years was higher (16-fold at age 60, 7-fold at age 50, 3-fold at age 40) among men with PSA in top quartile than men with PSA below median. Most metastatic cases occurred in men with PSA in top quartile at age 50 (69%) or 60 (73%). Among men with PSA levels above median, a pre-specified model based on four kallikrein markers improved prediction of distant metastasis documented 10-20 years later compared to PSA alone. Among men with PSA ≥2 ng/ml at age 50, discrimination increased from 0.77 (PSA alone) to 0.88 (kallikrein panel); for men with PSA ≥2 ng/ml at age 60, discrimination increased from 0.81 to 0.87. We also conducted a decision analysis evaluating hypothetical outcomes had the panel been used to aid decisions about biopsy in this cohort. Using the biopsy cutoff used in the European randomized prostate cancer screening trial (PSA ≥3 ng/ml) would have resulted in biopsies performed on 15.5% of men with blood drawn at age 60. This rate would have been reduced by 38% if biopsy were restricted to those with ≥7.5% risk of high-grade cancer according to the panel. However, 10 to 15-year risk of distant metastases was only 0.18% to 1.16% in this group; a 15-year risk of metastases less than an eighth of that for those with PSA ≥3 ng/ml and ≥7.5% risk score. **Conclusions:** The specificity of PSA screening can be improved by focusing on men with modestly elevated PSA at age 50-60 and by reflex testing of four kallikrein markers.

**5082 General Poster Session (Board #211), Mon, 1:15 PM-5:00 PM**

**A biopsy-based molecular diagnostic test for prediction of aggressive prostate cancer despite variability in pathology assessment.** *Presenting Author: Jeffry P. Simko, University of California, San Francisco, San Francisco, CA*

**Background:** The 17-gene Genomic Prostate Score, GPS (Genomic Health, Inc., Redwood City, CA), has been analytically (Knezevic et al. BMC Genomics 2013) and clinically validated as a biopsy-based predictor of adverse pathology at radical prostatectomy (RP) (Cooperberg et al. AUA 2013). In the clinical study, central review of biopsy and RP pathology was performed by a single expert uropathologist (JS). Given inter-observer variability of pathologic interpretations, we assessed the ability of GPS to predict adverse pathology at RP based on the original diagnostic reads. **Methods:** RP patients treated at UCSF from 1997-2011 for clinical low or low-intermediate risk PCa (biopsy Gleason score [GS] 3+3, or 3+4 with ≤ 3 (or 33%) positive cores; PSA ≤ 20; clinical stage ≤ T2) were eligible for the study. The original biopsy GS, RP GS and pathologic T stage reflected diagnoses rendered by > 15 different UCSF pathologists. GPS, using a 100-unit scale, was assessed by qRT-PCR of mRNA from microdissected biopsy tumor tissue. Adverse pathology at RP was defined as major pattern 4 or any pattern 5 and/or pT3 stage. Univariate and multivariable logistic regression models were used. **Results:** Of 395 patients, 295 (75%) had biopsy GS 6 disease based on original pathology review and 301 (76%) based on central review with 24% discordance. GPS was predictive of adverse pathology defined by central RP review after adjusting for either central biopsy GS (GPS OR/20 units=1.93, 95% CI: 1.30-2.88, p=0.001, GS OR=1.94, 95% CI: 1.17-3.21, p=0.011) or original biopsy GS (GPS OR/20 units=1.98, 95% CI: 1.33-2.93, p <0.001, GS OR=1.82, 95% CI: 1.11-2.98, p=0.019). At RP, 123 (31%) and 66 (17%) patients had adverse pathology based on central review and original review, respectively. Discordance for RP GS was 26% and for pT stage 14%. In univariate models, GPS was a significant predictor of adverse pathology at RP as assessed by central ($p < 0.001$) or original ($p < 0.001$) pathology review. **Conclusions:** The observed discordances between separate pathology assessments of grade and stage are consistent with previous studies. GPS is a robust predictor of adverse pathology despite differences in Gleason scoring and pathologic stage assessment.

**5083 General Poster Session (Board #212), Mon, 1:15 PM-5:00 PM**

**Active surveillance in phenotypically heterogeneous early-stage prostate cancer.** *Presenting Author: John W. Davis, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Active surveillance (AS) in prostate cancer (PC) is predicated on slow, stepwise disease (Dz) progression. Patient (Pt) selection, although not standardized in prospective AS trials, is based on clinical stage, prostate-specific antigen (PSA), and phenotypic characteristics of tumors on biopsy (BX). Changes on repeat BXs often trigger intervention. In a single-institution prospective cohort study, pts with early stage PC were stratified to AS group (GR) I (favorable risk), II (pt's choice), or III (competing comorbidities prevent local therapy [TX]). We describe early results for GR II, use of confirmatory and subsequent BX, and reclassification and TX rates. **Methods:** Enrolled 2006-2012 were 191 men into GR I, 369 into GR II, and 14 into GR III. GR I required a single core of Gleason score (GS) 3+3 < 3mm, or 3+4 < 2mm, and a PSA < 4 ng/mL. Pts with a life expectancy >10 years (yr) selecting AS were considered GR II. Pts had mandatory confirmatory BX at registration or within 6 months (mo) of diagnostic BX, and then repeat BXs every 1-2 yr. PSA and digital rectal examination were done every 6 mo. Dz was reclassified based on increases in tumor volume (TV) or grade. **Results:** In 369 GR II pts, clinical stage cT1c was found in 86%; median PSA was 4.4 ng/mL; and GS was 3+2 in 0.3%, 3+3 in 77.2%, 3+4 in 19.2%, and 4+3 in 3.3%. After a median 3 yr follow-up, 119 (32%) had been treated with curative modalities—surgery (43%), radiation (53%), and cryotherapy (3%). One pt (PSADT, <2 yrs; GS, 6 to 7) had an anterior tumor and a positive pelvic lymph node at 1.5 yrs. One pt with pT3b N0 at surgery at 9 mo had persistently elevated PSA. Time on study pre-TX was <6 mo in 53%, 6-<12 mo in 8%, 12-<24 mo in 24%, 24-<36 mo in 9%, and 36->48 mo in 5%. Dz was reclassified on BX that triggered TX in 106 pts based on increased BX TV and/or GS upgrading in 74 (70%) (6 to >7 in 61 [82%], 3+4 to 4+3 in 7 [10%], and Gleason 7 to >7 in 6 [8%]). **Conclusions:** In a prospective AS cohort with phenotypically heterogeneous tumors, one third were eventually treated for cure—mostly in the first yr, owing to BX variability. Biologically concerning TX triggers (GS 6/7 to 8/9) occurred in 12% of treated. Despite limitations of selection criteria and monitoring tools, AS is an important initial option in localized PC.

**5084 General Poster Session (Board #213), Mon, 1:15 PM-5:00 PM**

**Prognostic value of free testosterone (FT) levels during salvage chemotherapy with carboplatin plus weekly docetaxel in metastatic castration- and docetaxel-resistant prostate cancer (mDRPC).** *Presenting Author: Christoph W. Reuter, Department of Hematology, Hemostasis, Oncology, and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany*

**Background:** Recent data suggest that carboplatin plus weekly docetaxel (DC) may be effective in mDRPC. Platinum(II)-complexes have been shown to interfere with steroid biosynthesis lowering testosterone levels by inhibiting the cholesterol side chain cleavage enzyme (CYP11A1), 3$\beta$-hydroxysteroid dehydrogenase (HSD3B1,2) and 17$\alpha$ hydroxylase/C17,20-lyase (CYP17A1). **Methods:** Docetaxel failure/resistance was defined according to the Prostate Cancer Working Group (PCWG2 2007) criteria. Treatment consisted of at least two cycles of carboplatin AUC5 iv for 30 min on day 1 every 4 weeks (q4w), docetaxel at a dose of 35 mg/m2 iv for one hour on days 1, 8, (15) plus prednisone 2x5mg/day orally after receiving informed consent until disease progression or occurrence of intolerable adverse effects. Efficacy measures were done following PCWG2 recommendations. Free testosterone levels were measured before (n=59) and during DC chemotherapy (n=52). **Results:** Of the 84 pts. treated since February 2005, 95.2% had bone, 41.7% lymph node, 27.4% liver and 17.9% lung involvement. At the time of the current analysis, the median follow-up time was 15.1 months, 64 pts. had died and 75 had progressive disease. The objective response rate was 40.0% and the disease control rate 62.0% in the 50 pts. with measureable disease. Response of prostate-specific antigen (≥50%) was observed in 40/84 (47.6%) patients. Median progression-free survival (PFS) for all patients was 6.9 months (CI 95% 6.0, 7.8) and median OS was 17.9 months (CI 95% 12.6, 23.0). The most common reversible grade 3/4 toxicity was leukopenia/neutropenia (42.9/38.1%). Median free testosterone levels were 0.69 pg/ml before and <0.18 pg/ml during carboplatin/docetaxel treatment (p<0.001; detection limit <0.18 pg/ml). In multivariate analyses, LDH, number of radiation treatments, PSA response, free testosterone nadir levels, and total androgene nadir levels during DC treatment were associated with longer OS (p<0.05).**Conclusions:** These data suggest that DC may be an important second-line treatment option for DRPC patients by inhibiting the testosterone biosynthesis.

**5085 General Poster Session (Board #214), Mon, 1:15 PM-5:00 PM**

**Neuroendocrine differentiation patterns in metastases from advanced prostate cancer.** *Presenting Author: Rafael E. Jimenez, Mayo Clinic, Rochester, MN*

**Background:** Neuroendocrine differentiation (NED) in advanced prostate cancer (APC) is considered an aggressive phenotype with poor outcome and limited treatment options. Diagnosis depends on histological confirmation, which is not routinely performed during clinical care. Thus, information on NED in metastatic APC is rather limited. We evaluated an archival set of metastatic site biopsies (MSB) to determine NED expression patterns in APC. **Methods:** We searched medical and pathological databases for APC patients (pts) who underwent MSB during routine clinical care. Formalin-fixed, paraffin-embedded tissue sections were analyzed by immunohistochemistry (IHC) for expression of chromogranin-A (CGA) and synaptophysin (SYN), and graded as 0, 1+, 2+, or 3+, according to staining in none, <10%, 11-50%, or >50% of tumor cells, respectively. A score of 1+ or greater was considered positive. NED was considered present if positivity for either marker was observed **Results:** From 1994 to 2013, 237 MSB from 187 pts were identified (39, 9, and 2 pts had two, three and four MSB, respectively). MSB included bone (102), lung (40), liver (40), lymph node (20), bladder (14), soft tissue (11), brain (4), others (4). All tumors were adenocarcinomas or poorly differentiated carcinomas. No small cell carcinomas were identified. A total of 183 MSB from 157 pts were successfully stained for both markers, of which 92 MSB (50%) from 79 pts (50%) showed positive NED (72/142 1$^{st}$, 16/29 2$^{nd}$, 3/6 3$^{rd}$, and 1/1 4$^{th}$ MSB). In 7 of these patients the NED was demonstrated in a successive MSB, after a negative 1$^{st}$MSB. NED expression was positive in 41% bone sites, compared to 53% of non-bone sites (p=0.112). Clinical annotation was available for 72 pts, of which 47 underwent MSB during hormone sensitive stage (HSPC) and 25 during castrate resistant (CRPC) stage (median PSA 5.6 and 7.5 ng/ml, respectively). NED expression was observed in 21 (44%) HSPC cases, and 14 (56%) of CRPC cases (p=0.36). **Conclusions:** NED in APC was more common in this cohort than historically reported. This may have relevant prognostic or therapeutic implications. More than one MSB may be necessary to document NED in a patient with APC, as patterns of NED may vary within the same patient.

**5086 General Poster Session (Board #215), Mon, 1:15 PM-5:00 PM**

**Effect of abiraterone acetate and low-dose prednisone on PSA in patients with nonmetastatic castration-resistant prostate cancer: The results from IMAAGEN core study.** *Presenting Author: Charles J. Ryan, University of California San Francisco, San Francisco, CA*

**Background:** Abiraterone acetate (AA) is a prodrug of abiraterone, which is a selective, irreversible CYP17 inhibitor of androgen biosynthesis and significantly reduces testosterone production in the testes, adrenal glands and prostate cancer tissue. AA, 1000mg, in combination with prednisone (P), 10mg daily is indicated for the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC). Patients with non-metastatic CRPC (nmCRPC) will eventually progress to mCRPC. Currently there is no approved therapy for nmCRPC. This phase II, multi-center study evaluated the ability of AA plus 5 mg of prednisone to decrease PSA levels in patients with nmCRPC and rising PSA. **Methods:** All patients had nmCRPC but with clinical features placing them at higher risk of developing mCRPC: PSA value $\geq$ 10ng/mL or PSA doubling time $\leq$ 10 months at screening. Patients received AA 1000mg with P 5mg (AA+P5) daily. The primary endpoint was PSA response rate at 6 months. Key secondary endpoints included change in testosterone levels, safety, time to PSA progression and time to radiographic disease progression. PSA assessment and imaging scans were conducted every 3 months. **Results:** From May 2011 to July 2013, 131 patients were enrolled at 38 sites in the US. Data cutoff for this analysis was December 31, 2013. Median age was 72 years (range 48-90). Median baseline PSA was 13.7ng/mL (range 1.6-167.8ng/mL). There were 122 patients evaluable for the analysis of PSA response. By the end of 6 cycles of treatment, 87% (106/122) of patients had $\geq$ 50% reduction in PSA and 60% (73/122) had $\geq$ 90% PSA reduction. To date, no patient has had his prednisone dose increased to greater than 5mg to manage symptoms of mineralocorticoid excess. Complete details of radiographic progression and other secondary endpoints including safety will be available by the time of the ASCO meeting. **Conclusions:** In men with high-risk nmCRPC, treatment using AA+P5 is very effective in lowering PSA. The rate and depth of PSA decline appear superior to men with mCRPC. Clinical trial information: NCT01314118.

**5087 General Poster Session (Board #216), Mon, 1:15 PM-5:00 PM**

**Dose escalation with high-dose-3D-conformal (HD-3D-CRT) or low-dose 3D-conformal radiotherapy PLUS HDR brachytherapy (LD-3D-CRT+HDR-B) for intermediate- or high-risk prostate cancer: Higher disease control and survival with lower toxicity.** *Presenting Author: Benjamin Guix, IMOR Foundation, Barcelona, Spain*

**Background:** To report early and late toxicity and biochemical outcome in a prospective series of 445 patients with intermediate- or high-risk clinically localized prostate cancer treated with either HD-3D-CRT or with LD-3D-CRT+HDR-B. **Methods:** Between 12/1999 and 10/2005, 445 patients (pts) with PSA›10, Gleason score›6 and/or T2b-T3 N0 M0 prostate cancer entered the study. Pts were prospectively assigned to one of the two treatment groups: 76 Gy HD-3D-CRT to the prostate in 38 fractions (group 1; 223 patients) or 46 Gy LD-3D-CRT+ 16 Gy HDR-B given in 2 fractions of 8 Gy (group 2, 222 patients), limiting the maximum rectal dose to 85% of the prescribed dose. Both groups were well balanced taking into account patient's as well as tumors' characteristics. Toxicities were scored by the EORTC /RTOG morbidity grading scales. Special attention to local, regional or distant recurrence, survival, late effects, PSA and testosterone levels and quality of life was done. **Results:** All pts completed treatment. None pts included in the group 1 or 2 experienced grade 3 or more rectal toxicity. 28 pts of group 1 (12.5%) and 6 pts of group 2 (2.7%) developed grade 2 rectal toxicity (rectal bleeding or urgency). 15 pts in group 1 (6.7%) and 3 pts in group 2 (1.3%) developed grade 1 rectal bleeding (less than 2 times/week). With a mean follow-up of 96 months, the 10-year free-from-failure survival was 90.7% and 98.3% ($p<0.002$) in group 1 and 2 respectively; free-from-metastases survival 96.9% and 97.9% ($p<0,008$)for group 1 and 2 respectively; and cause-specific survival 97.4% and 98.3% ($p<0.09$). **Conclusions:** High-dose 3D-EBRT + HDR brachytherapy was a safe and effective method of escalating the dose to the prostate without increasing the risk of late effects. Acute as well as late rectal complications were significantly reduced with the combined treatment, compared with what was observed with high-dose conventional, 3D-conformal radiotherapy. Control rates were better with in the HDR-boosted patients as expected by higher effective-dose.

**5088 General Poster Session (Board #217), Mon, 1:15 PM-5:00 PM**

**Molecular profiling of metastatic castration-resistant prostate cancer (mCRPC): Preliminary results from the SU2C/PCF/AACR West Coast Prostate Cancer Dream Team (WCDT).** *Presenting Author: George Thomas, Oregon Health & Science University, OHSU Knight Cancer Institute, Portland, OR*

**Background:** The molecular basis of mCRPC has not been well characterized because of its bone tropism and difficulties in obtaining adequate tissue to evaluate. Bringing next-gen sequencing into clinical (CLIA-licensed) laboratories is an important step in the advancement of personalized cancer care in these patients (pts). As part of the WCDT project, we are conducting next-gen, semiconductor-based sequencing using the GeneTrails®Solid Tumor Panel, which covers 37 commonly mutated cancer genes. **Methods:** mCRPC pts, both abiraterone and enzalutamide naive and resistant, underwent biopsy (bx) at one of 5 WCDT clinical sites. Oncogenic mutations or amplifications in 37 genes were detected in formalin-fixed, paraffin embedded (FFPE) bone and soft issue bx using amplicon + semiconductor-based sequencing within a CLIA-certified laboratory. PTEN status was also examined by immunohistochemistry. **Results:** 60 of 300 planned mCRPC pts have undergone a metastasis bx. FFPE tissue has been evaluated by sequencing in 26 of these bx. Bx sites were: bone (n=8), lymph node (n=9) liver (n=7) lung (n=1), and adrenal (n=1). Mutations were found in 16 (62%) of the samples, with a greater rate of mutations in soft tissue (13/18) vs. bone (3/8). The most frequent mutations were in *TP53* (N = 11, 42%), followed by *PTEN* (N = 4, 15%), *RB1* (N = 4, 15%), *PIK3CA* (N = 2, 7.6%). Single instances of mutations were observed for *AKT1, DDR2, EGFR, KIT, NOTCH1, TSC1, TSC2* and *HRAS* (3.2% each). Amplification of *EGFR* and *FGFR1* were also noted. 90% of these alterations are known to result in either gain or loss of function. PTEN loss by IHC and/or mutation was seen in 12 of 26 (46%) of pts. Overall, 13 pts (50%) demonstrated at least one alteration in the PTEN/PI3K/AKT axis. **Conclusions:** Bx from mCRPC pts, including bone, can be used for prospective molecular profiling of tumor biopsy specimens. The most common alterations were found in the PTEN/PI3K/AKT pathway (50%), p53 (11%) and RB1 (15%). Combining amplicon + semiconductor-based next-gen sequencing provides a fast, cost-effective and reliable approach to potentially clinically actionable targeted sequencing data from mCRPC sites.

**5089 General Poster Session (Board #218), Mon, 1:15 PM-5:00 PM**

**Activity of subsequent new drugs (NDs) in post-docetaxel (DOC) failure for metastatic castration-resistant prostate cancer (mCRPC) patients (pts): A multicenter Italian experience.** *Presenting Author: Orazio Caffo, Santa Chiara Hospital, Trento, Italy*

**Background:** Abiraterone acetate (AA), cabazitaxel (CABA), and enzalutamide (ENZ) may prolong survival in mCRPC pts progressing after DOC, although it is not clear how to use NDs, to best exploit their efficacy and avoiding their possible cross resistances. We report a large series of pts, receiving 2 NDs (or 3 in a limited series), after DOC progression in routine clinical practice. **Methods:** All NDs were available in Italy through a compassionate use program, or after the regulatory authorities approval (only CABA in 2012 and AA in 2013). Based on a multi-institutional collaboration, we collected data of pts who received at least 2 NDs after DOC. **Results:** A consecutive series of 203 mCRPC pts, median age 70 yrs (46-91), with bone (87%), nodal (57%) or visceral (17%) mets, was identified. All received NDs as 2nd and 3rd line after DOC, but 31 also as 4th line. The biochemical response rate (bRR) ($PSA^- > 50\%$) was 37% in 2nd line, 17% in 3rd and 6% in 4thline, while the rate of objective response (oRR) was 17%, 16% and 6%, respectively and the median PFS was 6, 4 and 3 mos respectively. The table reports the outcomes of AA, CABA and ENZ according to the sequence adopted. **Conclusions:** At our knowledge this retrospective study reports the highest number of pts treated post-DOC with at least 2 NDs and it is the first to provide 4th line data. It appears from our findings that similar bRR and oRR are achieved by CABA and ENZ while AA seems less active in 3rd line and that responses in 4th line are rare (only with CABA).

**Distinguishing aggressive versus nonaggressive prostate cancer using a novel prognostic proteomics biopsy test, ProMark.** *Presenting Author: Fred Saad, University of Montréal Hospital Center, CRCHUM, Montréal, QC, Canada*

**Background:** Current clinical and pathological parameters are insufficient for accurate prediction of progression risk for patients with biopsy Gleason grades 3+3 or 3+4. Reasons for this include biopsy sampling error and pathologist grading discordance, resulting in inaccurate prostate pathology assessment. Consequently, a majority of these patients are over-treated. We have established a novel proteomics-based test, ProMark for automated quantitative measurements of biomarkers from tumor epithelium of intact FFPE biopsy tissue. The test generates a personalized risk score predictive of prostate tumor pathology at the time of biopsy. **Methods:** A clinical biopsy simulation study using prostatectomy tissue (N=380) was designed to identify 12 biomarkers that can predict surgical Gleason score and lethal disease despite sampling error. Next, a clinical study of 381 biopsies with matched prostatectomy annotation was done to select the best marker subset predictive of prostate pathology. Subsequently, the locked model was validated in a separate blinded clinical study with centralized Gleason grading (N=274). **Results:** The Promark risk scores were strongly predictive of prostate tumor pathology, the primary study objective. The test was able to separate 'favorable' cases [surgical Gleason score 3+3 or 3+4; organ-confined (<=pT2)] from 'non-favorable' cases [non-organ-confined disease (≥T3a, N, or M) or surgical Gleason >=4+3] with an AUC of 0.68 (0.61-0.74;p<0.0001). At risk score <0.33 the specificity for prediction of favorable disease is 90% with a predictive value of 81%. At a risk score > 0.8, the predictive value for non-favorable disease is 77%. Importantly, ProMark provides improved personalized disease prediction relative to standard risk stratification systems, including NCCN and D'Amico. **Conclusions:** We have established a novel prognostic test, ProMark, for prostate cancer biopsies. The risk scores are generated independent of clinical and pathological parameters and correlate strongly with pathological outcome. The test could be useful as an aid in clinical decision making for stratification of patients into good and poor candidates for active surveillance.

**5091 General Poster Session (Board #220), Mon, 1:15 PM-5:00 PM**

**The influence of insurance status on racial disparities in the treatment of African American men with high-risk prostate cancer.** *Presenting Author: Brandon A. Mahal, Harvard Medical School, Boston, MA*

**Background:** Treating high-risk prostate cancer (CaP) definitively improves survival. We evaluated whether having health insurance reduces racial disparities in the use of definitive therapy for high risk CaP. **Methods:** The Surveillance, Epidemiology and End Results Program was used to identify 70,006 men with localized high-risk CaP (PSA > 20 or Gleason 8-10 or stage > cT3a) diagnosed from 2007 – 2010. We used multivariable logistic regression to analyze the 64,277 patients with complete data to determine the factors associated with receipt of definitive therapy. **Results:** Compared to white men, African American (AA) men were significantly less likely to receive definitive treatment (adjusted odds ratio [OR] 0.60; 95% CI 0.56 – 0.64; $P < 0.001$) after adjusting for sociodemographics and known CaP prognostic factors. There was a significant interaction between race and insurance status ($P_{interaction} = 0.01$) such that among uninsured men, the adjusted OR for definitive treatment for AA vs. white was 0.38 (95% CI 0.27 – 0.54; P < 0.001), but among insured men, the adjusted OR was 0.62 (95% CI 0.57 – 0.66; P<0.001), suggesting that among insured men, there was a reduction in racial disparity between AA and white patients with regards to receipt of definitive therapy. **Conclusions:** AA men with high-risk CaP were significantly less likely to receive potentially life-saving definitive treatment when compared to white men. Having health insurance was associated with a reduction in this racial treatment disparity, suggesting that expansion of health insurance coverage may help reduce racial disparities in the management of aggressive cancers.

**Assessment of effect modification between insurance status and race for the outcome of employment of definitive therapy. All men were diagnosed with high-risk prostate cancer from 2007 – 2010 (N = 64,277).**

**5092 General Poster Session (Board #221), Mon, 1:15 PM-5:00 PM**

**Identifying biomarkers specific to bone metastases in castrate-resistant prostate cancer.** *Presenting Author: Maahum Ali Haider, University of Washington, Seattle, WA*

**Background:** Castrate-resistant prostate cancer (CRPC) has a propensity to metastasize to bone. There is evidence to suggest a differential response to treatment in bone versus visceral metastases. We sought to identify molecular targets specific to CRPC bone metastases. **Methods:** Liver (n=19), lymph node (n=68), and bone metastases (n=20) from 54 CRPC patients were laser capture microdissected to identify biomarkers using Agilent Expression Arrays. Tissue microarrays (TMAs) were used to validate the differential expression of proteins of interest in bone (n=117) and visceral (n=65) metastases. Prosaposin (PSAP) was evaluated in serial serum samples from men who presented with localized, recurrent, and metastatic disease. **Results:** Gene Set Enrichment and Ingenuity Pathway Analyses identified pathways that were altered between bone and visceral metastases (q<0.05): 1) Epithelial mesenchymal transition (ZEB1/2, SNAI1/2, TGFB1, VIM), 2) Survival (BAD, BAX), 3) Innate immune response (CNN2, COL4A1, CCL14, FPR1, TLR4, MMP9, SERPINF1) and 4) Osteomimetic (POSTN, SPP1, RUNX2, DKK1, DMP1, IBSP, THBS3). Based on TMAs, both nuclear and cytoplasmic Twist were higher in bone than in visceral metastases ($p<0.01$). Nuclear Twist and SLUG were associated with fibroblast-like epithelial cells, suggesting that a subset of nuclear-Twist positive CRPC cells in the bone have high metastatic potential. BCL-2 and MCL-1 survival proteins have been shown to be decreased in CRPC bone metastases. Here we show that BAX and BAD are overexpressed. Moreover, we validated the increased expression of osteomimetic proteins and determined that serum PSAP (which has been associated with disease progression) is elevated in patients who developed bone metastases. **Conclusions:** Heterogeneity of CRPC metastases both within and between patients is an obstacle in determining the appropriate treatment regimen for each patient. However, our data highlight that differential response to therapy could also be based on the site of metastasis. We have identified biomarkers that differentiate bone from visceral metastases that may represent new therapeutic targets for CRPC bone metastases.

**5093 General Poster Session (Board #222), Mon, 1:15 PM-5:00 PM**

**Incidence of second primary malignancies in veterans after prostate cancer diagnosis.** *Presenting Author: Narjust Perez-Florez, Department of Internal Medicine, Rutgers University-New Jersey Medical School, Newark, NJ*

**Background:** With the advancement of diagnostic and treatment modalities in prostate cancer (PC) over the past 20 years, PC specific survival rates have improved. The aim of this study was to evaluate the incidence of second primary malignancies in our veteran population after diagnosis of PC. **Methods:** We reviewed the records of 548 patients (pts) diagnosed with PC between 1999 and 2011. Data including demographics, veteran status (Vietnam vs. non-Vietnam), Gleason score, PSA, PC stage, treatment, incidence of second primary malignancy and survival were studied. Cox regression analysis was performed using SAS v 9.2. **Results:** There were 548 pts with a median (M) age of 71 years (45-98). 265 pts (48%) were Caucasian, 256 pts (47%) African American and 28 pts (5%) of other races; 158 pts (31%) were Vietnam veterans. The M Gleason score was 7 (4-10) and PSA 9.3 (0.7-7870). 153 pts (28%) had one or more second primary malignancies after PC diagnosis. The incidence of second malignancy was significantly higher among Vietnam veterans (OR: 2.08, p<0.0003) and pts with localized PC (OR: 5.53, p<0.0001) in univariate analysis. Sites for second malignancy were lung 42 (28%), hematologic 21 (14%), bladder 19 (12%), colorectal 11 (7%) and liver 10 (6.5%). Of the 95 pts who received radiotherapy for PC and later developed a second malignancy, 28 (29%) developed the second malignancy in the radiotherapy field (bladder, colon and rectal cancer) and 12 (11%) developed a hematologic malignancy. In 72 (47%) pts the second malignancy was diagnosed ≥4 years after the diagnosis of PC, 62 (41%) between 1-3 years and 18 (12%) within 12 months of the diagnosis of PC. Age (OR: 0.95, 95% CI: 0.93-0.97, p<0.0001), PC stage (OR: 0.18, 95% CI: 0.08-0.38, p<0.0001) and veteran status (Vietnam vs. non-Vietnam; OR: 1.65, 95% CI: 1.07-2.55, p<0.02) were independent and significant predictors of a second primary malignancy by multivariate analysis. **Conclusions:** In this cohort, 28% of veterans with prior PC developed a second primary malignancy. Vietnam veterans had 1.7 times greater risk to develop a second primary malignancy and patients with localized PC had 18% higher risk of developing a second primary malignancy compared to patients with metastatic PC.

**TPS5094 General Poster Session (Board #223A), Mon, 1:15 PM-5:00 PM**

**PROSPER: A phase 3 study of enzalutamide in nonmetastatic (M0) castration-resistant prostate cancer (CRPC) patients.** *Presenting Author: Maha Hussain, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

**Background:** There is no standard of care for patients with M0 CRPC. In a recent study, patients with a PSA ≥8 ng/mL or PSA doubling time of ≤10 months had a median time to bone metastasis of only 2 years (Smith et al. Lancet 2012; 379: 39–46). Prostate cancer growth is dependent on androgen receptor (AR) signaling. Enzalutamide (formerly MDV3100) is a novel oral AR inhibitor that targets multiple steps in the AR signaling pathway. In two large Phase 3 studies, enzalutamide was shown to prolong overall survival and radiographic progression-free survival in patients with metastatic CRPC. The objective of the PROSPER trial is to evaluate the efficacy and safety of enzalutamide in M0 CRPC patients. **Methods:** PROSPER is a randomized, double-blind, placebo-controlled, international Phase 3 study (NCT02003924) initiated in December 2013 and involving more than 200 sites globally. Eligibility criteria include: asymptomatic M0 CRPC; PSA doubling time ≤10 months; screening PSA ≥2 ng/mL; and adequate hematologic, hepatic, and renal function. Approximately 1560 patients will have continued androgen deprivation therapy and will be randomized 2:1 to enzalutamide 160 mg/day or placebo. Patients will be stratified by PSA doubling time (<6 vs 6-10 months) and baseline use of bone-targeting agent (yes vs no).The primary endpoint is metastasis-free survival (MFS) based on central independent review of whole-body radionuclide bone scans for bone disease assessment and CT or MRI scans for soft tissue disease assessment. Imaging will be undertaken at screening and every 16 weeks post randomization till radiographic progression. The study has 90% power to detect a target hazard ratio of 0.75 based on a 2-sided log-rank test at an overall significance level of 0.05. Secondary endpoints include: overall survival; time to pain progression; time to opiate use for prostate cancer pain; time to first use of cytotoxic chemotherapy; time to first use of new antineoplastic therapy; time to PSA progression; PSA response; time to functional status deterioration as assessed by the FACT-P global score; and quality of life as assessed by EQ-5D-5L and QLQ-PR25. Clinical trial information: NCT02003924.

**TPS5095 General Poster Session (Board #223B), Mon, 1:15 PM-5:00 PM**

**Prevention of symptomatic skeletal events with denosumab administered every 4 weeks versus every 12 weeks: A noninferiority phase III trial (SAKK 96/12, REDUSE).** *Presenting Author: Arnoud J. Templeton, Kantonsspital St. Gallen, St. Gallen, Switzerland*

**Background:** Denosumab, a monoclonal antibody against RANK-Ligand has been shown to be superior to zoledronic acid in delaying time to a first on-study skeletal-related event (SRE) in patients with solid tumors, with no effects on disease progression or survival (Stopeck et al. JCO 2010, Fizazi et al. Lancet 2011). Many SREs were silent compression fractures found only because of scheduled imaging. The approved dose of denosumab is 120mg sc every 4 weeks (q4w). Although generally well tolerated, there is a dose-dependent increase in osteonecrosis of the jaw in up to 8% of patients (Fizazi et al, ESMO 2012, 937P). Cases of fatal hypocalcaemia were observed during post marketing surveillance. In a study of 255 women with breast cancer and bone metastases randomized to 1 of 5 blinded denosumab cohorts (30mg q4w, 120 mg q4w, 180 mg q4w, 60mg q12w, 180mg q12w) or an open-label iv bisphosphonate, a similar degree of creatinine-corrected urinary N-telopeptide (uNTx/Cr) suppression at weeks 13 and 25 was observed in all cohorts (Lipton et al. CCR 2008). The optimal dose and schedule of denosumab is unknown. Denosumab is associated with considerable costs and adds toxicity; thus a study of de-escalation is warranted. **Methods:** The aim of the present trial is to test the hypothesis that the benefit of denosumab is maintained if administered 120mg q12w as compared to 120mg q4w. The primary endpoint of this open-label randomized phase III non-inferiority trial is time to first on-trial symptomatic skeletal events (SSE; clinically significant pathological fracture, radiation therapy to bone, surgery to bone or spinal cord compression). With a non-inferiority margin of 1.2 for the hazard ratio, power 80% and type I error 5%, the total sample size is 1380. Secondary endpoints include safety, time to subsequent on-trial SSE, quality of life, health economic outcomes, and change in bone turnover markers. Patients with breast or prostate cancer with bone metastases and adequate organ function are eligible. This trial is open for international collaboration. Clinical trial information: NCT02051218.

**TPS5096 General Poster Session (Board #224A), Mon, 1:15 PM-5:00 PM**

**Randomized phase II study of abiraterone acetate maintenance in combination with docetaxel after disease progression to abiraterone acetate in metastatic castration-resistant prostate cancer (mCRPC): ABIDO SOGUG trial.** *Presenting Author: Miguel Angel Climent, Fundación Instituto Valenciano de Oncología, Valencia, Spain*

**Background:** Docetaxel (D) is the standard treatment for symptomatic or aggressive disease in mCRPC patients. Abiraterone acetate (AA), a specific inhibitor of CYP17, blocks persistent extragonadal and testicular androgen biosynthesis in mCRPC (Massard C, 2011). AA in combination with prednisone improves OS and rPFS in mCRPC patients after D-failure and for pts with asymptomatic or minimally symptomatic CT naïve (Fizazi K, 2012; Ryan CJ, 2013; ZYTIGA Janssen Biotech, Inc., 2012). This study aims to evaluate efficacy and safety of AA maintenance in combination with D after disease progression to first line AA in mCRPC. **Methods:** This is a randomized phase II open-label study conducted in chemotherapy naïve mCRPC patients progressing after AA treatment. Primarily, patients will be included for AA treatment (1000 mg/d plus prednisone 10 mg/d) if histologically or cytologically adenocarcinoma of the prostate is confirmed, metastatic disease other than visceral, prostate cancer progression to previous castration treatment documented by PSA (PCWG2), radiographic progression (modified RECIST) or bone scan progression; ECOG PS 0-1, testosterone < 50 ng/dL and adequate, hematologic, hepatic, and renal function. Patients will receive AA until clinical and/or radiographic disease progression. In a second phase patients will be randomized to receive D 75 mg/m$^2$ plus prednisone 10 mg/d combined with AA 1000 mg/d (arm A) or D 75 mg/m$^2$ plus prednisone 10 mg/d (arm B) alone in 21 day cycles. Primary objective is 1 year radiographic PFS. Secondary objectives include OS, PFS (radiographic and PSA), Response Rate (radiographic and PSA), pain, skeletal events, QoL, TTP and safety profile. At least fifty four pts are planned to be included in each arm to assess the treatment efficacy in terms of rPFS. Sample size has been calculated using the Fleming method with $\alpha$=0.05 and $\beta$=80%. This study is planned include 119 pts in 17 sites in Spain and is expected to start in February 2014. Clinical trial information: NCT02036060.

**TPS5097 General Poster Session (Board #224B), Mon, 1:15 PM-5:00 PM**

**A phase 1-2 study of the type I progesterone receptor (PR) antagonist onapristone (ONA) in patients (pts) with advanced castration-resistant prostate cancer (CRPC).** *Presenting Author: Joaquin Mateo, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

**Background:** PR expression in prostate cancer increases with resistance to castration [Bonkhoff 2001]. The transcriptional, activated PR (APR), offers a potential target in advanced CRPC. ONA stops PR dimerization, inhibits ligand-induced PR phosphorylation and prevents PR association with co-activators, blocking PR-induced DNA transcription. ONA was active in preclinical models, with responses reported in pts with other PR+ cancers. An extended-release (ER) tablet formulation of ONA has been developed to achieve continuous exposure and to address the liver function abnormalities seen with an earlier formulation. Parallel development of an APR companion diagnostic allows for stratification of advanced CRPC pts. **Methods:** This is an open-label, phase 1-2 study with 2 stages: dose-selection and expansion (n~60). Main inclusion criteria are: metastatic/recurrent CRPC, good organ function, prior progression on abiraterone (AA) or enzalutamide (ENZ) and 1-2 lines of chemotherapy. Tumor biopsies are acquired from all pts at baseline to determine PR status. Paired biopsies at day 8-28 and upon progression are collected if possible. Primary endpoints are: determination of recommended phase 2 dose (RP2D) and response rate based on RECIST, circulating tumor cell (CTC) count conversion and/or >50% PSA decline. Secondary endpoints include safety and PK. Exploratory analyses of multiparametric MRI as a response biomarker in bone, circulating nucleic acids and hormone metabolism are included. Stage 1: Pts are randomized to 10 or 20 mg of ONA ER tablets BID (3-6 pts/cohort). Upon confirmation of safety, based on a dose-limiting toxicity (DLT) observation period of 8 weeks, a data review committee (DRC) will open randomization in parallel to the 30-40-50 mg cohorts (6pts/cohort). RP2D will be selected based on tolerability and PK. Stage 2: 36 pts will be treated at RP2D with an interim analysis after 21 pts. The DRC can permit continued AA/ENZ during ONA treatment at this stage. The adaptive design for biomarker-driven pt selection guarantees that >75% pts at RP2D will be APR+. The dose-selection stage of the study is open for accrual. Clinical trial information: NCT02049190.

**TPS5098 General Poster Session (Board #225A), Mon, 1:15 PM-5:00 PM**

**A randomized phase III, factorial design, of cabazitaxel and pelvic radiotherapy in patients with localized prostate cancer and high-risk features of relapse.** *Presenting Author: Karim Fizazi, Institut Gustave Roussy, Villejuif, France*

**Background:** Most patients (pts) with PC are currently diagnosed with localized disease and most of PC-related deaths occur in high risk (HR) pts due to metastatic dissemination. Combining androgen deprivation therapy (ADT) with radiotherapy (RT) improves the survival of pts with HR localized PC, but the risk of relapse in the HR population warrants investigation. In other epithelial neoplasms, chemotherapy (CT) regimens with proved activity in the metastatic setting often yielded a survival benefit when used in the localized setting. Cabazitaxel (Cbz) has demonstrated survival benefit in metastatic castrate-resistant PC post-docetaxel. One of the objectives is to evaluate the benefit of neoadjuvant Cbz in pts with HR localized PC. Dose-escalated RT benefits have been demonstrated in intermediate and HR PC. Randomized trials failed to demonstrate the superiority of pelvic over prostate only RT. In this trial involving HR PC pts the risk of occult pelvic lymph node metastases might be as high as 30%. With neoadjuvant CT, pelvic RT could help eradicate microscopic pelvic disease and improve PFS. As elective pelvic RT is still controversial, practices might vary between centers and potentially pts receiving Cbz or not. Therefore a second randomization is used to answer this major question concerning RT of the pelvis. **Methods**: This factorial design international trial started in December 2013 and aims to recruit 1048 pts with at least 2 HR criteria among Gleason score $\geq$ 8, T3 (MRI accepted)-T4 and PSA $\geq$ 20 ng/mL; localized disease (including pelvic lymph nodes $>$ 1 cm) and no prior treatment for PC. Pts are randomized between ADT + prostate-only RT +/- Cbz and ADT + pelvic RT +/- Cbz. Primary endpoint is clinical PFS (cPFS). 262 pts are needed in each of the four arms to detect an absolute difference in cPFS at 6 years of 7.5% (5% 2-sided test, power=80%) between ADT and ADT+CT arms and prostate only RT and pelvic RT arms. Planned accrual duration is 4 years. An interim analysis is planned at 50% of the events. **Conclusion**: The aim is to evaluate the benefits of neoadjuvant Cbz and pelvic IMRT in HR localized PC. This is a unique opportunity to study this paradigm in a largely powered trial. Clinical trial information: NCT01952223.

**TPS5099 General Poster Session (Board #225B), Mon, 1:15 PM-5:00 PM**

**Prostate Adenocarcinoma: TransCutaneous Hormones, PR09 (PATCH): A randomized controlled trial of transdermal estrogen patches versus luteinising hormone releasing hormone agonists in locally advanced and metastatic prostate cancer.** *Presenting Author: Ruth E Langley, Medical Research Council, Clinical Trials Unit at University College London, London, United Kingdom*

**Background:** Contemporary androgen deprivation therapy (ADT) with luteinising hormone releasing hormone agonists (LHRH) suppresses androgen to castrate levels but also depletes estrogen (synthesised from aromatised testosterone). Sex hormone depletion results in serious long term toxicities including osteoporosis and adverse metabolic changes potentially associated with increased cardiovascular (CVS) risk. Transdermal estrogen is a compelling alternative to LHRH for achieving castrate levels of testosterone, and should avoid the CVS toxicity associated with oral estrogen by circumventing first-pass hepatic metabolism, as well as mitigating estrogen depletion related toxicities. **Methods:** PATCHis a multi-centre, randomised, non-inferiority trial comparing the efficacy and safety of transdermal estrogen patches (FemSeven 100 $\mu$g/24 hour, 4 patches changed twice-weekly reducing to 3 after 4 weeks) against LHRH. Men (without significant CVS disease) with advanced prostate cancer (newly diagnosed or previous radical treatment and rising prostate specific antigen) are eligible. The trial was designed for evaluation in stages. Stage 1 (n=254) showed the patches produced castrate levels of testosterone similar to LHRH without additional CVS toxicity (Langley et al. Lancet Oncology 2013;14:306-16), and had more favourable blood glucose and lipid profiles. In stage 2, a pre-planned interim analysis (n=638) reviewed by the Independent Data Monitoring Committee (June 2013) led to the decision to extend the trial, with the aim of recruiting a total of 2,150 patients, to enable the evaluation of the patch efficacy to progress seamlessly from phase II to III. The design for the extension is based on the multi-stage, multi-arm (MAMS) approach and incorporates an interim analysis before continuing to the final stage. Primary outcome measures are overall and progression-free survival. The possibility of adding a new treatment arm for a phase II evaluation of an estrogen gel is being considered. Other international groups have been approached for potential collaboration. Clinical trial information: ISRCTN70406718.

**TPS5100 General Poster Session (Board #226A), Mon, 1:15 PM-5:00 PM**

**A randomized double-blind, comparative study of ARN-509 plus androgen deprivation therapy (ADT) versus ADT alone in nonmetastatic castration-resistant prostate cancer (M0-CRPC): The SPARTAN trial.** *Presenting Author: Matthew Raymond Smith, Harvard Medical School and Massachusetts General Hospital, Boston, MA*

**Background:** ADT is the standard of care for patients (pts) with metastatic prostate cancer and is frequently used in pts with non-metastatic prostate cancer. Initial ADT achieves responses in nearly all pts, but most progress to castration-resistant disease within a few years. Among men with M0-CRPC, a rising prostate-specific antigen (PSA) heralds the development of metastases and associated morbidity and mortality. Prevention of metastases is a major unmet medical need in M0-CRPC. ARN-509 (ARN) is a potent and selective androgen receptor (AR) antagonist that inhibits AR nuclear translocation and DNA binding without significant AR agonist properties (Clegg N et al. Cancer Res.2012). ARN demonstrates a 12- and 24-week PSA response rate of 91% in M0-CRPC pts and an excellent safety profile (Smith MR et al. ASCO GU 2013; Smith MR et al. ESMO 2013). **Methods:** This is a multicenter, double-blind, placebo-controlled, phase 3 trial evaluating the efficacy and safety of ARN in pts with M0-CRPC at high risk for progression (PSA doubling time [PSADT] $\leq$ 10 months). Continuous ADT is mandatory in order to maintain castrate concentrations of testosterone ($<$ 50 ng/dL). Pts are stratified based on PSADT ($\leq$ 6 vs $>$ 6 months), baseline use of bone-sparing agents for osteoporosis, and presence of locoregional disease, and randomized (2:1) to ARN + ADT or placebo + ADT. The absence of distant metastasis at screening is documented by central radiographic review. The primary end point is metastasis-free survival. Secondary end points include overall survival and other clinically relevant end points. Approximately 1200 pts will be randomized to provide appropriate statistical rigor to detect the hypothesized risk reduction in metastasis or death. This study uses group sequential design, including an interim analysis. The stratified log rank test will be used for the analysis. An independent data monitoring committee is commissioned to conduct reviews of the safety and efficacy data. Approximately 300 sites in 24 countries will participate. Pts are being screened and enrolled as of September 2013. Clinical trial information: NCT01946204.

**TPS5101 General Poster Session (Board #226B), Mon, 1:15 PM-5:00 PM**

**Carfilzomib for metastatic castration-resistant prostate cancer (mCRPC) following chemotherapy and androgen pathway inhibitors.** *Presenting Author: Guru Sonpavde, The University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

**Background:** mCRPC is an incurable disease despite increments in outcomes with new agents. Proteasome inhibitors are promising agents for the therapy of mCRPC. In a phase I trial of bortezomib in 47 men with mCRPC, 4% had $>$ 50% PSA decline, 25% had stable PSA; 9.5% had objective partial responses among 21 men with measurable disease. Dose-dependent inhibition of whole-blood 20S proteasome activity was seen. Carfilzomib is a second-generation epoxyketone proteasome inhibitor that binds selectively and irreversibly with its target. In vitro studies demonstrated potent pro-apoptotic activity across a broad panel of bortezomib-resistant tumor cell lines. The pharmacodynamic half-life of carfilzomib activity was $\geq$ 24 hours and doses of 15 to 36 mg/m$^2$ lead to 77% to 86% proteasome inhibition in whole blood 1 hour after dosing. The dose-limiting toxicity (DLT) in clinical trials was hematologic. Fatigue, nausea and diarrhea and neurotoxicity were manageable. Carfilzomib is approved for relapsed/refractory myeloma where the starting dose is 20 mg/m$^2$ over 2-10 minutes on days 1,2, 8,9,15,16 over 28 days in cycle 1, and the target dose is 27 mg/m$^2$ in subsequent cycles. With 30-minute infusions of carfilzomib, the MTD was 56 mg/m$^2$. **Methods:** A non-randomized proof-of-concept phase II trial (NCT02047253) was designed to evaluate carfilzomib for mCRPC following docetaxel and abiraterone acetate and/or enzalutamide. A 6-month PFS $\geq$30% is considered important, while PFS$<$10% is not; 28 patients are accrued to account for 10% inevaluable patients. Carfilzomib is administered on days 1,2,8,9,15,16 every 28 days. The starting dose is 20 mg/m$^2$ over 30 minutes during the first week followed by a target dose of 56 mg/m$^2$ if no DLTs occur. Daily oral acyclovir is administered for herpes zoster prophylaxis. Therapy will continue until progression or severe toxicities. PFS is the primary endpoint based on radiographic and symptomatic criteria (not PSA). Secondary endpoints are PSA declines, present pain index change, measurable tumor response, CTC (circulating tumor cell) declines and overall survival. Whole blood is collected at baseline for 20S proteasome activity. Clinical trial information: NCT02047253.

**TPS5102 General Poster Session (Board #227A), Mon, 1:15 PM-5:00 PM**

**SWOG S1216: A phase III randomized trial comparing androgen deprivation therapy (ADT) plus TAK-700 with ADT plus bicalutamide in patients with newly diagnosed metastatic hormone-sensitive prostate cancer (HSPC) (NCT01809691).** *Presenting Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

**Background:** Responses to ADT in new HSPC are not durable and the disease progresses with in a median of ~ 18 months. Median overall survival (OS) is 48 months. Despite the failure of ADT, tumor progression may be driven by CYP17 mediated intratumoral androgen production and/or androgen receptor (AR) signaling. TAK-700 (orteronel) is a CYP17 inhibitor with a potentially greater 17,20 lyase selectivity (ie, for androgen as opposed to corticosteroid synthesis), and has shown activity in castrate resistant tumors. Based on data from > 1000 men with new HSPC in the SWOG-9346 study, a failure to achieve a prostate-specific antigen (PSA) of ≤4 ng/ml (or to be experiencing a rise in PSA) after 7 months of undergoing ADT + bicalutamide, is a powerful negative predictor of survival (JCO 2006; 24:3984). These data provide the rationale for optimizing androgen blockade in new HSPC. **Methods:** In S1216, an intergroup study, men with new HSPC, a performance status (PS) of 0-2, and a PSA of ≥ 2 ng/ml are randomized to ADT+TAK-700 vs ADT+ bicalutamide, and stratified according to PS, extent of disease (minimal or extensive) , and if they have started ADT prior to registration. OS is the primary end point. Secondary endpoints are: progression free survival, PSA response at 7 months (<0.2 vs 0.2-4 vs. >4 ng/ml), adverse effect profile, and long term survival after 10 years of follow up. It is assumed that the median OS of those randomized to ADT+ bicalutamide is conservatively 54 months (48 months based on results from SWOG-9346 + an additional 6 months from novel agents). The experimental regimen with TAK-700 would be of interest if median OS were improved by 25% (i.e., median=68 months). With 4.5 years of accrual and 4 more years of follow-up, and assuming a one-sided alpha=0.025 and 90% statistical power, study needs 1486 eligible men to be randomized. Planned correlatives include serum androgens, bone markers, and circulating tumor cells. Current rate of accrual is ~28 men per month with 220 men accrued so far. Support: NIH/NCI CA32102, CA38926, CA31946 and CA21115, and Millennium: The Takeda Oncology Company. Clinical trial information: NCT01809691.

**TPS5103 General Poster Session (Board #227B), Mon, 1:15 PM-5:00 PM**

**A randomized open-label phase 2a study evaluating the efficacy and safety of radium-223 dichloride (Ra-223) in combination with abiraterone acetate or enzalutamide in patients with castration-resistant prostate cancer (CRPC) and bone metastases.** *Presenting Author: Daniel Peter Petrylak, Yale Cancer Center, New Haven, CT*

**Background:** Ra-223, a first-in-class alpha-pharmaceutical targeting bone metastases (mets), reduced risk of death by 30% versus placebo in patients (pts) with CRPC and symptomatic bone mets in the phase 3 ALSYMPCA trial (Parker et al. NEJM 2013). Ra-223 has a favorable safety profile, and the absence of significant toxicity supports combining Ra-223 with other agents for additional beneficial effect. Hormonal agents abiraterone acetate (AA) and enzalutamide (Enz) improved overall survival (OS) in CRPC pts with bone mets (de Bono et al. NEJM 2011; Scher et al. NEJM 2012), and their safety profiles indicate nonoverlapping toxicity with Ra-223. This study evaluates efficacy and safety of Ra-223 + AA or Enz in CRPC pts with bone mets. **Methods:** In this open-label, multicenter, phase 2a study (NCT02034552), ~66 pts with CRPC and bone mets, no visceral mets, and treatment (tx) naïve to Ra-223, other radiotherapy, AA, or Enz will be randomized to tx group (Grp) 1 (n = 22), 2 (n = 22), or 3 (n = 22). All pts will receive Ra-223 (50 kBq/kg IV) every 4 wk for up to 6 doses (d 1, wk 4, 8, 12, 16, 20). Grp 1 will receive only Ra-223. Grp 2 will receive concurrent AA 1000 mg daily and prednisone 5 mg twice daily. Grp 3 will receive concurrent Enz 160 mg daily. The primary end point is radiologic progression-free survival. Secondary end points include safety, symptomatic skeletal event–free survival, OS, and time to bone progression. Pts will be assessed at screening; wk 8, 16, and 24; then every 12 wk with MRI/CT of the chest, abdomen, and pelvis and whole-body technetium-99 bone scanning, until radiologic progression (bone or soft tissue). A subset of pts will have diffusion-weighted MRI and $^{18}$F-NaF PET/CT. Automated computer-based quantitation of bone scan imaging and associated response will be evaluated. Pts will be followed up to 2 y after last Ra-223 tx; late toxicities will be assessed up to 7 y. An interim analysis will be done 30 days after last pt's Ra-223 tx. Statistical analyses will be descriptive, with event variables summarized using Kaplan-Meier estimates. This trial is currently recruiting pts. Clinical trial information: NCT02034552.

**TPS5104 General Poster Session (Board #228A), Mon, 1:15 PM-5:00 PM**

**Identifying enzalutamide resistance mechanisms in men with castration-resistant prostate cancer.** *Presenting Author: Joshi J. Alumkal, Oregon Health & Science University, OHSU Knight Cancer Institute, Portland, OR*

**Background:** Multiple lines of evidence demonstrate that castration-resistant prostate cancers (CRPCs) remain reliant on androgens that activate the androgen receptor (AR). Treatment with the novel anti-androgen enzalutamide improves progression-free survival (PFS) and overall survival (OS) in CRPC patients (Scher 2012, Beer 2014). However, nearly 50% of patients never respond, and progression is universal. Mechanisms of enzalutamide resistance in CRPC patient tumors are largely unknown, and few treatments exist for enzalutamide-resistant CRPC. Recent work demonstrates that CRPC tumors carry countless genomic aberrations that control many hallmarks of cancer (Grasso 2012, Hanahan 2011). Based on our work (Heiser 2012), we hypothesize that these aberrations work in concert to drive enzalutamide resistance and influence specific cancer hallmarks. **Methods:** We are enrolling men with metastatic CRPC who are eligible to receive enzalutamide (N=65). Through a DOD Synergistic Idea Award and a West Coast Prostate Cancer Dream Team Award, we perform a CT-guided metastatic tumor biopsy prior to treatment and at the time of PSAWG2-defined disease progression (Scher 2008). We perform RNA-seq and array CGH followed by an integrative genomic analysis with the PARADIGM algorithm to identify deregulated gene networks in each tumor sample (Heiser 2012). Then, we use logistic regression and Random Forests classification analysis to determine the association of these deregulated gene networks and our outcome measures. The primary endpoint is: Identify molecular features/pathways associated with enzalutamide response (>50% PSA decline at 12 weeks). Secondary endpoints include: Identify molecular features/pathways associated with PFS, OS, objective response, and acquired enzalutamide resistance (by comparing each subject's pre-treatment and progression biopsies). We anticipate that this trial will identify distinct subsets of CRPC patients with specific enzalutamide resistance mechanisms. Identifying these mechanisms will lead to rationally designed clinical trials of specific enzalutamide drug combinations in distinct molecular subsets of CRPC patients in the near-term.

**TPS5105 General Poster Session (Board #228B), Mon, 1:15 PM-5:00 PM**

**Establishing a neoadjuvant platform for developing targeted agents: Degarelix prior to prostatectomy for patients with intermediate- and high-risk prostate cancer.** *Presenting Author: Karim A. Touijer, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** We hypothesize that the unmet drug development needs in prostate cancer can be addressed using a standardized short exposure neoadjuvant clinical trial framework that ensures tumor tissue is available for profiling, the biomarker assays used are validated, and that trials are designed to address specific questions. This ongoing pilot study explores the response to short exposure androgen deprivation therapy (ADT) with degarelix prior to prostatectomy. The aims of the trial are to assess: (1) two time intervals to determine the maximal change in PC proliferation (Ki-67) and apoptosis rates (caspase-3) following ADT; (2) the association between PTEN status and maximal changes in proliferation and apoptosis rates in patients treated with ADT; and (3) the association between PI3K pathway (pAKT and pS6) and proliferation and apoptosis rates after treatment with ADT in relation to other markers of PC (ERG, AR and NCOA2). **Methods:** Thirty intermediate and high risk patients planning to undergo prostatectomy will be accrued. Two or more cores of the diagnostic biopsy must involve at least 3 mm of tissue with adenocarcinoma. Patients are randomized to receive degarelix (240 mg SC) either 4 or 7 days prior to radical prostatectomy based on the proliferation and apoptotic indexes in malignant human prostate biopsies taken 1-10 days after surgical castration which have demonstrated that maximal changes occur by day 7. (Ohlson, N., et al. Prostate 2005) Patients undergo open, laparoscopic, or robotic radical prostatectomy and are followed 6 weeks post-operatively. The first 20 patients have been successfully treated. Supported by funds from NCI P50-CA92629 SPORE in Prostate Cancer and PCF. Drug supplied by Ferring Pharmaceuticals. Clinical trial information: NCT01542021.

**TPS5106 General Poster Session (Board #229A), Mon, 1:15 PM-5:00 PM**

**Targeting reciprocal feedback inhibition in the clinic: ARN509 and PI3K pathway inhibition in patients with metastatic castration-resistant prostate cancer (mCRPC).** *Presenting Author: Dana E. Rathkopf, Memorial Sloan Kettering Cancer Center, Brooklyn, NY*

**Background:** Next-generation androgen receptor (AR) targeted agents provide dramatic benefit to patients with mCRPC, but the durability of response can be limited by intrinsic and acquired resistance to these drugs. (Rathkopf D et al., Cancer J 2013) Studies in xenograft CRPC and PTEN-deficient prostate cancer models have shown synergistic anti-tumor activity of next-generation anti-androgens such as ARN509 when combined with mTOR or PI3K/mTOR inhibitors such as everolimus. (Carver B et al., Cancer Cell 2011) This hypothesis has been validated in breast cancer in the Phase III BOLERO-2 study in which the addition of everolimus to exemestane was able to overcome hormonal resistance in patients with metastatic breast cancer previously treated with tamoxifen and a non-steroidal aromatase inhibitor. (Baselga J et al., New Engl J Med, 2012) The primary hypothesis of this study is that the combination of ARN509 with everolimus in mCRPC will overcome resistance to prior hormonal therapy with abiraterone acetate (AA). We believe that this strategy will effect a major change in the natural history of the disease, with potential to overcome primary resistance and/or delay the development of secondary resistance to AR targeted therapies through inhibition of reciprocal feedback. **Methods:** The primary endpoint is to determine the safety, pharmacokinetics, and the recommended phase 2 dose (RP2D) of the combination. Approximately 12 patients with progressive mCRPC will be treated with 240 mg/day of ARN509 (RP2D) and 5-10 mg/day of everolimus depending on the safety seen during dose escalation. Dose expansion will include 40 patients with prior AA: 20 with intrinsic resistance ($<$3 months treatment) and 20 patients with acquired resistance ($>$6 months treatment). Mechanisms of sensitivity and resistance will be evaluated through exploratory correlative studies such as FDG and FDHT PET imaging, AR allelic status, circulating tumor cells, and tumor biopsies. Supported by Prostate Cancer Foundation Young Investigator Award, Janssen Pharmaceuticals, Novartis (Drug only), and The Experimental Therapeutics Center of MSKCC.

**TPS5107 General Poster Session (Board #229B), Mon, 1:15 PM-5:00 PM**

**A phase I/II study of the investigational drug alisertib in combination with abiraterone and prednisone (AP) for patients with metastatic castration-resistant prostate cancer (mCRPC) progressing on abiraterone.** *Presenting Author: Jianqing Lin, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

**Background:** Aurora A kinase (AK) over-expression is found in 98% prostate cancer (PCa) lesions. Its level is associated with Gleason score, Ki-67 expression, preoperative PSA and pathological staging. AK phosphorylates and interacts with androgen receptor (AR) and enhances AR DNA binding activity and potentiates androgen action in AR. Targeting AK could suppress tumour growth and enhances chemosensitivity in both AR positive and negative in vitro. We hypothesized that AK contributes to castration resistance in PCa and targeting AK can inhibit AR function and re-sensitize PCa cell to castration. **Methods:** This is a phase I/II, open label, single institution trial to determine the safe dose of the investigational AK inhibitor alisertib when given in combination with AP. Patients with mCRPC and disease progression by PCWG 2 criteria while on AP will be eligible. AP will be continued during the study and alisertib will be added to AP regimen. In phase I, standard 3+3 design with 3 dose cohorts (alisertib 30, 40, 50 mg PO BID days 1-7 every 21 days) will be carried out to determine RP2D of alisertib when given in combination with AP. The safety and toxicity profile will be examined. Data analysis of phase I studies is descriptive. Cohort 2 is currently enrolling. The primary endpoint of the phase II expansion is to determine the proportion of patients without disease progression after alisertib is added to AP, using Minimax Simon two-stage design. The study will analyze the effects of alisertib on PSA kinetics; changes in circulating tumor cells (CTCs) and serum neuroendocrine marker (chromogranin A and NSE) levels. CTCs will also be isolated to determine AK amplification. Clinical trial information: NCT01848067.

**TPS5108 General Poster Session (Board #230A), Mon, 1:15 PM-5:00 PM**

**Abiraterone plus prednisone alone or with dasatinib in chemotherapy-naive metastatic castrate-resistant prostate cancer (mCRPC).** *Presenting Author: Tanya B. Dorff, USC Norris Comprehensive Cancer Center, Los Angeles, CA*

**Background:** Skeletal complications dominate the morbidity of disease progression for men with mCRPC and resistance eventually emerges to all known androgen suppression therapies. Abiraterone acetate (AA) was approved by the FDA for mCRPC based on a survival advantage as well as delay in skeletal-related events, however resistance ultimately develops. Src kinases are involved in androgen receptor phosphorylation, and may represent one resistance pathway. Src kinases also mediate osteoclast-osteoblast interactions, and inhibition has been associated with reduction in bone metastasis formation. Dasatinib is an oral multi-targeted kinase inhibitor with strong Src inhibition. Based on these properties, we hypothesized that the combination of abiraterone plus dasatinib would delay the time to disease progression in mCRPC. The two agents have been combined at full doses in a phase I trial without dose-limiting toxicity. **Methods:** Design: randomized, phase II. Treatment: Arm A=AA 1000 mg PO daily, prednisone 5mg PO bid. Arm B=same plus dasatinib 100 mg PO daily. Eligibility criteria: mCRPC without prior chemotherapy treatment. Endpoint: disease progression. Assessment, including PSA, will be defined by PCWG2 criteria but patients will be encouraged to stay on study therapy until radiographic progression. Statistics: Rather than binomial testing, we will compare the probability of remaining progression-free at 12 and 24 weeks in Arm A vs Arm B using actual follow-up on a continuous scale. Correlatives: circulating tumor cells will be captured and analyzed using the hi-definition technology (Kuhn laboratory, Scripps) and protein changes will be evaluated in the samples (Gross laboratory, USC) at baseline, 4 weeks, and at progression. Biomarkers examined will be chosen to reflect acquired/somatic changes associated with therapeutic response to androgen or Src-kinase directed therapies. Progress: 21 of 96 planned subjects have been accrued. Clinical trial information: NCT01685125.

**TPS5109 General Poster Session (Board #230B), Mon, 1:15 PM-5:00 PM**

**Presurgical axitinib and androgen deprivation therapy (ADT) in prostate cancer (PCa) patients (pts) presenting with lymph node (LN) metastasis.** *Presenting Author: Amado J. Zurita, MD Anderson Cancer Center, Houston, TX*

**Background:** Strategies that integrate systemic therapy and curative-intent surgery/radiation are being considered for men presenting with PCa with regional spread. In our previous phase II study of pre-surgical chemotherapy and ADT followed by radical prostatectomy (RP) in LN metastatic pts (Pagliaro et al., ASCO 2011), we found no apparently better pathologic or survival outcomes than might be seen with ADT alone and surgery. To improve effectiveness of the pre-surgical therapy and characterize tumor changes associated with potent anti-angiogenic treatment response, we designed a trial testing the combination of the VEGF receptor inhibitor axitinib and ADT before consideration of consolidative RP. **Methods:** In this randomized phase II clinical trial, eligible pts either have biopsy-proven PCa and evidence of LN metastasis (TxN1M0 or TxNxM1a) on imaging (LN size $\geq$2 cm) or pathology (nodal biopsy or resection), or suspected LN extension based on the presence of any of the following: stage T3 (and Gleason score [GS] $\geq$7), stage T4 (any GS), or serum PSA concentration $\geq$25 ng/mL (and GS $\geq$8). Pts with bone or visceral involvement are excluded. After 2 months of ADT, pts are randomized to receive 4 more months of ADT in combination with open label axitinib (5 mg PO bid daily) vs. continuation of ADT until surgery in a 2:1 fashion (2 ADT + Axitinib to 1 ADT alone), for a total duration of pre-surgical therapy of 6 months. At that time, clinically responding pts are offered RP and extended pelvic LN dissection. Systemic therapy is discontinued postoperative and PSA measured every 3 months until 1 year. Pts are stratified based on LN metastatic status (present vs. suspected). The primary objective is to define the proportion of pts progression-free 12 months after surgery, defined as PSA $\leq$1.0 ng/mL and no radiation or ADT. Fifty-four pts are being accrued. This sample size ensures that, if the trial continues to completion, we will have an 80% power to detect a 35% difference in the proportions of pts progression-free between the two treatment arms. Early stopping rules for lack of efficacy and toxicity are included. Status: 35 pts have so far consented for participation, and accrual is ongoing. Clinical trial information: NCT01409200.

**TPS5110 General Poster Session (Board #231A), Mon, 1:15 PM-5:00 PM**

**A phase II randomized, open label study of sipuleucel-T versus sipuleucel-T and tasquinimod in patients with metastatic castrate-resistant prostate cancer (CRPC).** *Presenting Author: Roberto Pili, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** A barrier for cancer immunotherapy is the presence of suppressive cells including myeloid-derived suppressor cells (MDSCs) and tumor associated macrophages (TAMs). Tasquinimod is a novel anti-tumor agent that has shown clinical activity in patients with CRPC (Pili R et al JCO 2011). A potential target of tasquinimod is the inflammatory protein S100A9, which is associated with the accumulation and function of tumor suppressive myeloid cells. Our preclinical studies showed that combination of tasquinimod with a tumor vaccine in a prostate cancer model significantly enhanced the anti-tumor effects in mice. Compared to single treatment, tasquinimod inhibited MDSC and M2 polarized macrophages. T cell effector functions, including cell-mediated cytotoxicity and IFN-γ production, were potentiated. Taken together, these data suggest that pharmacological targeting of suppressive myeloid cells by tasquinimod induces therapeutic benefit in combination with cancer immunotherapies. **Methods:** This is a Phase II, open-label, randomized study to assess the immunomodulation of tasquinimod in combination with sipuleucel-T in patients with metastatic, castrate-refractory prostate cancer. 60 subjects will be randomized in a 1:2 ratio to either sipuleucel-T or sipuleucel-T + tasquinimod, respectively. The primary endpoint is change from baseline in immune response, which will be evaluated over time (Weeks 0, 2, 6, 26 and 52) with an IFN-γ ELISPOT assay specific for PA2024. Descriptive summaries of safety assessments and immune response parameters will be generated on a periodic basis. Key secondary endpoints include progression free survival and overall survival. Correlative studies will include assessment of immune response to sipuleucel-T and effects of tasquinimod on the inhibition MDSCs and other immune cells at defined time points post treatment. Blood samples will be analyzed for immune cell sub populations. CD4+, CD4+/Foxp3, CD8+ cells, NK cells will be quantitated by FACS analysis. Additional studies will include assessment of clinical efficacy based on PSA response, response on imaging, and change in circulating tumor cells.

**TPS5111 General Poster Session (Board #231B), Mon, 1:15 PM-5:00 PM**

**A randomized, double-blind phase 2 study of sipuleucel-T followed by indoximod or placebo in the treatment of patients with asymptomatic or minimally symptomatic metastatic castration-resistant prostate cancer.** *Presenting Author: Gautam Gopalji Jha, University of Minnesota, Minneapolis, MN*

**Background:** Vaccine development is complicated by tumor induced immune tolerance, a phenomenon in which the immune system identifies tumor antigens as "self" and allows immune evasion and subsequent sparing of the tumor to occur. This local and possibly systemic immunesuppression is primarily mediated by the inhibitory regulatory T cells (Tregs), which dominantly inhibit other T cells. Vaccine therapy is limited by this anergy and immunosuppressive microenvironment. Although sipuleucel-T has overcome this in part by its ex-vivo sensitization, Treg depletion or interfering with Treg function will likely potentiate its activity. Indoleamine 2,3-dioxygenase (IDO) is a key immune-modulatory enzyme within the IDO pathway that degrades tryptophan and promotes peripheral immune tolerance by T cell inhibition and conversion of naïve T cells to Tregs. We hypothesize that targeting the IDO pathway by indoximod (1-methyl tryptophan; 1-MT) will inhibit Treg and abrogate tumor-mediated immunosuppression permitting a robust and possibly more sustained immune response to sipuleucel-T. Primary Objective: To assess the augmentation of immune response to sipuleucel-T measured at 14 weeks from first leukapheresis, in response to indoximod or placebo therapy. Secondary Objectives: To assess safety, clinical efficacy (PFS, OS) and HR-QOL. **Methods:** Phase 2 investigator initiated multi-center, randomized, double-blind, placebo-controlled trial. Patients will be treated with indoximod or placebo for a period up to 6 months starting a day after completion sipuleucel-T therapy. Research-related correlatives will include serial blood sampling for immune monitoring and an optional prostate or metastatic site biopsy at enrollment and at week 14. Immune monitoring will include measurements of T cell subsets, Tregs, NK cell function, PA2024-specific response, and IDO pathway inhibition. Major eligibility: Patients will be eligible for sipuleucel-T therapy as per phase III IMPACT trial inclusion criteria (Kantoff PW, NEJM 2010). Sample size and accrual: Study is open and actively recruiting, n=50 patients. Clinical trial information: NCT01560923.

**LBA5500 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**A randomized phase 2 trial comparing efficacy of the combination of the PARP inhibitor olaparib and the antiangiogenic cediranib against olaparib alone in recurrent platinum-sensitive ovarian cancer.** *Presenting Author: Joyce Liu, Dana-Farber Cancer Institute, Boston, MA*

**The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Saturday, May 31, 2014, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2014, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.**

**5501 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Genomic alterations in paired pretreatment (pre) and progression (prog) tumor samples from ovarian cancer patients (pts) treated with pazopanib (pazo) or placebo (plb).** *Presenting Author: Florian Heitz, Department of Gynecology and Gynecologic Oncology, Klinken-Essen-Mitte, Essen, Germany*

**Background:** BRCA mutational status, in combination with the accumulation of somatic mutations, has been associated with ovarian cancer prog and response to chemotherapy. AGO-OVAR16/VEG110655 is a randomized study to evaluate pazo vs plb in women with advanced ovarian cancer that have not progressed after first line chemotherapy. Paired pre and prog tumor samples were examined by next generation sequencing (NGS) to evaluate differences in tumor genomics, and to identify potential biomarkers for, and mechanisms of, resistance to pazo. **Methods:** Samples (n=22 pairs) were collected from consenting pts. DNA was isolated, followed by PCR. NGS was run on the Ion Torrent Proton Platform with 2 gene panels (409 comprehensive cancer gene panel [CCP] and BRCA1/2; AltheaDx). Data were aligned to hg19 and processed using ANNOVAR1, SIFT, PolyPhen programs, and COSMIC, 1000g and BIC databases. Mutation changes in paired samples were identified by allele frequency (AF) differences (prog minus pre) greater than 3xIQR (interquartile range) of differences from all markers determined to be damaging by both SIFT and PolyPhen. **Results:** CCP: after QC, N=15 pairs (8 pazo, 7 plb) were available for analysis. Synonymous (syn) alterations (67% of total) were removed; remaining alterations (n=11,587) were primarily non-syn (92%) and stopgain (4%). The AF cutoff was determined to be ±32. Changes in damaging mutations were observed in 47 markers across 40 genes. Pts in plb arm had greater number of changes compared to pazo arm (average 7/pt in plb arm vs 1.3/pt in pazo arm). Potential driver genes were FLT3 and ITGA9. BRCA1/2: N=20 pairs (10 pazo, 10 plb). After removing syn alterations (28% of total), remaining were primarily non-syn SNV (93%) and stopgain SNV (6%). The AF cutoff was ±17.5; 5 and 10 markers (BRCA1/2) had changes, of which 14/15 were in plb arm. Additional results will be presented. **Conclusions:** Changes in the genetic composition of tumors can be detected using NGS. In pre and prog matched tumor pairs, pts in plb arm had 6 fold higher number of genetic alterations per pt compared to pts in pazo arm. Potential driver genes have been identified.

**5502 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Molecular subgroup of high-grade serous ovarian cancer (HGSOC) as a predictor of outcome following bevacizumab.** *Presenting Author: Charlie Gourley, Edinburgh Cancer Research UK Centre, Edinburgh, United Kingdom*

**Background:** HGSOC is a histopathological diagnosis and may represent multiple diseases at a molecular level. We investigated whether distinct molecular subgroups may influence treatment choice. **Methods:** mRNA was extracted from 265 macrodissected formalin fixed paraffin embedded HGSOCs from Scottish patients (pts) treated with primary debulking then platinum based chemotherapy. Transcriptional analysis was performed using the Ovarian DSA microarray. This was repeated using 283 UK samples from the ICON7 study [first line paclitaxel/carboplatin +/- concomitant and maintenance bevacizumab (bev) for 12 months]. **Results:** Unsupervised hierarchical clustering (Scottish tumours) identified three major subgroups, two with angiogenic gene upregulation and one with angiogenic gene repression and immune gene upregulation. This latter 'immune' subgroup had a superior overall survival (OS) compared to the other two subgroups combined [HR = 0.66 (0.46-0.94)]. A 63-gene expression signature to prospectively identify this subgroup was generated and validated as prognostic for OS in an independent dataset [HR = 0.32 (0.19-0.54)]. As the immune subgroup had repressed angiogenesis-related gene expression we hypothesised that these pts would benefit less from bev [power to detect interaction > 2 in predicted direction for progression free survival (PFS) in ICON7 was 88% ($\alpha$=0.1, one-tail)]. In ICON7 the gene signature showed a difference in impact of bev on PFS between the immune and proangiogenic subgroups (1-sided test for interaction, p=0.016). For the immune group (41% of cases), the addition of bev conferred a worse PFS [HR = 1.73 (1.12-2.68)] and OS [HR = 2.00 (1.11-3.61)] compared to chemotherapy alone. In the proangiogenic group there was a non-significant trend to improved PFS for the addition of bev (median 17.4 vs 12.3 months in controls). **Conclusions:** An immune molecular subgroup of HGSOC has superior survival to other HGSOC. The addition of bev appears to significantly reduce PFS and OS in this subgroup. Patients in the proangiogenic subgroups have a trend towards a PFS benefit from bev. These data suggest a mechanism for stratification of bev therapy and should be validated in additional datasets.

**5503^ Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**MITO-11: A randomized multicenter phase II trial testing the addition of pazopanib to weekly paclitaxel in platinum-resistant or -refractory advanced ovarian cancer (AOC).** *Presenting Author: Sandro Pignata, National Cancer Institute of Naples, Naples, Italy*

**Background:** few drugs are available for patients (pts) with platinum resistant or refractory AOC; their efficacy is scanty. Evidence on antiangiogenic drugs efficacy in AOC is increasing. Pazopanib is an oral multi-kinase inhibitor of VEGFR-1, -2, -3, PDGFR-$\alpha$ and -$\beta$ and c-Kit with antiangiogenic properties. **Methods:** AOC pts with disease progressing during or within 6 months from the last platinum-based chemotherapy, aged≤75, ECOG PS 0-1 were eligible for a multicenter comparative randomized phase 2 trial of weekly paclitaxel (wP, 80 mg/m$^2$ dd 1, 8, 15 q 28) vs wPP (wP + pazopanib 800 mg/day); both treatments could continue until progression. Primary endpoint was progression-free survival (PFS). With 61 events, the trial would have 80% power to detect a 0.65 hazard ratio (HR), prolonging median PFS from 3 to 4.6 months with one-tail alfa = 0.20; 72 pts were planned. Partially supported by GSK. Clinicaltrials.gov NCT 01644825. **Results:** 74 pts (37 in each arm) were enrolled by 11 centers. Median age 57; 46% had received only one prior platinum based treatment; 24% were platinum-refractory; no pt had received prior bevacizumab. As of Jan 24, 2014, with median follow-up 12.5 months (95% CI 11.6-16.3), 66 PFS events and 34 deaths were recorded. Median PFS was 3.5 months (95% CI 2.0-5.7) with wP and 6.3 months (95% CI 5.4-11.0) with wPP; log-rank test one-tail p=0.0008; HR 0.45 (95% CI 0.27-0.75). Median overall survival was 14.8 months (95% CI 9.1-NA) with wP and 18.7 months (95% CI 11.5-NA) with wPP; p=0.07; HR 0.60 (95% CI 0.30-1.21). There was no toxic death. Neutropenia (Wilcoxon-Mann-Whitney exact test p=0.0007), hypertension (p<0.0001), diarrhoea (p=0.0002), mucositis (p=0.0007), AST/ALT (0.019), sensory neuropathy (p=0.025), and other neurologic events (p= 0.023) were more frequent and severe with pazopanib. Any grade 3-4 toxicity occurred in 8 (22%) pts with wP and 20 (54%) with wPP (Chi-square p=0.0052). **Conclusions:** The addition of pazopanib to wP in the treatment of pts with platinum-resistant or refractory advanced ovarian cancer might produce a significant prolongation of PFS and OS. A phase 3 trial is strongly supported. Clinical trial information: NCT 01644825.

**5504 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Progression-free survival in ovarian cancer patients in second remission with mucin-1 autologous dendritic cell therapy.** *Presenting Author: Heidi J. Gray, Department of Obstetrics and Gynecology, University of Washington, Seattle, WA*

**Background:** CVac is an autologous cellular therapy made by culturing autologous dendritic cells with a mucin 1 fusion protein and is intended to elicit a killer T cell response that is specific to mucin 1 over-expressing ovarian cancer cells. CAN-003 is an open label phase 2 study evaluating Cvac as compared to standard of care (SOC) with the efficacy endpoints of progression free (PFS) and overall survival (OS), as well as safety and immune monitoring. **Methods:** Eligible patients were stage III or IV epithelial ovarian cancer (EOC) who obtained a complete response to standard first (CR1) or second line chemotherapy (CR2).The first 7 patients were non-randomized and received Cvac (NR Cvac) for manufacturing comparison. Thereafter patients were randomized to either Cvac (10 doses over 52 weeks) or to SOC. **Results:** 63 patients were enrolled into the trial; 7 NR Cvac, and 29 Cvac and 27 SOC randomized. 42 patients were CR1 and 21 CR2. Overall CR1 and CR2 demographics were similar regarding tissue histology, optimal debulking and staging. 9 SAEs were reported in total. None were unexpected and only one (small bowel obstruction) was classified as unlikely-related to Cvac. PFS was not improved in CR1 with Cvac over SOC (HR=1.18, p=0.69) where as in CR2, CVac demonstrated a significant improvement in PFS; median PFS for SOC was 4.94 months; the median PFS for Cvac was not reached but is greater than 12.91 months (p=0.04). Patient blood was assessed for antibodies to mucin 1; as anticipated, none were detected. Peripheral PBMC were assessed for T cell responses to mucin 1. Mucin 1 specific CD4 and CD8 T cell responses were observed, though without a significant correlation with PFS. **Conclusions:** Cvac treatment was safe and showed a significant improvement in PFS in 20 EOC patients in CR2. This strong efficacy signal in the CR2 population warrants further investigation in a larger trial. Clinical trial information: NCT01068509.

**5505 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Lurbinectedin (PM01183), an active compound in platinum-resistant/refractory ovarian cancer (PRROC) patients: Results of a two-stage, controlled phase II study.** *Presenting Author: Andres Poveda, Instituto Valenciano de Oncologia, Valencia, Spain*

**Background:** PM01183 is a new anticancer agent that blocks the trans-activated transcription and induces the formation of double-strand breaks in a wide range of cancer cell lines, including platinum-resistant (Pt-res). **Methods:** PRROC patients (pts) with less than 3 prior chemotherapy (CT) containing lines, adequate organ function and performance status (PS) 0-2 were included. The primary endpoint was overall response rate (ORR) (by RECIST v1.1 and/or Rustin criteria). Secondary endpoints were progression free survival (PFS), overall survival (OS) and safety. Pts were treated with i.v. PM01183 (P1), 7 mg flat dose, q3wk in the first stage. In the second stage, pts were randomized (1:1) to PM01183 (P2) or topotecan (T) (standard or weekly regimen). Cross-over to the P2 arm was allowed after progression to T. **Results:** 81 pts were included (P1/P2/T: 22/30/29). Global median characteristics of pts were balanced: age 61 years; PS 1; Pt-res (P1/P2/T: 16/17/16 pts); prior bevacizumab: 18.5% of pts, median prior advanced chemotherapy lines: 1 in each arm. Efficacy results are summarized in the Table. The most common PM01183 related AEs were neutropenia (Gr 3-4, 85%), febrile neutropenia (23%), thrombocytopenia (Gr 3-4, 29%), nausea/vomiting (Gr 3, 16%) and fatigue (Gr 3, 37%) **Conclusions:** PM01183 is an active drug in Pt-res/Pt-ref ovarian cancer. The study has met the primary endpoint, showing statistically significant superiority over T in terms of ORR, PFS and OS. The safety profile is predictable and manageable; prophylactic G CSF is recommended. A phase III study in Pt-res ovarian cancer is planned.

**5506 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Genotype matched treatment for patients with advanced type I epithelial ovarian cancer (EOC).** *Presenting Author: Anna Spreafico, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Type I EOCs are uncommon, genetically stable tumors that are often resistant to chemotherapy. Genomic alterations that activate the Mitogen-Activated Protein-Kinase (MAPK) signaling pathway frequently occur in Type I EOCs that may sensitize to downstream MEK inhibition. **Methods:** Formalin fixed paraffin embedded tumor tissues from patients (pts) with Type I EOC were prospectively screened for genomic alterations in a CLIA-certified laboratory using Sequenom MassArray genotyping or targeted sequencing using the Illumina MiSeq TruSeq Amplicon Cancer Panel. The outcomes of pts receiving treatment at Princess Margaret Cancer Centre were retrospectively reviewed. **Results:** From Mar/11 to Jan/14, 49 pts with type I EOC underwent molecular testing, including 80% low grade serous (LGS), 10% clear cell (CC), and 10% mucinous (MC) histologies. Thirty-two pts (65%) were found to have ≥1 somatic mutations: 23 *KRAS*, 6 *NRAS*, 2 *PIK3CA*, 1 *BRAF*, 1 *AKT*, 1 *PTEN*, 1 *TP53*, 1 *CTNNB1*. Fifteen pts (47%) with a median of 2 (range 0-4) prior systemic therapies were treated on genotype-matched phase I or II trials with targeted inhibitors. Fourteen pts (93%) with *KRAS/NRAS* mutations (12 LGS, 1 CC, 1 MC) were treated with targeted combinations that include a MEK inhibitor. Best RECIST 1.1 response for the 14 evaluable pts included: 5 PR (4 confirmed), 8 SD and 1 PD. In pts with PR/SD as best response, the median % of target-lesions shrinkage was 27% (range 12.5-62.5%). Gynecological Cancer Intergroup CA125 related-response was observed in 8/8 *KRAS* and/or *NRAS* mutant pts treated with MEK inhibitor combination treatments. Of 9 pts who had received prior systemic therapy for recurrent disease, the median duration of genotype-matched treatment was 19 weeks (range 6.5-58), compared with 9 weeks (range 4-53) for the immediate prior line of therapy. **Conclusions:** Genotyping and targeted sequencing of Type I EOCs frequently identifies actionable mutations. Matched treatment with MEK inhibitors in *KRAS* and/or *NRAS* mutant type I EOC pts is an active therapeutic strategy.

**5507 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Randomized phase III trial of paclitaxel/carboplatin (PC) versus cisplatin/irinotecan (CPT-P) as first-line chemotherapy in patients with clear cell carcinoma (CCC) of the ovary: A Japanese Gynecologic Oncology Group (JGOG)/GCIG study.** *Presenting Author: Aikou Okamoto, Jikei University School of Medicine, Tokyo, Japan*

**Background:** CCC is a histologic subtype of epithelial ovarian cancer showing different clinical and biological characteristics. CCC has become well known for its resistance to current standard chemotherapy (PC). Our previous trial demonstrated the potential benefit of CPT-P regimen on CCC. **Methods:** Patients (pts) with Stage I-IV CCC were randomized to receive paclitaxel 175mg/m$^2$ plus carboplatin AUC6 IV q3wk or irinotecan 60mg/m$^2$ IV (days 1, 8, 15) plus cisplatin 60mg/m$^2$ IV (day 1) q4wk for 6 cycles. International central pathologic review was performed for all cases. The primary endpoint was progression-free survival (PFS). Secondary endpoints were overall survival (OS), response rate per RECIST, and adverse events. Adverse events were graded according to NCI-CTCAE, version 3.0. **Results:** From November 2006 to March 2011, 667 patients were registered, and 619 pts were clinically and pathologically eligible for evaluation (305 pts in PC arm and 314 pts in CPT-P arm). Median age was 53 years. Baseline pt characteristics were not significantly different. Following 44.3 months median follow-up, 2-years PFS was 73.0% (95% CI:67.7-77.5) in the CPT-P arm vs. 77.6% (95% CI:72.4-81.9) in the PC arm, which was not significantly different (HR:1.171, 95% CI:0.867-1.581, p=0.303). Two-years OS was 85.5% in CPT-P arm (95% CI:81.1-89.0) and 87.4% in PC arm (95% CI:83.1-90.7), respectively (HR:1.133, 95% CI:0.796-1.613, p=0.486). Grade 3/4 leukopenia, neutropenia, thrombocytopenia, peripheral sensory neuropathy and joint pain occurred more frequently in the PC arm, whilst grade 3/4 anorexia, diarrhea, nausea, vomiting and febrile neutropenia occurred more frequently in the CPT-P arm. **Conclusions**: In this first CCC-specific international clinical trial, survival benefit was not observed by CPT-P. Since both regimens were well tolerated and the toxicity profiles were different, CPT-P can be an alternative regimen for CCC.

**5508 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Comparison of treatment invasiveness between upfront debulking surgery versus interval debulking surgery following neoadjuvant chemotherapy for stage III/IV ovarian, tubal, and peritoneal cancers in phase III randomized trial: JCOG0602.** *Presenting Author: Takashi Onda, Department of Gynecology, Kitasato University School of Medicine, Sagamihara, Japan*

**Background:** We conducted a phase III trial comparing upfront primary debulking surgery (PDS) and NAC for stage III/IV ovarian, tubal and peritoneal cancers (JCOG0602). Two preceding studies, EORTC55971 and CHORUS, successfully demonstrated non-inferior survival of patients treated with NAC. However, invasiveness of treatment (Tx) has not yet fully been analyzed. To prove efficacy of NAC compared to standard Tx, it is necessary to demonstrate apparently reduced invasiveness of Tx. (UMIN-CTR: UMIN000000523). **Methods:** JCOG0602 is now on-going and the primary analysis of OS is planned in 2016. Patients were randomized to standard arm (PDS followed by 8 cycles of paclitaxel and carboplatin, i.e. TC regimen) and NAC arm (4 cycles of TC, interval debulking surgery [IDS], 4 cycles of TC). In standard arm, IDS was optional for patients who underwent suboptimal or incomplete PDS. Surgical invasiveness and incidence of adverse events related to Tx were compared between two arms. **Results:** From Nov 2006 to Oct 2011, 301 patients (149 standard arm and 152 NAC arm) were randomized. In standard arm 147/149 underwent PDS and 46 of them and 132/152 in NAC arm underwent IDS. Though pelvic and paraaortic lymphadenectomy (PLA/PALA) were more frequently performed in NAC arm ($P<0.01$), frequency of bowel or organ resection was lower in NAC arm ($P<0.01$). In a comparison between PDS in standard arm and IDS in NAC arm, blood/ascites loss (<0.01), albumin transfusion (<0.01), and G3/4 adverse events after surgery in total were fewer in IDS. **Conclusions:** Tx with NAC is less invasive than standard Tx. When non-inferior survival will be confirmed in this trial and new staging system is established, Tx with NAC can become a new standard Tx for advanced ovarian cancer. Clinical trial information: UMIN000000523.

**5509 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM**

**Bevacizumab and improvement of progression-free survival (PFS) for patients with the mesenchymal molecular subtype of ovarian cancer.** *Presenting Author: Boris J. N. Winterhoff, Division of Gynecologic Surgery, Department of Obstetrics and Gynecology, Mayo Clinic Rochester, Rochester, MN*

**Background:** ICON7 demonstrated that the addition of bevacizumab to carboplatin and paclitaxel improves progression free survival (PFS), but not overall survival (OS) in first-line treatment of ovarian cancer. Our aim was to determine if response to bevacizumab was associated with the molecular classification as described by The Cancer Genome Atlas (TCGA) project. **Methods:** Core biopsies from formalin fixed paraffin embedded (FFPE) tissue blocks were examined to ensure >70% tumor nuclei from 425 of 455 ICON7 patients enrolled in Germany. Quality Illumina Whole-Genome DASL HT global gene expression data was generated to stratify 380 (89%) patients into four TCGA subclassifications. Median PFS with 95% confidence intervals (CI) and log rank tests were used to evaluate treatment effect on PFS in the presence of non-proportional hazards. **Results:** Molecular classification was as follows: 86 were differentiated (23%), 124 immunoreactive (33%), 73 mesenchymal (19%), and 97 proliferative (25%). The groups were balanced over treatment arms. 267 (70.3%) were of serous histology. Patients with serous carcinomas of mesenchymal subtype obtained the greatest benefit from bevacizumab with an improvement of median PFS of 9.5 months (25.5 [95%CI 21.1, NA] vs. 16 [95%CI 10.5, NA] months, p=0.053). In contrast, the differentiated, immunoreactive and proliferative subtypes demonstrated median PFS improvements of 5.8 (19.4 [18.6, NA] vs. 13.6 [9.7, 32.7], p=0.35), 3.4 (17.9 [15.9, NA] vs. 14.6 [12.4, NA], p=0.38) and 3.2 months (21.5 [19.8, 29] vs. 18.3 [13.8, NA], p=0.76), respectively. Patients with mesenchymal tumors or high risk clinical characteristics (suboptimal stage III, all stage IV) (46% of cohort) demonstrated a 7.3 month improvement in median PFS with bevacizumab (19.8 [18.3, 23.7] vs. 12.5 [10.1, 16.2] months, p<0.01). **Conclusions:** Assignment to molecular subclassifications based on gene expression signatures was feasible using FFPE tissue. Patients with mesenchymal subtype ovarian cancer may be most likely to obtain sustained benefit from treatment with bevacizumab.

**5510 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM**

**Prospective evaluation of the molecular effects of metformin on the endometrium in women with newly diagnosed endometrial cancer: A window of opportunity study.** *Presenting Author: Pamela T. Soliman, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Metformin reduces cancer incidence and improves overall survival in diabetic patients. Preclinical studies have shown that metformin decreases endometrial cancer (EC) cell growth by activation of AMPK and mTOR inhibition. The purpose of this study was to determine the effects of short-term metformin on serum and tumor biomarkers in women diagnosed with EC. **Methods:** In this IRB approved, prospective trial, women with newly diagnosed EC underwent a pre-treatment blood draw/endometrial biopsy, were administered oral metformin 850 mg daily for a minimum of seven days, and then underwent post-treatment blood draw/definitive surgery. Pre- and post- serum analyses were performed. Immunohistochemical analyses on tumor tissue from the pre- and post-treatment samples were compared to evaluate molecular changes in the PI3K/AKT pathway, apoptosis, proliferation, and AMPK activity. **Results:** Twenty patients completed the study. Median age and BMI were 54 years (range 27-68) and 36.0 kg/m$^2$ (range 21.9-50.0), respectively. Median waist circumference was 113 cm (range 80-156). Median duration of metformin treatment was 10 days (range 7-24). A majority of women had endometrioid adenocarcinomas (86.7%) and were early stage (93%). Two patients were noted to have *KRAS* mutations. After treatment with metformin, there were significant decreases in serum IGF-1 (p=0.046), omentin (p=0.007), insulin (p=0.012), C-peptide (p=0.018), and leptin (p=0.0035). Comparison of pre- and post-treatment tissue samples showed decreased levels of phospho-AKT (90%, p=0.0002), phosphor-S6rp (70%, p=0.057), and phosphor-p44/42MAPK (83.3%, p=0.0038). There was no difference in Ki67, phosphor-ACC, or caspase 3 staining in pre- and post-treatment samples. These changes did not correlate with BMI. **Conclusions:** In this prospective phase 0 study we demonstrate that relevant serum and molecular changes occur in patients with newly diagnosed EC after a short course of low dose metformin. Decreased circulating insulin and down regulation of the PI3K/AKT pathway signaling at the tissue level likely results in mTOR inhibition and a decrease in cell growth. Clinical trial information: NCI-2012-01796.

**5511 Clinical Science Symposium, Sun, 8:00 AM-9:30 AM**

**Efficacy and safety of anti-PD-1 antibody (Nivolumab: BMS-936558, ONO-4538) in patients with platinum-resistant ovarian cancer.** *Presenting Author: Junzo Hamanishi, Kyoto University, Kyoto, Japan*

**Background:** Programmed death-1 (PD-1) is a co-inhibitory receptor expressed on activated T cells which regulates antitumor immunity. Nivolumab is a fully-humanized IgG4 that blocks the engagement of PD-1 by PD-1 ligands. Here we report the first trial for clinical application of nivolumab in ovarian cancer patients. **Methods**: Nivolumab was administered every 2 weeks to patients with advanced or relapsed, platinum–resistant ovarian cancer, at the doses of 1 or 3 mg/kg during two cohort examination (10 patients each). The phase II efficacy trial defined 1$^{st}$ endpoint of response rate, and second endpoints of safety, and disease control rate. Patients receivednivolumab up to 6 cycles (4 doses/cycle) of treatment or until PD or disease progression. Response rate was assessed by RECIST **v**1.1, and adverse events were evaluated by CTCAE v4.0. The data were cut-off on January 1, 2014. **Results**: Fifteen patients were treated with nivolumab (1 mg/kg: n=10, 3mg/kg: n=5), and evaluated. Median duration of therapy was 14 wks. There was one patient who had severe adverse drug reaction with fever, disorientation and gait disturbance. Clinical response rates were shown in Table. At the time of data cut off, one of the three partial responders had responses for 5 months, and the other two were on study with response for 4 and 10 months. **Conclusions**: Nivolumab at 1 mg/kg cohort is well tolerated and has encouraging clinical efficacy for advanced or relapsed, platinum-resistant ovarian cancer patients. 3 mg/kg cohort is now under investigation. Clinical trial information: UMIN000005714.

**5512 Poster Highlights Session (Board #1), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A prospective evaluation of universal tumor testing strategies for Lynch syndrome in endometrial cancer.** *Presenting Author: Kari Lassen Ring, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Screening for Lynch Syndrome (LS) in endometrial cancer (EC) has traditionally been based on early age at diagnosis and family history. Universal tumor testing has been proposed given poor sensitivity of referral criteria and low referral rates. While immunohistochemistry (IHC) is cost effective and widely available, no prospective evaluation of concordance between screening strategies has been completed in EC to define the optimal approach. Our objective was to perform a prospective, population-based evaluation of universal tumor testing in EC to evaluate concordance between microsatellite instability (MSI) and IHC. **Methods:** MSI and IHC for expression of mismatch repair (MMR) proteins (MLH1, MSH2, MSH6, and PMS2) were performed prospectively on all EC undergoing surgical staging from August 2012 to August 2013 (n=184). PCR-based *MLH1* methylation analysis was performed on tumors with IHC loss of MLH1. **Results:** Forty-five tumors (24.9%) were MSI-H and 50 tumors (27.2%) had loss of ≥1 MMR protein on IHC. Overall concordance between MSI analysis and IHC was 93.9% (CI 89.4 – 96.9); however, 11 patients (6.1%) had discordant tumor studies. One of 45 MSI-H tumors (2.2%) had intact IHC for all 4 proteins and demonstrated MLH1 methylation. Five of 50 tumors (10.0%) with loss of ≥1 MMR protein on IHC were MS-stable (MSS). Three of these 5 tumors had heterogeneous loss of MLH1 and PMS2 and 1 tumor had complete loss of expression of MLH1 and PMS2. All 4 tumors had MLH1 methylation and presumed sporadic. One MSS tumor had isolated MSH6 loss and a confirmed germline mutation in MSH6. Five tumors (2.8%) were MSI-L, 4 of which had intact IHC. Of these 4, 2 had no germline mutation detected in MSH6, 1 had a variant of unknown significance (VUS) in MSH6, and one did not undergo germline testing. One MSI-L tumor had loss of MLH1 and PMS2, with MLH1 methylation. **Conclusions:** Overall concordance between MSI and IHC was high in this prospective EC population. However, 6.1% of patients had discordant tumor studies and 2 of 5 patients without MLH1 methylation had a confirmed germline mutation or VUS. Heterogeneous loss of expression on IHC and MSI-L tumors present clinical caveats that are not well defined in EC and warrant further evaluation.

**5513 Poster Highlights Session (Board #2), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II trial of GDC-0980 (dual PI3K/mTOR inhibitor) in patients with advanced endometrial carcinoma: Final study results.** *Presenting Author: Vicky Makker, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background**: Treatment options for patients with recurrent or persistent endometrial cancer (EC) are limited. The PI3K/AKT/mTOR pathway has been implicated in the pathogenesis of EC. This single arm, open-label trial was designed to evaluate the activity of GDC-0980, a dual PI3K/mTOR inhibitor, in patients with advanced EC. NCT01455493. **Methods**: Patients with recurrent or persistent EC treated with 1 or 2 prior lines of chemotherapy but no prior PI3K/mTOR inhibitor received oral GDC-0980 40 mg daily on a 28-day cycle until progression or intolerable toxicity. Type I/II diabetics requiring insulin were excluded. The primary endpoints were progression-free survival (PFS) at 6 months and objective response rate (ORR). Archival tissue samples were collected for PI3K pathway biomarker analysis. **Results**: A total of 56 women were enrolled including 13 (23%) with well-controlled diabetes at study entry. Discontinuation reasons were disease progression, 24 (43%); adverse events, 13 (23%); withdrawal by subject, 12 (21%). Frequency of Grade 3/4 related adverse events in all patients were hyperglycemia (46%), rash (30%), colitis (5%), and pneumonitis (4%). At 6 months, 20% of patients were progression free (K-M estimate 95% CI: 7%-33%). ORR was 9% (unconfirmed). Median PFS was 3.5 months (95% CI: 2.7-3.7 months). Median time on study was 69 (12-226) days for non-diabetic and 27(4-84) days for diabetic patients. Discontinuation prior to first tumor assessment occurred in 19 patients, with 8/13 diabetics discontinued prior to Cycle 2, due to hyperglycemia. Dose reductions were required for 4 (31%) diabetics and 18 (42%) non-diabetics. Evaluable archival tumor samples were obtained from 44 (85%) patients, and 52% of patients had at least one alteration in PIK3CA, PTEN or AKT1. All 3 patients with a confirmed response had at least one alteration in a PI3K pathway gene. **Conclusions**: Evaluation of the anti-tumor activity of 40mg GDC-0980 daily was limited by tolerability, especially in diabetic patients. The trial provides data about the PI3K pathway mutation frequency in patients with recurrent EC and suggests that patients with a PI3K pathway mutation may have derived enhanced benefit from GDC-0980. Clinical trial information: NCT01455493.

**5514 Poster Highlights Session (Board #3), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Advanced or recurrent endometrial cancer (EC) and co-occurring mutations in multiple oncogenic pathways.** *Presenting Author: Alexandra Leary, Department of Medicine and INSERM U981, Gustave Roussy, Villejuif, France*

**Background:** The prognosis of EC is excellent and mainly driven by early stage type I EC. However, for type II or advanced EC, relapses are frequent. Genomic studies so far included mainly early stage good prognosis primary tumors. Here, we aimed to characterize genetic alterations in high risk advanced or recurrent EC, determine the rate of co-occurring mutations and evaluate concordance between primary and metastatic sites. **Methods:** High risk EC patients were identified from the IGR tumor bank and defined as stage III or IV, or any stage with subsequent relapse. Samples with >30% cellularity were subjected to Sanger sequencing on 79 exons from 13 genes (*KRAS, NRAS, HRAS, BRAF, AKT1, PIK3CA, PIK3R1, PIK3R2, PTEN, STK11, ESR1, TP53, FGFR2*). Mutation calls were confirmed by an independent analysis. **Results:** 75 samples from 57 patients (pts) representative of high risk EC were identified: 49% (28/57) were type II EC, 70% were stage III/IV and the remaining stage I/II pts had all relapsed. By comparison, the TCGA set included 75% stage I/II pts of which only 11% had relapsed. 69 samples from 54 pts qualified for DNA analysis including 13 pts with both primary and metastatic tumors. 80% (43/54) of pts harbored at least one mutation (M+). The most frequent mutation was *TP53* in 35% (19/54) of pts. Alterations of core components of the PI3K pathway (*AKT1, PIK3CA, PIK3R1, PIK3R2, PTEN, STK11*) were identified in 65% of pts (81% and 48% for type I vs. type II EC). *RAS* M+ were identified in 24%. 65% of pts had >1 M+ including concomitant *TP53* M+ and PI3K related M+ (18%), concomitant *TP53* M+ and *RAS* M+ (7%); concomitant PI3K-related M+ and *RAS* M+ (15%), concomitant *FGFR2* M+ and PI3K-related M+ (9%) or concomitant *FGFR2* M+ and *RAS* M+ (4%). Among 13 cases with available primary and metastatic tumor, discordant M+ were found in 5/13 (38%). **Conclusions:** Co-occurring actionable oncogenic mutations are frequent in high risk advanced or recurrent EC. This may explain disappointing results with single agent targeted therapies in EC, but provides the rationale for trials investigating combined inhibition of PI3K and MEK, PI3K and FGFR, or MEK and FGFR in molecularly selected EC. Supported by a research grant from Sanofi Oncology.

**5515 Poster Highlights Session (Board #4), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II, single stage, cohort expansion study of MK-2206 in recurrent endometrial serous cancer.** *Presenting Author: Panagiotis Konstantinopoulos, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Although PTEN mutations or loss of PTEN expression are uncommon in endometrial serous carcinomas, approximately half of these tumors harbor PIK3CA mutations and/or amplification of PIK3CA. A Phase II, 2-stage, 2-arm PIK3CA mutation stratified trial of MK-2206 (an allosteric inhibitor of AKT) in recurrent or advanced endometrial cancer showed that all patients with 6 months progression free survival (PFS) had serous histology, leading to an expansion cohort in patients with endometrial serous tumors. **Methods:** Eligible patients had recurrent or advanced high grade endometrial carcinoma with a serous component. Up to 2 prior chemo lines were permitted; prior treatment with PI3K/MTOR inhibitors was not allowed. All patients were treated with MK-2206 135mg QW; dose was amended from 200mg QW to 135mg QW during the initial patient cohort because of skin toxicity. Primary objective was to evaluate the efficacy of MK-2206 using a composite endpoint of complete and partial response by RECIST 1.1 and PFS of ≥6 months. A target sample size of 14 patients was planned to allow greater than 80% power to reject a null rate of 10% if the true rate of clinical benefit is 36%, when using a binomial exact test with a one-sided alpha $< 0.05$. If 4 or more responses were seen among the 14 subjects, then the null hypothesis would be rejected to conclude sufficient efficacy for further investigation of MK-2206. **Results:** 14 patients were enrolled. There were no grade ≥4 toxicities. Potentially drug related grade 3 toxicities (rash, diarrhea, and anemia) were seen in 3 patients (21%). 10 (71%) patients developed disease progression without meeting any of the efficacy endpoints. The remaining 4 patients are currently on study; two (14%) have met the 6 month PFS endpoint with ongoing decrease in the sum of their target lesions of 27.5% and 21.8% from baseline respectively; the other 2 are on cycles 5 and 2 respectively. Updated results will be presented at the time of the meeting. **Conclusions:** MK-2206 activity has been detected in a fraction of uterine serous cancers. Translational studies including targeted exome sequencing and copy number analysis of PI3KCA are ongoing. We expect to know whether the goal of 4 responses is reached in the next 4 months. Clinical trial information: NCT01312753.

**5516 Poster Highlights Session (Board #5), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Molecular profiling of clear cell ovarian carcinoma.** *Presenting Author: Michael Friedlander, Prince of Wales Hospital, Sydney, Australia*

**Background:** Clear cell ovarian carcinomas (CCOCs) are a distinct histopathological subtype and account for 5-10% of epithelial ovarian cancers (EOCs). They have a poor prognosis in advanced stages and at recurrence. They are commonly resistant to platinum-based chemotherapy and treatment options are limited in patients with progressive disease. Molecular profiling may identify patient subsets who could benefit from targeted therapies when standard treatment has failed and also provide an insight into the genomic heterogeneity of CCOC's that share a similar phenotype. **Methods:** Over 435 CCOC's referred to Caris Life Sciences (from 2009 - 2014) were evaluated; diagnoses were based on reported pathology. Specific testing was performed per physician request and included a combination of sequencing (Sanger, NGS or pyrosequencing), protein expression (IHC), gene amplification (CISH or FISH), and/or RNA fragment analysis. **Results:** Patients were further grouped into pure CCOCs (n=363) and mixed CCOCs (n=72). The most common findings in CCOC's were overexpression of TOP2A (61%), TS (52%), TLE3 (48%), loss of TUBB3 (49%) and MGMT (56%). cMET was overexpressed in 19% of CCOCs tested and in 6% of mixed CCOCs. CCOCs had lower expression of AR, ER, and PR (7%, 9%, and 15%) than mixed CCOCs (21%, 39%, and 31%) and EOCs (24%, 45%, and 30%). In 69 CCOC's analyzed by NGS, PIK3CA was the most common mutation (52% - vs. 8% in all EOCs and 14% in mixed CCOCs) followed by TP53 (16%) and KRAS (11%). Mutations in FBXW7 (10%), APC (7%) and ATM (6%) were observed at a higher rate than in all EOCs. No BRAF mutations were seen. In the 33 CCOCs with PIK3CA mutations, 4 (12%) had co-existing mutations in KRAS and 2 (6%) had TP53 mutations while 70% (23/33) overexpressed cMET and 12% had a loss of PTEN. **Conclusions:** Molecular profiling of proteins, gene expression, and mutations underscores the heterogeneity of CCOC and the potential role in better selecting patients for clinical trials. Drugs, which target the mTOR pathway or cMET may have therapeutic potential in selected subsets. Mutations in FBXW7, APC and ATM may also help direct patients to trials of targeted therapies.

**5517 Poster Highlights Session (Board #6), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Combination chemotherapy with temsirolimus and trabectedin for recurrent clear cell carcinoma of the ovary: A phase II single arm clinical trial.** *Presenting Author: Masashi Takano, Department of Obstetrics and Gynecology, National Defense Medical College, Tokorozawa, Japan*

**Background:** Recurrent clear cell carcinoma (RCCC) of the ovary showed exceedingly chemo-resistant phenotype, especially in the case with recurrent or refractory to previous therapy. A phase II trial to evaluate the effect of combination therapy with temsirolimus and trabectedin for patients with RCCC was performed. **Methods:** Simon's two-stage design was used. In the first stage, 9 patients were accrued. If there were no responder in these patients, the study would be stopped. Otherwise, eight additional patients will be accrued for a total of 17. If three or more responder were observed in 17patients, this design yields a type I error rate of 0.05 and power of 0.81 when the true response rate were 25%. Patients with RCCC were treated with weekly regimen using two drugs: 15mg/m$^2$ of temsirolimus and 0.15mg/m$^2$ of trabectedin (3 weeks, one week rest) with written informed consents. Treatment was continued until development of progressive disease (PD) or unmanageable adverse effects. **Results:** Among 9 patients in the first stage, two responses were observed, and a total of 17 patients were analyzed in this study. There were no cases that discontinued the therapy due to toxicities. Median age was 60 years (range: 30-69), and median number of previous chemotherapy was 3 (range: 1-6). All cases were assessable by RECIST and CTCAE. One patient (6%) had a complete response (CR), and two cases (12%) achieved a partial response (PR), and 5 patients (29%) had a stable disease (SD) beyond three months, resulting in clinical benefit rate (CBR; CR+PR+SD>3month) of 47%. Median response duration in CBR case was 3.5 months (range: 3-24+). There were no cases that developed toxicities more than grade2. **Conclusions:** Combination therapy with temsirolimus and trabectedin was a candidate for salvage therapy for patients with RCCC. These results warrant further study in such clinical settings.

**5519 Poster Highlights Session (Board #8), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase II randomized open-label study of MM-121, a fully human monoclonal antibody targeting ErbB3, in combination with weekly paclitaxel versus weekly paclitaxel in patients with platinum-resistant/refractory ovarian cancers.** *Presenting Author: Joyce Liu, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Heregulin induced activation of ErbB3 has been implicated as a mechanism of resistance to many targeted and cytotoxic therapies such as paclitaxel in preclinical models. MM-121 is a monoclonal antibody designed to interfere with this mechanism of resistance. **Methods:** This was a global, open-label, randomized Phase II study of MM-121 in patients with platinum resistant ovarian cancer. Patients were randomized (Ratio 2:1) to receive MM-121 plus paclitaxel (M+P) or paclitaxel alone (P). The primary objective was to compare progression-free survival (PFS) between the groups. Pretreatment fresh biopsies obtained from all patients were analyzed to assess a pre-specified set of mechanistically-linked biomarkers (BM): heregulin (HRG), betacellulin, EGFR, ErbB2, and ErbB3. **Results:** 223 patients (140 (M+P), 83 (P)) were included in the efficacy analyses. Baseline demographics and disease characteristics were balanced. Most patients (80.3%) had received 2 or more prior platinum-based regimens. Median PFS was analyzed after 171 events (115 (M+P), 56 (P)) and was 3.75 months (M+P) and 3.68 months (P) with a stratified hazard ratio (HR) of 1.027 [95% CI 0.741 - 1.425]. Two biomarkers based on pre-clinical predictions were used to identify a subset of BM positive patients (34%: 57/169 patients with BM available). In this BM positive group the HR for PFS was 0.37 [0.2 - 0.8] and the HR in the BM negative group was 1.54 [1.0 - 2.4]. The overall safety profile was consistent with expected adverse events (AEs), with the exception of an increase in the pulmonary embolism rate (5.0% (M+P) vs. 1.2% (P)). However, the overall rate of venous thromboembolic events was comparable (5.7% (M+P) vs. 7.5% (P)). Most AEs were reported as mild to moderate in severity and included diarrhea, vomiting, stomatitis, and mucosal inflammation. **Conclusions:** A signal of benefit was observed in a biomarker positive subpopulation, althoughthe study regimen was not effective at prolonging PFS in the overall study population. Any further development of MM-121 in ovarian cancer should focus on biomarker-selected patients. Clinical trial information: NCT01447706.

**5520 Poster Highlights Session (Board #9), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Clinical and genetic aspects of ovarian stromal tumors: A report from the International Ovarian and Testicular Stromal Tumor Registry.** *Presenting Author: Kris Ann Pinekenstein Schultz, Children's Hospitals and Clinics of Minnesota, Minneapolis, MN*

**Background:** Ovarian sex cord-stromal tumors are rare tumors that tend to occur in children, adolescents and young adults. The International Ovarian and Testicular Stromal Tumor (OTST) Registry was established in December 2011 to investigate the clinical and biologic aspects of these rare tumors. **Methods:** For each Registry participant, clinical data and biologic specimens including germline DNA and tumor tissue were collected. Pathology was centrally reviewed and germline *DICER1* testing was performed. **Results:** Overall, 52 patients with ovarian tumors have enrolled. Forty-one of these have SLCT (n=22), juvenile granulosa cell tumor (n=14), Sertoli cell tumor (n=4) or gynandroblastoma (n=1) and are presented here. Median overall survival is 25 months (range 3 to 223). Four patients have recurred and 2 have died from disease. Median age at diagnosis was 15 (range ≤1 to 51 years, 73% younger than 21 years). Eleven of 32 patients tested (34%) have a deleterious germline *DICER1* mutation. *DICER1* mutations were seen in 56% of patients with SLCT. Additional tumors, including carcinoid, pleuropulmonary blastoma, cystic nephroma and rhabdomyosarcoma, were seen in 18% of patients prior to or following the diagnosis of SLCT. **Conclusions:** Establishment of the International OTST Registry allowed rapid accrual of patients with these rare tumors. Although most patients are alive, recurrences and other tumors occurred, especially in SLCT. Germline *DICER1* mutations were seen in more than half of patients with SLCT as well as in one patient with juvenile granulosa cell tumor and one with gynandroblastoma. Further analysis of *DICER1* in tumor tissue is underway.

| Diagnosis | n | Age at diagnosis (yrs), median (range) | *DICER1*+ n (%) | Thyroid nodules n (%) | Other (non-thyroid) tumors n (%) | Recurrence n (%) | Overall survival n (%) | Overall survival (months) median (range) |
|---|---|---|---|---|---|---|---|---|
| SLCT | 22 | 17 (3-40) | 9/16 (56%) | 4 (18%) | 4 (18%) | 3 (14%) | 21 (95%) | 13 (3-202) |
| Juvenile granulosa cell tumor | 14 | 9 (<1-18) | 1/12 (8%) | 1 (7%) | 0 | 1 (7%) | 13 (93%) | 28 (15-223) |
| Sertoli cell tumor | 4 | 46 (34-51) | 0/3 | 2 (50%) | 1 (25%) | 0 | 4 (100%) | 27 (9-37) |

| Total | 41 | 15 (<1-51) | 11/32 (34%) | 8 (20%) | 5 (12%) | 4 (10%) | 39 (95%) | 25 (3-223) |

**5521 Poster Highlights Session (Board #10), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase 1/1b study of the FAK inhibitor defactinib (VS-6063) in combination with weekly paclitaxel for advanced ovarian cancer.** *Presenting Author: Manish R. Patel, Florida Cancer Specialists and Research Institute, Sarasota, FL*

**Background**: Defactinib (VS-6063) is an oral inhibitor of focal adhesion kinase (FAK). Blockade of FAK has been shown to reduce tumor growth and metastasis through inhibition of tumor cell survival, proliferation, invasion and tumor angiogenesis. FAK inhibitors also reduce the proportion of cancer stem cells (CSCs) while paclitaxel (PTX) treatment enriches for CSCs. This multicenter study investigated the safety/tolerability and activity of defactinib in combination with weekly PTX. **Methods:** Pts with advanced or refractory ovarian cancer were enrolled. In the Phase 1, defactinib was administered at either 200mg or 400mg BID with PTX 80 mg/m$^2$ on days 1, 8, and 15, every 28 days. In the Phase 1b, an additional 12 pts were enrolled at a dose of 400 mg BID defactinib with 80 mg/m$^2$ PTX. In pts with biopsiable disease, paired tumor biopsies were collected following a 10-day run-in with defactinib alone. **Results:** Eighteen pts were enrolled (6 in phase I and 12 in phase Ib): median age was 67.5 years (50-77); ECOG PS was 0 or 1. Pts received a median of 3 (1-9) prior regimens of therapy. All patients had prior taxane exposure and 15/18 (83%) were platinum resistant. The combination therapy was well tolerated with no DLT observed. The recommended dose was determined to be defactinib 400 mg BID with PTX 80 mg/m$^2$. Reported treatment related grade 3 toxicities included: neutropenia (n=5), hyperbilirubinemia (3), thrombocytopenia (1), anemia (1), leukopenia (1), nausea (1), vomiting (1), increased alanine aminotransferase (1). No grade 4/5 drug related toxicities were observed. Defactinib did not alter PTX exposure. A decrease of p-FAK was observed in all 3 patients who underwent paired biopsies. One pt had a CR by RECIST, 1 pt has an ongoing PR of >6 months and 1 pt has ongoing SD of >8 months. Nine of the 18 pts remain on study. **Conclusions:** Defactinib was generally well tolerated in combination with weekly PTX, and further analysis of PD and biomarkers is ongoing. Radiographic tumor changes, normalization of serum markers, and tumor reductions in pFAK support further development of this combination. Clinical trial information: NCT01778803.

**5522 Poster Highlights Session (Board #11), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Preclinical and early clinical activity of the oral selective inhibitor of nuclear export (SINE) exportin 1 (XPO1) antagonist KPT-330 (Selinexor) in patients (pts) with platinum-resistant/refractory ovarian cancer (OvCa).** *Presenting Author: John Martignetti, Mount Sinai School of Medicine, New York, NY*

**Background:** Increased XPO1 expression has been linked to progression of OvCa and is an independent poor prognostic for survival. Most tumor suppressor proteins (TSP) are transported out of the nucleus exclusively by XPO1 and thereby rendered non-functional. KPT-330 is a slowly reversible inhibitor of XPO1, and forces the nuclear retention and activation of over 10 TSP resulting in OvCa cell death while sparing normal cells. **Methods:** SINE compounds were tested for their ability to localize OvCa-relevant TSP to the nucleus and induce apoptosis in platinum sensitive and resistant cell lines *in vitro*. Combination with cisplatin was assessed *in vitro* and in patient-derived xenograft models (30 mg/m$^2$ po, 3 times/week). As part of an on-going Phase 1 (KCP-330-002) in pts with solid tumors, oral KPT-330 (8-10 doses/4-weeks cycle) was administered to pts with heavily pre-treated OvCa that were progressing on study entry. Pharmacokinetic (PK) analyses were performed. Response was evaluated every 2 cycles (RECIST 1.1). **Results:** SINE potently induced OvCa cell death in platinum sensitive and resistant cell lines ($IC_{50}$s $< 0.12$ $\mu$M). Nuclear accumulation and functional activation of p53 and other TSP was demonstrated. Synergy between SINE and cisplatin was shown *in vitro* and *in vivo* in OvCa models with diverse genetic backgrounds, and increased overall survival. Seven OvCa pts resistant/refractory to platinums and other agents (median age 55 yrs; ECOG PS 0/1: 3/4; median number of prior therapies 5) were treated with 30-35 mg/m$^2$ oral KPT-330 (300 mg/cycle or 280 mg/cycle). No grade 4 AEs were reported. The most common AEs were fatigue, nausea, diarrhea, and vomiting; manageable with supportive care. PK analysis showed $C_{max}$ of 0.5-1 mM and $AUC_{0\text{-}inf}$ 2800-4000 ng*h/mL, which exceed levels *in vitro* and in animal models. RECIST response was evaluable in 5 pts: 1 PR (5 months), 2 SD (4 and 7+ months) and 2 PD. **Conclusions:** KPT-330 treatment is generally well tolerated and shows preliminary antitumor activity in pts with platinum resistant or refractory OvCa. Additional single agent and combination studies are planned. Clinical trial information: NCT01607905.

**5523 Poster Highlights Session (Board #12), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized phase II trial of NGR-hTNF with an anthracycline in platinum-refractory or -resistant ovarian cancer (OC).** *Presenting Author: Domenica Lorusso, Fondazione IRCCS National Cancer Institute, Milan, Italy*

**Background:** Low-dose NGR-hTNF induces in preclinical models an early tumor blood vessel stabilization that enhances T-lymphocyte infiltration and survival, an effect that is mediated by CD8$^+$ effector cells **Methods:** OC patients with disease progression while receiving or within 6 months after completion of $\leq$ 2 platinum/taxane lines were stratified by platinum resistance (refractory or resistant), PS (0 or 1/2) and anthracycline (doxorubicin, D or pegylated liposomal doxorubicin, PLD) and randomly assigned to receive D (60 mg/m$^2$ q3w) or PLD (50 mg/m$^2$ q4w) with (arm A) or without (arm B) NGR-hTNF (0.8 $\mu$g/m$^2$ q3w). Progression free survival (PFS) was primary endpoint ($\beta$=20%; $\alpha$=20%, hazard ratio, HR=0.62; n=100). Main secondary aims were overall survival (OS), response rate (RR, complete plus partial response) and adverse events (AE) **Results:** Baseline characteristics in arm A (n=58) vs B (n=51): median age, 60 vs 60 years; resistant, 71% vs 75%; PS of 0, 79% vs 82%; serous, 67% vs 71%; two prior lines, 48% vs 35%; D, 81% vs 84%; median baseline peripheral blood lymphocyte count (PBLC), 1.4/mL vs 1.6/mL. In all, 262 cycles were given in arm A (mean 4.5; range 1-20) and 227 in B (4.4; 1-8). Grade 3/4 AEs (arm A vs B): neutropenia, 29% vs 22%; anemia, 4% vs 6%. With median follow-up time of 16.1 months, there was no significant difference between the two arms in PFS (stratified HR=1.08; 95% CI, 0.70-1.65), RR (odds ratio=1.34; 0.21-8.33) and OS (HR=0.70; 0.42-1.17). Median and 18-month OS rates were 12.1 months (6.9-17.2) and 44% ($\pm$7) vs 9.4 months (8.4-10.4) and 22% ($\pm$7) for arm A vs B, respectively. In resistant disease (n=79), median OS was 14.2 months for arm A and 9.5 months for arm B (HR=0.66; 0.36-1.21). In patients with baseline PBLC above the median value (n=56), median OS was not reached yet for arm A compared with 9.5 months for arm B (HR=0.45; 0.22-0.91; p=0.02). Follow-up assessment for a next patient cohort (n=24) receiving a weekly schedule of NGR-hTNF is ongoing **Conclusions:** NGR-hTNF plus D/PLD was safely given, without increase in PFS over D/PLD in unselected population. Consistently with previous findings, significantly improved OS rates for the combination were noted in patients with high baseline lymphocyte counts Clinical trial information: NCT01358071.

**5524^ Poster Highlights Session (Board #14), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase I study of the vascular-disrupting agent BNC105P in combination with gemcitabine-carboplatin in platinum-sensitive ovarian cancer patients in first or second relapse.** *Presenting Author: Danny Rischin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia*

**Background:** BNC105P is a tubulin polymerization inhibitor and a vascular disrupting agent (VDA) selectively active against tumor endothelium. Pre-clinical data has demonstrated greater than additive activity of BNC105P when combined with platinum or with gemcitabine. The primary objective of this study was to evaluate the safety and tolerability of BNC105P in combination with gemcitabine and carboplatin in patients with recurrent ovarian cancer, and to find a dose suitable for evaluation in a randomized trial. **Methods:** Patients with ovarian cancer who progressed > 4 months after first or second-line platinum based chemotherapy received carboplatin AUC4 at day 1 in combination with escalating doses of gemcitabine at day 1 and 8 and escalating doses of BNC105P at day 2 and 9 every 21 days for a maximum for 6 cycles. Maintenance treatment with 16 mg/m$^2$BNC105P treatment continued for a maximum of 6 additional cycles. Blood samples were collected at baseline and 4 hours post BNC105P to study potential pharmacodynamic biomarkers associated with BNC105P biological action in previous trials. **Results:** 15 patients were enrolled in the study. Adverse events were most commonly of haematological origin. Dose limiting toxicities occurred in 1 patient on dose level 1 and 2 patients on dose level 2a and consisted of thrombocytopenia and neutropenia. The recommended dose was gemcitabine 1,000 mg/m$^2$, carboplatin AUC 4 and BNC105P 12 mg/m$^2$. 10 patients achieved a response according to GCIG CA125 and/or RECIST 1.1 criteria. Increases in blood levels of ferritin, interleukin-8, interleukin-16 and macrophage inflammatory protein-1beta post 12 mg/m$^2$BNC105P were consistent with a pharmacodynamic response.. **Conclusions:** The combination of BNC105P with gemcitabine and carboplatin is safe and tolerable in patients with potentially platinum sensitive recurrent ovarian cancer. The data supports continued development of BNC105P in this setting. Clinical trial information: ACTRN12612000522819.

**Adoption and impact of concurrent chemotherapy with radiation in the treatment of patients with vaginal cancer: A National Cancer Data Base (NCDB) study.** *Presenting Author: Malolan Sri Rajagopalan, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** Vaginal cancer is uncommon entity for which concurrent chemoradiation (CCRT) is increasingly used based on extrapolation from cervical cancer. However, studies supporting CCRT use are limited to single-institution reports. We sought to explore the adoption rate of CCRT and determine its impact on survival in vaginal cancer patients. **Methods:** We identified patients in the NCDB diagnosed with vaginal cancer from 1998-2011 who received definitive radiation therapy with or without chemotherapy. Univariate and multivariable exploratory analyses of factors associated with CCRT use were performed. Log-rank test and Cox proportional hazards modeling identified the overall and independent contribution of CCRT use on overall survival (OS) in the context of known/putative prognostic factors. **Results:** A total of 13,689 patients were identified of whom 8,086 (59.1%) received radiation therapy. Of these, 3,932 (48.6%) received CCRT, the use of which increased from 20.8% in 1998 to 59.1% in 2011. Of the 23 patient, disease, treating facility, and treatment factors explored, 13 were found to have significant associations in chi-square testing and were entered into a binary logistic regression model. Younger age, larger tumor size, later year of diagnosis, treatment at a higher volume facility, squamous histology, and higher stage (in order of increasing association) are independently associated with increased use of CCRT. Median OS of patients who received CCRT is significantly longer than those who did not (56.2 vs. 41.2 months, $p<0.0005$). On multivariable analysis, younger age, treatment at a facility with higher-volume, squamous histology, lower Charlson-Deyo comorbidity score, treatment with CCRT, treatment with brachytherapy and lower stage (in order of increasing association) are independently prognostic of improved survival. **Conclusions:** Use of concurrent chemotherapy with radiation therapy in the treatment of vaginal cancer has become increasingly adopted over the past decade and is associated with a significant improvement in OS in this large national cohort. CCRT should be integrated into treatment guidelines for vaginal cancer.

**5526 Poster Highlights Session (Board #16), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Cisplatin with dose-dense paclitaxel before and after radical hysterectomy for locally advanced cervical cancer: Final results of a multicenter phase II study (Sankai Gynecology Study Group 013).** *Presenting Author: Satoshi Yamaguchi, Gynecologic Oncology Division, Hyogo Cancer Center, Akashi, Hyogo, Japan*

**Background:** The primary objective of the study was to investigate survival after cisplatin plus dose-dense paclitaxel (ddTP) before and after radical hysterectomy (RH) without radiotherapy of patients for locally advanced cervical cancer. **Methods:** Patients with stage IB2, IIA2, or IIB cervical cancer received 3 cycles of cisplatin (75 mg/m$^2$, day 1) with paclitaxel (80 mg/m$^2$, days 1, 8, and 15) every 21 days, RH, and another 2 cycles of the same regimen. Primary endpoint was 2-year recurrence-free survival (RFS). Secondary endpoints were 2-year overall survival (OS), safety, response, and pathologic complete response (pCR), defined as no evidence of malignancy in all surgical specimens. **Results:** Fifty one patients were enrolled from 2010 to 2012 (41 with squamous cell carcinoma [SCC], 9 with adeno/adenosquamous carcinoma, and 1 with small cell carcinoma). Median age was 52 years (range 30-70). The FIGO stage was IB2 in 14 patients, IIA2 in 3, and IIB in 34. All but 1 non-responsive patient underwent RH. At the median follow-up time of 27 months, 2-year RFS and OS were 88.2% and 94.1%, respectively. Six recurrences occurred within 1 year from last treatment. Five patients died. Except 1 patient with grade 4 hypersensitivity during the first paclitaxel infusion, 18 patients achieved complete response and 29 achieved partial response, with response rate of 94% (47/50). Fourteen patients (28%; 13 with SCC, 1 with adenocarinoma) achieved pCR. Eight good responders refused to receive adjuvant ddTP, with no recurrence. Grade 3/4 adverse events were neutropenia (34%), nausea (12%), appetite loss (10%), fatigue (6%), and anemia (6%). Febrile neutropenia was uncommon (2%). No serious long-term adverse events occurred. **Conclusions:** Administering with ddTP before and after RH for locally advanced cervical cancer achieves good survival and is feasible, evidenced by the acceptable toxicity. Phase III studies should compare this with concurrent chemoradiation. Clinical trial information: UMIN000006440.

**5527 Poster Highlights Session (Board #17), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase Ib/II with expansion of patients at the MTD study of olaparib plus weekly (metronomic) carboplatin and paclitaxel in relapsed ovarian cancer patients.** *Presenting Author: Saul E. Rivkin, Marsha Rivkin Center for Ovarian Cancer Research, Seattle, WA*

**Background:** To establish the maximum-tolerated dose (MTD) and evaluate dose-limiting toxicities (DLTs) and response to therapy of combination therapy with carboplatin/paclitaxel and olaparib, an oral tablet inhibitor of poly ADP ribose polymerase (PARP) of BRCA 1 and 2, in advanced (Stage III or IV) relapsed ovarian cancer. **Methods:** Eligibility required measurable disease, adequate organ function and ECOG performance status of $\leq 2$. Subjects had to have failed first line platinum containing chemotherapy. All subjects were tested for BRCA 1 and 2. Subjects received the metronomic therapy of paclitaxel 60mg/m2 IV and carboplatin AUC 2 IV weekly, 3 weeks out of 4 and increasing doses of olaparib until the maximum tolerated dose was obtained. Olaparib started at 50 mg bid administered orally for 3 consecutive days (D1-D3), every week for each cycle. Subjects were assessed for toxicity and response according to the protocol. Subjects received combination therapy until DLT or disease progression. **Results:** The MTD was found to be olaparib 150 mg bid, three (D1-D3) consecutive days of each week of each cycle. Total number of patients enrolled in the phase 1b part of this study was 14. Median age was 58. Median number of prior therapeutic regimens was 4. Median number of cycles on study to date is 9.3. There have been no deaths due to study regimen or grade 4 toxicities. The most common grade 3 toxicities were neutropenia, lymphopenia, anemia, fatigue, and MDS (1pt.). There was no evidence of GI, cardiac, hepatic, pulmonary or dermatologic toxicities in any of these patients. 4 subjects had a complete remission (CR), 3 had partial remissions (PR), 3 had stable disease (SD), 2 had progressive disease (PD) and 2 were not evaluable. Of the 4 CR's three were BRCA positive Of the PR's two were BRCA positive and one was variant. Of the SD's there were 2 BRCA positive. Of the PD's one was BRCA positive. **Conclusions:** Olaparib, an oral tablet can be safely administered with a weekly regimen of carboplatin and paclitaxel in heavily pretreated, ovarian cancer patients. This is the first successful combination of olaparib with carboplatin and paclitaxel that has been well tolerated with minimal toxicity. Clinical trial information: NCT01650376.

**5528 Poster Highlights Session (Board #18), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II trial of intraperitoneal (IP) administration of catumaxomab (C) as consolidation therapy for patients (pts) with relapsed epithelial ovarian cancer (OC) in second or third complete remission: GEICO 1001 study.** *Presenting Author: Ignacio Romero, Area Clinica Oncologia Ginecológica. Instituto Valenciano de Oncologia, Valencia, Spain*

**Background:** Treatment with the trifunctional anti-EpCAM x anti-CD3 antibody, Catumaxomab, has shown antitumor activity in patients with advanced OC and refractory ascites. We explored prospectively the potential activity of C as consolidation therapy in pts with clinical complete response (CCR) following treatment for relapse. **Methods:** Pts with 2nd or 3rd CCR (CA-125 $<$ 35 UI/ml and no evidence of disease in CT Scan), received IP C 10 $\mu$g day 0, 20 $\mu$g d3, 50 $\mu$g d7, 200 $\mu$g d10 . All pts received premedication with paracetamol and methylprednisolone 20 mg. Primary endpoint was progression-free survival (PFS) defined as time in months (m) from beginning of therapy for the most recent relapse until progression by RECIST criteria in the Intent to treat population (at least 1 dose of C). CA-125 was double-blinded during follow-up. Secondary end-points were safety, 2nd PFS (PFS of pts in 2nd CCR), 3rd PFS (PFS of pts in 3rd CCR) and PFS from first C dose. A median PFS $>$ 14 m would be considered clinically meaningful to assess a confirmatory randomized trial. **Results:** 46 pts were included, 39 received 1st dose (29 in 2nd and 10 in 3rd CR) and 32pts completed 4 doses. Catheter-related issues preclude 4 pts to receive 1st dose and 3 pts to complete the 4 doses. Median duration of C therapy was 13 d (1-22). Grade 3-4 AE were observed in 29 pts (74.4%) and lead to interruption of C in 4 pts (10.2%). Grade 3-4 AE in $>$ 5% of pts: GGT (35.9%), ALT/AST(20.5%), abdominal pain (12.8%), nausea (10.3%), asthenia (7.7%), Bilirubin (7.7%), diarrhea (5.1%), vomiting (5.1%) and non-neutropenic infection (5.1%). Additionally, pyrexia grade 2 in 33.3% of pts. Median PFS is 17.08 m (CI 95%: 12.9-21.5), 2nd PFS is 17.28 m (CI 95%: 12.9-21.5), 3rd PFS is 17.08 m (CI 95%: 9.26-25.5) and median PFS from first C dose is 8.71 m (CI 95%: 6.01-12.3). **Conclusions:** Intraperitoneal catumaxomab as consolidation therapy for pts with relapsed OC in 2nd or 3rd CCR is feasible. Median PFS of 17.08 m from most recent relapse and 8.71 m from C first dose may indicate an impact of C in relapsed OC with minimal residual disease after 2nd or 3rd CCR, and should be confirmed in a randomized trial. Clinical trial information: NCT01246440.

**5529 Poster Highlights Session (Board #19), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase II, multicenter, randomized, double-blind, placebo-controlled trial of ganitumab or placebo in combination with carboplatin/paclitaxel as front-line therapy for optimally debulked primary ovarian cancer: The TRIO14 trial.** *Presenting Author: Gottfried E. Konecny, David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA*

**Background**: IGF signaling has been implicated in the pathogenesis and progression of ovarian cancer (OC). Ganitumab (GAN; AMG 479) is an investigational, fully human, monoclonal antibody inhibitor of IGF1R. We explored the efficacy and safety of adding GAN to carboplatin and paclitaxel (CP) front line chemotherapy in patients with optimally debulked (<1 cm) FIGO stage III and IV (positive pleural cytology only) ovarian epithelial (including fallopian tube and primary peritoneal) cancer. **Methods**: Patients were randomized in a 1:1 fashion to receive CP (C AUC6/ P 175 mg/m$^2$ q3w) plus GAN (18 mg/kg q3w) or placebo (PLB) for 6 cycles followed by 6 additional cycles of single agent GAN (18 mg/kg q3w) or PLB. The primary endpoint was PFS. Secondary objectives were: Overall survival (OS), safety, quality of life (QOL FACT-O), and to explore the relationship between PFS and molecular OC subtypes (gene expression) or IGFR1 signaling (phospho-proteins). **Results**: 170 patients were enrolled. Median age was 58 yrs (range 18-77); ECOG PS 0/1/2, 41%/53%/6%. 165 patients were assessable for toxicity; most frequent grade 3/4 adverse events for CP+GAN vs. CP+PLB were neutropenia (42% vs. 38%), thrombocytopenia (23% vs. 13%), hyperglycemia (3.4% vs. 1.3%) and skin rash (3.4% vs. 0%). The median PFS estimates were 15.7 mos (CP+GAN) vs. 16.7 mos (CP+PLB); HR (PFS): 1.22 (95% CI:0.81-1.82); median OS not yet reached. Self-reported QOL showed no difference between treatment arms. Correlative biomarker studies in 116 patients are ongoing and will be presented. **Conclusions**: PC+GAN was well tolerated in this population, however, the addition of GAN did not prolong PFS with respect to PC in unselected OC patients. Clinical trial information: NCT00718523.

**5530^ Poster Highlights Session (Board #20), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase II prospective study on trabectedin (T) in BRCA-mutated and BRCAness phenotype advanced ovarian cancer (AOC) patients (pts): The MITO 15 trial.** *Presenting Author: Domenica Lorusso, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

**Background:** T is a minor groove DNA binding agent with suggested activity in homologous recombinant defective (HRD) pts. This prospective phase II study was designed to evaluate activity of T in BRCA mutated and BRCAness phenotype AOC pts**. T**he trial was partially supported by Pharma-Mar. **Methods:** AOC pts with documented BRCA mutation or BRCAness phenotype defined as at least 2 previous response to platinum (P), were treated with T (1.3 mg/m$^2$q 21 i.v.) until disease progression. According to the number (N) of previous P responses, pts were stratified in moderately P sensitive (MPS, <3 P responses) and highly P sensitive (HPS, > 3 previous P responses). **Results:** 100 pts were enrolled and 88 were evaluable for response (52MPS, 46 HPS) after a median FU of 6 months (range: 1.5-20). Patient characteristics: median age 59 (range 49-73); 86% of tumours were serous and 60% were grade 3; median N of previous chemotherapy lines was 4 (range 2-14); median N of administered T cycles/pt was 6 (1-15), median cumulative T dose 11.0 mg/m$^2$(range 1.9-30). In the whole population ORR was 41%, media PFS 18 weeks and median OS was not reached (NR). Oncologic outcome according to P sensitivity is shown in the Table. Among 518 administered cycles the most frequent Grade 3-4 haematological toxicities (per cycle) were: neutropenia 17.3%, leukopenia 7.7%, anemia 2.7%, thrombocytopenia 2.3%; the most frequent non-haematological Grade 3 toxicity was transaminitis 5.2%. Evaluation of responses according to BRCA mutational status, expression profiling and DNA polymorphisms of genes involved in DNA repair is ongoing. **Conclusions:** T represents a valuable treatment option in the specific setting of AOC pts showing multiple platinum responses. Clinical trial information: 2011-001298-17.

**Meta-analysis of public microarray databases for prognostic and predictive gene signatures of late-stage ovarian cancer.** *Presenting Author: Michael J. Birrer, Massachusetts General Hospital/Dana-Farber Cancer Center/ Harvard Medical School, Boston, MA*

**Background:** Numerous gene signatures of patient prognosis for late-stage, high-grade ovarian cancer have been published, but diverse data and methods have made these difficult to compare objectively. However, the corresponding large volume of publicly available expression data creates an opportunity to validate previous findings and to develop more robust signatures. **Methods:** We built a database of uniformly processed and curated public ovarian cancer microarray data and clinical annotations, and re-implemented and validated 14 prognostic signatures published between 2007 and 2012. **Results:** For the microarray datasets investigated, twelve published models performed better than 97.5% of randomized risk scores, and six out-performed 97.5% of random signatures of the same size trained on the same data. The most accurate prognostic model was that of The Cancer Genome Atlas Consortium. By meta-analysis and "leave-one-dataset-out cross-validation" of 1,622 samples we generated and tested a prognostic signature that improved on all previously published signatures. In addition, we established a predictive signature for suboptimal surgical debulking which was 90% accurate and validated by immunohistochemistry. The debulking signature reveals activated TGF-beta pathway which promotes tumor migration, invasion and progression. **Conclusions:** The debulking signature, if further validated, has the potential to change clinical practice by identifying women for triage to alternative adjuvant therapy and interval debulking.

**5532 Poster Highlights Session (Board #22), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Molecular profiling of serous ovarian carcinoma to identify extreme response phenotypes and diagnostic discrepancies.** *Presenting Author: Douglas A. Levine, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Patients with serous ovarian cancer (SOC) generally require multiple lines of chemotherapy for the long-term management of disease. Clinical trials and standard care are increasingly stratified by histologic subtypes. Molecular profiling may help to select chemotherapy regimens and identify diagnostic discrepancies that influence treatment decisions and clinical trial stratification. We aimed to identify extreme resistance phenotypes and diagnostic discrepancies through commercial molecular profiling. **Methods:** Patients with a clinical diagnosis of SOC who underwent molecular profiling in a CLIA-certified laboratory were identified through database searches. Results from immunohistochemistry and target capture next-generation sequencing were reviewed. Extreme phenotypes were identified through a combination of putative resistance markers. Diagnostic discrepancies were identified when mutation profiles were inconsistent with reference frequencies defined by The Cancer Genome Atlas (TCGA) ovarian cancer project. Two-sided statistical tests were used, as appropriate, with significance at $P < 0.05$. **Results:** An extreme drug resistance phenotype was identified in 20 (3.4%) of 597 patients through a combination of ABCB1 overexpression and either high expression of TUBB3 or low expression of TOP2A, suggesting resistance to taxanes and anthracyclines, respectively. PTEN loss was identified in 60 (16.6%) of 361 patients with pathogenic *TP53* mutations, suggesting potential therapeutic utility for AKT/mTOR pathway inhibitors. *KRAS, NRAS* or *BRAF* mutations were identified in 41 (7.1%) of 578 patients sequenced. Most (82.9%) of these mutations were in patients without *TP53* mutations, suggesting a diagnostic discrepancy as SOCs typically have universal somatic *TP53* mutations and no RAS/RAF mutations. **Conclusions:** Molecular profiling can identify putative extreme resistance phenotypes and diagnostic discrepancies. As gynecologic oncology moves toward stratified treatments for SOC, accurate histologic subtyping is increasingly important. Future studies are needed to demonstrate the predictive accuracy of putative resistance phenotypes.

**5533 Poster Highlights Session (Board #23), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Real-time identification of tumor lesions and response to vintafolide treatment.** *Presenting Author: Wael A. Harb, Horizon Oncology Center, Lafayette, IN*

**Background:** In treating cancer, companion diagnostics are most useful when they can identify patients who cannot benefit from treatment. However, existing tests suffer from inaccuracy due to dependence on single specimens of a multifocal tumor or dependence on historically obtained specimens that may not represent the current tumor state. This analysis evaluates the performance characteristics of etarfolatide (EC20), a technetium-folate imaging diagnostic designed to provide real-time information on all patient tumor lesions that may respond to treatment with vintafolide (desacetylvinblastine-folate conjugate, EC145). **Methods:** 209 baseline lesions from 44 patients were evaluated in a phase 2 open-label, multicenter study of vintafolide in advanced ovarian cancer (EC-FV-02, NCT00507741). Data from 9 patients (52 lesions) without follow-up were excluded. 21 lesions were categorized as not evaluable, and 6 lesions were categorized as not imaged. 8 lesions that did not meet minimal size criteria were also excluded. The final analysis set included 107 lesions from 33 patients. **Results:** Etarfolatide correctly identified 24 of 26 lesions whose tumor size numerically decreased following vintafolide treatment (sensitivity for numerical decrease=92%). The corresponding negative predictive value (NPV=percent of EC20− lesions that did not numerically decrease) was 86% with a specificity of 15% and a positive predictive value (PPV=percent of EC20+ lesions that numerically decreased) of 26%. Among the etarfolatide negative lesions, 0 decreased by at least 30%. Among the etarfolatide positive lesions, 5 decreased by at least 30%. Therefore, among the 5 lesions that decreased by at least 30%, 5 were etarfolatide positive (sensitivity=100%). Among 102 lesions that did not decrease by at least 30%, 14 were etarfolatide negative (specificity=14%), corresponding to PPV and NPV of 5% and 100%, respectively. **Conclusions:** Etarfolatide identified nearly all tumor lesions that responded to vintafolide treatment in a phase 2 ovarian cancer study. Lesions that do not demonstrate etarfolatide uptake will not demonstrate major shrinkage (>30%) following vintafolide treatment. Clinical trial information: NCT00507741.

**5534 Poster Highlights Session (Board #24), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Characterization of ovarian cancer long-term responders on olaparib.** *Presenting Author: Stephanie Odile Lheureux, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** *BRCA1/2* mutations (*BRCA*m) appear to predict benefit from PARP inhibition. However, non-mutation carriers also benefit and not all patients (pts) with *BRCAm* respond to PARP inhibitors. The objective of this study was to identify and clinically characterize pts remaining on durable olaparib therapy for further molecular analyses to determine the features underlying long-term response. **Methods:** A retrospective meta-analysis comprised pts with recurrent ovarian cancer (OC) from trials in the olaparib clinical program. Long- and short-term benefits were defined as olaparib treatment for > 2 years and < 6 months respectively, segregated by monotherapy or maintenance. **Results:** 372 OC pts, 323 with *BRCA*m have been already treated with olaparib 400 mg bid capsule as monotherapy at time of relapse (Studies D0810C000001-02-09-12-20-24-42). In these trials, 197 pts (53%) were treated < 6 months from which 169 pts (52.3%) had *BRCA*m. Conversely, there were pts with long-term benefit from olaparib, such as 6 pts in the D0810C000020 study, treated for > 4 years. The table shows the OC pts treated with maintenance olaparib (n=136) and also with olaparib in combination with chemotherapy followed by maintenance (n=81), separating out the pts with *BRCA*m. **Conclusions:** Although many long-term responders to olaparib have *BRCA*m, there are several with no known *BRCA*m. Response durability may be related to a number of factors including germline and somatic *BRCA*mutations. The clinical and molecular characterization of these pts and comparison with short- or median-term disease control will improve understanding of response and resistance to PARP inhibitors.

| Treatment duration | D0810C000019: Olaparib maintenance 400 mg bid capsule monotherapy* | | | | D0810C000041: Combination with carboplatin/paclitaxel followed by maintenance 400 mg bid capsule monotherapy* | | | |

**5535 Poster Highlights Session (Board #25), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Biomarker correlates from the randomized phase 2 trial of the PARP inhibitor olaparib (O) with or without the antiangiogenic TKI cediranib (C) in recurrent platinum-sensitive ovarian cancer (NCT01116648).** *Presenting Author: Jung-min Lee, National Cancer Institute, National Institutes of Health, Bethesda, MD*

**Background:** O and C have single agent activity in recurrent platinum-sensitive high-grade serous ovarian cancer (HGSOC). A multi-institutional phase 2 open label study evaluated the efficacy of O with or without C in HGSOC pts. We hypothesized O+C combination may yield greater inhibition in tumor vascularity and VEGF pathways than O alone and these changes may correlate with response rate (RR) and progression-free survival (PFS). **Methods:** A self-selected subset of eligible pts were randomized 1:1 to O (400mg capsules BID) or O+C (O 200 mg capsules BID; C 30 mg daily). No prior anti-angiogenic therapy in the recurrent setting or prior PARPi was allowed. Blood samples were collected at baseline and day 3 to measure circulating endothelial cells (CEC: nucleated CD133-CD146+CD31+CD45-), circulating endothelial progenitor cells (CPC: viable nucleated CD133+, CD146-, CD31+ CD45 - or dim), plasma for cytokine concentrations of IL-6, IL-8, VEGF, and sVEGFR-2. DCE-MRI obtained at baseline and day 3 on therapy were evaluated for changes of $K^{trans}$ and $K^{ep}$as a result of decreases in angiogenesis. **Results:** The clinical cohort and results of the full trial will be presented independently. 13 pts (median age 53 yr [32-70]; 7pts on O, 6pts on O+C) had paired correlative studies including DCE-MRI (10pts), CEC/CPC (10pts), and cytokine measurements (12pts). Median PFS with RR for O and O+C were 11mo, 57% and 14mo, 83%, respectively for this subset. Pts on O+C had a greater decrease in IL-8 and a median 3.5 fold increase in CEC compared to O alone ($p$=0.016 and 0.013, respectively). The increase of CEC pretreatment to day 3 was correlated with PFS>6mo in 6 pts on O+C ($p$=0.011, 95%CI 0.47-0.99, $R^2$=0.91). Pre-day3 $K^{trans}$ and $K^{ep}$ did not correlate with RR or PFS in either arm. **Conclusions:** Significant changes of IL-8 concentration and CEC number with O+C suggest greater inhibition in angiogenesis compared with O alone. Further studies of this combination with prospectively planned validation of these potential predictive biomarkers may yield information to focus therapy to HGSOC pts who may best respond. Clinical trial information: NCT01116648.

**5536 Poster Highlights Session (Board #26), Mon, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Analysis of candidate homologous repair deficiency genes in a clinical trial of olaparib in patients (pts) with platinum-sensitive, relapsed serous ovarian cancer (PSR SOC).** *Presenting Author: Brian Dougherty, AstraZeneca, Waltham, MA*

**Background:** In a randomized trial of 265 pts with PSR SOC, maintenance therapy with the PARP inhibitor olaparib led to a PFS benefit vs placebo in pts with *BRCA1/2* mutations (hazard ratio, 0.18; Study 19 [NCT00753545]; Ledermann *et al* ASCO 2013). A PFS hazard ratio of 0.54 (0.34–0.85; $P$=0.007) in BRCA wild type/VUS (variant of unknown significance) pts is consistent with preclinical and clinical evidence that homologous recombination repair-associated genes (HRR genes) in addition to *BRCA1/2* may contribute to PARP inhibitor response. **Objective:** Exploratory characterization of genetic changes in tumors from PSR SOC pts to determine the frequency and co-occurrence patterns of mutations in *BRCA1/2* and other HRR genes, and the presence of these mutations in pts with a long-term response (LTR; treatment duration >24 mo) (olaparib, 24%; placebo, 4%). **Methods:** Using Foundation Medicine's 287-gene, next-generation sequencing test, alterations were categorized based on loss-of-function mutations and *BRCA1/2* mutual exclusivity, and analyzed for loss of heterozygosity and tumor heterogeneity. **Results:** Compared with ovarian pts from The Cancer Genome Atlas (TCGA; n=316), Study 19 pts with sequenced tumors (n=209) had considerably higher mutation rates in *BRCA1* (36% vs 12%) and *BRCA2* (17% vs 9%). As with TCGA, most HRR genes had low mutation rates, but the proportion of Study 19 pts with *BRCA1/2*-mutually exclusive mutations was lower for *PTEN* (2% vs 6%) and higher for HRR genes (14% vs 9%). *BRCA1/2*-mutually exclusive HRR gene mutations in ≥1 pt were *BRIP1* (5 pts), *RAD54L* (3 pts), *CDK12* (3 pts), *RAD51B* (2 pts). Of 33 sequenced LTR pts, 7 (21%) had no candidate *BRCA1/2* loss-of-function mutation: 5 had candidate HRR gene mutations (*BRIP1*, *RAD51B*, *FANCL*, *PTEN*, *MSH2*) and 2 had no clear HRR mutation among the genes tested. **Conclusions:** Prior Study 19 analyses showed a greater clinical benefit in pts with *BRCA1/2* mutations. The proportion of pts with non-*BRCA1/2* HRR gene mutations is relatively small in Study 19, but could include candidate genes deserving further study for a potential role in prolonged treatment benefit and survival on platinum or PARP inhibitors. Clinical trial information: NCT00753545.

**5537 General Poster Session (Board #319), Sat, 8:00 AM-11:45 AM**

**Frequent use of complex surgeries and survival outcomes in ovarian cancer patients: A propensity score analysis from the Korean Gynecologic Oncology Group.** *Presenting Author: Sokbom Kang, National Cancer Center, Koyang, South Korea*

**Background:** To develop an indicator representing the quality of ovarian cancer surgery and to determine its predictive role in a prognostic model. **Methods:** From January 2002 to December 2008, the clinical records and computed tomography (CT) data of epithelial ovarian cancer patients were reviewed from the KGOG-3022 dataset. A propensity score was developed from a multivariable logistic model and used as a stratification factor or co-variable in Cox models to balance the differences between the high- and low/intermediate-complexity surgery group. **Results:** Data for 331 patients from six specialized teaching hospitals were reviewed. Complex surgery, defined as a surgery with a surgical complexity score $> 7$, was more frequently performed in patients with an 'upper abdominal extension' pattern, 'diffuse peritoneal spread' pattern, and grade III disease ($P <$ 0.001, 0.017, and 0.001, respectively). To balance the differences, a propensity score for complex surgery was developed. The use of complex surgery for greater than 25% of advanced cases at the institutional level was consistently associated with improved progression-free survival (PFS) when the score was used as a covariate (Hazard ratio [HR] = 0.69, $P =$ 0.038) or as a stratification factor (HR = 0.68, $P = 0.033$). In contrast, the complexity of individual surgery showed no significant association with PFS regardless of the adjustment methods ($P = 0.90$ and 0.76, respectively). **Conclusions:** The institutions that perform complex surgeries for greater than 25% of advanced ovarian cancer patients were associated with an approximately 30% reduction in recurrence risk after primary treatment.

**5538 General Poster Session (Board #320), Sat, 8:00 AM-11:45 AM**

**Carboplatin hypersensitivity reaction (HSR): Analysis of safety and success of a short outpatient platinum rechallenge protocol (PRP) in epithelial ovarian carcinoma (EOC).** *Presenting Author: Los Vincent Newton, Auckland City Hospital, Auckland, New Zealand*

**Background:** Platinum remains mainstay to EOC therapy, in first line and relapse. HSR to Carboplatin(Cb) is well reported and limits utility of further platinum therapy. Reported desensitisation regimes are lengthy, involving inpatient high dependency care. In 2005 our centre developed a standardised rapid 1.5 hour, 3 step outpatient PRP for patients(pts) who had HSR to Cb. We performed a retrospective review of the outcomes and safety of our PRP. **Methods:** All pts given Cb for stage I - IV EOC from 2005 to 2012 were identified. Data was obtained on baseline characteristics, all therapy, HSR, safety and efficacy of the PRP. HSR severity was graded consistent with published data. Our PRP consists of pre- and post-medication with antihistamine and steroids, a 15 minute infusion of diluted Cb or Cisplatin (Cis), then 15min of undiluted platinum at reduced rate, with the remainder administered thereafter over 1 hour. **Results:** 406 pts were identified. Median age 60.6 years (range 21-88). 64pts (15.8%) had an HSR to Cb. First HSR occurred at median cycle 8.5 (range 1-24) of Cb exposure. 67% of HSR occurred during second line Cb. 8/64 pts had a moderate-severe HSR to Cb. The incidence of pts having a Cb HSR during second line treatment at PFI of 6-12 months, 12-24 months and >24 months was 44%, 36% and 27% respectively. 51/64 pts (79.7%) were retreated with either the Cb PRP (29pts) or Cis PRP (22pts) at clinician discretion. 14/29 pts had a HSR on Cb PRP, 1/22pts on Cis PRP. The Cis PRP was significantly less likely to result in second HSR, OR=0.05 (p=0.006). Second HSR grade was a higher than initial HSR in 4pts but none graded severe. 9/14 pts having second HSR on Cb PRP were subsequently treated with Cis PRP. 7/9 pts had no further HSR. Using our PRP, patients received a median of 4 further cycles of platinum on the PRP (range 1-11). There were no deaths from HSR in our cohort **Conclusions:** Our rapid outpatient PRP is safe and allowed a significant proportion of patients to continue further platinum chemotherapy. Treatment with Cis PRP has significantly fewer reactions than Cb PRP and should be considered the preferred platinum for rechallenge in suitable patients.

**5539 General Poster Session (Board #321), Sat, 8:00 AM-11:45 AM**

**Female germ cell tumors (GCT): The Memorial Sloan Kettering Cancer Center (MSKCC) experience.** *Presenting Author: Jane Lowe Meisel, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background**: Due to their rarity, little is known about female GCT biology and response to therapy. Management is largely based on studies of male GCT and epithelial ovarian cancer. **Methods**: We identified 111 female patients (pts) treated at MSKCC for malignant GCT of gynecologic origin from 1990 to 2012 and reviewed their clinical characteristics and outcomes. Pts receiving chemotherapy (CT) were classified using a modification of the IGCCCG system for men. Kaplan-Meier methods were used to estimate progression-free (PFS) and overall survival (OS) and the log-rank test to assess differences. **Results**: Histologies in the 111 pts (107 ovarian) included immature teratoma (28), dysgerminoma (DG) (24), mixed GCT (20), yolk sac (18), mature cystic teratoma (MCT) (12), struma ovarii (SO) (6), and other (3). 72 (65%) were stage I, 5 (5%) stage II, 28 (25%) stage III, and 6 (5%) stage IV. All pts underwent primary surgery and 85 (77%) received CT; in 67 (79%), BEP was the 1st-line regimen. IGCCCG risk was good in 46 (54%), intermediate in 12 (14%), poor in 10 (12%) and unknown in 17 (serum tumor markers (STM) not drawn at CT start). AFP, HCG, and LDH were elevated in 36, 6, and 11 pts, respectively. Complete response (CR) to 1st-line CT was seen in 64 (75%), partial response in 1, and incomplete response (IR) in 20 (24%). 29 (26%) pts progressed after initial therapy (26 after CT), with 14/29 (52%) diagnosed by imaging, 6 by STM, 1 by exam, and 8 by multiple methods. 11/26 (42%) who progressed after CT received high-dose CT (HDCT) with ASCT resulting in 6 CRs and 5 IRs. 4/6 CRs had received only 1 prior CT regimen vs 2/5 IR pts. With median f/u of 4.9 years (y), 3yOS for all pts was 86% (95% CI 79-93%), with a trend favoring DG, SO, and MCT vs other histologies (97% vs 83%, p=0.056) and Stage I/II vs III/IV (88% vs 81%, p=0.067). IGCCCG group was significantly associated with PFS and OS (Table). **Conclusions**: IGCCCG status can help estimate prognosis to CT for female GCT pts. Thus, STM should always be drawn prior to CT, and poor-risk pts might benefit from more intensive 1st-line CT. Salvage HDCT, especially if given early, can be curative.

**PFS and OS to CT by IGCCCG Group.**

| | Good (n=45)* | Intermediate (n=12) | Poor (n=10) | Log-rank P |
|---|---|---|---|---|
| **3y-PFS** | 84% | 83% | 20% | <0.001 |
| **3y-OS** | 89% | 89% | 40% | <0.001 |

**5540^ General Poster Session (Board #322), Sat, 8:00 AM-11:45 AM**

**Independent radiologic review of AURELIA, a phase 3 trial of bevacizumab (BV) plus chemotherapy (CT) for platinum (PT)-resistant recurrent ovarian cancer (OC).** *Presenting Author: Amreen Husain, Genentech, Inc., South San Francisco, CA*

**Background:** AURELIA is a phase 3, randomized, open-label trial in patients (pts) with PT-resistant, recurrent OC (NCT00976911). Based on investigator (INV) assessment of radiographic data, CT + BV showed significant improvement vs CT alone in the primary end point of progression-free survival (PFS) (Pujade-Lauraine, JCO in press). Median PFS was 3.4 months for CT vs 6.8 months for CT + BV (stratified hazard ratio [HR], 0.38; 95% confidence interval [CI], 0.30–0.49; $P<.001$). As this was an open-label trial, an independent review committee (IRC) assessment of radiologic data was conducted retrospectively to confirm these results. **Methods:** Radiologic images were provided to the IRC for 92.2% of randomized pts; 82.5% of pts were IRC-evaluable. Data were reviewed in a blinded manner according to a prespecified charter following modified RECIST v.1.0. PFS analysis was based on the intent-to-treat population. **Results:** IRC results were consistent with those from the INV, demonstrating a statistically significant and clinically meaningful improvement in PFS with BV (Table). The concordance rate for progression status (yes, no) was similar across arms (CT, 69.9%; CT + BV, 68.2%), as was agreement on the date of progressive disease (PD; CT, 69.1%; CT + BV, 67.2%). The early discrepancy rates (INV-determined PD earlier than IRC-determined PD) were similar in the 2 arms (CT, 0.372; CT + BV, 0.364), whereas the late discrepancy rate was higher in the CT + BV arm (CT, 0.329, CT + BV, 0.463). The differential discordance of 0.134 suggests some degree of INV bias toward the CT + BV arm. **Conclusions:** The PFS analysis results from the IRC assessment were consistent with those from the primary INV-led PFS analysis, despite a trend for INV assessment of PD at a later date in the CT + BV arm in this trial. The results provided further evidence that INV-determined PFS based on RECIST is reliable and reproducible in OC clinical trials. Clinical trial information: NCT00976911.

**5541^ General Poster Session (Board #323), Sat, 8:00 AM-11:45 AM**

**Phase I trial of pegylated liposomal doxorubicin in combination with BIBF 1120 (nintedanib) in platinum-resistant ovarian cancer: Hoosier Oncology Group GYN10-149.** *Presenting Author: Maria Creselda deLeon, Indiana University School of Medicine, Indianapolis, IN*

**Background:** The triple PDGFR$\alpha/\beta$, VEGFR1-3, FGFR1-3 angiokinase inhibitor BIBF 1120 (B) is active in ovarian cancer (OC). This phase I/II trial evaluates tolerability and efficacy of B combined with pegylated liposomal doxorubicin hydrochloride (D) in platinum-resistant OC. **Methods:** The primary endpoints (EPs) are to determine the maximum-tolerated dose (MTD, phase I) and response rate (RR, phase II) to D+B. Secondary EPs were PFS, toxicities and rate of clinical benefit. Translational EPs were treatment effects on circulating hematopoietic stem and progenitor cells (CHSPCs), containing 2 phenotypically distinct populations; pro-angiogenic (p) CHSPCs ($ViViD^-CD14^-glyA^-CD34^+AC133^+CD45^{dim}CD31^+$ cells) and non-angiogenic (n) CHSPCs ($ViViD^-CD14^-glyA^-CD34^+AC133^-CD45^{dim}CD31^+$ cells). Eligible pts had measurable OC, primary peritoneal (PP), fallopian tube and uterine (phase I only) cancer, up to 3 prior regimens, ECOG PS of 0-1 and normal end-organ function. B was given orally BID and D was given IV at 40mg/m$^2$every 28 days. 3+3 dose escalation was used, starting with B at 150mg BID. **Results:** Eleven pts were enrolled in phase I. Median age was 59 (range 26-82); 8 pts had OC, 2 uterine and 1 PP cancer. Histologic types: serous (73%), endometrioid (18%) and mucinous (9%) carcinoma. Dose level+1 (B at 150mg BID) was not tolerated due to grade 3 fatigue, and grade 2 diarrhea, causing treatment interruption (DLT). Among 6 pts at dose level-1 (B at 100mg BID), 1 pt with history of chemotherapy induced myelosupression had grade 4 neutropenia (DLT). Other toxicities were diarrhea (36.4%), fatigue (36.4%), vomiting (27.3%), headache (27.3%), allergic reaction (9.1%) and oral pain (9.1%). Three pts had PRs, 3 SD and 4 disease progression; 1 was not evaluable. A decrease in the pCHSPC/nCHSPC ratio was observed after 1 cycle (1.58, n=8) compared to baseline (1.68, n=10, p=0.4). At treatment discontinuation, the pCHSPC/nCHSPC ratio was 1.97 (n=4). Analyses are ongoing. **Conclusions:** In summary, D+B is tolerated at 40mg/m$^2$ and 100mg BID. An expanded cohort using generic liposomal doxorubicin and B at level -1 is planned before initiation of the phase II cohort. Clinical trial information: NCT01485874.

**5542 General Poster Session (Board #324), Sat, 8:00 AM-11:45 AM**

**Expression of angiopoietin (Ang) pathway markers and their relationship to progression-free survival (PFS) in TRINOVA-1.** *Presenting Author: Andres Poveda, Instituto Valenciano de Oncologia, Valencia, Spain*

**Background:** Trebananib, an investigational recombinant peptide Fc-fusion protein, targets Ang1 and 2. In TRINOVA-1, a randomized phase 3 study, trebananib plus paclitaxel (P) compared with placebo plus P significantly improved PFS (primary endpoint) in recurrent ovarian cancer. Biomarker evaluation was an exploratory endpoint. **Methods:** Women ($\geq$ 18 years, GOG $\leq$ 1) with recurrent epithelial ovarian, primary peritoneal, or fallopian tube cancer received trebananib 15 mg/kg IV QW or placebo IV QW plus P 80 mg/m$^2$ IV QW (3 wks on/1 wk off). Serum samples were collected pre-infusion at wk 1 to evaluate baseline levels of Ang1, Ang2, and soluble Tie2 (sTie2). Analytes were quantified using enzyme-linked immunosorbent assays (ELISA; R&D Systems). Analyses of PFS as a function of biomarker expression addressing prognostic and predictive testing included: 1) subpopulation treatment effect pattern plots (STEPP) for Ang1, Ang2, sTie2, Ang1/Ang2, and Ang2/Ang1 (prognostic test); 2) evaluation of Ang1, Ang2, sTie2, Ang1/Ang2, and Ang2/Ang1 as continuous variables (prognostic test); and 3) median thresholds to dichotomize Ang1, Ang2, and sTie2 levels (prognostic and predictive tests). **Results:** Serum samples were available for 834 of 919 enrolled women. Per STEPP, no threshold in biomarker expression was associated with PFS. Using continuous models, there was no linear association with PFS (Ang1, $p = 0.55$; Ang2, $p = 0.47$; sTie2, $p = 0.63$; Ang1/Ang2, $p = 0.17$; Ang2/Ang1, $p = 0.66$). Using median thresholds, low Ang1 (median, 23.30 ng/mL) or Ang2 (median, 2.86 ng/mL) levels were associated with improved PFS ($p = 0.044$ and 0.009, respectively) when not corrected for multiple testing. Those relationships were not consistent at the extreme Ang1 or Ang2 values. There was no evidence of an interaction of either Ang1 or Ang2 by treatment arm ($p = 0.10$ and 0.68, respectively). sTie2 (median, 27.8 ng/mL) was not predictive or prognostic of PFS. **Conclusions:** In TRINOVA-1, no consistent predictive or prognostic relationships between baseline levels of Ang1, Ang2, or sTie2 were observed. Clinical trial information: NCT01204749.

**5543 General Poster Session (Board #325), Sat, 8:00 AM-11:45 AM**

**Adjuvant radiation for patients (pts) with high-grade serous ovarian cancer (HGSC) and T-cell infiltration.** *Presenting Author: Aalok Kumar, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** CD8 positive intra-epithelial tumor infiltrating T cells (TIL) are associated with improved outcomes in ovarian cancer, particularly in HGSC. Radiotherapy (XRT) has immunologic effects including tumour necrosis, activation of antigen presenting cells and T cell recruitment. Adjuvant XRT in ovarian cancer was historically used at the BC Cancer Agency (BCCA). We hypothesized that adjuvant XRT for HGSC may have a beneficial impact on outcomes within the TIL+ subgroup. **Methods:** Stage I and II and optimally debulked (no visible residual disease) stage III HGSC pts treated at the BCCA from 1984to 2004 were included in this analysis. All cases underwent pathologic review to confirm histology and to score for TIL, either present ($\geq$1 CD8 cell / 6mm core) or absent via immunohistochemistry. Treatment was platinum based chemotherapy (3-6 cycles) and abdominal-pelvic radiotherapy (45 Gy and 32 fractions to pelvis and whole abdomen). Kaplan-Meier and Cox proportional hazards methods were used to correlate XRT use (yes vs. no) with overall survival (OS) and disease free survival (DFS). **Results:** We identified 205 pts, of whom 174 scored positive for TIL. Of the 174, 76 (44%) were treated with XRT and 98 (56%) no XRT. Most pts (97%) also received adjuvant chemotherapy. Median follow up was 6.5 years. Pts who received XRT were younger (mean age 56.6 vs. 63.5 years, p<0.001) and had lower stage disease (p=0.0008). On univariate analysis, XRT was associated with an increased median OS (10 vs. 6 years, p=0.03) and a non significant increased DFS. On multivariate analysis, adjuvant XRT did not impact OS or DFS (HR 0.99, 95CI 0.66-1.49,p=0.97 and HR 1.05,95CI 0.67-1.67,p=0.82 respectively). Stage 3 disease was associated with worse OS and DFS (HR 1.71, 95CI 1.03-2.85, p=0.04 and HR 2.26, 95CI 1.26-4.04,p=0.006 respectively). Older age was associated with decreased OS (HR 1.03, 95CI 1.01-1.04,p=0.005). **Conclusions:** In this population based cohort study, adjuvant XRT for early stage or microscopic residual stage III HGSC with TIL was not associated with an OS or DFS advantage. Adjuvant XRT has no defined role in the treatment of HGSC.

**5544 General Poster Session (Board #326), Sat, 8:00 AM-11:45 AM**

**Relative influence of factors determining a woman's preference for treatment options in ovarian cancer.** *Presenting Author: Laura Jean Havrilesky, Duke University Medical Center, Durham, NC*

**Background:** We examined relative preferences of women with ovarian cancer for symptoms, treatment-related side-effects, and progression-free survival (PFS) when considering a treatment regimen. **Methods:** Women with advanced or recurrent ovarian cancer were recruited at a single institution to a prospective discrete choice experiment. In each discrete choice, subjects were asked to choose between two treatment scenarios, modeled on the characteristics of standard intravenous (IV) and intraperitoneal/intravenous (IP/IV) treatments for ovarian cancer. Each scenario described 7 attributes with 2-3 levels each: mode of administration (IV versus IP/IV); visit frequency (weekly, twice per 3 weeks, once per 3 weeks); treatment related symptoms (mild to severe nausea and vomiting, abdominal symptoms, neuropathy, and fatigue); and PFS (15, 18, 21, and 24 months). We used a balanced overlap design with 10 versions of the survey. Each subject evaluated 12 random choice scenarios (in which levels of each attribute were varied). We applied mixed logit regression to model participants choices as a function of attribute levels. **Results:** 95 women completed the survey. Mean age 57; 81% Caucasian. 47% had experienced disease recurrence and 49% were currently receiving chemotherapy. Compared to scenarios with 15 months of PFS, the relative odds that a participant would choose a scenario with 18, 21, and 24 months of PFS were 1.5 (p=0.01), 3.4 (p<0.001) and 7.5 (p<0.001), respectively. However, subjects were willing to give up PFS to avoid severe treatment-related side effects (6.7 months to reduce severe nausea and vomiting during treatment to mild, 5.0 months to reduce severe neuropathy to mild, and 3.7 months to reduce severe IP–related abdominal symptoms to moderate). Findings were similar between women currently receiving chemotherapy and those who were not and between women with disease recurrence and those without. **Conclusions:** PFS is the predominant driver of patient preferences for chemotherapy. However, women are willing to trade significant PFS time for reductions in treatment-related toxicity. Patient preferences should be considered when interpreting clinical trial results and making treatment decisions.

**5545 General Poster Session (Board #327), Sat, 8:00 AM-11:45 AM**

**Pretreatment serum mitochondrial DNA (mtDNA) correlates with shorter progression-free and overall survival in patients with advanced ovarian cancer (OC).** *Presenting Author: Kassondra S. Grzankowski, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** Mitochondrial damage-associated molecular patterns, comprised of mtDNA and formylated peptides, are released after cellular injury and activate innate immune responses. Extracellular mtDNA activates TLR-9 and other pathogen recognition receptors. While mitochondrial metabolism and DNA mutations have been widely studied in tumor cells, this study analyzes mtDNA at an extracellular level as a marker of injury. Since OC is associated with cellular necrosis, we reason that extracellular mtDNA may be a molecular prognostic marker. **Methods:** Serum collected in OC patients prior to primary surgery (n=41) and from age-matched cancer free women (n=3) was analyzed for mtDNA. Q-PCR with cytochrome B primers specific for mtDNA was done. The high group was pre-specified as patients with serum mtDNA > 5-fold above the mean control level, and the remainder was defined as the low group. Primary endpoint was PFS. **Results:** 41% had high levels of mtDNA. 76% in the high mtDNA and 74% in the low groups were Stage 3. Histology and grade were similar. The mean age at diagnosis was 69. Median PFS in the high and low groups was 228 vs. 489 days, respectively (p = 0.17). The high mtDNA group had quicker relapse (HR=2.7; p = 0.0278) and a reduced OS trend (HR=3.5; p = 0.0593) within the first year of surgery. Consistent with this effect, additional exploratory analysis showed that patients with serum mtDNA in the highest 15% had markedly reduced PFS (5 vs. 16 mo; p = 0.0015) and OS (8 vs. 50 mo; p = 0.00022) compared to the remaining patients. The relationship between pre-treatment serum mtDNA levels and PFS and OS involve a threshold effect rather than a direct linear relationship. Comparing pre-treatment serum mtDNA levels to published data on serum CA-125 levels from a Gynecology Oncology Group study that analyzed 1,299 patients with OC, we observed significantly greater effect sizes with serum mtDNA in predicting prognosis, with the greatest effect in the top 15% serum mtDNA group. **Conclusions:** Increased levels of circulating mtDNA correlated with significantly reduced PFS and OS. If validated in an independent cohort, pre-treatment serum mtDNA may be of value as a prognostic marker for OC.

**5546 General Poster Session (Board #328), Sat, 8:00 AM-11:45 AM**

**A randomized phase II trial of bevacizumab (BV) plus oral everolimus (EV) versus bevacizumab alone for recurrent or persistent epithelial ovarian (EOC), fallopian tube (FTC), or primary peritoneal cancer (PPC).** *Presenting Author: William P. Tew, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** BV monotherapy leads to compensatory upregulation of multiple signaling pathways, resulting in persistent mTOR activation, which if blocked, may circumvent resistance to anti-VEGF therapy.We evaluated the efficacy and tolerability of combining BV and oral everolimus (EV), an mTOR kinase inhibitor, in women with EOC/FTC/PPC. **Methods:** Eligible pts had persistent or recurrent EOC/FTC/PPC, measurable (RECIST 1.1) or detectable (CA125 ≥ 2x upper limit normal), 1-3 prior regimens, performance status (PS) 0-2, and no prior m-TOR inhibitor. All pts received BV 10 mg/kg IV every 2wks in 4wk cycles. Pts were randomized (1:1) to oral EV (10 mg daily) or placebo with stratification for platinum-free interval (PFI), measurable disease and prior BV. Primary endpoint was progression-free survival (PFS); secondary endpoints included safety and response evaluated every 8wks. **Results:** 150 evaluable pts were randomized to BV with (n=75) and without (n=75) EV. Arms were well-balanced for age (median 63: range 28-92), PS (0: 73%, 1-2: 27%), prior regimens (1: 37%, 2: 47%, 3: 16%), prior BV (11%), PFI (<6mos: 65%) and measurable disease (81%). The BV+EV vs BV median PFS was 5.9 vs 4.5 mos, respectively (hazard for progression 0.95 (95% CI, 0.66-1.37, p=0.39); pts with PFI>6mos had HR 0.615 (95% CI 0.33~1.15, p=NS). Median OS was 16.6 vs 17.3 mos (hazard of death 1.16 (95% CI, 0.72~1.87, p=NS). Among pts with measureable disease, objective responses were higher with BV+EV (19% vs 9%). Study removal due to toxicity was high with BV+EV (29%) compared to BV alone (12%). Toxicity (≥g3) most significantly associated with addition of EV were "other GI" (17 vs 1pts) and "metabolic/nutrition" (14 vs. 5pt). Most common toxicities ( ≥g2) were anemia (24 vs 6pt), neutropenia (20 vs 1pts), oral mucositis (22 vs 0pts), nausea (24 vs 9pts), fatigue (24 vs 15pts), and hypertension (20 vs. 21pts). **Conclusions:** The combination regimen (BV+EV) is active in this population but did not significantly reduce the hazard of progression or death and was associated with higher rates of study discontinuation for tolerability when compared to BV alone.

**5547 General Poster Session (Board #329), Sat, 8:00 AM-11:45 AM**

**High-dose chemotherapy (HDCT) for recurrent ovarian germ cell tumors (OGCT): Indiana University (IU) experience.** *Presenting Author: Natraj Reddy Ammakkanavar, Department of Hematology/Oncology, Indiana University School of Medicine, Indianapolis, IN*

**Background:** OGCT are rare subtype of ovarian cancer, accounting for less than 5% of malignant ovarian cancer cases. First-line cisplatin combination chemotherapy has a 70-80% cure rate. There is very little data for salvage chemotherapy. The objective of this study was to determine the outcomes with HDCT in patients with recurrent OGCT treated at Indiana University (IU). This represents the largest reported data with HDCT in OGCT. **Methods:** We performed a retrospective review of 12 patients with diagnosis of recurrent OGCT who underwent HDCT at IU during 1990-2013. Demographics, disease variables, treatments and outcomes were analyzed. **Results:** Median age at the time of HDCT was 25 years (range: 14 - 39 years). 11 of 12 patients had yolk sac tumor (median AFP: 1021). 7 patients had platinum resistant disease. Median number of prior chemotherapy treatments were 2 (range: 1- 4). At the start of HDCT, median serum alpha-fetoprotein (AFP) level was 792 for all patients. 4 of 12 patients had liver metastasis. 10 of 12 patients received 2 courses of HDCT cycles, consisting of carboplatin at 700mg/m2/day and etoposide 750mg/m2/day for 3 consecutive days followed by autologous stem cell rescue in each treatment cycle. 7 patients achieved complete response (CR) including 4 who are continuously disease free at 4+ months, 15+ months, 10+ years and 22+ years. 3 of the 5 patients, who received HDCT as a first-line salvage therapy, are continuously disease free. Only 1 of the 7 patients, who received HDCT as a second-line salvage therapy or later, is continuously disease free. 3 of the 5 patients with platinum sensitive disease are disease free. Median overall survival was 11.5 months (range: 4 months - 22 years). Toxicities noted were as expected and reported with HDCT for testicular germ cell tumors (NEJM 2007; 357:340-348). No treatment related deaths were noted. **Conclusions:** Our data demonstrates that HDCT is an effective treatment for recurrent OGCT. Better outcomes were observed for first line salvage and platinum sensitive recurrences.

**5548 General Poster Session (Board #330), Sat, 8:00 AM-11:45 AM**

**Analysis of outcomes in patients (pts) with recurrent ovarian clear cell carcinoma (ROCCC): Time to rethink our approach to treatment.** *Presenting Author: David Shao Peng Tan, Princess Margaret Cancer Center, Toronto, ON, Canada*

**Background:** Advanced stage primary OCCC is associated with a poor prognosis following primary surgery and chemotherapy, but scant data exists regarding response rates (RR = RECIST PR/CR), progression free (PFS) and overall survival (OS) following treatment (rx) for ROCCC. **Methods:** We conducted a retrospective review of pts with ROCCC treated at 2 cancer centres to evaluate RR, clinical benefit rate (CBR=PR/CR or SD with PFS ≥12wks), PFS (time from start of rx to RECIST/clinical PD) and OS (time from 1st relapse after primary rx to death) following rx, and response/ symptomatic benefit after palliative radiotherapy (PRT). Platinum (plt) resistance was defined as PD < 6mths after plt. **Results:** In total, 137/256 pts developed ROCCC. Recurrences by FIGO stage at diagnosis were: Stage 1A/B (15/49, 29%), Stage 1C (16/67, 24%), Stage 2 (40/62, 65%), Stage 3 (46/54, 85%), Stage 4 (20/21, 91%), p<0.0001. Pts received a median of 1 line (range = 1-6, total = 166) of rx with an overall RR of 13/142 (9%) evaluable lines of treatment. Across all rxs, median PFS was 11 wks (95% CI: 8,14) and median OS was 40 wks (95% CI: 28,52). At 1st relapse, 72/86 treated pts were evaluable for response with RR=14% (10/72), CBR=31% (22/72) and median PFS=12wks (95% CI: 9,15). At 2nd relapse, 36/42 treated pts were evaluable for response with RR=8% (3/36) and CBR=33% (12/36) and median PFS=14wks (95% CI: 8,20). No significant PFS difference was observed for plt-sensitive pts treated with plt-based or non-plt-based rx at 1st relapse (HR=1.2; 95% CI: 0.6, 2.5; p=0.57) or at any relapse (HR=0.9; 95% CI: 0.4, 1.7; p=0.65). Outcomes for all rxs are shown in the Table. 6/12 (50%) pts derived benefit following PRT. **Conclusions:** ROCCC is a chemoresistant disease with a short median OS of 10mths. PRT offers symptomatic benefit. More clinical trials to identify effective systemic rxs for ROCCC are urgently required.

**Individual rx outcomes across all lines of rx.**

**5549 General Poster Session (Board #331), Sat, 8:00 AM-11:45 AM**

**Duration of systemic therapy for ovarian cancer: A systematic review and meta-analysis.** *Presenting Author: Adnan Nagrial, The Kinghorn Cancer Centre, The Garvan Institute of Medical Research, Sydney, Australia*

**Background:** The optimal duration of systemic treatment to maximise survival and quality of life (QOL) in ovarian cancer following surgery or in the recurrent setting is unclear. In addition maintenance therapy is not universally recommended in published guidelines. We performed a systematic review and meta-analysis of published randomized controlled trials (RCT) comparing longer versus shorter durations of systemic treatment as well as maintenance regimens. **Methods:** We searched MEDLINE, EMBASE, and CENTRAL to December 2013 for RCTs comparing (1) duration - a defined number of cycles of treatment versus a higher number of cycles of the same treatment and (2) maintenance - initial treatment versus the same initial therapy followed by additional cycles of a different treatment. The primary outcome was overall survival (OS). Secondary outcomes included progression-free survival (PFS), adverse events (AE) and QOL. Hazard ratios (HR), confidence intervals (CI) and p-values (p) were estimated with a fixed-effects or random-effects model based on the heterogeneity of included studies using Revman 5.2.3. **Results:** We included 22 eligible trials (6 assessing duration, 16 assessing maintenance treatment) including 7,609 patients. Longer duration of chemotherapy prolonged PFS significantly (HR 0.77, 95% CI 0.66 to 0.90, p = 0.001) but not OS (HR 0.95, 95% CI 0.81 to 1.12, p = 0.54). Maintenance therapy did not prolong PFS (HR 0.91, 95% CI 0.81 to 1.02, p= 0.11) or OS (HR 0.94, 95% CI 0.87 to 1.02, p = 0.15). However, subgroup analysis showed that the effect of maintenance therapy on PFS was greater in the recurrent cancer setting (HR 0.57 vs. 0.96, p value for interaction = 0.02). Effects of maintenance therapy on PFS were similar with the use of chemotherapy or targeted therapy (HR 0.96 vs. 0.84, p = 0.31). The AEs were more frequent with both longer durations of therapy and during maintenance therapy. QOL was assessed in only 5 trials with inconsistent results. **Conclusions:** A longer duration of therapy in ovarian cancer significantly increased PFS but not OS at the cost of increased AEs. Maintenance therapy improved PFS in the recurrent cancer setting. Future studies of extended and maintenance therapy should focus on QOL as well as survival.

**5550 General Poster Session (Board #332), Sat, 8:00 AM-11:45 AM**

**Protein network mapping of glucose metabolism in ovarian cancer.** *Presenting Author: Maria Isabella Sereni, George Mason University, Manassas, VA*

**Background:** Epithelial ovarian carcinoma (EOC) is the fifth leading cause of tumor related death in the female population, with a 5-year survival after diagnosis of only 30% of patients in case of an advanced disease. The aim of the study was to perform broad-scale drug target activation analysis of EOC to determine if the drug target activation architecture was different in early vs late stage EOC tumors, and if so then to identify new druggable targets for personalized therapy in the context of early vs late stage/advanced disease. **Methods:** 72 ovarian primary lesions collected from chemo-naïve EOC patients were analyzed. Highly enriched tumor epithelial cells were isolated by laser capture microdissection, lysed and subjected to reverse phase protein microarray analysis for multiplexed protein pathway activation mapping. The activation/phosphorylation level of 157 key signaling proteins involved in tumorigenesis and metastatic colonization was analyzed. Based on the FIGO staging at diagnosis, the patients were segregated into early stages (stage I-IIB, 15 patients) and advanced stages (stage IIC-IV, 57 patients). Wilcoxon rank-sum test was used to detect significant differences between the two groups in the drug target activation profile. **Results:** Activation of canonical AKT/mTOR and AMPK/ACC signaling pathway architecture (i.e.. AMPKalpha1 (S485), AMPKbeta1 (S108), ACC (S79), LKB1 (S428), AKT (S473), AKT (T308), mTOR (S2448); p=0.0007, p=0.0043, p<0.0001, p=0.0473, p=0.0031, p=0.0068, and p=0.0415 respectively) were found to be significantly higher in early stage tumors compared to advanced stage disease. **Conclusions:** Functional drug target activation mapping uncovered a systemic alteration of drug targets known to play a critical importance in the metabolic rate of tumors. Activation of AMPK-ACC signaling as well as AKT/mTOR networks in early stage EOC may be the result of the central role for pro-survival signaling activation and a compensatory hyperactivation of AMPK pathway in response to the Warburg effect and mTOR activation. These results, confirmed in an independent study set, suggest that the utilization of drugs targeting AMPK, such as metformin, could be very useful in advanced ovarian cancer.

**5551 General Poster Session (Board #333), Sat, 8:00 AM-11:45 AM**

**Trabectedin plus pegylated liposomal doxorubicin (PLD) prior to subsequent platinum chemotherapy in patients with platinum-resistant (PR) recurrent ovarian cancer (ROC): Results from OVA-301 follow-up.** *Presenting Author: Nicoletta Colombo, MaNGO and University of Milan-Bicocca, Milan, Italy*

**Background:** OVA-301, a randomized phase III study of trabectedin plus PLD (n=337) *vs.* PLD alone (n=335) in patients with ROC demonstrated a statistically longer progression-free survival (PFS) in the combination arm (median PFS: 7.3 *vs.* 5.8 months; HR: 0.79; $p$=0.0190) (Monk, JCO 2010). However, among PR patients PFS (4.0 *vs.* 3.7 months) and overall survival (OS; 14.2 *vs.* 12.4 months) were not statistically different (Monk, EJC 2013). Based on *in vitro* (D'Incalci, AACR 2013) and clinical (Casado, ASCO 2013) data, trabectedin may lead to an increased sensitivity to subsequent platinum even in PR patients. **Methods:** An exploratory analysis of OS, counted from the administration of trabectedin/PLD or PLD until death, was performed in PR patients retreated with third-line platinum after OVA-301. **Results:** Overall, 59 PR patients with a median age of 55 years (range 26-79) were analyzed. Similar proportions of patients in each arm received subsequent platinum (trabectedin/PLD: 27/115, 23.5%; PLD: 32/117, 27.4%). Both in trabectedin/PLD (55.6%) and PLD (68.8%) arm most had serous-papillary histology and a median progression-free interval of 4.5 (range 0.7-6) and 4.2 (range 1.1-5.9) months, respectively. A median of 6 trabectedin/PLD cycles (range 1-20) and 5 PLD cycles (range 1-9) was given. Trabectedin/PLD resulted in a 42% risk reduction of disease progression or death compared with PLD (median PFS: 5.6 vs. 5.0; $p$=0.062). Patients with PR ROC treated with trabectedin/PLD, followed by the subsequent reintroduction of platinum achieved a 38% decrease in the risk of death compared with PLD (median OS: 22.2 vs. 15.50; $p$=0.078). Besides, patients pretreated with trabectedin/PLD who received a platinum salt had a 7.8-months longer median OS than those retreated with a non-platinum regimen (median OS: 22.2 vs. 14.4; $p$=0.055). **Conclusions:** Our results hypothesize that the intercalation with trabectedin/PLD prior to subsequent platinum retreatment may contribute to prolong PFS with apparent sensitization of the PR patients to allow further platinum retreatment which could ultimately lead to longer survival. Clinical trial information: NCT00113607.

**5552 General Poster Session (Board #334), Sat, 8:00 AM-11:45 AM**

**Pertuzumab (P) plus chemotherapy (CT) for platinum-resistant ovarian cancer: Safety run-in results of the PENELOPE trial.** *Presenting Author: Antonio Gonzalez-Martin, GEICO and Medical Oncology Service, Centro Oncológico M. D. Anderson International Spain, Madrid, Spain*

**Background:** In platinum-resistant ovarian cancer, the monoclonal antibody P, which inhibits HER2 heterodimerization, improved PFS when added to gemcitabine in the subgroup of pts with low tumor HER3 mRNA expression [Makhija, 2010]. The 2-part PENELOPE trial (NCT01684878) is prospectively investigating P added to single-agent CT in this population. **Methods:** Part 1 (safety run-in) of PENELOPE evaluated P + either topotecan (TOP) or paclitaxel (PAC). Pts with platinum-refractory or -resistant recurrent ovarian, primary peritoneal, or fallopian tube cancer (progression [PD] during or within 6 mo of completing ≥4 platinum cycles) and low HER3 mRNA expression (concentration ratio ≤2.81 by central qRT-PCR testing on cobas z480) received IV P 840→420 mg q3w + investigator's choice of TOP (1.25 mg/m$^2$ d1–5 q3w; cohort 1) or PAC (80 mg/m$^2$ d1, 8, 15 q3w; cohort 2) until PD or unacceptable toxicity. The primary objective was to assess safety and tolerability. After all pts had received ≥3 cycles, the Independent Data Monitoring Committee (IDMC) assessed safety results to recommend which regimen(s) should be included in Part 2. **Results:** InPart 1, 50 pts were enrolled and treated between Oct 2012 and Jul 2013. At data cut-off (Aug 27, 2013), 8 TOP and 17 PAC pts remained on treatment. **Conclusions:** Both regimens were tolerable. Based on these results, the IDMC had no objection to the trial proceeding to Part 2 (double-blind randomized comparison of CT [TOP, PAC, or gemcitabine] + P or placebo). Clinical trial information: NCT01684878.

**5553 General Poster Session (Board #335), Sat, 8:00 AM-11:45 AM**

**A phase II study of intermittent sorafenib with bevacizumab (B) in B-naive and prior B-exposed epithelial ovarian cancer (EOC) patients.** *Presenting Author: Jung-min Lee, National Cancer Institute, National Institutes of Health, Bethesda, MD*

**Background**: We targeted the VEGF pathway at multiple points combining the VEGFR2/Raf inhibitor sorafenib (S) with bevacizumab (B), an anti-VEGF antibody. Our goals were to define efficacy and explore correlative endpoints for a B+S regimen in B-naïve (B-) or prior B-treated (B+) EOC pts. **Methods:** Eligible pts had recurrent EOC, ECOG PS 0-1, good end organ function, were B- or B+ (progression ≤ 6 mo from last B dose). The primary endpoint was objective response rate (CR+PR). A Simon 2-stage optimal design targeted a 40%, and 20% RR in B- and B+ pts, respectively. All pts received S 200mg bid days 1-5/wk and B 5mg/kg q2wk in 4 wk cycles. Pts were evaluated every 2 cycles using RECISTv1.0, underwent functional imaging, research biopsies, and serial FACT-O quality of life (QoL) studies. Pretreatment plasma cytokine concentrations of IL-6, IL-8, VEGF, and sVEGFR-2 were evaluated. **Results:** 54 EOC pts were enrolled (B- 41; B+ 13; median 49 yrs [27-79]). Median prior treatments exceeded 5. 48 pts (B- 35; B+ 13) were evaluable; 6 were not because of intercurrent illness (5), and withdrawal (1), absent progression prior to the first reassessment. Clinical benefit (CR+PR+SD≥4mo) occurred in 30/35 (86%) B- pts, PR occurred in 9/35 pts (26%; median duration 14mo; 5-22mo), and SD ≥4mo in 21/35 pts (median 6mo; 4-18mo). 7/13 (54%) B+ pts had SD with a median response of 6mo (4-23+mo). Therapy-related gr3/4 events included hypertension (33%), DVT or PE (9%), and renal hemorrhage, perforation, anal fissure, and HFS, 2% each. HFS resulted in S reduction to 200mg qd in 76% of pts at a median of 2 cycles (1-7). Pts experienced improvement in QoL scores. Pretreatment low IL8 (n=52 ITT) was predictive of PFS >4mo ($p<0.0001$; ROC AUC 0.8). Under analysis and to be presented are: pretreatment v. day 3 DCE-MRI and 18FDG-PET scan analysis, and RPPA tumor biopsy proteomics changes pretreatment to wk6. **Conclusions**: S+B yields promising clinical benefit in heavily pretreated B-EOC pts, with manageable toxicity, although did not meet the primary response endpoint. Extensive prospectively planned biomarker and functional imaging studies may yield information to focus therapy to those EOC patients who may best respond. Clinical trial information: NCT00436215.

**5554 General Poster Session (Board #336), Sat, 8:00 AM-11:45 AM**

**Surgical site infection after primary debulking surgery for epithelial ovarian cancer: Predictors and impact on survival.** *Presenting Author: Christine Tran, Mayo Clinic, Rochester, MN*

**Background:** Surgical site infection (SSI) following epithelial ovarian cancer (EOC) primary debulking surgery (PDS) occurs in 10-15% of patients. Perioperative factors associated with SSI as well as the impact of SSI on EOC survival were determined. **Methods:** All EOC cases that underwent PDS between 1/1/03 and 12/31/11 were retrospectively reviewed. SSIs were defined according to the American College of Surgeons National Surgical Quality Improvement Program and limited to the first 30 postoperative days. Bowel leaks were considered organ/space SSIs. Logistic regression models were fit to identify factors associated with SSI. Cox proportional hazards models were utilized to evaluate the association of patient and perioperative characteristics (including SSI as a time-dependent covariate) with overall survival (OS) and disease-free survival (DFS). **Results:** Among 888 cases, 96 (10.8%) developed an SSI: 32 superficial SSI, 2 deep SSI, and 62 organ/space SSI. Factors independently associated with superficial SSI were increasing BMI (OR 1.41 [95% CI, 1.12, 1.76] per 5 kg/m2), increasing operative time (1.24 [1.02, 1.50] per hour), and advanced stage (III/IV) (10.22 [1.37, 76.20]). Factors independently associated with organ/space SSI were history of GERD (2.13 [1.23, 3.71]), surgical complexity (intermediate 3.11 [1.02, 9.49]; high 8.07 [2.60, 25.09]), and residual disease (RD) (measureable ≤1cm 1.77 [0.96, 3.27]; >1cm (3.36 [1.48, 7.61]). Occurrence of superficial (HR 1.69 [1.12, 2.57]) or organ/space (HR 1.46 [1.07, 2.00]) SSI was independently associated with worse OS in a multivariable model adjusted for the following factors ($p<0.05$): age, ECOG performance status, ASA level, FIGO stage, ascites, RD, and histology. SSI occurrence did not independently influence DFS. History of stroke, ascites, and increasing RD and stage were associated with worse DFS. **Conclusions:** Development of SSI after PDS worsens OS. Most risk factors for SSI are not modifiable. Alternative measures to lower rates of superficial and organ/space SSI are needed as reduction of SSI may improve OS. Preoperative identification of SSI risk factors may also assist in risk assessment and operative decision making.

**5555 General Poster Session (Board #337), Sat, 8:00 AM-11:45 AM**

**Phase I/Ib clinical and immunologic assessment of immunotherapeutic vaccine, DPX-Survivac in women with ovarian, Fallopian tube, or peritoneal cancer (OC).** *Presenting Author: Michelle Wilson, Department of Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Survivin plays a key role in apoptosis, proliferation and angiogenesis. It is overexpressed in 90% of epithelial OC making it an attractive target. Increases in expression have been correlated with progression and drug resistance. DPX-Survivac is a vaccine containing a mix of survivin HLA class I peptides designed to evoke a cytotoxic T cell response against survivin. This Phase I/Ib de-escalation study reports the safety and immune potency of DPX-Survivac in combination with metronomic low dose oral cyclophosphamide (CPA) in OC. **Methods:** 30 Stage IIc-IV advanced or recurrent OC patients (pts) with no evidence of disease progression post chemotherapy were enrolled. Dose limiting toxicities (DLT) were defined as ≥gd3 AEs, ≥gd2 allergic or autoimmune reactions by CTCAE v4.03. Immune correlates (MDSCs; T regs; B cells) and vaccine induced T cell immunity (ELISpot; tetramer analysis; multi-parametric intracellular cytokine staining) were assessed in purified PBMC and blood. Clinical response was evaluated by RECIST and CA125. **Results:** No significant systemic AEs were seen. The most severe local injection site reactions were gd 3 skin ulcerations with 2 in cohort C. Phase Ib cohorts were de-escalated to 2 priming doses (0.25ml) 3 wks apart followed by boosters (0.1ml) every 8 wks with CPA. Immune response increased with dose (B vs. C p=0.013) and with use of CPA (A vs. C p=0.015). Despite de-escalation 6/6 pts in cohort 1 mounted a significant immune response by d77 with 1 gd 3 skin ulceration seen. In this cohort a PR by RECIST1.1 and GCIG CA125 criteria was confirmed in 1 pt with residual disease post platinum therapy and persisted on stopping vaccine and CPA. The PR correlated with a robust immune response verified by IFN-γ ELISpot and MHC tetramer assay. **Conclusions:** DPX-Survivac is well tolerated with proven immunogenicity. Early evidence of clinical activity is promising. A randomized phase II trial to assess vaccine efficacy in OC will commence in 2014. Clinical trial information: NCT01416038.

**5556^ General Poster Session (Board #338), Sat, 8:00 AM-11:45 AM**

**Independent review of AGO-OVAR 12, a GCIG/ENGOT-Intergroup phase III trial of nintedanib (N) in first-line therapy for ovarian cancer (OC).** *Presenting Author: Gunnar Kristensen, NSGO and Department of gynecologic oncology and medical informatics, Norwegian Radium Hospital, Oslo University Hospital, Oslo, Norway*

**Background:** N is an oral inhibitor of VEGFR, PDGFR, and FGFR. As reported earlier, in the AGO-OVAR12 trial, N compared to placebo (Pl), added to standard chemotherapy, significantly prolonged investigator (inv)-determined PFS (1° endpoint [EP]) in first-line OC. Here we report independent review committee (IRC)-determined PFS. **Methods:** IRC-PFS was predefined as sensitivity analysis to the 1° EP (database lock triggered by inv-PFS events). IRC-PFS was analyzed in the intent-to-treat population (n=1366), based on RECIST 1.1 and restrictive predefined clinical (clin) criteria. Debulking surgery details were provided to the IRC radiologist to support assessment of baseline (BL) tumor burden, and additional clin data to the IRC oncologist for a final integrative review. **Results:** Adherence to prescheduled imaging within 4 weeks of the prescribed date was high (>75%); independent review was completed for 94% of patients (pts). The IRC identified 4.3% of pts without tumor lesions at BL compared to 31.5% in on-site imaging; and 50.7% were stratified as free of residual tumor (integrating also surgery information) at randomization. Event concordance between IRC- and inv-PFS was very high (85.8%). Low discordance overall was primarily due to 19.5% (N) and 16.5% (Pl) of inv-determined PFS events (n=752 events) not detected by IRC, IRC detected an event in 9.2% (N) and 8.5% (Pl) of patients without inv-determined event (IRC total n=668 events). Concordance for event date was high, 75% of dates differed by <4 weeks. IRC-PFS was similar to inv-PFS (IRC: HR 0.86 [0.74-1.01], mPFS N=19.5 mo vs Pl=16.8 mo; inv: HR 0.84 [0.72-0.98], mPFS N=17.2 mo vs Pl=16.6 mo). Outcome of post hoc defined subgroup analysis (risk groups by stage and tumor burden) were also similar ('low-risk', IRC: HR 0.77 [0.62-0.96], mPFS N=27.8 mo vs Pl=21.9 mo; inv: HR 0.74 [0.61-0.91], mPFS N=27.1 mo vs Pl=20.8 mo). **Conclusions:** IRC-PFS (sensitivity analysis of 1° was highly concordant with inv-PFS regarding PFS events, event dates, and overall outcome. Consistency of BL tumor assessment by the IRC, site-radiologists and clinical inv was low, possibly affecting individual PFS assessment but not overall HR. Clinical trial information: NCT01015118.

**5557 General Poster Session (Board #339), Sat, 8:00 AM-11:45 AM**

**Inhibition of MEK1 increases carboplatin sensitivity in ovarian cancer.** *Presenting Author: Balazs Gyorffy, Ist Department of Pediatrics, Semmelweis University, Budapest, Hungary*

**Background:** Primary systemic treatments for ovarian cancer are paclitaxel and carboplatin chemotherapy. Platinum resistant cancers progress/recur in approximately 25% of cases within six months. We aimed to identify clinically useful biomarkers of platinum resistance. **Methods:** A database of ovarian cancer transcriptomic datasets including treatment and response data was set up by mining the GEO and TCGA repositories. Receiver operator characteristics (ROC) analysis was performed in R for each gene and these were then ranked using their achieved area under the curve (AUC) values. The most significant candidates were selected and *in vitro*functionally evaluated using RNA interference, qRT-PCR, MTT tests and FACS in four epithelial ovarian cancer cell lines (SKOV-3-, CAOV-3, ES-2, OVCAR-3). We collected 94 tumor samples and the strongest candidate was validated by IHC and qRT-PCR in these. **Results:** All together 1,152 eligible patients were identified, the median relapse-free survival was 24.8 months with 731 progressions. Based on the ROC analysis the eight most significant genes were *JRK, CNOT8, RTF1, CCT3, NFAT2CIP, MEK1, FUBP1* and *CSDE1*. The silencing of *MEK1, CSDE1, CNOT8, RTF1* and *FUBP1*, and the pharmacological inhibition of MEK1caused significant sensitization in the cell lines. Of the eight genes, *JRK* (p=3.2E-05), *MEK1* (p=0.0078), *FUBP1* (p=0.014), *CNOT8* (p=0.00022) also correlated to progression free survival. The correlation between the best biomarker candidate *MEK1* and survival was validated in two independent cohorts by qRT-PCR (n=35, HR=5.8, p=0.003) and IHC (n=59, HR=4.3, p=0.033). **Conclusions:** We identified *MEK1* as a promising biomarker candidate of response to platinum based chemotherapy in ovarian cancer.

**5558 General Poster Session (Board #340), Sat, 8:00 AM-11:45 AM**

**Ketoconazole as inhibitor of the enzyme CYP17 in locally advanced or disseminated granulosa cell tumors of the ovary (the GreKo I study) (gethi 11-03).** *Presenting Author: Laia Garrigos, Medical Oncology, Hospital del Mar, Barcelona, Spain*

**Background:** Granulosa-cell tumors (GCTs) of the ovary are a rare entity characterized by its genomic stability, presenting a punctual mutation at the FOXL2 gene, 402C→G (C134W), in the vast majority of cases. The protein encoded by this gene directly interacts with the Steroidogenic Factor-1 (SF-1) that regulates the expression of the enzyme CYP17. Since CYP17 inhibition has shown major activity in some cancers, we aimed to test the role of ketoconazole in GCT in a proof of concept trial. **Methods:** An open-label phase II trial was designed. Main inclusion criteria was adult women with advanced non-resectable GCT. Primary objective was radiological response, centrally assessed. Taking as a basis the two-stage Gehan model, 17 patients would need to be included in the first stage to demonstrate a treatment efficacy of at least 15% (type I error $\alpha = 0.05$, power of the test $(1 - \beta) = 0.8$). Treatment consisted on oral Ketoconazole 400 mg tid plus hydrocortisone 30 mg in morning and 20 mg in evening. 10 institutions, members of the Grupo Español de Tumores e Histologías Infrecuentes (GETHI) were involved. **Results:** From October 1st 2012 to January 31st 2014 seven patients were included. Recruitment was early finished due to ketoconazole shortage. Median age was 59.5 (range 44 to 63). All patients had 3 to 4 metastatic localizations and had received at least one prior treatment. With a median follow up of 4.6 months (range 2 to 11 months) all cases achieved tumor stabilization as best response. Only one patient has finally progressed thus, median Progression Free Survival (PFS) has not been reached. No grade >2 toxicity has been reported. A preplanned analysis of FOXL2 showed that the case that progressed did not present the pathognomonic mutation 402C→G (C134W) supporting partially the rationale of the study. Mature data with a follow up of 6 months for all cases and complete mutational analysis will be presented at the meeting. **Conclusions:** CYP17 inhibition seems to be a useful strategy in GCT. These results have prompted a second study (GREKO II) that will assess the role of orteronel, a new generation CYP17 inhibitor, in GCT. Clinical trial information: NCT01584297.

**5559 General Poster Session (Board #341), Sat, 8:00 AM-11:45 AM**

**Comparison of recurrent and nonrecurrent ovarian and uterine cancer patients undergoing adjuvant folate receptor vaccine therapy.** *Presenting Author: Erika J Schneble, San Antonio Military Medical Center, San Antonio, TX*

**Background:** Folate Receptor Alpha (FRa) (aka Folate Binding protein (FBP)) is an immunogenic protein that is over-expressed in breast, lung, endometrial (EC) and ovarian cancers (OC). In fact, FRa expression in malignant cells is 20-fold higher compared to normal cells. We are conducting a phase 1 clinical trial with E39, an HLA-A2 restricted, FRa peptide + GM-CSF vaccine, administered in the adjuvant setting to prevent recurrences in high-risk EC and OC patients (pts) rendered clinically disease-free after standard-of-care therapy. In this analysis, we compare *in vivo* immunologic responses (IR) and disease features between vaccinated recurrent (vR) and vaccinated non-recurrent (vNR) pts. **Methods:** HLA-A2+ pts enrolled into the vaccine group received 6 monthly intradermal inoculations of E39+250 mcg GM-CSF during the primary vaccine series (PVS). *In vivo* IR was assessed by both local reaction (LR) after each inoculation (R1-R5) and delayed hypersensitivity (DTH) reaction measured pre-vaccination (DTH1) and post-PVS (DTH2). The LR index is calculated by dividing LR at each time point by the corresponding LR at R0. **Results:** Overall, 30 pts have been enrolled. Of 14 control pts, 7 (50%) have recurred. Of 16 vaccinated pts, 4 (25%) have recurred after completing the PVS and 2 (12.5%) recurred prior to completing the PVS. One vaccinated pt withdrew due to an intercurrent illness leaving 6 vR and 9 vNR pts for analysis. vR were younger than vNR (60.4 v 65.6, p=0.14) although no significant differences in age, grade, stage, or nodal status existed between groups (all p>0.05). LR index was lower in vR pts at every time point (R1: 1.5 v 3.4, R2: 2.0 v 4.8, R3: 1.9 v 5.5, R4: 1.8 v 4.1, R5: 2.1 v 4.7). vR also displayed lower DTH1 (9.7mm±3.5 v 12.6mm±2.6, p=0.5) and DTH2 (14.4mm±11.4 v 7.4mm±4.8, p=0.78). **Conclusions:** Comparison between vR and vNR pts demonstrates recurrences are likely related to trends in both disease features (age but not stage) as well as diminished response to the vaccine as seen by LR and DTH. As decreased vaccine response may be related to more aggressive disease, the most viable way to address this is to vaccinate less advanced disease. Clinical trial information: NCT01580696.

**5560 General Poster Session (Board #342), Sat, 8:00 AM-11:45 AM**

**What factors influence advanced ovarian cancer patient (AOC pt) outcomes to phase I trial treatments?** *Presenting Author: Timothy Anthony Yap, The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, London, United Kingdom*

**Background:** Relapse to approved anticancer treatments is almost inevitable in AOC pt. Novel agents in phase I trials may benefit such pt. **Methods:** Retrospective study of pt records 6/1998-10/2010 from AOC pt allocated to Phase I trials including efficacy expansion phases of novel therapies in the Drug Development Unit at Royal Marsden Hospital (RMH). **Results:** 200 AOC pt were allocated to ≥1 trial each (281 allocations). 187 (94%) ECOG PS 0-1; 10 (5%) PS 2-3; 3 (1%) unknown. 51 (24%) platinum (pl) sensitive; 145 (67%) pl resistant; 20 (9%) unknown. 53 (27%) *BRCA* mutant, 9 (4%) *BRCA* wildtype and 138 (69%) unknown. 135 (68%) pt started ≥1 trial (mean 1.4 [1-8]; total 216 trials); 63 (32%) pt did not start due to progressive disease (PD). Median time from allocation to start of trial was 23 days. There were 43 (20%) RECIST complete/partial responses (CR/PR), including CR/PR with PARP inhibitors (18/79 [23%]), antiangiogenics (9/65 [14%]) and pl/taxane chemotherapy combinations (14/43 [33%]). Factors associated with CR/PR versus (v) those who did not start trial due to PD were: fewer prior treatments (mean 3 [1-6] v 4.3 [1-9]; p=0.02), pl sensitive v resistant (<0.001), CR/PR v PD with previous therapy (p<0.0001), better ECOG PS at allocation (mean 0.6 v 0.9; p=0.02), fewer metastatic sites (1.7 v 2.1; p=0.04), higher albumin (38 v 32g/L; p<0.0001) and hemoglobin (12.8 v 11.6g/dL; p<0.0001) levels, lower white cell counts (6.2 v 7.2; p=0.02) and baseline CA125 levels (1049 v 3649; p=0.02), *BRCA* mutation (p<0.0001), and better RMH-Prognostic Score (0.56 v 1.34; p<0.0001). Mean trial duration was 163 days (10-1483 days). Mean survival was 902 days for CR/PR pt v 117 days for pt who did not start treatment due to PD (p<0.0001). Treatments were well tolerated; of 385 adverse events, 351 (91%) Grade (G) 1/2; 34 (9%) G3/4. A substantial proportion of AOC pt (134/200 [67%]) received ≥1 (mean 1.3 [1-8]) subsequent lines of therapy after Phase I trials. **Conclusions:** Phase I trial treatments provided pt benefit in AOC although 32% of pt allocated to such trials failed to start treatment due to PD. These data suggest that phase I trial referrals should be considered earlier in AOC treatment pathways, particularly with the emergence of promising novel agents.

**5561 General Poster Session (Board #343), Sat, 8:00 AM-11:45 AM**

**Prognostic significance of urinary neopterin in ovarian cancer a study of the Austrian Gynecologic Oncology Group.** *Presenting Author: Christian Marth, Medical University of Innsbruck, Innsbruck, Austria*

**Background:** Neopterin is produced by activated macrophages upon stimulation with interferon-gamma (IFN-g) and thus elevated concentrations in patients indicate cellular immune response. Most studies in patients with malignant diseases found an association between higher neopterin concentrations with reduced survival and impaired prognosis, although it is not a classical tumor marker since it is not produced by cancer cells. **Methods:** In a study of the Austrian Gynecologic Oncology Group in 114 patients with cystadenomas and 17 patients with borderline ovarian tumors as well as 223 invasive ovarian cancer patients urinary neopterin was determined before and after primary therapy. **Results:** Elevated levels (cutoff 250 $\mu$mol/mol creatinine) were found less frequently in women with benign ovarian cystadenomas (24%) and borderline tumors (29%) compared to patients with malignant disease. We observed stage dependency with 16%, 25%, 65% and 91% in FIGO stage I-IV, respectively. By univariate analysis residual tumor, FIGO stage, age, histological type, and neopterin was significantly associated with overall and progression-free survival (OS and PFS). Median OS was 81 versus 24 months for patients with normal and elevated neopterin, median PFS was 52 and 12 months respectively ($p<.001$ for both). In a multivariate Cox regression analysis, residual tumor, neopterin and age were independently associated with OS, while only residual tumor was predictive for PFS. Thirty patients with surgically staged FIGO I or II invasive ovarian cancer were analyzed separately. Two of three patients with elevated levels died of disease in contrast to 2/27 deaths in women with normal neopterin ($p=.004$, Fisher's exact test). **Conclusions:** In ovarian cancer the negative impact of pretreatment urinary neopterin indicates a detrimental role of immune activation for the course of the disease.

**5562 General Poster Session (Board #344), Sat, 8:00 AM-11:45 AM**

**Surgical staging and its prognostic impact on patients with borderline ovarian tumors (BOT): A subanalysis of the Arbeitsgemeinschaft Gynaekologische Onkologie (AGO) ROBOT study.** *Presenting Author: Fabian Trillsch, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

**Background:** Incomplete surgical staging was shown to be a negative prognostic factor for patients with borderline ovarian tumors (BOT). However, little is known about the prognostic impact of each individual staging procedure. **Methods:** Clinical parameters of 950 patients with BOT (confirmed by central reference pathology) treated between 1998 and 2008 in 24 German AGO centers were analyzed. Staging quality was evaluated following German guidelines. In patients with adequate surgery regarding their reproductive organs (bilateral salpingo-oophorectomy or intended fertility preserving surgery in patients $\leq$55 years), other recommended staging procedures (omentectomy, peritoneal biopsies, cytology, and, for mucinous histology, appendectomy) were evaluated applying uni- and multivariate regression models with respect to progression-free survival (PFS), separately for serous and mucinous histology. **Results:** A total of 559 serous BOT (64.1%) were opposed to 268 mucinous BOT (30.7%). For patients with serous histology, each additionally skipped staging procedure raised the risk for recurrence by at least 25% (HR 1.25; 1.95; 2.37 respectively) becoming statistically significant in case of two or more missing steps. The most crucial procedures were omentectomy in serous and appendectomy in mucinous BOT with HR of 2.00 ($p=0.004$) and HR of 4.86 ($p=0.012$) in univariate analyses. Together with established prognostic factors as FIGO stage, tumor residuals, and fertility preservation, omentectomy (HR 1.91; 95%CI 1.15, 3.19; $p=0.01$) retained a statistically significant impact on PFS in multivariate analysis for serous BOT as did appendectomy in case of mucinous histology (HR 4.60; 95%CI 1.33, 15.86; $p=0.02$). **Conclusions:** Individual surgical staging procedures appear to have prognostic importance for BOT patients. Despite excellent overall prognosis, the risk for recurrence rises with each skipped surgical step. This should be considered when re-staging procedures following incomplete primary surgery are discussed.

**5563 General Poster Session (Board #345), Sat, 8:00 AM-11:45 AM**

**Genome-wide association study for identification of candidate SNPs associated with carboplatin and paclitaxel clearance in ovarian cancer patients.** *Presenting Author: Bo Gao, Blacktown Hospital, Sydney, Australia*

**Background:** Epithelial ovarian cancer (EOC) is generally treated by cytoreductive surgery and carboplatin/paclitaxel chemotherapy. Five-year survival is ~20% for patients with advanced disease. There is wide inter-individual variation in chemotherapy pharmacokinetics (PK), response and toxicity. Identifying single nucleotide polymorphisms (SNPs) that influence chemotherapy disposition may help optimize treatment. **Methods:** Carboplatin and paclitaxel concentrations were collected during cycle one (N=61) and three (N=7) of chemotherapy on 61 prospectively recruited Australian women with EOC. Paclitaxel concentrations were also obtained on 38 Dutch patients for meta-analysis. A genome wide association study (GWAS) was performed in all patients using Illumina OmniExpress arrays (719,665 SNPs). PK parameters were obtained using nonlinear mixed-effect modelling (NONMEM). Covariates associated with carboplatin and paclitaxel PK parameters were identified and for each SNP, both unadjusted and adjusted analysis were performed to test associations with carboplatin clearance (CL) and time of paclitaxel concentration $>$ 0.05 $\mu$mol/L ($T_{c>0.05}$). **Results:** There was a 5- and 4-fold inter-individual variation in carboplatin and paclitaxel CL respectively, with little intra-individual variation. Carboplatin CL correlated with relative thrombocytopenia ($p$ = 0.018) , whereas paclitaxel $T_{c>0.05}$ predicted relative neutropenia ($p$ = 0.002). In the GWAS, SNPs in *ABCC2* were associated with carboplatin CL ($p = 10^{-6}$), and a novel SNP in chromosome 1 (rs17130142) was associated with paclitaxel $T_{c>0.05}$ with genome wide significance ($p = 2.0 \times 10^{-9}$). **Conclusions:** Our GWAS approach identified SNPs associated with carboplatin and paclitaxel PK parameters. In the case of carboplatin, SNPs were identified in the ABCC2 gene, which encodes a known carboplatin transporter, indicating biological plausibility. These findings support a GWAS approach as an effective strategy for identification of novel pharmacogenomic markers. Validation of these candidates in further studies may provide novel biomarkers for EOC treatment optimisation.

**5564 General Poster Session (Board #346), Sat, 8:00 AM-11:45 AM**

**A phase II trial on the combination of bevacizumab and irinotecan in recurrent ovarian cancer.** *Presenting Author: Huichung Tina Ling, The Permanente Medical Group, Hayward, CA*

**Background**: Irinotecan and bevacizumab have single agent activity in both platinum sensitive and resistant recurrent ovarian cancer. We sought to evaluate the efficacy and safety of the combination in this setting. The primary endpoint is to estimate the progression free survival (PFS) at 6 months. Secondary objectives include overall survival (OS), observed response rate (ORR), duration of response, and toxicity. **Methods**: Ovarian cancer patients with recurrence after any number of prior regimens were eligible. Irinotecan 250 mg/m2 (amended to 175 mg/m2 after treatment-related toxicities in the first 6 patients) and bevacizumab 15 mg/kg were administered every 3 weeks until disease progression or toxicity. Response was assessed by RECIST every 2 cycles and by CA-125 criteria for those without measurable disease. **Results**: Of the 29 patients enrolled, 10 were platinum-sensitive and 19 were platinum-resistant. The median number of prior regimens was 5 (range 1-12): 13 patients had prior bevacizumab and 11 patients prior topotecan. The median number of study cycles given was 7 (range 1-34); 5 patients withdrew after 1 cycle (3 due to toxicity). Of the 24 patients assessable for response, 8 patients experienced partial response (PR), 13 maintained stable disease (SD), and 3 had progressive disease; 12 patients with PR/SD were platinum resistant. The ORR was 27.6% (95% CI: 0.127-0.472) and the clinical benefit rate was 72.4% (95% CI: 0.565-0.873) for the intention-to-treat population (n=29). Twelve patients had longer than 6 months of sustained response. Median PFS was 8.1 months (95% CI: 5.1-12.3 months); median OS was 15.9 months (95% CI: 13.4 months- upper bound not reached). The PFS rate at 6 months was 55.2% (95% CI: 0.397-0.766). The most common grade 3/4 toxicities included diarrhea (5 pts), neutropenia (3), hypertension (3), proteinuria (2), fatigue (2), nausea (2), abdominal pain (2), and GI perforation (1). No treatment-related deaths were observed. **Conclusions**: The combination of irinotecan and bevacizumab showed encouraging activity in heavily-pretreated patients with recurrent ovarian cancer. The median PFS of 8.1 months is comparable to other bevacizumab-containing doublets reported in the AURELIA trial. Clinical trial information: NCT01091259.

**5565 General Poster Session (Board #347), Sat, 8:00 AM-11:45 AM**

**Temsirolimus in women with platinum-resistant ovarian cancer or advanced/recurrent endometrial cancer: A multicenter phase II trial of the AGO Study Group (AGO-GYN 8).** *Presenting Author: Guenter Emons, Department of Obstetrics and Gynecology, University of Goettingen, Goettingen, Germany*

**Background:** Inhibition of mTOR with temsirolimus (T) might be an efficacious treatment of patients with epithelial ovarian cancer (OC) or endometrial cancer (EC). **Methods:** Patients (pts) with platinum and taxane resistant OC (n = 22) or with advanced/recurrent EC, who had not received previous chemotherapy (n = 22) were treated with weekly IV infusions of T (25 mg). Primary endpoint was progression free survival after 4 months (OC) or 6 months (EC). A two stage design was used with second stage of accrual if < 10 of the first 22 pts (OC) or < 7 of the first 22 pts (EC) had progressive disease after the first 8 weeks of T-treatment. **Results:** 22 pts each were treated in the OC and the EC cohort respectively. Median age was 56 years (OC) or 63 years (EC). After 8 weeks of treatment with T, 10 pts in the OC cohort and 7 pts in the EC group had progressive disease. Toxicity of T was mild: grade 4: 1 ileus (OC), grade 3: anemia 1, abdominal pain 1, ALT elevation 1, ascites 3 (OC), diarrhea 1, vomiting 2. **Conclusions:** T-treatment was well tolerated in our patients. It did, however, not meet the predefined efficacy criteria with 10 of 22 pts (OC) and 7 of 22 pts (EC) having progressive disease after 8 weeks of treatment. Clinical trial information: EudraCT Nr. 2011-000299-33.

**5566 General Poster Session (Board #348), Sat, 8:00 AM-11:45 AM**

**Weekly administration of bevacizumab, eribulin, and oxalilplatin in patients with platinum-resistant and refractory ovarian carcinomas: A phase II study.** *Presenting Author: Yuji Ikeda, The University of Tokyo, Hongo, Japan*

**Background:** Eribulin, inhibiting a protein component of tubulin, is a candidate for paclitaxel-refractory breast cancers, and Bevacizumab (B) is known to enhance efficacy of anti-cancer agents in ovarian cancers. A phase II study to evaluate weekly administration of B with eribulin and oxaliplatin (EriOX) in patients with platinum-resistant and refractory ovarian carcinomas (PR-ROC) was performed. **Methods:** Simon's two-stage design was used. In the first stage, 15 patients were accrued. If there were no responder in these patients, the study would be stopped. Otherwise, eight additional patients will be accrued for a total of 23. If three or more responder were observed in 23 patients, this design yields a type I error rate of 0.03 and power of 0.80 when the true response rate were 18%. Patients with PR-ROC were treated with weekly-B-EriOX consisting of B (2mg/kg), eribulin (1mg/m2) and oxaliplatin (30mg/m2). **Results:** Among 15 patients in the first stage, four responses were observed, and a total of 23 patients were analyzed in this study. There were no cases that discontinued the therapy due to toxicities. Median age of the patient was 58 years (range:38-71). Median number of previous regimen was 4 (range:2-8). Two patients (9%) had a complete response (CR), 3 patients (13%) had a partial remission (PR) and 9 patients (39%) had a stable disease (SD). The response rate and clinical benefit rate (CR+PR+SD) were 17% and 56%, respectively. Median progression-free survival was 3 months (range: 1-8+). Hematological adverse effects (AE) with grade 3/4 were observed in 4 patients (17%). Hypo albuminemia and edema with grade 3 were in 1 patient (8%), respectively. However, all AE were manageable and tolerable. **Conclusions:** Weekly B and EriOX administration had significant activity with mild AE in patients with PR-ROC. These results warrant further prospective study.

**5567 General Poster Session (Board #349), Sat, 8:00 AM-11:45 AM**

**Microscopic residual carcinoma at interval debulking surgery after neoadjuvant chemotherapy in patients with IIIc/IV Müllerian carcinoma.** *Presenting Author: Kyoko Nishikimi, Departments of Reproductive Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan*

**Background:** Neoadjuvant chemotherapy (NAC) followed by interval debulking surgery (IDS) is a treatment option in patients with bulky stage IIIC/IV müllerian carcinoma. Because disseminated tumors may have disappeared macroscopically following chemotherapy, a potential drawback of IDS is difficulty deciding which sites should be excised. We therefore evaluate microscopic residual carcinoma after NAC in each previously disseminated site. **Methods:** Fifty patients with stage IIIc /IV müllerian carcinoma with a poor general condition, or those with a widely metastatic tumor and extensive ascites who had an unresectable residual tumor at the time of initial laparotomy, were included in the study. At the time of the initial laparotomy, we performed either a salpingo-oophorectomy or biopsy only, and then marked the residual tumors >1 cm with silk sutures. We then recorded the site and size of the tumors and placed an implantable port system (IPS) in the pelvis for peritoneal washing cytology during NAC (platinum/taxane). IDS was performed after the patients were shown to be IPS-cytology negative. At the time of IDS, we excised the initially marked site even if the tumors were macroscopically negative, and then investigated whether or not microscopic residual carcinoma was present in each disseminated site. **Results:** Forty-one patients (38 high-grade serous carcinomas, 3 other histological types) underwent IDS (39 complete resection, 2 with residual tumor <1 cm). Microscopic examination revealed residual carcinoma in each site as follows: 82% (28/ 34) in the recto-uterine pouch/rectosigmoid colon, 71% (5/7) in the ileocecal area, 69% (20/29) in the paracolic gutters, 65%(15/23) in the small intestine and mesentery, 63% (5/8) in the transverse mesocolon, 57% (20/35) in the vesicouterine pouch, 53% (19/36) in the right diaphragm, 53% (18/34) in the lymph nodes, 50% (3/6) in the hepatic capsule, 44% (8/18) in the splenic capsule, and 40% (6/15) in the left diaphragm. **Conclusions:** Our results suggest that it is necessary to excise all sites during IDS after NAC in patients with a disseminated tumor >1 cm at the initial exploratory laparotomy, but with negative peritoneal cytology. Clinical trial information: UMIN000013079.

**5568 General Poster Session (Board #350), Sat, 8:00 AM-11:45 AM**

**Phase II study of gemcitabine and vinorebline in patients with persistent or recurrent platinum-resistant ovarian or primary peritoneal cancer: A study of the Korean Cancer Study Group.** *Presenting Author: Sook Hee Hong, Division of Oncology, Department of Internal Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea, Seoul, South Korea*

**Background:** To evaluate the antitumor activity and safety of gemcitabine and vinorelbine in patients with persistent or recurrent platinum-resistant epithelial ovarian or primary peritoneal cancer **Methods:** A phase II trial was conducted by the Korean Cancer Study Group. Patients with cancer that progressed on platinum-based primary chemotherapy or recurred within 6 months were enrolled. One prior chemotherapy regimen for the treatment of persistent or recurren platinum resistant disease was allowed. Vinorelbine at 25mg/m$^2$ followed by gemcitabine 1000mg/m$^2$was administered intravenously on day 1 and 8 every 3weeks . Dose delay and adjustment was permitted for toxicity. Treatment was continued until disease progression or unacceptable adverse effects. **Results:** From December, 2011 to January, 2013, 44 patients were enrolled. A total of 219 cylces (median, four: range one to 24cycles) of vinorelbine and gemcitabine were administered, with fifteen (34.1%) of patients receiving six or more cycles. Two patients (4.5%) had a complete response and seven patients (15.9%) had partial responses, with a median duration response of 9.4 (95% Confidential Interval (CI) 4.6-18.3) months. Nineteen patients (43.18%) had stable disease for a median of 3.6 (95% CI: 2.5-4.4) months. Twelve patients (27.3%) had progressed disease. Four patients (9.0%) were not assessable. Median progression-free survival was 3.4 (95% CI: 2.5-4.2) months, and overall survival was 12.2 months. Grade 3 or 4 neutropenia, the most frequent toxicity occurred in 50% of patients. 4 patients experienced grade 3 febrile neutropenia and one patient experienced grade 4 febrile neutropenia. Non- hematologic toxicities were tolerable. A 25% dose reduction was required for 33patients (75%; 61.8% of cycles). No treatment related death observed. **Conclusions:** Gemcitabine and vinorelbine combination chemotherapy has sufficient activity in the treatment of recurrent platinum-resistant ovarian cancer at the dose and schedule tested to warrant further investigation. Clinical trial information: NCT01196559.

**5569 General Poster Session (Board #351), Sat, 8:00 AM-11:45 AM**

**Evaluation of the hematologic safety of same day versus standard administration of pegfilgrastim in gynecology oncology patients undergoing platinum-based chemotherapy.** *Presenting Author: Caroline C Billingsley, Ohio State University Wexner Medical Center, Columbus, OH*

**Background:** The safety of the timing of pegfilgrastim administration in women with gynecologic malignancies has been questioned. We aimed to assess the safety and efficacy of administration of pegfilgrastim on the same day (D1) as chemotherapy compared to standard administration (24-72 hours after chemotherapy) in patients with gynecologic malignancies. **Methods:** A retrospective review was conducted on gynecologic oncology patients who received pegfilgrastim to mitigate the myelosuppressive consequences of chemotherapy from January 1, 2002 through July 31, 2012. Data collected included demographics, pathology, blood counts, toxicity, chemotherapy regimen and day of pegfilgrastim administration. **Results:** 2071 injections of pegfilgrastim in 421 patients were identified. 506 doses of pegfilgrastim were given on D1 compared to 1565 standard administrations. The most common malignancy was ovarian cancer (79%). Median age was 60 years (23-90). 318 (76%) patients had stage III, IV, or recurrent disease and 83% of patients received their initial dose during their primary chemotherapy regimen. The most common chemotherapy regimen was carboplatin/paclitaxel (42%), followed by carboplatin/docetaxel (11%). The median ANC was 3888 cells/mL (68-57,724). Grade 3/4 neutropenia was observed in 2.6% of the D1 cohort versus 1.8% in the standard cohort (G3: 1.2% vs 1.3%, G4:1.4% vs 0.5%) (adjusted relative risk (aRR) 1.4 (90% CI: 0.8-3.2)). There was one episode of FN per group. Further comparing D1 to standard pegfilgrastim administration, dose modifications occurred in 6.5% and 4.9% (aRR: 1.3 (90% CI: 0.9-1.9), while treatment delays occurred in 7.3% and 9.4%, respectively (aRR: 0.8 (90%CI: 0.6-1.1)). **Conclusions:** The incidence of neutropenia, dose modification, and treatment delays did not differ substantially between patients who had pegfilgrastim administered on D1 compared to standard dosing. Pegfilgrastim can be safely administered on the same day as chemotherapy in patients receiving treatment for gynecologic malignancy. We report on the largest series of pegfilgrastim administration in gynecologic malignancies to date.

**5570 General Poster Session (Board #352), Sat, 8:00 AM-11:45 AM**

**Molecular analysis of non-epithelial ovarian cancer by histologic subtype.** *Presenting Author: Maise Al Bakir, Ovarian Cancer Action Research Centre, Imperial College London, London, United Kingdom*

**Background:** Non-epithelial malignancies of the ovary account for <2%–4% of all ovarian tumors. The classification of non-epithelial ovarian cancer can be broadly divided into two histological subtypes, ovarian germ cell tumors (OGCTs) and ovarian sex cord stromal tumors (OSCSTs). Molecular phenotypes of these groupings may identify genetic susceptibilities to existing therapies and thus improve patient care. **Methods:** 275 non-epithelial ovarian cancers (non-EOC) were profiled by Caris Life Sciences between 2009 and 2013 using a multiplatform approach. Within this cohort, patients could be further grouped according to histopathological subtypes, particularly OGCTs (n=42) and OSCSTs (n=217). Testing of FFPE tissues included a combination of sequencing (Sanger, NGS and pyrosequencing), protein expression (IHC), gene amplification (CISH or FISH), and/or RNA fragment analysis. **Results:** Of interest, the frequency of positive hormone receptor over-expression was higher in OSCSTs than OGCTs(AR 76%v 0%, PR 90% v 12%, ER 12% v 0%). Granulosa Cell tumors (n=173) were particularly strongly expressing for AR (81.7%), PR (95.9%) but not for ER (9.3%), with Alk, APC, and ATM mutations occurring rarely. Sertoli-leydig tumors (n=25) were characterized by high Topo2A (66.7%), TUBB3 (65%), BRAF (14.3%) and kras (20%) mutation, with lower AR (38%) and PR (60%) and higher ER (28%) expression than granulosa cell tumors. OGCT (n=42) cohorts exhibited RRM1 (51%), TLE3 (55%), TOP2A (87%), TUBB3 (51%), PTEN loss (67%) with mutations of P53 (56%) and PI3K (22%) also occurring. Kras mutation was observed in 1 of 9 OGCTs tested. **Conclusions:** Tumor profiling has identified molecular differences between non-EOC histological subtypes, by both expression and NGS mutational approaches in FFPE tissues. Identification of these changes can provide a rationale for treatment options not routinely considered or those associated with targeted therapies and warrant future clinical trials in this cancer type

**5571 General Poster Session (Board #353), Sat, 8:00 AM-11:45 AM**

**Relationship of pharmacokinetics (PK), toxicity, and initial evidence of clinical activity with IMGN853, a folate receptor alpha (FRa) targeting antibody drug conjugate in patients (Pts) with epithelial ovarian cancer (EOC) and other FRa-positive solid tumors.** *Presenting Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

**Background:** IMGN853 is a FR$\alpha$-targeting ADC that comprises a FRa-binding antibody conjugated with the potent maytansinoid tubulin inhibitor, DM4. FRa is highly expressed on many solid tumors, particularly EOC, endometrial, non-small cell lung cancer, and clear cell renal cancer **Methods:** The phase I primary objectives are to determine the maximum tolerated dose and recommended phase 2 dose. The secondary objectives include evaluation of safety, PK, pharmacodynamics and preliminary efficacy. Analysis of PK data and the relationship with ocular toxicity, the dose limiting toxicity at 7.0 mg/kg total body weight (TBW) and initial evidence of clinical activity from patients in this ongoing study is described. **Results:** Thirty pts have been enrolled across 7 dose levels 0.15 to 7.0 mg/kg TBW (IV) every 21 days (Q3W). The occurrence of ocular toxicity was associated with high $C_{max}$ (p=0.0004 Fisher exact test) and high early exposure levels, (area under the curve in the first 24 hours ($AUC_{0\text{-}24}$) (p=0.0001)). Covariate analysis indicated a correlation between weight and $C_{max}$ (Pearson r=0.48, p=0.02). Preliminary evidence of clinical activity (CA125 CGIC response criteria, partial response (PR), SD > 6 cycles) was observed in 10/24 patients receiving doses > 3.3 mg/kg (TBW). There was evidence of a threshold exposure level for activity around $AUC_{0-\infty}$>12,944 (hr ug/ml). In patients with these exposure levels, clinical activity was observed in 5/6 serous or transitional EOC pts and 2/4 endometrial pts. The final clinical activity threshold may vary slightly as additional pts are enrolled. Based on these results, and PK modeling, dosing by adjusted ideal body weight (ADJ) was identified as a means to decrease PK variability due to body weight dependence. The phase I trial has been amended to evaluate this hypothesis. **Conclusions:** Preliminary evidence of anti-tumor activity is encouraging, and results from the PK analysis suggest ADJ dosing should enable more pts to be treated within a clinically relevant therapeutic window. Clinical trial information: IMGN853-0401NCT01609556.

**5572 General Poster Session (Board #354), Sat, 8:00 AM-11:45 AM**

**Impact of neoadjuvant chemotherapy cycles prior to interval surgery in patients with advanced epithelial ovarian cancer.** *Presenting Author: Pierre-Emmanuel Colombo, ICM, Montpellier, France*

**Background:** Complete surgery with no macroscopic residual disease at primary or interval debulking surgery (IDS) is the principal goal of the surgical management of advanced epithelial ovarian cancer (EOC). In the case of neoadjuvant chemotherapy (NAC), IDS is generally recommended after 3 to 4 cycles, but few studies have specifically analyzed this point. The aim of this work was to evaluate the impact on survival of the number of NAC cycles before IDS in a large cohort of EOC patients. **Methods:** Data from patients with advanced EOC (stages IIIC-IV), operated between 1995 and 2010 were consecutively recorded in a prospective database and evaluated retrospectively. Patients treated withNAC/ IDS (group B) were analyzed according to the number of NAC cycles ($\leq 4$ = group B1; $> 4$ = group B2) and compared with patients receiving primary surgery (group A). Patients with complete resection were specifically analyzed in both groups. **Results:** Clinical data of 367 patients with advanced EOC were analyzed. 219 received upfront surgery (group A) and 148 had IDS after NAC (group B). The average follow-up was 82 months. In group B, 38 patients (26%) received more than 4 NAC cycles before IDS (group B2). Patients in group B2 presented more frequently stage IV disease (p=0.015). The rate of complete cytoreduction was higher in group B2 (67%) compared to groups B1 (62%) and A (44%) (p=0.002). Patients in group B2 had worse survival compared to patients in group B1 (p=0.04). Patients with complete surgery at the end of IDS and who had received more than 4 cycles of NAC had poor survival (p<0.001) with a relative risk of death after multivariate analysis of 3 (95% CI : 1.7-5.5]) with an independent impact from stage and performance status. Conclusions*:* Patients with advanced EOC receiving complete IDS after more than 4 cycles of NAC have poor prognosis. Despite worse prognostic factors observed in this group of patients, our study reinforces the concept of early and complete removal of all macroscopic tumors in the therapeutic sequence of EOC. These results call into question the interest of a delayed debulking in advanced cases thought to be unresectable after 3 to 4 cycles of NAC.

**5573 General Poster Session (Board #355), Sat, 8:00 AM-11:45 AM**

**Blocking and randomization to improve molecular biomarker discovery.** *Presenting Author: Li-Xuan Qin, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Randomization and blocking have the potential to prevent the negative impacts of non-biological effects on molecular biomarker discovery. Their use in practice, however, has been scarce. **Methods:** To demonstrate the logistic feasibility and scientific benefits of randomization and blocking, we conducted a microRNA study of endometrial tumors (n=96) and ovarian tumors (n=96) using a blocked randomization design to control for non-biological effects; we profiled the same set of tumors for a second time using no blocking or randomization. We assessed empirical evidence of differential expression in the randomized study and the non-randomized study. We conducted simulation studies to further evaluate the benefits of randomization and blocking on the accuracy of biomarker detection. **Results:** There was moderate and asymmetric differential expression (10%=351/3,523) between endometrial and ovarian tumors in the randomized dataset. Array effects were observed in the non-randomized dataset and 1,934 markers (55%) were called differentially expressed (DE). Among them, 181 were deemed DE (181/351, 53%) and 1,749 non-DE (1,749/1,934, 90%) in the randomized dataset. In the simulation study, when randomization was applied to all samples at once or within each of multiple batches balanced in sample groups, blocking improved the true positive rate (TPR) from 0.95 to 0.97 and the false positive rate (FPR) from to 0.02 to 0.002. When sample batches are unbalanced, randomization within each batch had a worse TPR (0.92) and FPR (0.10) regardless of blocking. Normalization improved the detection of true positive markers often at the price of increased false positive markers. **Conclusions:** Through empirical and simulated studies, we showed that blocking and randomization (across all samples or within balanced batches) can effectively improve the accuracy of detecting disease markers. They should be used to more fully reap the benefits of genomics technologies.

**5574 General Poster Session (Board #356), Sat, 8:00 AM-11:45 AM**

**Genome-wide association study (GWAS) of pazopanib efficacy and safety in patients with ovarian cancer who have not progressed following first-line standard therapy.** *Presenting Author: Giovanni Scambia, Universita Cattolica del Sacro Cuore Policlinico Agostino Gemelli, Rome, Italy*

**Background:** Pazopanib is an oral multi-kinase inhibitor of VEGFR-1, -2, -3, PDGFR-$\alpha$ and -$\beta$ and c-Kit. In the phase III AGO-OVAR16 study (NCT00866697), pazopanib maintenance therapy significantly increased progression free survival (PFS) in patients with ovarian cancer who have not progressed after first line therapy; however such benefit was not observed in a phase II study (NCT01227928) conducted in East Asian countries. In both studies, there is heterogeneity in patient response (safety and efficacy) to pazopanib; we hypothesized that germline genetic variation may contribute to this heterogeneity. **Methods:** GWAS analyses were conducted using combined patient data from the AGO-OVAR16 study (N=477, pazopanib) and the East Asian phase II study (N=73, pazopanib), which had similar eligibility criteria and treatment schedules. In aggregate N=387 patients receiving pazopanib provided consent for pharmacogenetic research. GWAS were conducted using normal, ordinal, and Cox regression models to test 30M genetic variants (genotyped or imputed) for association with PFS, overall survival, CA-125 change, bilirubin elevation, transaminase elevation, blood pressure change, hand foot syndrome, diarrhoea, fatigue, neutropenia, thrombocytopenia, and dose reduction or dose discontinuation. **Results:** At the genome wide significance level ($P \leq 5x10^{-8}$), common variants near *UGT1A1* were associated with bilirubin elevation ($P = 1.1x10^{-21}$), consistent with our previous observations in pazopanib treated patients with renal cell carcinoma. Common variants near a disintegrin and metalloprotease (ADAM) domain family genes *ADAM28–ADAM7* were associated with CA-125 change ($P = 2.9x10^{-10}$). No other common variants reached genome-wide significance. **Conclusions:** Some instances of isolated bilirubin elevation in pazopanib treated patients with ovarian cancer may be benign manifestations of Gilbert's syndrome. We identified a novel association between germline variants in *ADAM28–ADAM7* and CA-125 change; further studies of this finding may yield insights into mechanisms underlying differential response to pazopanib in patients with ovarian cancer.

**5575 General Poster Session (Board #357), Sat, 8:00 AM-11:45 AM**

**Frequency and timing of thoracic tumor spread in 198 consecutive patients with advanced-stage high-grade serous ovarian cancer (HGSC).** *Presenting Author: Atul B Shinagare, Dana-Farber Cancer Center Institute/Brigham and Women's Hospital, Boston, MA*

**Background:** HGSC is the most common type of ovarian cancer. While routinely used, the necessity of chest CT in these patients is unknown. We hypothesize that thoracic metastases in HGSC occur late, after development of abdominal disease. We aimed to describe the frequency and timing of occurrence of thoracic disease in advanced (stage III and IV) HGSC in relation to the abdominal disease. **Methods:** In this IRB-approved, HIPAA-compliant retrospective study, we included 198 consecutive patients with pathologically proven advanced HGSC seen from January 2012 through December 2012 (mean age 60 years, SD±9.5 years; median follow-up 40 months, IQR 25-63). Time to development of abdominal and thoracic disease and survival thereafter was recorded by review of thoracic and abdominal imaging and electronic medical records, and compared using Mann-Whitney test. Predictors of occurrence and time to development of thoracic disease were identified using multivariate analysis. **Results:** Abdominal disease developed in 177 patients (89%) and thoracic disease in 69 (35%). The first site of thoracic disease was visible on the abdominal CT in 51 (74%) patients (pleural effusion, n=27; epiphrenic and/or retrocrural lymph nodes, n=24), and of the remaining 18 (26%) patients with high thoracic disease (mediastinal, supraclavicular or axillary nodes, n=9; lung nodules, n=9) all except one had preexisting abdominal disease. Median time to development of thoracic disease was longer than abdominal disease (24 months, IQR 13-43 vs 13 months, IQR 7-25; p<0.0001) and survival after thoracic disease was shorter than after development of abdominal disease (13 months, IQR 6-28 vs 26 months, IQR 12-45; p=0.0002). Presence of abdominal disease was the only predictor of development of thoracic disease (p=0.0009; OR 12.08, 95%CI 2.36-221.20); time to abdominal disease predicted time to thoracic disease (p=0.003). **Conclusions:** Thoracic disease develops late in the course of advanced HGSC and occurs in patients with preexisting abdominal disease. Presence of abdominal disease is the only predictor of thoracic metastases. Therefore, potential exists for limiting the use of chest CT in patients with advanced HGSC.

**5576 General Poster Session (Board #358), Sat, 8:00 AM-11:45 AM**

**Effect of intraperitoneal chemotherapy on survival for ovarian cancer in clinical practice and frequency of use.** *Presenting Author: Alexi A. Wright, Dana-Farber Cancer Institute, Boston, MA*

**Background:** In 2006 the National Cancer Institute (NCI) issued a rare clinical alert recommending intraperitoneal chemotherapy (IP) to treat ovarian cancer after GOG-172, a randomized clinical trial comparing IP and intravenous chemotherapy (IV), demonstrated a 16-month survival advantage with IP. The aims of this study were to determine: (1) changes in IP utilization over time, (2) factors associated with adoption of IP therapy, and (3) the impact of IP on survival. **Methods:** Prospective cohort study of women with stage III, optimally-cytoreduced ovarian cancer treated at National Comprehensive Cancer Network (NCCN) institutions. Trends were evaluated in 823 patients between 2003-2012. In 603 patients, diagnosed after 2006, multivariable logistic regression and propensity-score analyses were used to examine factors associated with receipt of IP therapy and associations between treatment modality, adverse events, and overall survival. **Results:** IP utilization rose from 0% to 33% between 2003-2006, increased to 50% in 2007-2008, and decreased to 43% during 2009-2012. At treatment initiation 43% of patients received modified IP regimens, 29% received the GOG 172 regimen, and 28% received IP on a clinical trial. In adjusted analyses, younger age, fewer comorbid conditions, and clinical trial enrollment were associated with IP therapy (all P≤0.01). NCCN center was independently associated with receipt of IP; the adjusted proportion of patients receiving IP varied by site between 16% and 71% (P<0.001). After propensity-score weighted adjustment, patients receiving IP were more likely to switch to IV due to toxicity (AOR=2.01, 95% CI=1.30-3.12) compared with IV. Adjusted 5-year overall survival rates were 57% for IP vs. 44% for IV (hazard ratio=0.69, 95% CI=0.50-0.94). **Conclusions:** The use of IP therapy increased significantly over the past decade at NCCN centers. However, recently only a minority of eligible patients have received it. Despite frequent modifications, IP chemotherapy is associated with significantly improved survival in clinical practice. Future studies should examine whether site-specific variations in IP utilization reflect patients' informed treatment preferences.

**5577 General Poster Session (Board #359), Sat, 8:00 AM-11:45 AM**

**Identification of predictive factors of response to the BH3-mimetic molecule ABT-737: An ex vivo experiment in human serous ovarian carcinoma.** *Presenting Author: Stephanie Odile Lheureux, Centre de Lutte Contre le Cancer François Baclesse, Caen, France*

**Background:** Ovarian cancers are addicted to Bcl-$x_L$ and Mcl-1, anti-apoptotic members of the Bcl-2 family. Bcl-$x_L$ can be inhibited by the BH3-mimetic ABT-737. *In vitro*, ABT-737 can induce apoptosis of cancer cells, and its activity is potentiated by Mcl-1 inactivation. **Methods:** Here we assessed the sensitivity of human ovarian tumor nodes to ABT-737 when combined with carboplatin, which can indirectly inhibit Mcl-1. Fresh samples from 25 high-grade serous ovarian cancer (HGSOC) chemo-naïve patients who had undergone surgery were prospectively exposed *ex vivo* to ABT-737 alone or in combination with carboplatin. The treatment effect was studied on sliced tumor nodes by assessment of cleaved-caspase 3 immunostaining. We also studied the association between baseline Bcl-2 family protein expression (immunohistochemistry) and the response of nodes to treatment (NCT01440504). **Results:** ABT-737 induced massive apoptotic cell death as single agent but its efficacy was not improved by the addition of carboplatin. Bim was frequently expressed (20/25) and its absence or low expression was associated with the absence of response to ABT-737, p value = 0.019 by Fisher's test and sensitivity = 93%, (95% confidence interval, 66-100). Moreover, we observed that in tumors in which Bim was expressed, a low expression of Mcl-1 or phospho-ERK1/2 improved the proportion of responses. **Conclusions:** This pilot study showed that ABT-737 has promise as monotherapy for HGSOC in a specific subgroup of tumors. Bim, Mcl-1 and phospho-ERK1/2 appeared to be relevant biomarkers that could be used for the selection of patients in the design of clinical trials using navitoclax (an orally available compound related to ABT-737). Clinical trial information: NCT01440504.

**5578 General Poster Session (Board #360), Sat, 8:00 AM-11:45 AM**

**Molecular profiling in gynecologic cancer and matched targeted therapy: A step toward improving personalized medicine.** *Presenting Author: Ana C. Garrido-Castro, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** In the wake of personalized medicine in Oncology, genetic tumor profiling has become a cornerstone to select patients (pts) for clinical trials, exploring new molecular targeted agents. **Methods:** As part of the Vall d'Hebron University Hospital Molecular Prescreening/Phase 1 Trials Program, advanced gynecologic cancer (GYNT) pts were screened for molecular alterations (MA) (KRAS/PIK3CA/AKT/BRAF mutations [mut]; PD-L1 expression; PTEN loss, H score<50) and allocated to receive matched targeted therapy (MTT). We present a summary of molecular characteristics and clinical outcomes, using previous treatment as reference to evaluate potential efficacy. **Results:** From 01/2012 to 11/2013, 86 consecutive GYNT pts (mean age: 53.3 yrs; median no. previous treatments: 3 [0-7]) were screened for MA; 60 (69.8%) ovarian (OvC), 18 (20.9%) endometrial (EC) and 8 (9.3%) cervical carcinomas (CC). Median time from diagnosis to molecular analysis was 2.96 yrs. MA were identified in 23 pts (26.7%) as specified in Table 1: 5 type-I/8 type-II OvC; 4 type-I/4 type-II EC; 2 CC. Fifteen pts received MTT according to MA. Six harbored PIK3CA mut; 5 were treated with $\alpha$-specific PI3K inh and 1 with PI3K/mTOR inh. Pts with KRAS mut (8) received MEK inh-based combinations: 6 MEK/PI3K inh, 1 MEK/AKT inh, 1 MEK/IGFR1 inh. A double-mutated pt (PIK3CA/KRAS mut) was treated with mTOR inh. Median PFS of the MTT population was 19.5 wks [CI95%: 10.7-NA], slightly superior to 17.0 wks [CI95%: 12.9-38.6] achieved with the immediately previous line of systemic therapy (p=0.121). **Conclusions:** Treatment based on MA may improve clinical outcome in heavily pre-treated GYNT, as results in this analysis were superior to standard therapy. Statistical significance was not reached, probably due to small sample size. Our work warrants further studies of MTT in larger less pre-treated population.

**5579 General Poster Session (Board #361), Sat, 8:00 AM-11:45 AM**

**Expression III: Final results of an international survey in eight European countries with 1,830 patients—What are the differences in expectations from their doctors and therapy management of patients with primary and recurrent ovarian cancer? (NOGGO/ENGOT-ov4 study).** *Presenting Author: Gülten Oskay-Özcelik, NOGGO e.V., Berlin, Germany*

**Background:** The primary aim of this study was to investigate information needs and preferences among patients with ovarian cancer, in different European countries, focusing on patients with primary and recurrent ovarian cancer. **Methods:** A questionnaire was developed based on the experiences of "German-Expression II", and then provided to ovarian cancer patients via internet or print-version in 8 European countries (Austria, Belgium, France, Germany, Italy, Poland, Romania, Spain). Basic data and questions concerning the expectations and needs regarding their therapy management and doctor-patient communication were requested from the patient. **Results:** From December 2009 to October 2012, a total of 1,830 patients with ovarian cancer from 8 European countries participated in the survey, 902 patients with primary ovarian cancer and 731 with recurrent ovarian cancer. The median age was 58 years. Concerning the completeness and understandability of the explanations about the therapies from their doctors there was no significant difference in both groups. In contrast to patients with primary disease the recurrent patients measure the success of the therapy on the development of their CA 125. Recurrent patients attach more importance to know how long they must stay in the hospital and how many patients with their sickness are being treated for by their doctor. The three most important aspects for recurrent ovarian cancer patients to improve the therapy were: "therapy should be more effective," "therapy should not induce alopecia," "there must be more done to counter fatigue." **Conclusions:** This survey underlines the high need of ovarian cancer patients to discuss all details concerning treatment options and clinical management with only minor difference between the primary and recurrent ovarian cancer patients. It was also shown that more information about side effects of therapies and second opinion opportunities was needed.

**5580 General Poster Session (Board #362), Sat, 8:00 AM-11:45 AM**

**Phase II trial of oxaliplatin and 5-FU in patients (pts) with platinum-resistant recurrent (PRR) ovarian carcinoma (OVCA).** *Presenting Author: Joseph N. Kerger, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium*

**Background:** Based on clinical data and the partially non-cross-resistance of oxaliplatin with other platinum compounds, this phase II trial evaluated the safety and efficacy of a modified FOLFOX6 regimen in pts with PRR OVCA with a platinum-free interval of less than 6 months after any previous platinum-containing line of therapy. **Methods:** From 10/2008 till 08/2013, a total of 43 eligible pts with measurable (RECIST) and/or evaluable (CA125) disease were included in this study and received a median number of 8 courses (range: 1-14) of a modified FOLFOX6 regimen consisting in oxaliplatin 85 mg/m$^2$ d1, L-leucovorin 200 mg/m$^2$ d1 followed by a continuous iv infusion of 5-FU 2600 mg/m$^2$/48hrs every 2 weeks until disease progression or unacceptable toxicity. Pt characteristics: median age 57 years (range: 37-81), median PS 1 (0-2), serous histological subtype 60%, median number of previous lines 3 (1-12), prior exposure to carboplatin 100%, paclitaxel 98%, pegylated liposomal doxorubicin 63%, gemcitabine 23%, topotecan 23%, cyclophosphamide 14%, bevacizumab 9%. **Results:** Antitumor activity was seen in 35 cases with measurable disease: 1 CR + 15 PR, for an objective response rate of 46% (95%CI: 29-63%) and a median duration of response of 7.0 months (95%CI: 5.5-8.4 months); 13 SD (37%); 6 PD (17%). A clinical benefit rate (CR + PR + SD > 6 months) was observed in 21/43 (49%) pts (95% CI: 34-64%). Overall, the median time to progression was 5.8 months (95%CI: 4.9-6.5). Most side effects were moderate (G1&2): anemia in 88%, thrombocytopenia 67%, leucopenia 56%, neurological 81%, fatigue 72%, liver 51%, mucositis 41%, diarrhea 30%, renal 18%, hand-foot syndrome 9% of the pts. G3 toxicities included febrile neutropenia in 9%, neurological 9%, diarrhea 7%, mucosal 2% and liver toxicity 2% of the pts, leading to dose reductions in 13 pts (30%). Two hypersensitivity reactions to oxaliplatin also occurred. **Conclusions:** In this heavily pretreated patient population with PRR OVCA, this modified FOLFOX6 regimen exhibited a promising activity with an expected, but acceptable safety profile and might deserve further exploration, maybe in combination with biological or targeted agents. Clinical trial information: NCT01481701.

**5581 General Poster Session (Board #363), Sat, 8:00 AM-11:45 AM**

**Phase II clinical trial evaluating CRLX101 in recurrent ovarian, tubal, and peritoneal cancer.** *Presenting Author: Carolyn N. Krasner, Massachusetts General Hospital/Dana-Farber Harvard Cancer Center, Boston, MA*

**Background:** Ovarian cancer (Ov.Ca.) is the leading cause of death among gyn malignancies in the United States with over 20,000 new cases diagnosed in 2013. Limited treatment options exist for women whose tumors have progressed after 1st-line platinum-based therapy. Current approved therapy for relapsed Ov.Ca. includes the topo-1 inhibitor topotecan, which provides limited survival benefit and remains compromised by toxicity. CRLX101 is a novel cyclodextrin-containing polymer conjugate of camptothecin (CPT) that self-assembles into nanoparticles and delivers sustained CPT into cancer cells while reducing systemic exposure. *In vitro* and *in vivo*data suggest superior activity of CRLX101 compared to approved agents in Ov.Ca. models. The monotherapy MTD of 15 mg/m2 IV q. 2 wks. has now been administered to over 200 solid tumor pts (pts.) across 7 clinical trials. **Methods:** This phase 2 clinical trial evaluated CRLX101 in pts. with relapsed Ov.Ca. progressing after 1-3 prior regimens of chemotherapy, and included platinum refractory, resistant and sensitive pts. Pts. received CRLX101 every 14 days on 28-day cycles and underwent CT-based tumor evaluation every 2 cycles. The primary endpoint is progression free survival at 6 mos (PFS6) and secondary objectives include tumor response rate and safety. **Results:** Enrollment is this clinical trial is complete with 30 pts. having received 1-13 cycles of therapy and 5 pts. remaining on study. CRLX101 appears well tolerated with no drug-related SAEs, treatment discontinuations, or deaths observed. Related grade 3/4 AEs include G3 vasovagal reaction (n=1), G3 pneumonia (n=1), and G3 pulmonary embolism (n=1) . The primary efficacy endpoint has been met with mPFS of 161 days and 6 pts. achieving PFS $\geq$ 6 mos. Among 19 platinum resistant pts. with evaluable scans, 3 pts. (16%) achieved durable RECIST partial responses and 14 pts. (74%) achieved net tumor reductions. **Conclusions:** CRLX101 administered to pretreated pts. with relapsed Ov.Ca. appears safe, well tolerated, and effective. As CRLX101 appears to durably inhibit HIF-1$\alpha$ and demonstrates elsewhere notable synergy in combination with VEGF inhibiting agents, the drug is currently being evaluated in combination with bevacizumab. Clinical trial information: NCT01652079.

**5582 General Poster Session (Board #364), Sat, 8:00 AM-11:45 AM**

**Early-stage ovarian cancer: Clinical outcome and analysis of prognostic factors—Results from a prospective registry of GEICO (Spanish Group for Ovarian Cancer Research).** *Presenting Author: Belen Ojeda, GEICO and Hospital de la Santa Creu i Sant Pau, Department of Medical Oncology, Barcelona, Spain*

**Background:** Early stage ovarian cancer (ESOC) represents 10-15% of all Ovarian Cancer (OC) cases and the reported experience is limited. **Methods:** A centralized prospective register of ESOC (I-IIb) patients treated at GEICO centers was initiated on January 1998 and updated up to November 2013. Description of cases as well as correlation with Relapse Free Survival (RFS) and Disease Specific Survival (DSS) and an exploratory multivariate analysis was undertaken. **Results:** A total of 1179 cases with a median age of 48 (17-66) have been included: 983 (83.4%) Stages I, of which 369 (31.3%) were stage Ia, 49 (4,2%) stage Ib and 565 (47.9%) stage Ic, 169 (14,3%) were Stage II and 27 (2.3%) unknown. The most frequent histological type was Endometrioid (E) (n: 320, 27.1%), followed by Serous (S) (n: 297, 25.2%), Clear-cell carcinoma (CCC) (n: 244, 20.7%) and Mucinous (M) (n: 176, 14.9,%). Among E histology grade 1-2 vs grade 3 were present in 19.3% and 5.9% respectively while S grade 1 vs grade 2-3 were 5.9% and 15.2%. Surgical staging was categorized as complete surgery (22%), modified surgery (50%) and inadequate (28%). 1010 patients (88.3%) received adjuvant chemotherapy (ACT). With a median follow-up of 69 months (1-250), 16% of cases have relapsed and 8.1% were dead due to OC. Five-years RFS and DSS are 83% and 92% respectively. M and low grade E together have a 5-years RFS of 91% compared to other subtypes 79% (p<0.0001) and CCC a 5-years RFS 77%, compared to other subtypes RFS 85% (p<0.035). Prognostic factors including histology, histology and grade, stage and ACT were included in the multivariate analysis showing that stage (p=0.0001), low grade E (p=0.004) and ACT (p=0.005), remained of prognostic importance. **Conclusions:** In this large prospective cohort of ESOC, surgical staging remains inadequate in one fourth of cases according to current guidelines. E subtype is the most reported. Better prognosis is observed in low grade E, low stage and patients treated with ACT.

**5583 General Poster Session (Board #365), Sat, 8:00 AM-11:45 AM**

**Central pathology review of early-stage ovarian carcinoma: Description and correlation with follow-up—A study by the Spanish Group for Ovarian Cancer Research (GEICO).** *Presenting Author: Jose Antonio Lopez-Guerrero, Laboratory of Molecular Biology, Instituto Valenciano de Oncologia, Valencia, Spain*

**Background:** The reported experience with early-stage (FIGO stage I/IIB) ovarian carcinoma (ESOC) is limited. It represents 15% of all diagnosed cases and the impact on prognosis of their different histological subtypes has not been clearly defined. The aim of this study is to analyze the frequency of ESOC histologies and their correlation with follow-up. **Methods:** A centralized pathological review of ESOC was performed from samples belonging to the GEICO ESOC Registry, which includes 1179 patients. A total of 573 samples from 24 Spanish Hospitals were collected, stained with H&E and reviewed by two pathologists. Final diagnosis was achieved by consensus and compared with diagnosis of origin (DO). Histological classification was performed according to WHO criteria, except for serous subtype classified with 2-tier grading system (Malpica et al. Am J Surg Pathol 2004; 28:496-594). **Results:** Thirty-four cases (6%) were excluded after revision. The remaining 539 were classified as following: 130 (24%) high-grade serous (HGS), 24 (4%) low-grade serous (LGS), 45 (8%) high-grade endometrioid (HGE), 96 (18%) low-grade endometrioid (LGE), 75 (14%) mucinous (MUC), 134 (25%) clear cell carcinoma (CCC), 35 (6.6%) mixed (Mix) and 2 (0.4%) undifferentiated (U). Concordance with DO was of 76% (Kappa=0.495; p<0.0001), discrepancies being more frequent for Mix and U histologies. Median follow-up was 74 months (range: 0-250) and 105 (18%) recurrences were reported. The univariate analysis showed a 5-years recurrence free survival (RFS) of 70% for HGS vs 83% of other histologies (p=0.008); a 74% for CCC vs. 82% (p=0.06); and a 89% for LGE vs. 78% (p=0.021). The multivariate analysis showed that higher stage [HR= 3 (1.6-5.7); p=0.001], HGS [HR= 2 (1.2-3.3); p=0.005] and CCC [HR= 2.1 (1.3-3.4); p=0.003] constituted independent factors of poor prognosis. **Conclusions:** Frequency of histological subtypes in ESOC differs from advanced stages. HGS and CCC histological subtypes constitute independent poor prognostic factors in ESOC. The series herein reported could provide the basis for exploring molecular profiles in order to design specific clinical trials in ESOC.

**5584 General Poster Session (Board #366), Sat, 8:00 AM-11:45 AM**

**Autoantibodies (AA) against the EGF/EGFR and VEGFA/VEGFR1 as prognosticator in epithelial ovarian cancer (EOC) patients.** *Presenting Author: Elena Ioana Braicu, Charité Medical University, Berlin, Germany*

**Background:** Angiogenesis plays a major role in EOC. Anti-angiogenic therapy prolongs progression free survival in both primary and recurrent EOC, but no predictive biomarkers are currently known. **Methods:** In this study 132 healthy women and 201 primary EOC patients were enrolled. Most of the EOC patients had a FIGO IIIc (66%) and high grade serous ovarian cancer (96.4%). All EOC patients were treated with primary tumor debulking and platinum based chemotherapy. Mean follow up period was 62 months (range 19-149). Autoantibodies (AA) against epidermal growth factor (AA-EGF), epidermal growth factor receptor (AA-EGFR), vascular growth factor A (AA-VEGFA) and against vascular growth factor receptor 1 (AA-VEGFR1) were detected in preoperative serum samples using ELISA. **Results:** AA-EGF, AA-EGFR and AA-VEGFA, AA-VEGFR1 were detected in both control and EOC patients. AA concentrations were significantly lower in EOC (p<0.001). In the multivariate analysis AA-EGF, AA-EGFR, AA-VEGFA,AA-VEGFR1 were a significant predictor for mortality (p=0.001, 95%CI=0.12-0.154; p<0.001, 95%CI=0.0.047-0.83; p=0.001, 95%CI=0.118-0.173; p=0.001, 95%CI=0.125-0.167, respectively) and the combined endpoint (mortality or relapse) (p=0.001, 95% CI=-0.094-0.114; p=0.001, 95%CI=0.07-0.123; p=0.001, 95% CI=-0.093-0.028; p<0.01, 95%CI=-0.08-0.057). **Conclusions:** This is the first study that attests the existence of AA against EGF, EGFR and VEGFA, VEGFR1. AAs seem to have a protective role for the development of ovarian cancer. Furthermore higher AAs levels were associated with longer progression free and overall survival in EOC patients.

**5585 General Poster Session (Board #367), Sat, 8:00 AM-11:45 AM**

**Pharmacodynamic biomarkers from phase II study of the SMAC (Second Mitochondrial-Derived Activator of Caspases)-mimetic birinapant (TL32711; NSC 756502) in relapsed platinum-resistant epithelial ovarian cancer (EOC), primary peritoneal cancer (PPC), or fallopian tube cancer (FTC) (NCT01681368).** *Presenting Author: Kristen Paige Bunch, Women's Malignancies Branch, Center for Cancer Research, Bethesda, MD*

**Background:** Inhibitor of apoptosis (IAP) proteins prevent apoptosis in part by inhibiting caspases. IAPs also activate pro-survival NFkB signaling. SMAC is their endogenous inhibitor. Cancers, long known to avoid apoptosis, show IAP gene amplification and protein over-expression, or SMAC gene deletion and reduced protein. Birinapant (B) is a first in class bivalent peptidomimetic of SMAC. B mimics SMAC's modulation of IAPs including cIAP1, cIAP2, XIAP and ML-IAP. In preclinical models B depleted cIAP1, activated caspase 3 and inhibited growth of tumor cells. **Methods:** Phase II CTEP-sponsored single agent study of B in relapsed EOC, PPC or FTC. Patients received B 47mg/m$^2$ IV on days 1, 8 and 15 of a 28-day cycle. Percutaneous tumor biopsy was performed prior to cycle 1, and repeated on cycle 2 day 15. Plasma and PBMC were collected for additional research studies. **Results:** We collected pre-treatment biopsies on 11 patients, and paired on-treatment biopsies on 7 patients. Four cores were harvested at each timepoint; two cores were flash-frozen and two were fixed in formalin and embedded in paraffin. Correlative studies verified on-target activity of B and developed biomarkers of drug effect: Clinical trial information: NCT01681368. **Conclusions:** Birinapant is a promising novel therapeutic with clear evidence of IAP suppression in vivo. The biomarkers developed in this study will be incorporated into future clinical trials in order to better understand mechanisms of response and resistance to apoptosis-inducing therapies.

**5586 General Poster Session (Board #368), Sat, 8:00 AM-11:45 AM**

**Current practice and use of neoadjuvant therapy in ovarian cancer in the National Cancer Database.** *Presenting Author: Angela Jain, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Most ovarian cancer (OC) patients can expect significant tumor cytoreduction with platinum based therapy, but unfortunately no better than a 10-20% chance of cure. A previous study demonstrated that neoadjuvant chemotherapy (NAC) was not inferior to primary surgery followed by chemotherapy, and survival depended on the ability to resect all macroscopic disease. This is a retrospective study using the National Cancer Database (NCDB) to understand national trends in using NAC in OC. **Methods:** We identified women with advanced stage OC diagnosed between 1998 and 2011 and treated with chemotherapy and surgery using the NCDB. Using Chi-squared tests and multivariate logistic regression, we analyzed rates of NAC by age, facility type, race, payor status, income, location, Charlson score, year of diagnosis and facility location. Due to data availability, survival analysis was restricted to patients diagnosed between 2003 and 2005. We used Kaplan-Meier curves and proportional hazards regression to assess overall survival in patients treated with neoadjuvant vs adjuvant chemotherapy. **Results:** Among the 58,048 patients, on multivariate analysis, women were more likely to receive NAC if they were older ($<50$, $>70$ years vs. 50-70 years, OR=0.61, 1.16, $p<0.0001$, respectively), have Medicaid or Medicare vs Private insurance (OR= 1.71, 1.21 respectively, $p<0.0001$), or had a Charlson score $\geq 1$ (OR=1.19, $P<0.0001$). Race and rural/urban location were not associated with differences in therapy type in multivariate analysis. Use of NAC increased from 8.94% of patients in 1998 to 26.72% of patients in 2011 ($p<0.0001$). In the survival cohort (12,554 patients) median survival was 30.7 months vs 41.1 months for neoadjvant vs adjuvant patients ($P<0.0001$), and this difference remained on adjusted analysis (HR 1.31, $p<.0001$). **Conclusions:** The use of neo-adjuvant chemotherapy in OC has increased over time. Although we found significantly lower survival among patients given neoadjuvant therapy, this result is limited by potential selection bias. We found that patients treated with neoadjuvant therapy also had risk factors such as increased co-morbidities, coverage by Medicaid, and older age.

**5587 General Poster Session (Board #369), Sat, 8:00 AM-11:45 AM**

**Patterns of care and overall survival in the Medicare ovarian cancer population.** *Presenting Author: Larissa Meyer, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Tumor reductive surgery and combination chemotherapy is the standard of care for advanced ovarian cancer. Comorbid conditions and poor performance status can affect treatment options. Population level outcomes data in the geriatric population is lacking for women with ovarian cancer. The objective of this study is to characterize the patterns of care and overall survival in women over the age of 65 with epithelial ovarian cancer. **Methods:** Using the SEER-Medicare database, a cohort of patients who died of epithelial ovarian cancer between 2002-2009 was identified. All patients had pathologic confirmation of disease to be included in the cohort. Charlson comorbidity score was used to estimate health status. Kaplan-Meier analysis, Chi-square and ANOVA test were utilized. **Results:** A total of 4,672 women were included in the analysis and stratified into 4 groups based on previous therapy: No chemotherapy or surgery (NoCS), surgery only (S), chemotherapy only (C) or surgery and chemotherapy (CS). Mean age for the groups were 81 years (NoCS), 79 years (S), 78 years (C) and 74 years (CS). 1026 women (22%) received no treatment for their ovarian cancer (NoCS). 627 women (13.4%) underwent surgery but no chemotherapy. 988 women (21%) received chemotherapy but never underwent surgery. 2,031 women (44%) of the cohort underwent surgery and chemotherapy. 9.6% of women in the (CS) group had a comorbidity index of $> 2$ compared to 21% (C) group, 18% (S) group and 23% of the (NoCS) group ($p<0.0001$). There was a significant difference in survival between the groups with median survival time of 1.2 months for women who received no treatment, 1.8 months for surgery alone, 7.9 months for chemotherapy alone, and 21.2 months for patients who underwent the standard of care treatment of surgery and chemotherapy ($p<0.05$). **Conclusions:** Over half of patients over 65 do not or are not able to receive optimal therapy for epithelial ovarian cancer. Younger age and lower Charlson comorbidity index are associated with ability to undergo surgery and chemotherapy. This subset of patients is able to reach a significantly improved median survival time of 21 months compared to $<2$ months for patients who do not receive chemotherapy.

**5588 General Poster Session (Board #370), Sat, 8:00 AM-11:45 AM**

**Primary versus interval debulking surgery and the risk to induce platinum resitance.** *Presenting Author: Alexandre Andre Balieiro Anastacio da Costa, Hospital A.C. Camargo, São Paulo, Brazil*

**Background:** Interval debulking surgery (IDS) is an option to treat patients with stage IIIC and IV ovarian carcinoma. Two randomized trials have shown similar survival for primary debulking sugery (PDS) and IDS. One of the concerns with IDS is the potentialy higher risk to induce platinum resistance when treating patients with larger disease volume. At least one retrospective analysis sugest that patients treated with IDS have a higher risk to develop platinum resistance at second relapse. **Methods:** We did a retroscpective review of medical records from 213 patients with stage IIIC and IV ovarian carcinoma treated at a single institution from 2000 to 2013. We analysed the association of baseline clinical and pathological characteristics with time to first platinum resistant relapse (TTPR), platinum resitant disease at first relapse, defined as a platinum free interval (PFI) after first line chemotherapy less than 6 months, and overall response rate (ORR) to chemotherapy at first platinum sensitive relapse. **Results:** For a median follow-up time of 58.6 months, the overall survival was 45.2 months and progression free survival was 18.3 months. Factors related to a shorter TTPR in univariate analysis were residual disease (RD) $>$ 10mm after surgery, CA 125$>$150 before first treatment (chemotheray or surgery) and IDS compared to PDS. In the multivariate cox regression model including these three variables and age and stage (IIIC vs IV), RD$>$10mm (HR 1.87, CI95% 1.37-2.44, $p<0.001$) CA 125$>$150 (HR 3.39, CI95% 1.31-8.81, $p=0.012$) and IDS (HR 1.79, CI95% 1.02-3.18, $p=0.043$) remained associated to a shorter TTPR. The only factor associated to a greater risk of a PFI$<$6 months at first relapse was RD$>$10mm (OR 1.59, CI95% 1.14-2.20, $p=0.005$) and the only factor associated to a worse ORR to chemotherapy at first platinum sensitive relapse was IDS (OR 4.32, CI95% 1.15-16.15, $p=0.030$. **Conclusions:** IDS may be associated to a greater risk of platinum resistance induction. Some of the bias in choosing PDS or IDS may not have been accounted in this analysis due to its the retrospective nature, but it supports the hypotesis of other papers and suggests that it would be interesting to see this analysis done in patients from PDS vs IDS clincal trials already published.

**5589 General Poster Session (Board #371), Sat, 8:00 AM-11:45 AM**

**Laparoscopic versus laparotomic cytoreduction in patients with advanced ovarian cancer submitted to NACT: Evaluation of oncologic safety.** *Presenting Author: Giovanni Favero, Department of Gynecology - Instituto do Câncer do Estado de São Paulo - ICESP Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil*

**Background:** Surgery represents the cornerstone in the treatment of advanced ovarian cancer (AOC). In contrast to other gynecological cancers, the use of laparoscopy in AOC is presently considered the ultimate frontier for the method. However, modern technology couple with skilled laparoscopic surgeons afforded performance of diverse oncologic procedures. In parallel, neoadjuvant chemotherapy (NACT) followed by interval debulking surgery (DS) is an alternative for patients with AOC unresectable disease. In selected cases, complete endoscopic DS may be technically possible and considered an alternative to laparotomy. The current paucity of prospective trials addressing the use of laparoscopy in AOC after NACT motived us to investigate the oncologic safety of the method. **Methods:** Prospective pilot study with patients with initially unresectable advanced high-grade serous ovarian carcinoma (Stages IIIc or IVa) treated with six cycles of Carboplatin and Paclitaxel followed by DS between 2011 and 2014. Major inclusion criteria were: clinical complete response, normalization of the CA-125, absence of disease in critical areas according to radiology after NACT and optimal debulking surgery. Patients were randomized into laparoscopic versus laparotomic cytoreduction. **Results:** Twenty-one patients were included in the study; 10 patients in the laparoscopic group and 11 in the laparotomic group. The epidemiologic and oncologic features of the groups were not different. Median age was 58 years (45–78) and BMI was 29 Kg/m$^2$ (21 – 40). Complete resection of all macroscopic and microscopic disease (R0) in both groups was achieved in 100%. Surgical morbidity were equally uncommon; 2 patients needed a second procedure due to complications. Over a median follow-up period of 24.2 (15 – 36) months, 80% of the patients in the laparoscopic group and 88% in the open surgery group recurred (CI not reached). Nevertheless, the mean chemotherapy- free interval was significantly inferior in the laparoscopic group; 8,3 versus 15,3 months, respectively *(p – 0,02).* **Conclusions:** Laparoscopic cytoreduction seems to be not oncologically safe in patients with AOC submitted to NACT.

**5590 General Poster Session (Board #372), Sat, 8:00 AM-11:45 AM**

**Randomized phase II trial comparing IG-001 versus paclitaxel against first-line advanced ovarian cancer.** *Presenting Author: Vuong N. Trieu, Sorrento Therapeutics, Irvine, CA*

**Background:** IG-001 is a Cremophor-free, non-biologic, nanoparticle formulation of paclitaxel. Preclinical in vivo studies with IG-001 demonstrated a 3-fold increase in the MTD and a significantly increased antitumor efficacy over paclitaxel in multidrug-resistant human xenograft models. IG-001 has shown consistently positive response in Phase I/II clinical trials across five major cancer types: lung, breast, ovarian, pancreatic, and bladder cancers. The lack of effective therapy for chemoresistant patients with primary advanced epithelial ovarian cancer (EOC) underscores the need for new approaches to this disease. This study compared the response of IG-001 vs. paclitaxel in patients with primary advanced EOC. **Methods:** Preclinical efficacy of IG-001 vs. paclitaxel at equitoxic dose level was investigated in the paclitaxel resistant SKOV-3 xenograft model. Tumor bearing mice (n = 10/group) were treated i.v. with saline or equitoxic dose of paclitaxel (20 mg/kg) or IG-001 (60 mg/kg) on days 0, 4 and 8 (q3dx3). The safety and clinical efficacy of IG-001 vs. paclitaxel against EOC was evaluated in a Phase 1 (n = 18) and Phase II (n = 98) study. For the Phase I trial, six patients/dose level were treated with IG-001 at 220, 260, and 300 mg/m$^2$. Phase II trial was a randomized, two-arm trial for advanced EOC (Experimental Arm: n = 50, IG-001 [260 mg/m$^2$ IV] + Carboplatin [5 AUC IV 3 weeks, 6 cycles]; Control Arm: n = 48; paclitaxel [175 mg/m2 IV] + Carboplatin [AUC IV 3 weeks, 6 cycles]). **Results:** In the paclitaxel-resistant human SKOV-3 ovarian tumors, IG-001 was more effective than paclitaxel (p = 0.002, ANOVA). Though we did not reach MTD during our phase I study, 260 mg/m$^2$was designated as the dose level for the phase II study. IG-001 + Carbo vs. paclitaxel + Carbo in patients with EOC demonstrated significant overall response rate (P = 0.017, Chi-square test) after 6 cycles/patient with 46% and 26% achieving complete response, respectively. **Conclusions:** IG-001 was found to be effective against EOC in preclinical and clinical studies. IG-001/Carboplatin combination chemotherapy was well-tolerated in women with advanced EOC and produced a doubling of overall response rates relative to those obtained with paclitaxel/Carboplatin-containing regimen. Clinical trial information: NCT01276548.

**The impact of tumor molecular profile-directed treatment on survival in recurrent ovarian cancer.** *Presenting Author: Kate Eleanor Oliver, Walter Reed National Military Medical Center, Bethesda, MD*

**Background:** We sought to determine whether tumor molecular profile-directed treatment of recurrent ovarian, primary peritoneal and fallopian tube carcinomas influenced survival. **Methods:** With IRB approval, Caris Life Sciences, Ltd maintains the Caris Registry, a database of clinicopathologic and outcome variables from consenting patients whose tumors underwent molecular profiling. Molecular profiling was performed using a multiplatform approach to stratify agents by degree of potential therapeutic benefit. The Caris Registry was queried for all patients with a diagnosis of ovarian, primary peritoneal and fallopian tube carcinomas enrolled between 2010 and 2014. Patients were stratified based on chemotherapeutic agents employed during their disease course: the molecularly-guided (MG) cohort received at least one agent designated to be of potential benefit and no agents with potential lack of benefit while the non-molecularly-guided cohort (non-MG) received at least one agent with potential lack of benefit. Survival was calculated from the date of profiling and from the date of diagnosis to the date of death/censoring using the Kaplan-Meier method. **Results:** Of 445 patients identified in the registry, 90 were excluded due to non-invasive pathology, non-epithelial histology, and missing or ambiguous treatment information. Of the remaining 355 eligible and evaluable patients, 166 formed the MG cohort and the remaining 189 were assigned to the non-MG cohort. There were no significant differences in baseline clinicopathologic characteristics between the two groups. Patients in the MG cohort experienced significantly longer post-profiling survival when compared with patients in the non-MG cohort, HR 0.64 (CI 0.41 – 0.97, p = 0.03). Additionally, there was a trend toward longer overall survival in the MG cohort. **Conclusions:** Tumor molecular profile-directed treatment significantly improves post-profiling survival in patients with recurrent ovarian, primary peritoneal and fallopian tube carcinomas. Despite immature outcome data, trends toward improved overall survival were also demonstrated.

**5592 General Poster Session (Board #374), Sat, 8:00 AM-11:45 AM**

**A phase II study of medroxyprogesterone acetate plus metformin as fertility-sparing treatment for atypical endometrial hyperplasia and endometrial cancer.** *Presenting Author: Akira Mitsuhashi, Departments of Reproductive Medicine, Graduate School of Medicine, Chiba University, Chiba, Japan*

**Background:** Metformin, a drug widely used in the treatment of type 2 diabetes mellitus, has been shown to reduce the risk of cancer and relapse after treatment. To determine whether the concomitant use of metformin prevents recurrence after progestin therapy, we conducted a phase II study of medroxyprogesterone acetate (MPA) plus metformin as fertility-sparing treatment for atypical endometrial hyperplasia and endometrial cancer. **Methods:** Patients with endometrial cancer or atypical endometrial hyperplasia were treated with MPA (400 mg/day) and metformin (750 mg up to 2250 mg/day) for 24 weeks. In cases of partial histological regression but remarkable hormonal effects (partial response, PR), treatment was continued for another 12 weeks. Metformin was administered until conception, even after MPA was discontinued. The primary endpoint was the relapse rate after remission, and the secondary endpoints were the overall response rate and safety profile. An independent data and safety monitoring committee performed an interim analysis of efficacy and safety at 12 months after the completion of enrollment. **Results:** From July 2009 to December 2012, 36 patients (17 with endometrial cancer and 19 with atypical endometrial hyperplasia) were enrolled. Most patients were obese and had insulin resistance; the mean body mass index was ≥25 in 28 patients (mean, 31 kg/m$^2$; range, 19–51 kg/m$^2$) and the homeostasis model assessment for insulin resistance index was ≥2.5 in 25 patients (mean, 4.8; range, 0.7–21). One patient showed progression at 12 weeks (2.8%). At 36 weeks, 31 patients (86.1%) had achieved complete response (CR) and the remaining 4 (11.1%) had achieved PR. During a median follow-up period of 34 months (range, 12–54 months), relapse was confirmed in 2 of the 31 patients who had achieved CR, resulting in a relapse rate of 6.4% compared to a previously reported rate of 30-50% without metformin. The 3-year estimated relapse-free survival rate was 93%. None of the patients experienced severe toxicity. **Conclusions:** The use of metformin inhibited disease relapse after progestin therapy. Clinical trial information: UMIN 000002210.

**5593 General Poster Session (Board #375), Sat, 8:00 AM-11:45 AM**

**Phase 2 clinical trial of ixabepilone in metastatic cervical carcinoma.** *Presenting Author: Mauricio Emmanuel Burotto Pichun, National Cancer Institute at the National Institutes of Health, Bethesda, MD*

**Background:** Ixabepilone is a microtubule-stabilizing agent approved for metastatic breast cancer. Preclinical data indicates activity in taxane-sensitive and resistant cells. Metastatic cervical carcinoma (mCC) has a poor prognosis and no accepted second line therapies. This study assessed the efficacy and safety of Ixabepilone in previously treated mCC. **Methods:** Patients with histologically confirmed mCC and at least one prior regimen received ixabepilone [6mg/m$^2$/d X 5d] every 21 days. Primary endpoint was PFS by RECIST. Secondary endpoints were response rate, overall survival, and safety. We calculated the rate of tumor growth (g) as an additional efficacy measure. **Results:** Forty-one patients were enrolled; thirty four tumors were squamous. The median number of prior therapies was 2 (range1-6). Four patients (9.7%) had partial responses. Median time to progression in months was 2.3 for all, 3.84 for taxane-naive and 2.03 for taxane pre-treated patients ($p=0.13$). Consistent with this we found the rate of growth (g) in taxane-naive patients (0.0035/day) to be two-thirds the rate in taxane pre-treated patients (0.0053/day). Median overall survival (OS) was 5.84 months. Thirty-two patients discontinued treatment due to progression, two because of death, two for toxicity, and five for other reasons. The most frequent toxicities included vomiting (43%), sensory neuropathy (21%), and fatigue (60%). G3/4 toxicities were noted in 53% patients; all resolved without interventions **Conclusions:** Ixabepilone was well tolerated but showed very modest activity in second or higher line mCC. A trend to worse outcomes and a faster rate of growth was observed in taxane-pre-treated patients compared to taxane-naive patients. New strategies are needed for refractory mCC. Clinical trial information: NCT00924066.

**5594 General Poster Session (Board #376), Sat, 8:00 AM-11:45 AM**

**Phase II evaluation of dalantercept, a soluble recombinant activin receptor-like kinase 1 (ALK1) receptor-fusion protein, for treatment of recurrent/persistent endometrial cancer: GOG-0229N.** *Presenting Author: Vicky Makker, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Angiogenesis has a role in endometrial cancer (EC) progression and prognosis. Single agent bevacizumab had a response rate (RR) of 13% and 6 month progression-free survival of 40% in recurrent EC with 1-2 prior cytotoxics. ALK1 is selectively expressed on activated endothelial cells unlike constitutively expressed VEGFR2. ALK1 pathway is essential for vascular morphogenesis and the formation of functional capillary networks in developing vasculature. EC vasculature has variable ALK1 expression. Dalantercept (Dal), a first-in-class ALK1 receptor fusion protein, binds to BMP9/BMP10 and prevents ALK1 pathway activation. **Methods:** A 2-stage design was used to estimate number of pts with persistent/recurrent EC who survived progression-free without receiving non-protocol therapy (TPFS) for at least 6 mos and number of pts who had objective tumor response (ORR) and determine toxicity of Dal 1.2 mg/kg SC Q3W. Recurrent/persistent epithelial EC, measurable disease, and 1- 2 prior chemotherapy lines were required. Biologic adjuvant therapy was permitted. **Results:** 28 pts ages 47-79 years were enrolled. G1/2 Endometrioid (n=9, 32%) and serous (n=15, 54%) tumors were most common. 82% of pts had 1 prior regimen. Pts received 1-12 cycles of Dal; 13 pts (46%) received $\leq$2 cycles. Most common adverse events (AE) regardless of attribution were fatigue, anemia, constipation, and limb edema. Grade (G) 3 and 4 AEs occurred in 39% and 4% of pts. There was 1 G 5 AE possibly Dal associated: gastric hemorrhage in pt with history of radiation fibrosis/small bowel obstruction. All pts are off study treatment: 24 for disease progression (PD), 1 consent withdrawal, 2 for toxicity, 1 for death. By RECIST 1.1: ORR was 0%; stable disease 57%, PD 39%, and indeterminate 4%. 11% of pts had TPFS $>$ 6 mos; median PFS 2.1 mos (90% CI: 1.4-3.2) and median OS 9.4 mos (90% CI: 8.9-11.7). **Conclusions:** Dal has insufficient single agent activity in recurrent EC to warrant further investigation at this dose/schedule. Studies of IHC expression of VEGF, FGF, PDGF, TGF-$\beta$, ALK1, CD105, ALK1 gene expression, plasma concentration of VEGF, BMP9, BMP10, and ALK1 via ELISA are ongoing. Clinical trial information: NCT01642082.

**5595 General Poster Session (Board #377), Sat, 8:00 AM-11:45 AM**

**A cohort study of gastric-type adenocarcinoma (GAS) of the uterine cervix: Multi-institutional study by Gynecologic Cancer Study Group of the Japan Clinical Oncology Group (JCOG).** *Presenting Author: Shin Nishio, Kurume University School of Medicine, Kurume, Japan*

**Background:** GAS is a novel variant of mucinous adenocarcinoma of the uterine cervix. A Japanese group reported that GAS represents more aggressive disease compared with usual-type endocervical adenocarcinoma (UEA), possibly due to chemoresistancy (ASCO 2013). However, the conclusion remains to be confirmed by larger series. **Methods:** Patients were enrolled at the Gynecologic Cancer Study Group of the JCOG after receiving approval from Institutional Review Board. The study group comprised women with stage I to II disease who underwent surgery without receiving neoadjuvant chemotherapy between 2000 and 2009. The study variables included the incidence of GAS as evaluated by central pathological review (CPR) and the diffences in clinicopathologic features between GAS and UEA. In addition, outcomes of patients with each type were statistically compared. **Results:** Among 393 cases of endocervical adenocarcinoma enrolled, 328 cases met the CPR and eligibility criteria for further analysis. A total of 95 of 328 (28.9%) tumors were re-classified as GAS. As compared with UEA, GAS was more significantly associated with a bulky mass, deep stromal invasion, lymph vascular space invasion, parametrial invasion, ovarian metastasis, positive ascitic fluid cytology, pelvic lymph node metastasis, and pathological (p) T stage, but was not related to the degree of histological differentiation. Disease-free survival ($p<0.0001$) and overall survival ($p<0.0001$) were poorer in patients with GAS than in those with UEA. When the data were analyzed according to disease stage, patients with a diagnosis of pTIA-IB1 adenocarcinoma had poorer outcomes ($p<0.0001$), but the difference in outcomes as compared with patients who had pTIB2 or more advanced disease was not significant. **Conclusions:** GAS is significantly associated with histopathologic predictors of poor outcomes as well as with poorer survival outcomes, and therefore is considered to be distinct entity which should be distinguished from UEA. Clinical trial information:UMIN000007987

**5596 General Poster Session (Board #378), Sat, 8:00 AM-11:45 AM**

**Obesity and robotic surgery: Associated ventilator indices and perioperative pulmonary complications.** *Presenting Author: Weiya Zhang Wysham, University of North Carolina, Chapel Hill, NC*

**Background:** Robotic surgery has been shown to be feasible in obese patients. However, there remains concern about the safety of robotic surgery in obese women who need gynecologic surgery, as the positioning required for pelvic surgery can exacerbate obesity-related changes in respiratory physiology. Our objective was to evaluate success and complication rates in obese women undergoing robotic gynecologic surgery and to assess variables that may be associated with complications. **Methods:** A retrospective chart review was performed on 1,035 obese patients who underwent robotic gynecologic surgery at two academic institutions between 2006 and 2012. Primary outcome was pulmonary complications. Secondary outcome was all-cause complications. Univariate logistic regression analysis was used to determine associations between patient baseline variables (age, BMI), operative variables (case length, trendelenburg time), ventilator parameters (tidal volume, peak inspiratory pressure) and complications (pulmonary, cardiac, other). **Results:** 146 patients (14%) had any complication. Only 33 patients (3%) had a pulmonary complication. Mean BMI was 39. Only increasing age was associated with a higher rate of pulmonary complications ($p=0.03$). None of the other patient variables including BMI, operative variables, or ventilator parameters were associated with pulmonary complications. Both age and longer case time were associated with a higher rate of all-cause complications ($p<0.0005$ and $p=0.0028$ respectively). **Conclusions:** The vast majority of obese patients can successfully tolerate robotic gynecologic surgery, and have overall low complications rates and even lower rates of pulmonary complications. Obesity was not predictive of robotic surgery tolerance or complications and can be safely undertaken in obese and even morbidly obese patients without significant complications.

**5597 General Poster Session (Board #379), Sat, 8:00 AM-11:45 AM**

**Pelvic sentinel lymph node status and risk of aortic nodal metastasis in patients with endometrial cancer.** *Presenting Author: Robert W. Holloway, Florida Hospital Cancer Institute, Orlando, FL*

**Background:** Pelvic sentinel lymph node (SLN) mapping is hypothesized to improve the accuracy of surgical staging. The clinical relevance of isolated tumor cell (ITC) metastasis compared to H&E micro- or macro-metastases in pelvic SLN are unknown. The purpose of this study was to evaluate aortic nodal status (infra-renal [IR] or infra-mesenteric IM]) in relation to pelvic SLN in patients with clinical stage I endometrial cancer (EC). **Methods:** 80 patients with EC underwent robotic-assisted laparoscopic hysterectomy and pelvic SLN mapping (isosulfan blue and/or indocyanine green with near-infrared imaging) from 4/11-8/13. A systematic pelvic and aortic lymphadenectomy to the left renal vein was performed and data were gathered prospectively. SLN were ultra-sectioned and evaluated with both H&E and IHC stains. The dataset was examined for peri-operative and clinico-pathologic factors including presence and type of lymph node (LN) metastasis (ITC vs. H&E). The disease status of pelvic SLN was compared to aortic nodal status. **Results:** Mean age was 65.9±12.0 yr, BMI 33.8±8.4 kg/m$^2$, height 65.3±10.6 inches, operative time 178±33 min, and length of hospital stay 1.4±1.1 days. Histologies included: endometrioid G1 (18.8%), G2 (45%), G3 (12.5%), and type II cancers (23.8%). Mean depth of invasion (DOI) was 43.1±30.4% (39% cases >50% DOI) and lymphovascular space invasion was present in 46.3% of cases. Mean pelvic and aortic LN yields were 26.6±16.4 and 12.7±6.4, respectively. 34 (42.5%) patients had pelvic LN metastasis with 33 having (+) SLN [7 (21.2%) ITC vs. 26 (81.8%) H&E]. 15/80 (18.8%) patients had aortic LN metastasis [2 IR, 8 IR+IM, and 5 IM] and all cases had (+) SLN. 15/33 (45.5%) patients with SLN metastasis had aortic metastasis. The risk of aortic metastasis with ITC-SLN was 2/7 (28.6%) vs. 13/26 (50%) for micro- plus macro-metastasis SLN. There were no cases with isolated infra-renal or infra-mesenteric LN metastasis. **Conclusions:** These findings suggest that SLN metastasis whether identified by IHC isolated tumor cells or H&E pose a significant risk for aortic LN metastasis. The phenomenon of "isolated infra-renal metastasis" in EC appears uncommon with pelvic SLN mapping.

**5598 General Poster Session (Board #380), Sat, 8:00 AM-11:45 AM**

**Systemic chemotherapy compared with radiation therapy as adjuvant therapy after radical surgery in high-risk stage IB-IIB cervical adenocarcinoma.** *Presenting Author: Toshiyuki Seki, Jikei University School of Medicine, Tokyo, Japan*

**Background:** Radiation therapy (RT) and concurrent chemo-radiation therapy (CCRT) are commonly used adjuvant therapies for FIGO stage IB-IIB cervical cancer patients regardless of their histological subtypes. However, given that patients with adeno/adenosquamous carcinoma (AC) reportedly have poorer prognosis compared to patients with squamous cell carcinoma (SCC), a more effective adjuvant therapy targeting AC patients should be investigated. Hence, we conducted this study to evaluate the efficacy of systemic chemotherapy (CT) to AC patients compared with RT/CCRT. **Methods:** The medical records of the patients with IB-IIB cervical cancer who underwent primary surgery at our 4 institutes from January 2001 to December 2010 were retrospectively reviewed, and the patients with pathologically confirmed bulky tumor (≥4cm), nodal metastasis, and/or parametrium invasion were included. The patients were classified into 3 groups; group 1: patients with SCC who received RT/CCRT, group 2: patients with AC who received RT/CCRT, and group 3: patients with AC who received CT. At first, to determine the efficacy of RT/CCRT to AC patients compared to SCC patients, the progression-free survival (PFS) of group 1 and 2 was compared. Secondly, to investigate the efficacy of CT compared to RT/CCRT for AC patients, the PFS of group 2 and 3 was compared. **Results:** A total of 135 patients were enrolled (group 1: 90, 2: 23, and 3: 22). The median follow up period was 48 (range: 1-132) months. There was no statistical difference in the proportion of patients with nodal metastasis, parametrial involvement, and bulky tumor between each group. A significant difference in PFS curves was detected between group 1 and 2; AC patients treated with RT/CCRT had poorer prognosis than SCC patients treated with RT/CCRT (RR: 2.504 (95%CI: 1.284-8.871), p=0.014). A significant difference in PFS curves was also detected between group 2 and 3; AC patients had more favorable prognosis when treated with CT compared to RT/CCRT (RR: 0.288 (95%CI: 0.109-0.965), p=0.043). **Conclusions:** Adjuvant RT/CCRT may be less effective for AC patients, and CT has a potential benefit greater than that of RT/CCRT for AC patients.

**5599 General Poster Session (Board #381), Sat, 8:00 AM-11:45 AM**

**Endometrial cancer survivors: What is their knowledge about obesity?** *Presenting Author: Leslie Horn Clark, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Obesity is a well-established risk factor for development of endometrial cancer (EC); it has been linked to decreased survival, worse surgical outcomes, and poor quality of life in EC patients. We sought to assess EC survivor's awareness of obesity and its role in EC. **Methods:** Following IRB approval, women diagnosed with EC from 2011 – 2012 were identified. Patients with persistent/recurrent disease or those actively undergoing treatment were excluded. A pre-survey invitation to participate was sent 1 week prior to the survey. Surveys were mailed to 233 women. Reminder postcards were sent 2 weeks following the survey. Demographics, weight and weight assessment, patient's health behaviors, and information regarding physician counseling was collected. Along with descriptive statistics, the kappa statistic was reported as a measure of agreement. **Results:** Of 233 surveys sent, 46% (n=108) were returned. The median BMI of responders was 29.8 (range 17.1-64.8) When asked to identify their BMI into four categories, 14% self-reported as "normal weight", 3% as "underweight", 39% as "a little overweight", and 44% as "a lot overweight". Self-reported BMI assessment was compared to actual BMI and good to moderate agreement was noted (weighted kappa 0.66). 85% of women correctly identified their BMI category. When asked if they were obese, 96% (43/45) of obese patients correctly answered "yes" (kappa 0.86). 52% (n=46) reported attempted weight loss following their diagnosis. Of those not attempting weight loss, reasons included: not needing to (37%), not wanting to (23%), not knowing how (14%), not having time (12%), and not having money (20%). Only 34% of patients reported being counseled by a gynecologic oncologist to lose weight. 92% of patients correctly identified obesity as a risk factor for EC. **Conclusions:** EC survivors are relatively knowledgeable about the role of obesity in EC and their own personal weight. Patients were generally motivated to make lifestyle changes after their cancer diagnosis. Unfortunately, only 1/3 of patients reported their providers encouraged weight loss. Gynecologic oncologists should take full advantage of the "teachable moment" for this highly obesity-driven cancer.

**5600 General Poster Session (Board #382), Sat, 8:00 AM-11:45 AM**

**Feasibility of circulating tumour cell (CTC) enumeration and molecular profiling (MP) as a biomarker in advanced endometrial cancer (aEC).** *Presenting Author: Charlotte Rose Lemech, Sarah Cannon Research Institute, London, United Kingdom*

**Background:** CTCs are prognostic and predictive markers in many solid tumours. There are no validated biomarkers to assess treatment (tx) response or molecular therapies in aEC. We conducted a feasibility study to determine whether CTCs were detectable and suitable for MP in aEC. **Methods:** As of January 2014, 30 patients (pt) with aEC had baseline (B) and up to 3 follow-up (FU) blood samples at intervals of 2-3 months (m) up to 6m. CTCs were evaluated using the Veridex CellSearch platform, with stathmin (S) antibody in the 4$^{th}$channel. EpCAM, S and phospho-S6 immunohistochemistry (IHC) was performed on pt FFPE tumour tissue. **Results:** 17/30 (57%) pt had detectable CTCs [1 CTC (n=6), 2 (5), 4 (2), 7 (1), 8 (1), 22 (1), 172 (1)]. 11/17 CTCs were S positive (+), 1 S negative (-) and 5 non-evaluable (NE). Of the 17 CTC+ pt: 11 were sampled at B and during first-line C for mEC; 6 were CTC+ at B but FU was not available (5 died, 1 refused). Of the 11 CTC+ pts sampled during tx: 7pt were B CTC+ and had decreased CTC during C, 6 of which correlated with CT response and 1 of the 6 had increased CTC on 3$^{rd}$FU correlating with CT progression (PD); 4pt were B CTC- and became CTC+ during tx, 2 at PD and 2 are in FU. 18 available FFPE blocks had EpCAM+ staining on IHC, consistent with aEC epithelial origin. **Conclusions:** To our knowledge, this is the first published data confirming CTC enumeration and molecular analysis is feasible in aEC. 57% of pt were CTC+ which was associated with increased stage and tumour burden. Of the 11 pt sampled at B and during tx, 8 (72%) had CTC counts that correlated with CT response. FU is ongoing. CTC may be useful as a biomarker of response as well as molecular profiling in aEC.

**5601 General Poster Session (Board #383), Sat, 8:00 AM-11:45 AM**

**Prediagnostic diabetes, body mass index, and survival of endometrial cancer: A prospective study.** *Presenting Author: Kristina Lindemann, Oslo University Hospital, Norwegian Radium Hospital, Department of Gynecological Cancer, Oslo, Norway*

**Background:** Diabetes and obesity are well known risk factors of endometrial cancer (EC). However, the associations of these factors with survival after EC diagnosis are not established. The aim of this population-based study was to assess the association between diabetes, BMI and risk of all-cause and EC-specific mortality. **Methods:** During 1984-1986 and 1995-1997 two health surveys were conducted in the Nord-Trøndelag county in Norway (HUNT 1 and 2). Women in both surveys who developed EC were identified through individual linkage to the Cancer Registry of Norway. Our primary outcome measure was risk of death from any cause after the diagnosis of EC. Follow-up time was calculated from the date of EC diagnosis until the date of death or the end of follow-up, June 30th 2012. Secondary outcome was death due to EC adjusted for competing causes of death. Both Cox proportional hazards models and Fine and Grey models (competing risk models) adjusted for age, stage of cancer and histological subtype were fitted. In stratified analyses, we studied the risk associated with diabetes in normal weight (BMI $<25$ kg/m$^2$) and overweight/obese women (BMI $\geq 25$ kg/m$^2$). **Results:** Among the 31 865 women included in the HUNT surveys, 337 women who developed EC were eligible for survival analyses. During a median follow-up of 6.6 years (range 0.1-27), 166 (49%) of the women died. We found no statistically significant association between BMI and overall or EC specific mortality. However, the overall risk of death in EC patients with diabetes was more than doubled as compared to patients without diabetes (HR 2.14; 95% CI: 1.26-3.63). Also, the EC specific mortality was more than doubled in women with diabetes (SHR 2.69, 95% CI: 1.09-6.66). In stratified analyses, normal weight women with diabetes had higher, but not statistically significant, risk of both overall and EC-specific death compared to overweight/obese women. **Conclusions:** Diabetes, but not BMI, was associated with increased risk of all-cause and EC-specific mortality. This association between diabetes and mortality may be especially pronounced in normal weight women.

**5602 General Poster Session (Board #384), Sat, 8:00 AM-11:45 AM**

**The effect of raloxifene hydrochloride for the prevention of health care problems of patients who underwent surgeries for endometrial cancer: A multicenter clinical trial.** *Presenting Author: Koji Nakamura, Department of Obstetrics and Gynecology, Osaka University Faculty of Medicine, Suita, Japan*

**Background:** The removal of ovaries is necessary at the surgery for endometrial cancer. However, since the loss of ovaries cause several health problems in patients, the establishment of the prevention therapy after surgeries should be required. We conducted a multicenter clinical trial and assessed the effect of raloxifene on bone mineral density (BMD), bone metabolism and lipid profile of the patients who underwent surgeries for endometrial cancer. **Methods:** 77 women were enrolled after their surgeries. After a written informed consent, participants were randomized into two groups: group I; 39 women received alfacalcidol (1 $\mu$g/day) alone and group II; 38 received the study drug, raloxifene hydrochloride, at a dose of 60 mg/day with alfacalcidol. All patients received supplemental calcium 1.2g/day. BMD, serum bone markers (NTx and BAP) and lipid profiles were evaluated at the enrollment, 6, 12, and 24 months after the enrollment. **Results:** 64 (83%) finished 24-month follow-up. No significant differences between the groups were seen in the baseline data. At 24 months, lumbar and femoral neck BMD were significantly increased in group II compared with group I (3.0% vs -0.8% ($p=0.009$), +2.0% vs -2.8% ($p=0.003$)). In group II, values of total cholesterol as well as LDL-cholesterol were significantly reduced by 8.4% ($p=0.0006$), 14.9% ($p<0.0001$), whereas in group I, no significant reduction were seen. In group II, both serum NTX and BAP values were significantly reduced by 16.1% ($p=0.0006$), 24.7% ($p<0.0001$). Recurrence was found in two (2.6%) case in group I and no severe adverse events were noted in any cases throughout the study period. In sub-analyses, the patients who received chemotherapy showed significantly higher response to raloxifene. **Conclusions:** The treatment of raloxifene to the patients after surgeries not only significantly increased lumbar and femoral neck BMD, but decreased serum bone markers as well as total and LDL-cholesterol values with safety profiles. It suggests that raloxifene could constitute a good therapeutic option to improve the health care problems of the patients with endometrial cancer after surgeries. Clinical trial information: UMIN000013039.

**5603 General Poster Session (Board #385), Sat, 8:00 AM-11:45 AM**

**Effects of temozolomide and bevacizumab in patients with pretreated relapsed uterine leiomyosarcoma.** *Presenting Author: Naoki Sasaki, National Defense Medical College, Tokoorzawa, Japan*

**Background:** Treatments for patients with uterine leiomyosarcoma (ULM) include anthracyclin-based chemotherapy and Docetaxel/Gemcitabine, but these regimens are not satisfactory. Temozolomide (T) has been reported to show a moderate response rate in advanced or recurrent ULM. In addition, ULM has a plenty of vascularity, unlike leiomyoma. Thus, we evaluated the effects of T combined with bevacizumab (B) in patients with pretreated/relapsed ULM. **Methods:** Simon's two-stage design was used. In the first stage, 7 patients were accrued. If there were no responder in these patients, the study would be stopped. Otherwise, seven additional patients will be accrued for a total of 14. If three or more responder were observed in 14 patients, this design yields a type I error rate of 0.03 and power of 0.81 when the true response rate were 30%. Enrolled patients with pretreated/relapsed ULM were treated with weekly B (2mg/kg; days 1, 8, and 15, q4w) and T (80mg/day, daily), and treatment continued until disease progression. **Results:** Among 7 patients in the first stage, two responses were observed, and a total of 14 patients were analyzed in this study. Among 14 cases, two (14%) had a complete response (CR) and three (21%) had a partial response (PR). Additionally, six patients (43%) had a stable disease (SD) for at least three months. The response rate (CR+PR) and clinical benefit rate (CR+PR+SD>3mo) were 35% and 78%, respectively. The median progression-free survival was 10.5 months (range from 3 to 44 months). There were no treatment-related deaths or CTCAE grade 4 toxicities, and no dose reduction due to toxicity was observed. **Conclusions:** T combined with B was effective in patients with relapsed ULM with tolerable toxicity profile. Remarkably, two cases achieved a complete remission more than 6 months. The regimen could be a candidate for the patients with ULM in further prospective studies.

**5604 General Poster Session (Board #386), Sat, 8:00 AM-11:45 AM**

**Carboplatin-based chemoradiotherapy in advanced cervical cancer: An alternative to cisplatin-based regimen?** *Presenting Author: Ana Morais Sebastião, Instituto do Cancer do Estado de Sao Paulo- Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil*

**Background:** Cisplatin based chemoradiotherapy (cis-RT) is the standard treatment in locally advanced cervical cancer (CC). Carboplatin chemoradiotherapy (carbo-RT) has not been validated in prospective phase III studies, although it is used in the presence of renal impairment, advanced age or comorbidities. **Methods:** Retrospective analysis of patients (pts) with CC stage IIB-IVA consecutively treated at Instituto do Cancer do Estado de Sao Paulo from May/2008 to December/2012. Primary endpoint was PSF and secondary OS and ORR (CR + PR). Survival was assessed by Kaplan-Meier curves, compared by the log-rank test, frequencies were compared by chi-square test **Results:** We analyzed 184 pts, 159 treated with cis-Rt and 25 carbo-RT. All received whole pelvic region external-been RT (45Gy and boost-12-14Gy- followed by brachytherapy-4x700cGy). Chemo was weekly cis (40mg/m2) or carbo (AUC2). Median age was 50.42 (21-80) in cis-RT and 64.18y (42-83) in carbo-RT. Most pts have squamous cell carcinoma and ECOG 0-1. Carbo-RT pts have more advanced disease: 52% stage IIIb-IVA vs 36.1% in cis-RT. At least one comorbidity was present in 41.8% in cis-RT and 84% in carbo-RT pts. Five or more chemo cycles were applied 87.3% in cis-RT and 84% pts in carbo-RT ($p=0.749$). PFS at 3 y was 24m in cis-RT (95% CI 18.8-29.3) vs 27.5m in carbo-RT (95% CI 25.6-29.4) ($p=0.249$). OS in 3y was 30.3m (95% CI 26.2-32.7) in cis-RT pts and 31.4m in carbo-RT (95% CI 29.9-32.9) ($p=0.298$). ORR (95.3% vs 95.4%) ($p=0.911$) and grade $\geq$ 3 toxicities (8.5% cis-RT vs 11.8% carbo-RT) ($p=0.757$) were similar. In multivariate analysis, only the ORR was a significance predictor of survival **Conclusions:** Patients with advanced CC treated with carbo-RT have no different 3 year OS, PFS ORR and toxicities when compared to cis-RT. Carbo-RT may be a treatment alternative in patients that could not receive cisplatin

**5605 General Poster Session (Board #387), Sat, 8:00 AM-11:45 AM**

**Population-based analysis of mortality over time in endometrial cancer.** *Presenting Author: Michael Joseph Eblan, Department of Radiation Oncology, The University of North Carolina, Chapel Hill, NC*

**Background:** Endometrial cancer is the most common gynecologic malignancy in developed countries. In this population-based study, we analyzed mortality over a 25-year period**. Methods:** 62513 patients in the Surveillance, Epidemiology & End Results (SEER) database diagnosed with endometrial cancer between 1980 and 2005, with at least 5 years' follow-up, were included. Cases with multiple malignancies or secondary endometrial cancer were excluded. Multivariate analysis examined factors associated with all-cause mortality (ACM) and cancer-specific mortality (CSM) using Cox proportional hazards model and Fine-Gray competing risk model, respectively. **Results:** There were 10886 deaths from endometrial cancer and 10184 from other causes. ACM and CSM decreased in more recent years (Table). Older age at diagnosis, black race, advanced stages, higher grade and sarcoma histology were associated with increased hazards for ACM and CSM. Receipt of total hysterectomy, external beam radiation therapy (EBRT) and implant were associated with decreased ACM. **Conclusions:** When accounting for patient, diagnostic and treatment factors, ACM and CSM have decreased over time for endometrial cancer. However, racial disparity in mortality outcomes persists.

**Factors associated with ACM and CSM.**

**Absence of occult micrometastases in histologically negative lymph nodes among patients with distant recurrent endometrial cancer.** *Presenting Author: Amanda Lynn Jackson, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Lymph node metastasis is a criterion for adjuvant therapy in endometrial cancer (EC). The incidence of immunohistochemical (IHC) stain-positive micrometastases in H&E-negative lymph nodes is low in surgically staged EC. Ultrastaging, however, is used to detect low volume disease in sentinel lymph node dissection. Our goal was to determine the frequency of occult micrometastases in histologically negative lymph nodes in patients who have distant recurrent endometrial cancer. **Methods:** The records of patients diagnosed with endometrial cancer from 2005 to 2010 were reviewed. Twenty patients that were previously reported to be negative for lymph node metastases using conventional histologic analysis presented with distant recurrent high-grade endometrioid adenocarcinoma. All nodal tissue was submitted for review and ultrastaging with H&E and IHC staining to detect micrometastasis. Two pathologists interpreted slides and positive IHC staining for micrometastases was defined as positive staining of cells <2 mm in greatest dimension. **Results:** 1063 patients underwent surgery for endometrial cancer. Twenty patients with early stage, high-grade node negative endometrioid cancers presented with a distant recurrence to sites other than isolated vaginal, pelvic or retroperitoneal sites; 2 patients were excluded secondary to unavailable pathologic samples. The histological grade was 2 in 9 patients and 3 in 9 patients. Nine patients had Stage IA disease, 6 Stage IB, and 3 Stage II. 536 lymph nodes were reviewed from the cohort of 18 patients; the median number of lymph nodes per patient was 27.5(10-52). No micrometastases were identified in any of the lymph nodes. **Conclusions:** It was previously shown that the incidence of IHC stain-positive micrometastases in H&E-negative lymph nodes is low in surgically staged endometrial cancers. Our study shows that in patients with a distant recurrence the incidence remains very low, suggesting alternative routes of metastasis for these patients and questions the utility for ultrastaging in sentinel lymph nodes to predict distant recurrences.

**5607 General Poster Session (Board #389), Sat, 8:00 AM-11:45 AM**

**A retrospective analysis of the relationship between diabetes, metformin use, and survival in advanced endometrial cancer patients treated with chemotherapy.** *Presenting Author: Obiageli Chinaka Ezewuiro, University of Chicago, Chicago, IL*

**Background:** Pre-clinical data suggests that the diabetic medication, metformin, has anti-cancer effects. We hypothesized that advanced stage endometrial cancer (EC) patients who used metformin would have improved survival. **Methods:** We conducted a single institution retrospective review of women receiving chemotherapy in the setting of stage III, IV or recurrent EC or carcinosarcoma from 1992 to 2011. **Results:** We identified 418 pts with stage III, IV or recurrent EC, of whom 237 received chemotherapy, and 220 were included in the study. Median age at time of chemotherapy was 64.8 (range 21.1-87.0); race: 56% white, 40% African American (AA), 4% other. Histologies were 28% endometrioid, 28% serous, 16% carcinosarcoma, 7% clear cell and 21% other. Median OS was 24.5 months (95%CI: 20.1-28.5). AA pts had worse OS than whites (p=.02), with median OS of 16.9 (95%CI: 12.7-24.6) vs 28.5 (95%CI: 23.4-35.2) months, respectively. Older patients had worse OS (p=0.001). 43 pts had diabetes and 19 of them were taking metformin at the time of chemotherapy. Median OS for diabetics taking metformin, diabetics not taking metformin, and non-diabetics was 51.9 (95%CI: 17.9-127.5), 13.3 (95%CI: 8.0-24.6) and 24.2 (95%CI: 20.1-29.8) months. OS difference between the three groups was not statistically significant (p=0.12), but when comparing survival only among the diabetic groups, patients treated with metformin had a borderline statistically significant longer OS (p=0.066, logrank test). The difference was also borderline significant in the multivariate Cox regression model adjusted for race and age (HR=2.12, p=0.057). **Conclusions:** In this study of advanced EC, patients receiving chemotherapy who were concurrently treated with metformin had improved survival. Our study adds to the body of evidence suggesting potential anti-cancer effects of metformin and supports prospective testing of metformin added to standard chemotherapy for advanced EC. Supported by NCI K12CA139160 and CTSA-ITM CS UL1 RR024999 to TG, NCI 2K12HD00849-22 and University of Chicago Cancer Center to IR.

**5608 General Poster Session (Board #390), Sat, 8:00 AM-11:45 AM**

**Resection margin and locoregional control in vulvar cancer: A subset analysis of the AGO CARE-1 multicenter study.** *Presenting Author: Linn Lena Woelber, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

**Background:** Recently, the standard of minimal pathological resection margin distance of 8mm in surgery for primary vulvar cancer has been challenged since several single center analyses failed to show impact of smaller margins for disease control. **Methods:** The AGO CaRE-1 study is a retrospective survey of treatment patterns and prognostic factors in vulvar cancer. Patients with primary squamous-cell vulvar cancer FIGO stage 1B and higher (UICC-TNM version 6) treated at 29 gynecologic cancer centers in Germany 1998-2008 were included in a centralized database. While a total of 1,618 patients were documented, this subgroup analysis focuses only on surgically staged node-negative patients with complete tumor resection and known margin distance without radio/chemotherapy (n=289). **Results:** Median age of the 289 analyzed patients was 66 years (22-94); 141 (48.8%) had pT1b, 140 (48.4%) pT2 and 8 (2.8%) pT3 tumors. 125 (43.3%) underwent complete, 127 (43.9%) partial vulvectomy and 37 (12.8%) radical local excision. The median minimal resection margin was 5 mm (1mm–33mm); median follow-up was 38.8 months. 46 patients (15.9%) developed disease recurrence, thereof 34 (11.8%) at the vulva, after a median of 18.3 months. Vulvar recurrence rates were 12.6% in the group of patients with a resection margin <8mm and 10.2% in patients with a margin ≥8mm. Other sites of recurrent disease were groins (8 cases; 2.8%), pelvis (1 case; 0.3%) and distant (3 cases; 1.0%). When analyzed as a continuous variable, margin distance had no significant impact on disease-free survival (HR per mm increase 0.945, 95% CI 0.886 – 1.009, p=0.090). Similarly, neither uni- nor multivariate analysis adjusted for age, tumor stage, tumor grade, depth of invasion and tumor diameter could reveal a significant difference in disease-free survival between the subgroup of patients with a margin ≥8 or <8mm (multivariate HR 0.642, 95% CI 0.355 – 1.162, p=0.143). Results were consistent when looking at vulvar recurrences only. **Conclusions:** Tumor-free resection margins are crucial for loco-regional control in vulvar cancer. The need for a minimal margin of 8mm could, however, not be observed in the large cohort of the AGO-CaRE database.

**5609 General Poster Session (Board #391), Sat, 8:00 AM-11:45 AM**

**Evaluation of the diagnostic accuracy of cervical biopsy and determination of associated risk factors for positive margin status in recurrent cervical dysplasia after leep or conization.** *Presenting Author: Diana Peta-gay English, Yale School of Medicine, New Haven, CT*

**Background:** Severe dysplasia on a cervical biopsy is often followed by an excisional procedure such as a loop electrosurgical excisional procedure (LEEP) or cone biopsy. The objective of this study was to determine the prevalence and associated risk factors for positive surgical margins on cold knife conization or LEEP as well as the recurrence of dysplasia after these procedures. Secondary objective was to determine the correlation of cervical biopsy revealing CIN II with degree of dysplasia found on final pathology. **Methods:** This is a descriptive analytical study of 118 patients who underwent a LEEP or cone biopsy during a 12 year period (1999-2011) by trained gynecologic oncologists at our institution. Medical records were reviewed from a prospectively maintained pathology database. Cases were identified through a search performed for all patients in this period with a CIN II diagnosis. All pathology specimens were reviewed by one of four board specialized gynecologic pathologists. The need for cervical biopsy was determined based on pap results according to the ASCCP guidelines. Univariate analysis was performed with the chi-square test and the Student's t-test. **Results:** Of the 118 patients, 29 cases had a positive cone/LEEP margin (24.6%). Of the patients with positive margins, 48.2 % of these patients were considered to be immuno-compromised due to factors such as chronic steroid use and smoking, chemotherapy or HIV positivity. Recurrence of abnormal pap smears within 2 years of an excisional procedure was 19% in the margin negative group and 31% in the margin positive group ($P < 0.0001$). The positive predictive value of cervical biopsy for determining CIN II on an excisional procedure was 94.1%. **Conclusions:** Positive surgical margins on LEEP/cone biopsy is not uncommon and increases the risk for abnormal cervical cytology in the subsequent years post-procedure. Cervical biopsies when performed by trained physicians correlate well with final pathology on cone biopsy/LEEP. Risk factor assessment continues to be important in following patients after cervical excisional procedures.

**5610 General Poster Session (Board #392), Sat, 8:00 AM-11:45 AM**

**ADXS11-001 immunotherapy targeting HPV-E7: Final results from a phase 2 study in Indian women with recurrent cervical cancer.** *Presenting Author: Partha Basu, Chittaranjan National Cancer Institute, Kolkata, India*

**Background:** ADXS11-001 immunotherapy is a live attenuated *Listeria monocytogenes* (*Lm*) bioengineered to secrete a HPV-16-E7 fusion protein targeting HPV transformed cells. The *Lm* vector serves as its own adjuvant and infects APC where it cross presents, stimulating MHC class 1 and 2 pathways resulting in specific T-cell immunity to tumors. Here we describe final results from *Lm*-LLO-E7-015, a randomized P2 study designed to evaluate the safety and efficacy of ADXS11-001 with and without cisplatin in 110 patients with recurrent cervical cancer in India; previously treated with chemotherapy, radiotherapy or both. **Methods:** Patients were randomized to either 3 doses of ADXS11-001 at $1 \times 10^9$ cfu or 4 doses of ADXS11-001 at $1 \times 10^9$ cfu with cisplatin chemotherapy (40 mg/m$^2$). Naprosyn and oral promethazine were given as premedications and a course of ampicillin was given 72h after infusion. Patients received CT scans at baseline and 3, 6, 9, 12 and 18 months. The primary endpoint was overall survival. **Results:** The final 12 month survival was 36% (39/110) and 18-month survival was 28% (31/110). The response rate was 11% (6 CRs and 6 PRs/110) with tumor responses observed in both treatment arms; 35 additional patients had stable disease $> 3$ months, for a disease control rate of 43% (47/110). Average duration of response in both treatment groups was 10.5 months. Activity against different high-risk HPV strains was observed. The incidence of SAEs possibly related or related to ADXS11-001 was 2% (G3). The majority of non-serious adverse events were predominately infusion associated, and either resolved on their own or responded to symptomatic treatment. **Conclusions:** The addition of cisplatin to ADXS11-001 did not significantly improve survival outcomes or tumor responses. Baseline ECOG performance status, type of prior therapy, or aggressiveness of disease had no effect on survival outcomes and tumor responses. The 36% 12 month survival, 28% 18 month survival, and 11% response rate observed in this recurrent disease setting is encouraging and suggests that ADXS11-001 is an active agent in recurrent cervical cancer. Additional sub-analyses will be presented at the meeting.

**TPS5611 General Poster Session (Board #393A), Sat, 8:00 AM-11:45 AM**

**ICON8: An international randomized trial comparing two dose-dense regimens, 3-weekly carboplatin plus weekly paclitaxel (CwT), and weekly carboplatin-paclitaxel (wCwT), to standard 3-weekly treatment in women with newly diagnosed ovarian, fallopian tube, and primary peritoneal cancer.** *Presenting Author: Jane Hook, Medical Research Council Clinical Trials Unit at University College London, London, United Kingdom*

**Background:** Three-weekly intravenous carboplatin-paclitaxel (CT) is a standard of care for the first-line treatment of ovarian cancer. Dose-dense weekly (w) CwT improved survival in the JGOG3016 trial (Katsumata, Lancet Oncol 2012) but its benefit was unclear in GOG262 (Chan, 18th ESGO Meeting 2013), as most women received bevacizumab in addition to CT or CwT. ICON8 is the largest trial of dose-dense therapy in ovarian cancer. It will compare the efficacy and safety of CT with CwT and wCwT regimens. **Methods:** ICON8 (NCT01654146) is a Gynecologic Cancer Intergroup, 3-stage phase III trial open at 111 centres in the UK, S Korea, Mexico, Ireland, Australia, and New Zealand. Patients (pts) with histologically proven FIGO Stage IC-IV ovarian, fallopian tube, primary peritoneal cancer or ovarian carcinosarcoma, age ≥18 years and ECOG PS 0-2 are eligible. Pts may enter after immediate primary surgery (IPS) or receive neoadjuvant chemotherapy + delayed primary surgery (DPS) after cycle 3. ICON8 is the first trial designed to permit variation in timing of surgery; randomization is stratified by IPS/DPS. Pts are randomized (1:1:1) to receive 6 21-d cycles of (1) carboplatin AUC5 + paclitaxel 175mg/m$^2$ q3w, (2) carboplatin AUC5 q3w + paclitaxel 80mg/m$^2$ q1w or (3) carboplatin AUC2 + paclitaxel 80mg/m$^2$ q1w. Stage 1 (safety and feasibility) is complete (Hook, 18th ESGO Meeting 2013). The IDMC reviewed stage 2 (activity) in January 2014 and recommended that recruitment continue to all arms. Stage 3 (efficacy) is powered for dual primary outcome measures: progression free and overall survival. Secondary outcomes are toxicity, quality of life and cost effectiveness. 1,000 of 1,485 women have been recruited. Accrual is expected to complete in Q4 2014. Collection of tumor tissue, germline DNA and serial plasma is ongoing in parallel (TRICON8) with 90% pts participating. ICON8B, an extension in high risk pts comparing CwT with or without bevacizumab and CT + bevacizumab is planned. The trial is sponsored by the MRC and funded by Cancer Research UK, CRUK/10/030. Clinical trial information: NCT01654146.

**TPS5612 General Poster Session (Board #393B), Sat, 8:00 AM-11:45 AM**

**A phase 3 study of trabectedin (T) plus pegylated liposomal doxorubicin (PLD) versus PLD for treatment of advanced-relapsed epithelial ovarian, primary peritoneal, or fallopian tube cancer.** *Presenting Author: Robert L. Coleman, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Ovarian cancer (OVC) is the eighth most common cancer among women globally, with approximately 60%–70% of cases being diagnosed at an advanced stage (III or IV). Five-year survival rate for stage IV is <20%. In a previous pivotal trial, patients with OVC who relapsed after first-line platinum-based chemotherapy (PCT) demonstrated superior progression free survival (PFS) when treated with the T+PLD combination vs. PLD monotherapy (7.3 vs. 5.8 months; HR=0.79; p=0.019). In a subgroup analysis by platinum free interval (PFI), T+PLD showed an improved overall survival (OS) for patients with PFI of 6–12 months (HR=0.64). Given this demonstrated efficacy, we are conducting a global phase 3 registration trial to investigate the OS of T+PLD vs. PLD in patients with platinum sensitive epithelial OVC, peritoneal or fallopian tube cancer, in the third-line setting. **Methods:** In this open-label, active-controlled trial, approximately 670 women who have received 2 prior lines of PCT will be enrolled at approximately 135 sites in 9 countries. Key inclusion criteria: all women must be platinum sensitive defined as no evidence of disease progression for ≥6 months after the last dose of first-line PCT, and have known BRCA mutation status prior to randomization. Key exclusion criteria: OVC with mucinous histology and >2 prior lines of chemotherapy. Patients will be stratified by PFI (6–12 months vs. >12–24 months vs. >24 months), ECOG performance status (0 vs. 1), BRCA 1 or 2 mutation status (yes vs. no), and prior PLD therapy (yes vs. no). Stratified patients will be randomized (1:1) to receive PLD (30 mg/m$^2$, 1.5 h, i.v.) followed by T (1.1 mg/m$^2$, 3 h, i.v.) every 3 weeks or PLD alone (50 mg/m$^2$, 1.5 h, i.v.) every 4 weeks. Primary endpoint is OS. Secondary endpoints include PFS, overall response rate (ORR), safety, and pharmacokinetics of T. Planned study duration is 64 months. An interim OS analysis is planned after 308 deaths. Final OS analysis will be done after ≥514 deaths have been observed. As of 29 January 2014, 11 patients have been randomized. Clinical trial information: NCT01846611.

**TPS5613 General Poster Session (Board #394A), Sat, 8:00 AM-11:45 AM**

**PENELOPE/AGO-OVAR 2.20: A double-blind placebo (PLA)-controlled randomized phase III ENGOT trial evaluating chemotherapy (CT) with or without pertuzumab (P) for platinum-resistant ovarian cancer.** *Presenting Author: Christian Kurzeder, Kliniken Essen Mitte, Essen, Germany*

**Background:** Adding P to gemcitabine (GEM) for platinum-resistant ovarian cancer improved progression-free survival (PFS) in a subset of patients (pts) with low tumor HER3 mRNA expression [Makhija 2010]. PENELOPE (NCT01684878) comprises a safety run-in (Part 1, complete) and PLA-controlled randomized assessment of CT ± P (Part 2, below). **Methods:** Eligible pts have: measurable/non-measurable recurrent platinum-resistant epithelial ovarian, primary peritoneal or fallopian tube cancer (progression during or within 6 mo of completing ≥4 platinum cycles); centrally tested low HER3 mRNA expression (concentration ratio ≤2.81 by qRT-PCR on cobas z480); and have received ≤2 prior lines of CT. The primary Part 2 objective is to determine if PFS (assessed by independent review committee; IRC) is superior with P + CT vs PLA + CT. The key secondary endpoint is overall survival (OS). Both endpoints are part of a closed testing procedure. Additional endpoints include investigator-assessed PFS, objective response rate (RECIST v1.1), safety (NCI CTCAE v4.0), quality of life (including EORTC QLQ-C30 and QLQ-OV28) and pharmacokinetic parameters. Translational studies aiming to scrutinize and validate the preselection concept by correlating markers of signal pathway activation with efficacy have been implemented. Additional exploratory analyses will include gene expression profiling. Investigators select CT (topotecan, paclitaxel or GEM) before 1:1 randomization to P or PLA. Treatment is continued until progression or unacceptable toxicity. Stratification factors are: selected CT; prior anti-angiogenic therapy; and platinum-free interval (<3 vs 3–6 mo). The planned Part 2 enrollment is 154 pts. Recruitment to each CT cohort is capped at 1/3 of the total sample size. Primary PFS analysis will be done after 109 IRC-assessed PFS events, providing 95% power to detect a PFS hazard ratio (HR) of 0.50 (median PFS 1.4→2.8 mo) with 2-sided log-rank at $\alpha$=0.05. Final OS analysis is planned after 129 deaths in Part 2, providing 80% power to detect an OS HR of 0.61 (median OS 8.4→13.8 mo); 2-sided log-rank at $\alpha$=0.05. By 27 Jan 2014, 62 pts were randomized. Clinical trial information: NCT01684878.

**TPS5614 General Poster Session (Board #394B), Sat, 8:00 AM-11:45 AM**

**A randomized, open-label, phase II study assessing the efficacy and the safety of bevacizumab in neoadjuvant therapy in patients with FIGO stage IIIc/IV ovarian, tubal, or peritoneal adenocarcinoma, initially unresectable.** *Presenting Author: Roman Rouzier, Institut Curie, Saint-Cloud, France*

**Background:** We hypothesize that improving the response rate of stage IIIC or IV and non-optimally resectable ovarian cancer patients to neoadjuvant chemotherapy would improve the optimal debulking rate at interval debulking surgery (IDS) and ultimately the survival. In the ICON7 and OCEANS trials, addition of bevacizumab to chemotherapy has been shown to improve the response rates. We assume that its administration in the neoadjuvant setting would improve the response rate and consequently will help to achieve optimal debulking rate at IDS. **Methods:** This study, named ANTHALYA, is a multicenter, open-label, randomised phase II study, conducted in 15 sites in France. 90 patients with FIGO stage IIIC/IV ovarian, tubal or peritoneal adenocarcinoma, initially unresectable are to be enrolled. At inclusion, patients are randomised (2:1) to receive 4 cycles of neoadjuvant carboplatin and paclitaxel chemotherapy either combined to 3 cycles of bevacizumab in the treatment arm (not given the cycle before surgery) or alone in the control arm. The control arm will be used to assess the complete resection rate in the arm treated without bevacizumab in the neoadjuvant setting. The primary objective for this study is to evaluate the efficacy of neoadjuvant bevacizumab and chemotherapy measured by the complete resection rate after IDS. Complete resection is defined as the removal of all macroscopic residual tumour at IDS (CC score = 0). The secondary objectives for this study are as follows: (1) to evaluate the safety profile of bevacizumab when added to carboplatin and paclitaxel in the neoadjuvant setting; (2) to assess the efficacy of bevacizumab measured by Objective Response Rate (ORR) for neoadjuvant period and after all courses of treatment, assessed according to RECIST criteria and CA-125 levels; and (3) to evaluate progression-free survival (PFS). Exploratory analysis are conducted to evaluate the biomarkers profile and to explore prognosis and predictive markers. Clinical trial information: NCT01739218.

**TPS5615 General Poster Session (Board #395A), Sat, 8:00 AM-11:45 AM**

**Measuring subjective improvement of palliative chemotherapy in women with platinum-resistant or -refractory ovarian cancer: The symptom benefit study (ANZGOG-0701/ GCIG/PoCoG).** *Presenting Author: Michael Friedlander, Prince of Wales Hospital, Sydney, Australia*

**Background:** The objective of chemotherapy in women with platinum resistant recurrent ovarian cancer is symptom palliation. Response rates or time to progression are used to assess "clinical benefit", but fail to incorporate subjective benefit. There is international consensus that a valid measure of subjective symptom benefit is required. The aims of Stage 2 of this study are to assess the validity, reliability and statistical efficiency of a new patient-reported outcome measure, the Measure of Ovarian Symptoms and Treatment concerns (MOST, developed in Stage 1), relative to the best candidate scales of existing ovarian cancer specific quality of life measures (QLQ-C30/OV28, FACT-O/FOSI), develop criteria for defining subjective symptom benefit, determine how many women have subjective benefit with palliative chemotherapy and develop a prognostic model to better predict benefit, time to progression and survival in this heterogeneous group of patients. **Methods:** Prospective observational cohort study in women with platinum resistant or refractory recurrent ovarian cancer who are about to commence palliative chemotherapy. Changes in perceived ovarian cancer symptoms are assessed from baseline to post treatment using QLQ-C30/OV28, FACT-O/FOSI and MOST. Eligibility: Women with platinum resistant/refractory epithelial ovarian, primary peritoneal or fallopian tube cancer with life expectancy > 3 months and ECOG PS 0-3 who are about to start palliative (2nd or subsequent line) chemotherapy. Trial status: Stage 2 opened in Feb 2011 with a target recruitment of 750 patients. To date 623 patients have been recruited from Australia, New Zealand, Ireland, Germany and Italy, Canada, the UK, the US, France, Sweden, Norway and Japan. **Summary:** This study will identify the most statistically efficient measure of subjective symptom benefit of palliative chemotherapy for use in endpoint analysis in clinical trials. Ultimately, it will help physicians and patients make more informed decisions regarding treatment options based on the likelihood of benefit and their potential impact on symptom control and improved quality of life. Clinical trial information: ACTRN12607000603415.

**TPS5616 General Poster Session (Board #395B), Sat, 8:00 AM-11:45 AM**

**SOLO1 and SOLO2: Randomized phase III trials of olaparib in patients (pts) with ovarian cancer and a *BRCA1/2* mutation (BRCAm).** *Presenting Author: Kathleen N. Moore, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

**Background:** In a pivotal Phase II trial (NCT00753545), maintenance treatment with the oral PARP inhibitor olaparib (400 mg bid; capsules) led to a significant PFS improvement vs placebo in pts with platinum-sensitive, relapsed serous ovarian cancer (Ledermann et al *NEJM* 2012), with the greatest PFS benefit seen in pts with a BRCAm (HR=0.18, 95% CI 0.10–0.31, *P*<0.00001; Ledermann et al ASCO 2013). Two AstraZeneca-sponsored Phase III trials of olaparib maintenance monotherapy have been initiated in ovarian cancer pts with a BRCAm: SOLO1 (NCT01844986); SOLO2 (NCT01874353). **Methods:** SOLO1 and SOLO2 are double-blind multicenter studies in which pts are being randomized (2:1) to receive olaparib (300 mg [2 x 150 mg tablets] bid) or placebo. Both trials are recruiting pts with high-grade serous or endometrioid ovarian cancer, including primary peritoneal and/or fallopian tube cancer, who have a known deleterious (or suspected deleterious) BRCAm and who are in complete or partial response following the completion of platinum-based chemotherapy. To be eligible for SOLO1, pts must have newly diagnosed, advanced (FIGO stage III–IV) disease and have responded to first-line platinum therapy, whereas pts in SOLO2 must have completed ≥2 lines of platinum therapy. All eligible pts will have a BRCAm and will undergo germline BRCA testing (Myriad Integrated BRAC*Analysis*) as part of the trials. For both trials, the primary objective is PFS by blinded independent central review using RECIST v1.1. Radiologic scans will be performed at baseline and every 12 weeks for 120 (SOLO1) or 72 (SOLO2) weeks, and every 24 weeks thereafter. Blinded treatment will continue until objective disease progression. Primary analyses will be performed at ≈60% maturity using log-rank tests. Other objectives for both trials include: overall survival; time to earliest progression (RECIST or CA-125); time from randomization to second progression (PFS2); HRQoL; tolerability. Enrollment began in Sep 2013. As of Jan 2014, both trials have recruited approximately 10% of the target patient population. Target recruitment: SOLO1, n≈344 randomized pts (≈110 sites worldwide); SOLO2, n≈264 randomized pts (≈80 sites worldwide). Clinical trial information: NCT01844986 and NCT01874353.

**TPS5617 General Poster Session (Board #396A), Sat, 8:00 AM-11:45 AM**

**A phase 2 study of live-attenuated listeria monocytogenes cancer immunotherapy (ADXS11-001) in the treatment of persistent or recurrent cancer of the cervix (GOG-0265).** *Presenting Author: Warner King Huh, The University of Alabama at Birmingham Comprehensive Cancer Center, Birmingham, AL*

**Background:** This is a Gynecologic Oncology Group (GOG) Phase 2 study (NCT01266460, GOG 0265) of ADXS11-001 in patients with persistent or recurrent cancer of the cervix. ADXS11-001 is a live attenuated *Listeria monocytogenes* (*Lm*) immunotherapy bioengineered to secret a HPV E7 fusion protein targeting HPV-E7 transformed cells. A previous Phase I dose escalation study evaluated the safety of ADXS11-001 in patients with advanced cervical cancer (Maciag PA. Vaccine. 2009 Jun 18;27(30):3975-83). The primary objectives of this study are: to evaluate the tolerability and safety of ADXS11-001; and to assess the activity of ADXS11-001 in patients with persistent or recurrent cancer of the cervix. Secondary objectives are progression-free survival, overall survival and objective tumor response. **Methods:** Patient eligibility criteria: Females age $\geq$ 18 years with persistent or recurrent squamous or non-squamous cell carcinoma, adenosquamous carcinoma, or adenocarcinoma of the cervix with documented disease progression (disease not amenable to curative therapy). Patients must have measurable disease as defined by RECIST 1.1; have had one prior systemic chemotherapeutic regimen for management of their disease; have adequate organ function and must be free of active infection and not on antibiotics. This protocol is a 2-stage design with 12-month survival as the primary endpoint and with a planned sample size of up to 67 patients. Patients will receive ADXS11-001 at a dose of $1x10^9$ CFU on Day 1 and repeat every 28 days for 3 total doses in the absence of disease progression or unacceptable toxicity, with each dose followed at 72 hours by a 7 day course of ampicillin, 500 mg QID. Tumor tissue and serum samples may be collected periodically for translational research. After completion of study treatment, patients are followed every 3 months for 2 years and then every 6 months for 3 years. As of January 31, 2014, enrollment has been completed in the 9 patient safety lead-in portion of the study and enrollment continues. Clinical trial information: NCT01266460.

**TPS5618 General Poster Session (Board #396B), Sat, 8:00 AM-11:45 AM**

**The MEK Inhibitor in Low-Grade Serous Ovarian Cancer (MILO)/ENGOT-ov11 study: A multinational, randomized, open-label phase 3 study of binimetinib (MEK162) versus physician's choice chemotherapy in patients with recurrent or persistent low-grade serous carcinomas of the ovary, fallopian tube, or primary peritoneum.** *Presenting Author: Bradley J. Monk, University of Arizona Cancer Center, Phoenix, AZ*

**Background:** Low-grade serous (LGS) carcinomas of the ovary, fallopian tube and primary peritoneum are rare and unique tumors for which current therapies (chemotherapy, hormonal) have demonstrated limited efficacy. As LGS carcinoma is characterized by mutations in genes of the RAS/RAF/MEK/ERK signaling pathway, such as BRAF and KRAS, evaluating therapies that target this pathway is warranted. This study will evaluate the efficacy of the MEK1/2 inhibitor binimetinib (MEK162) vs physician's choice chemotherapy in patients with LGS carcinoma. This study will enroll patients regardless of RAS/RAF mutational status; however, tumor tissue will be retrospectively analyzed for mutations in RAS/RAF and other genes (NCT01849874). **Methods:** This is a 2-arm, open-label, 2:1 randomized Phase 3 study of binimetinib vs physician's choice chemotherapy (pegylated liposomal doxorubicin, paclitaxel or topotecan). Eligible patients must have LGS carcinoma that is recurrent or persistent following at least 1 prior platinum-based chemotherapy and no more than 3 prior lines of chemotherapy, and must have RECIST v1.1-defined measurable disease confirmed by independent central review. Prior to randomization, independent central review of a patient's tumor specimen is required to confirm LGS diagnosis. Prior treatment with a MEK or BRAF inhibitor is prohibited. Randomization is stratified by last platinum-free interval and number of prior systemic therapy regimens. The primary endpoint is progression-free survival as determined by blinded independent central review; secondary endpoints include overall survival, overall response, duration of response, disease control rate, safety, quality of life and pharmacokinetics of binimetinib. Binimetinib is administered 45 mg BID orally. Patients receive therapy until disease progression or unacceptable toxicity. This study will enroll 300 patients worldwide. Clinical trial information: NCT01849874.

**TPS5619 General Poster Session (Board #397A), Sat, 8:00 AM-11:45 AM**

**ARIEL 2/3: An integrated clinical trial program to assess activity of rucaparib in ovarian cancer and to identify tumor molecular characteristics predictive of response.** *Presenting Author: Elizabeth M. Swisher, University of Washington, School of Medicine, Seattle, WA*

**Background:** PARP inhibitors (PARPi) are active in patients (pts) with mutations in BRCA, a critical component of homologous recombination repair (HRR). PARPi activity extends beyond BRCA, most likely in tumors with other mutations leading to homologous recombination deficiency (HRD), although the best molecular predictors of PARPi response are unknown. Platinum sensitivity, often used as a surrogate predictive indicator for PARPi response, does not adequately identify all pts likely to respond. Next generation sequencing (NGS) analysis of tumor tissue can identify somatic BRCA mutations as well as other gene alterations in the DNA repair pathway and thus may be a superior method for selection of pts for PARPi therapy. Rucaparib, an oral PARPi, is being developed for treatment of high grade ovarian cancer (HGOC). A novel, integrated, translational-clinical program (ARIEL) is ongoing to identify pts who may benefit from rucaparib treatment. **Methods:** ARIEL2 (NCT01891344) is a Phase 2 trial of rucaparib that aims to identify a molecular HRD signature that predicts response. The signature will be applied prospectively to the analysis of ARIEL 3 (NCT01968213), a Phase 3 study in a similar population. ARIEL2 is ongoing. Eligible pts (n=180) have relapsed, platinum-sensitive HGOC and measurable disease. All pts have a pre-dose biopsy and provide archival tumor tissue. Tumor tissue HRR status assessment uses Foundation Medicine's NGS platform and Univ. of Washington's BROCA-HR panel, with the initial HRD algorithm developed using in vitro/in vivo and TCGA (and similar) bioinformatic data. Key efficacy analyses to be correlated with tumor HRR status are PFS and response (RECIST v1.1, GCIG CA-125). The number of *gBRCA* pts is limited to maximize analysis of non-*gBRCA* response predictors. The optimized algorithm will then be tested prospectively in ARIEL3 (n=540), an ongoing, randomized (2:1), placebo-controlled maintenance trial in platinum-sensitive HGOC in remission after platinum-based therapy. The primary endpoint of ARIEL3 is PFS in HRD subgroups determined by NGS analysis of archival tumor tissue using the ARIEL2 optimized algorithm. Clinical trial information: NCT01891344 and NCT01968213.

**TPS5620 General Poster Session (Board #397B), Sat, 8:00 AM-11:45 AM**

**Phase II study of oral ENMD-2076 administered to patients with ovarian clear cell carcinoma: A trial of the Princess Margaret Phase II Consortium.** *Presenting Author: Cristina Martin-Lorente, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Ovarian clear cell carcinoma (OCCC) represents nearly 15% of all epithelial ovarian carcinomas (EOC). This histology is associated with resistance to chemotherapy and a worse prognosis. VEGF has been found to be strongly expressed in OCCC. Somatic mutations in the ARID1A (the AT-rich interactive domain 1A gene that encodes BAF250a, a key component of the SWI/SNF chromatin remodeling complex) has also been demonstrated in 46-57% of OCCCs. Alteration of this chromatin remodeling complex may result in upregulation and overexpression of Aurora A. ENMD-2076 is a multi-target kinase inhibitor, which has selective activity against Aurora A and multiple antiangiogenesis and lymphangiogenesis targets. In a Phase II study in platinum-resistant EOC, 58% of the patients treated with single agent ENMD-2076 showed partial response or stable disease, the PFS at 6 month was 22% with a median time to progression of 3.6 months. Two out of 3 patients with OCCC who were enrolled had a longer PFS than the median. **Methods:** This is a multi-center, Phase II study, in patients with recurrent OCCC to assess response rate and progression free survival rate, as primary endpoints, and duration of overall response, as a secondary endpoint, of single agent ENMD-2076 275 mg/day. Exploratory endpoints include association of somatic mutations in PI3KCA, ARID1A and PTEN, and ARID1A and PTEN expression with outcome and response. Patients ECOG $\leq$2, with histologically documented diagnosis of recurrence OCCC, any number of prior treatment regimens (chemotherapy, biologics or other target therapies except for Aurora A targeted therapies), and measurable disease (RECIST criteria 1.1) are eligible. Based on data from previous studies, a sample size of 36 patients will provide 95% power to detect an improvement in response rate from 10 to 30% and 90% power to detect an increase in 6 month PFS from 20 to 40%. Since September 2013, 6 patien Clinical trial information: NCT01914510.

**TPS5621 General Poster Session (Board #398A), Sat, 8:00 AM-11:45 AM**

**The PARAGON phase 2 trial of anastrozole in women with potentially hormone responsive recurrent/metastatic gynecologic neoplasms.** *Presenting Author: Katrin Marie Sjoquist, NHMRC Clinical Trials Centre (CTC), University of Sydney and Cancer Care Centre, St George Hospital, Sydney, Australia*

**Background:** Gynaecological cancers of several pathological subtypes express estrogen and/or progesterone hormone receptors (ER/PR). Previous studies, [all or mostly] retrospective, have reported variable rates of tumour response and clinical benefit. Prospective studies are needed to determine the activity of aromatase inhibitors in women with potentially hormone responsive recurrent gynaecological cancers, and to determine possible predictors of response. **Methods:** PARAGON is a Gynecologic Cancer InterGroup phase 2 trial lead by the Australia New Zealand Gynaecological Oncology Group and NHMRC Clinical Trials Centre, in collaboration with Cancer Research UK and the Belgian Gynaecological Oncology Group. The study is designed to facilitate research in rare tumours. The protocol enrols postmenopausal women with recurrent gynaecological cancers of 7 different subtypes: epithelial ovarian cancer (EOC) with only rising CA125 after first line chemotherapy; platinum resistant/refractory EOC; low grade EOC; endometrial carcinomas; endometrial stromal sarcomas; miscellaneous sarcomas; and, granulosa cell and other sex cord stromal tumours. ER/PR positivity must be demonstrated by immunohistochemistry. Each subgroup will enrol 25-50 patients with defined stopping rules based on response and reviewed by an independent data monitoring committee (IDMC). Study treatment is anastrozole 1 mg daily until disease progression or unacceptable toxicity. The primary endpoint is clinical benefit (complete response, partial response, or stable disease at x months). Secondary endpoints include progression free survival, response duration, aspects of QoL, toxicity. Blood and tumour samples are being collected for translational studies and confirmation of ER/PR positivity. Recruitment commenced in 2011 in Australia, New Zealand and the United Kingdom. 236 of 350 planned patients have been enrolled to February 2014. Accrual to the platinum resistant/refractory subgroup closed on 9 December 2013. Anastrozole is being provided by AstraZeneca for study participants in Australia and the UK. This study has been partially funded by a grant from Cancer Australia (APP632740). Clinical trial information: ACTRN12610000796088.

**TPS5622 General Poster Session (Board #398B), Sat, 8:00 AM-11:45 AM**

**Double-blind, placebo-controlled, randomized, phase 2 study to evaluate the efficacy and safety of maintenance therapy with anti-TA-MUC1 monoclonal antibody PankoMab after chemotherapy in patients with recurrent epithelial ovarian carcinoma.** *Presenting Author: Jonathan A. Ledermann, UCL Cancer Institute, University College London, and University College London Hospitals, London, United Kingdom*

**Background:** PankoMab is a potent humanized glyco-engineered IgG1 recognizing the tumor-specific carbohydrate/protein epitope TA-MUC1 expressed virtually only on tumor cells of a wide variety of cancers with up to 95% expression in ovarian (OvCa), NSCL and breast cancers. Phase 1 study results were presented at ECCO 2013 (C. Sessa et al., Abstract 849). Drug was well tolerated, clinical benefit (CB: CR, PR and SD) observed in pts. with solid tumors with CB rate of 40% incl. 1 CR of 485 d out of 20 pts. with OvCa. OvCa was selected as target indication for a randomized phase 2 maintenance therapy trial of PankoMab in TA-MUC1 positive pts. **Methods:** Study design: Randomized, placebo-controlled, double-blind Phase 2 multinational study at 40 sites in 8 European countries. Pts. with outcome of CR, PR or SD after most recent line of chemotherapy (CT) are randomized in a 2:1 ratio for treatment with either PankoMab or placebo. Treatment regimen: 500 mg starting dose followed by 1700 mg 7 d later, to be repeated q3w. Pt. stratification by: (i) Duration of treatment-free interval of the most recent platinum based CT preceding the CT to which the pt. has just responded, (ii) Type of response to CT the patient has just received, (iii) Number of prior lines of CT. Sample size: Total of210 assuming median PFS of 4 m. in placebo and 6 m. in PankoMab arm (HR 0.67; overall 1-sided significance level 0.05). Study endpoints: Primary: PFS using modified immune related RECIST v1.1 criteria; secondary: OS, tumor response, safety, QoL, correlation of efficacy/safety with TA-MUC1 IHC score, soluble TA-MUC1 levels, Fc□ receptor status, and PK. Main entry criteria: TA-MUC1 pos. tumor samples, recurrent epithelial OvCa; 2 – 4 lines of previous CT; CR, PR, or SD after most recent CT; ≤5 wk. interval between last CT dose and randomization.; treatment-free interval of ≤12 mo. before most recent CT; sensitive or resistant but not refractory to most recent platinum based CT; ECOG PS ≤1. Current status: All sites initiated, 36 pts. pre-screened, 6 pts. enrolled, results expected 2015. EudraCT: 2013-000931-28. Clinical trial information: NCT01899599.

**TPS5623 General Poster Session (Board #399A), Sat, 8:00 AM-11:45 AM**

**A first-in-human dose escalation and dose-finding phase I/II trial of IMAB027 in patients with recurrent advanced ovarian cancer (GM-IMAB-002-01).** *Presenting Author: Dirk Jaeger, National Center for Tumor Diseases, University of Heidelberg, Heidelberg, Germany*

**Background:** Ovarian cancer is a commonly diagnosed incurable disease with approximately 29,000 deaths annually. Surgery followed by platinum-based chemotherapy is the initial standard of care. However, the majority of patients relapse and therapy options are very limited. 25-53% of ovarian cancers express claudin 6 (CLDN6) a carcino-embryonic transmembrane protein, which is absent from normal adult tissue. IMAB027 is a chimeric antibody specifically binding to CLDN6 and not cross-reacting with other proteins. Based on preclinical data and compassionate use data, IMAB027 may provide a well tolerable treatment option with a high potential to be clinically beneficial. **Methods:** This first-in-human, open-label, combined dose escalation Phase I/II trial assesses the safety/tolerability and the clinical efficacy of IMAB027 in patients with ovarian cancer. The Phase I part includes two stages: stage 1 comprises an intra-patient accelerated dose escalation and stage 2 a classical 3+3 inter-patient dose escalation design to determine the MTD based on DLTs and to define the recommended dose for the subsequent Phase II part. The Phase II part is a single-arm, safety/tolerability study with a planned enrolment of about 60 patients. Our novel combinatory approach enables a smooth transition of patients from Phase I to Phase II and ensures continuous treatment of patients benefitting from IMAB027. An independent DSMB is continuously monitoring the conduct of the study. The trial was approved by responsible local regulatory authorities/ethics committees and is registered at ClinicalTrials.gov (NCT02054351). Eligible patients had to have CLDN6+ ovarian cancer which was either symptomatic or asymptomatic (patients with CA125-rise without detectable tumor lesions, who had at least one line of standard treatment). Currently, there is no treatment available for asymptomatic patients with a high risk of disease recurrence. IMAB027 may provide a non-aggressive treatment solution for such patients. In addition, we evaluate an extensive set of biomarkers with prognostic potential, and correlation analysis with clinical outcome will be performed. Clinical trial information: NCT02054351.

**TPS5624 General Poster Session (Board #399B), Sat, 8:00 AM-11:45 AM**

**Randomized phase II study of 3 versus 6 courses of neoadjuvant carboplatin-paclitaxel chemotherapy in stage IIIC or IV epithelial ovarian cancer.** *Presenting Author: Claudio Zamagni, Addarii Medical Oncology Unit, S.Orsola-Malpighi Hospital, Bologna, Italy*

**Background:** The role and the duration of neoadjuvant chemotherapy (NACT) in advanced epithelial ovarian cancer (AOC) are still debated. A phase III randomized trial showed that 3 courses of NACT followed by surgery were not inferior to primary debulking surgery followed by chemotherapy (CHT) for patients (pts) with AOC. Moreover, the absence of residual tumor after surgery was found to be the single most important independent prognostic factor. In our preliminary experience pts with bulky stage IIIC or IV AOC were treated with 6 courses of NACT followed by surgery and we observed a complete cytoreduction rate up to 63% ; the survival data did not suggest a detrimental effect of such strategy. Considering the lack of evidence regarding the best standard of care for pts with AOC, a randomized study of 3 *vs* 6 courses of NACT was designed to verify if 3 more courses of NACT are associated to an increase of complete cytoreductive surgery rate (CCSR) (primary end-point). **Methods:** this is a multicenter randomized, phase II study of 3 *vs* 6 courses of NACT in AOC. The main eligibility criteria are ECOG PS ≥ 2, histologically confirmed FIGO stage IIIC-IV epithelial ovarian cancer, unsuitable for complete primary cytoreductive surgery (inoperability confirmed by open laparoscopy or laparotomy). Pts will receive 3 or 6 courses of i.v. carboplatin AUC 5 and paclitaxel 175 mg/m$^2$ every 3 weeks, followed by surgery.Tumor tissue will be collected for analyses of prognostic and predictive biomarkers, including ESR1 mRNA, HER2 and HER3 expression, BRCA1, BRCA2 and PI3KCA mutations. By hypothesizing a CCSR of 43% in Arm A (3 courses) and 63% in Arm B (6 courses), with a two-sided alpha error of 0.05 and a power of 0.80, 214 pts (107 in each arm) are to be enrolled in 2 years. An interim analysis has been scheduled after the first 120 pts in order to end the enrollment in the phase II and to start a phase III (with survival as primary endpoint) in case of the endpoint for efficacy (CCSR) will be reached at that time. The sample size of the interim analysis was calculated by considering the same alpha error (0.05) but a lower power value (0.50) than those of the global sample size calculation. The first patient was enrolled in January 2014. Clinical trial information: 2013-002520-17.

**TPS5625 General Poster Session (Board #400A), Sat, 8:00 AM-11:45 AM**

**A phase 3 randomized double-blind trial of maintenance with niraparib versus placebo in patients with platinum-sensitive ovarian cancer (ENGOT-OV16/NOVA trial).** *Presenting Author: Ursula Matulonis, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Niraparib is a potent, oral poly(ADP-ribose)polymerase (PARP)1/2 inhibitor with efficacy in both germline BRCA mutation (gBRCA-mut) ovarian cancer (OvCa) and BRCA negative (nongBRCAmut) high grade serous OvCa (HGSC). Ph I data established a RP2D of 300 mg with anti-OvCa activity and is well-tolerated. **Methods:** The ENGOT-OV16/NOVA study is a double-blind, 2:1 randomized, placebo controlled international ph III study of oral niraparib versus placebo in patients (pts) with platinum (plat) sensitive recurrent OvCa. Primary objective is to evaluate efficacy of niraparib as maintenance therapy in pts who have plat sensitive OvCa as assessed by the prolongation of progression free survival (PFS). PFS will be independently evaluated in a cohort of gBRCAmut pts and in pts who have HGSC histology and are nongBRCAmut. Secondary objectives are: (1) bridge the centralized BRCA mutation test method to the candidate companion diagnostic test, if needed; (2) evaluate add'l measures of clinical benefit including pt reported outcomes, PFS2, chemotherapy free interval, overall survival; (3) evaluate the safety/tolerability of niraparib vs placebo; (4) evaluate QTc in a subset of niraparib-treated OvCa pts. A recent food effect sub study in 15 pts demonstrated no effect of a high fat meal on the PK's of a single 300 mg dose of niraparib in OvCa pts. Main study eligibility includes: histologically confirmed OvCa, fallopian tube or peritoneal cancer, HGSC histology or known gBRCAmut, plat sensitive recurrence, completion of at least 2 previous courses of plat-containing therapy and sensitivity to both via radiographic imaging, normal or CA125 decrease by 90% after last plat, agreement by pt to undergo gBRCA status prior to randomization, availability of FFPE archival tumor, ECOG PS 0-1, normal organ function, and can take PO. The main study is sized to address PFS endpoint w/ an accrual goal of 360 pts. As of 04 February 2014, 37 pts have been enrolled and randomized in the study. The trial will be open at $>$100 sites in 15 countries in collaboration with ENGOT (NSGO, AGO, NCRI, GEICO, BGOG, GINECO, MaNGO, AGO Austria, MITO). Clinical trial information: NCT01847274.

**TPS5626 General Poster Session (Board #400B), Sat, 8:00 AM-11:45 AM**

**Open-label phase II clinical trial of orteronel (TAK-700) in metastatic or advanced nonresectable granulosa cell ovarian tumors: The GREKO II study.** *Presenting Author: Alicia Hurtado, Hospital Universitario Fundación Alcorcón, Alcorcón, Spain*

**Background:** Granulosa-cell tumors (GCT) of the ovary are a rare entity characterized by its genomic stability. A punctual mutation at the FOXL2 gene 402C→G (C134W) is present in up to 90% of cases. FOXL2 is a transcription factor that physiologically regulates the expression of the Steroidogenic Factor-1 (SF-1). This factor is known downregulate the expression of the enzyme CYP17 (key in androgens and 17-OH-progesterone synthesis). Thus FOXL2 mutations could impact hormonal synthesis by CYP17 in GCT. In fact, a previous study by our group has found clinical activity of ketoconazole, a well known CYP17 inhibitor, in this tumor (GREKO I trial). Orteronel (TAK700) is a selective inhibitor of 17, 20-lyase, that is being developed as an endocrine therapy for relevant hormone-sensitive cancers such as prostate and breast cancer. Orteronel is expected to suppress sex hormone levels in both circulation and relevant hormone-dependent malignant tissue. Thus we aimed to test the clinical activity of such drug in GCT. **Methods:** An open-label phase II single arm clinical trial has been designed for women with metastatic or locally advanced nonresectable granulosa cell ovarian tumor that harbors the somatic mutation FOXL2 402C→G (C134W) and who have not received prior treatment with any CYP17 inhibitor. Treatment will consist on Orteronel 300mg BID, given orally, continuously in a 28-day treatment cycle. The primary objective is to assess the clinical benefit rate. Since this is an extremely unfrequent disease, 10 Spanish institutions will get involved. The active support of a big collaborative group (GETHI) will guarantee candidates to be refereed to such institutions. An extensive translational research will be included in order to improve our scarce knowledge of GCT. Clinical trial information: 2013-003128-35.

**TPS5627 General Poster Session (Board #401A), Sat, 8:00 AM-11:45 AM**

**The REZOLVE phase II trial to evaluate the safety and potential palliative benefit of intraperitoneal bevacizumab in patients with symptomatic ascites due to advanced, chemotherapy-resistant ovarian cancer.** *Presenting Author: Katrin Marie Sjoquist, NHMRC Clinical Trials Centre (CTC), University of Sydney and Cancer Care Centre, St George Hospital, Sydney, Australia*

**Background:** We hypothesise that intraperitoneal (IP) administration of bevacizumab will reduce formation, and delay time to re-accumulation, of ascites in patients with malignant ascites and chemotherapy-resistant ovarian and related cancers. The aim is to evaluate the activity of IP bevacizumab in delaying re-accumulation of ascites in patients with chemotherapy resistant ovarian, peritoneal and fallopian tube cancers with symptomatic ascites. The primary objective is to evaluate the activity of IP bevacizumab to reduce formation or delay re-accumulation of malignant ascites (median time from first to second therapeutic ascitic drainage). Secondary outcomes: (1) safety (2) activity of a second dose of IP bevacizumab (median time from second to third therapeutic ascitic drainage) (3) HRQOL. Correlative objectives include assessment of molecular mechanisms of ascites formation and changes in inflammatory markers over time. **Methods:** Eligibility: Patients with platinum resistant/refractory recurrent ovarian cancer with symptomatic, cytologically confirmed malignant ascites that has recurred following therapeutic ascitic drainage within 4 weeks prior to study registration, who are no longer receiving chemotherapy. Treatment: Patients will undergo therapeutic drainage and bevacizumab (5 mg/kg) administered as an IP infusion in 100ml saline followed by 400mL saline over 30-60 minutes. This procedure may be repeated, providing the paracentesis occurs at least 42 days after each administration of bevacizumab. Post-drainage abdominal ultrasound will document remaining fluid volume. Ultrasound and estimation of ascites volume will be performed within 48 hours prior to each clinical assessment (every 3 weeks while on study). 16 patients will give 80% power with 95% confidence to exclude a rate of 20% in favour of a clinically meaningful rate of 54% of patients paracentesis-free at 6 weeks **Summary:**Study is open at 3 of 5 planned sites and 1 patient has been recruited. Funding: Cancer Australia (APP1050134) and seed funding from the Ovarian Cancer Research Foundation. Clinical trial information: ACTRN12611000801910.

**TPS5628 General Poster Session (Board #401B), Sat, 8:00 AM-11:45 AM**

**A phase III trial of postoperative chemotherapy or no further treatment for patients with node-negative stage I-II intermediate- or high-risk endometrial cancer. ENGOT-EN2-DGCG/EORTC 55102.** *Presenting Author: Mansoor Raza Mirza, Danish Gynecologic Cancer Group, Copenhagen, Denmark*

**Background:** Patients with medium and high-risk stage I and II endometrial cancers have, despite radical surgery, high risk for local and distant progression. Adjuvant radiotherapy was unable to improve survival. Two phase III studies failed to show any difference in survival between radiotherapy and chemotherapy, though both studies had suboptimal chemotherapy regimens/included good prognosis patients. The GOG-122 phase 3 study in stage III and IV found significant improvement in survival in the chemotherapy arm. It is of utmost importance to clarify the role of adjuvant combination chemotherapy comparing to no further treatment in this patient population. Paclitaxel-Carboplatin combination chemotherapy is effective and well tolerated. **Methods:** This multicenter, open-label, 1:1 randomized, phase 3 investigator-initiated study is evaluating postoperative chemotherapy compared with no further treatment in patients with medium- or high-risk, node negative stage I, or stage II endometrial cancer (stage 1: grade 3 endometrioid or any type 2 histology; stage 2: all patients). Patients have undergone hysterectomy and bilateral salpingo-oopherectomy and pelvic lymphadenectomy (minimum 12 pelvic nodes. Para-aortic LNE is optional). Adjuvant brachytherapy is permitted in both arms, though external beam radiotherapy is not allowed. Primary endpoint is overall survival, and secondary endpoints include disease specific survival, progression-free survival, rates of isolated pelvic, distant and mix relapses, quality of life, compliance and toxicity. Carboplatin (AUC5) and paclitaxel (175mg/m2) is given iv every 3 weeks, total 6 courses. This trial will enrol 678 patients. This trial is enrolling patients. Interested institutions are welcome to join the study. Clinical trial information: NCT01244789.

**TPS5629 General Poster Session (Board #402A), Sat, 8:00 AM-11:45 AM**

**Phase II study of XL184 (cabozantinib) in recurrent or metastatic endometrial cancer: A trial of the PMH, Chicago, and California Phase II Consortia.** *Presenting Author: Michelle Wilson, Department of Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Recurrent endometrial cancer (EC) has a poor prognosis with few therapeutic options. Targeting angiogenesis through VEGF inhibition has demonstrated real but limited efficacy. Simultaneous inhibition of angiogenesis and putative resistance mechanisms may provide more durable therapeutic responses. MET/HGF (hepatocyte growth factor) paracrine signaling has been implicated in more aggressive tumour biology, angiogenesis and resistance to VEGF targeting in EC. XL-184 (cabozantinib) is an orally bioavailable, multi-targeted inhibitor with activity against MET and VEGFR2 in addition to TIE2, RET, AXL and KIT. **Methods:** This phase II, multicenter single arm trial has a planned enrollment of 36 pts utilizing a Simon 2-stage design to evaluate co-primary endpoints of response rate and 12 week progression-free-survival (PFS) in pts with serous, endometrioid or mixed histology EC (experimental cohort). Eligible pts must have radiographic progression after 1 line of chemotherapy for metastatic disease, or progression within 12 months of adjuvant chemotherapy; prior radio- and hormonal therapy is allowed. Stage I has a planned accrual of 18 pts, study will proceed to stage II with observation of $> 2$ partial responses (PR) and $> 6$ 12-wk PFS. Pts are also accrued to an exploratory cohort (maximum 30 pts) of rare histology EC (clear cell, carcinosarcoma). XL-184 is administered at a starting dose of 60mg orally once daily on a continuous 28 day cycle. Adverse event (AE) reporting is as per CTCAE v4.0. Pts undergo first CT evaluation after 1 cycle, those with SD or PD and $\leq$ grade 1 toxicity are eligible for dose escalation. Response assessment is completed every 2 cycles (starting with cycle 3) and per RECIST 1.1. Correlative studies will explore associations between tumour response and baseline mutational and met amplification status. To date 14 (experimental) and 6 (exploratory) pts have been enrolled. Median age is 64 (range 51-80). All pts have received chemotherapy and 70% prior radiation. 44 cycles have been completed (median 2 range 1-5). Once the final pts have been accrued to the experimental arm, a decision to proceed to stage II will be made. Clinical trial information: NCT01935934.

**TPS5630^ General Poster Session (Board #402B), Sat, 8:00 AM-11:45 AM**

**ZoptEC: Phase III study of zoptarelin doxorubicin (AEZS-108) in platinum-taxane pretreated endometrial cancer (Study AEZS-108-050).** *Presenting Author: David S. Miller, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** A platinum-taxane combination is commonly used both as adjuvant and first line therapy for advanced, recurrent, and metastatic endometrial cancer (EC). Zoptarelin doxorubicin (AEZS-108) is a hybrid anticancer agent in which doxorubicin is chemically linked to zoptarelin, a D-$Lys_6$-analogue of luteinizing hormone releasing hormone (LHRH). Zoptarelin doxorubicin was initially evaluated in tumor types reported to express receptors for LHRH. Depending on the method used to determine LHRH receptor expression, LHRH receptors have been found in 40% to 90% of ECs. A Phase II study of zoptarelin doxorubicin in EC patients showed activity, including those previously treated with platinum-taxane [Emons et al. 2014]. **Methods:** This open-label, randomized-controlled study compares the efficacy and safety of AEZS-108 and doxorubicin (ClinicalTrials.gov Identifier: NCT01767155; EudraCT No: 2012-005546-38; ZoptEC**:** Zoptarelin doxorubicin in endometrial cancer). The study is expected to include 500 EC patients progressing after prior therapy with platinum-taxane-based chemotherapy. There are about 120 expected study sites in North America, Western and Central/Eastern Europe, and Israel. Patients are centrally randomized in a 1:1 ratio and receive either AEZS-108 (267 $mg/m^2$) or doxorubicin (60 $mg/m^2$) intravenously, every 3 weeks and for up to 9 cycles. Response will be evaluated every 3 cycles during treatment, thereafter every 12 weeks until progression. All patients will be followed for survival as the primary efficacy endpoint (EP). The final analysis is planned after about 384 deaths have occurred, interim analyses after about 128 (futility only) and 192 deaths. Secondary EPs include progression-free survival (PFS), objective response rate (ORR), and clinical benefit rate (CBR). Quality of life will be compared based on EORTC QLQ-30 and EN-24 questionnaires. A substudy in about 40 patients compares the pharmacokinetics of AEZS-108 and doxorubicin and doxorubicinol. Clinical trial information: NCT01767155.

**TPS5631 General Poster Session (Board #403A), Sat, 8:00 AM-11:45 AM**

**A phase 1/2 study of ipilimumab in women with metastatic or recurrent HPV-related cervical carcinoma: A study of the Princess Margaret and Chicago N01 Consortia.** *Presenting Author: Stephanie Odile Lheureux, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Cervical cancer (CC) is the second cause of cancer-related mortality in women worldwide. Response to second-line chemotherapy is infrequent and the poor outcome of patients with advanced disease (median survival 9 months) warrants novel therapeutic strategies that exploit abnormal tumor biology. Based on new evidence that host-dependent immunologic status and HPV-induced immune evasion are responsible for persistent HPV infection, the prime causal factor of CC, immunotherapy is an attractive emerging strategy to target this disease. Ipilimumab is a fully humanized monoclonal antibody that blocks cytotoxic T-lymphocyte antigen-4 (CTLA-4), a molecule that acts to downregulate the T cell immune response. **Methods:** A 2-step multicenter trial was designed to evaluate ipilimumab IV in metastatic or recurrent HPV-related CC (NCT01693783). Eligible patients require measurable disease progression and at least one previous platinum based line of chemotherapy. A safety phase I cohort was planned with ipilimumab 3 mg/kg every 21 days for four cycles in 6 evaluable patients. After demonstration of safety, a phase II trial was planned with ipilimumab 10 mg/kg at the same schedule; followed by four additional cycles maintenance therapy at the same dose every 12 weeks for patients with radiologic confirmed response or stabilization. The primary objective is to assess the safety and the objective response rate at the end of cycle 4. 18 evaluable patients are scheduled and if at least 1 partial response is seen, an additional 14 patients will be enrolled. Immune assessment studies are performed on peripheral blood collected prior to and following ipilimumab therapy and on archived and fresh tumour tissue obtained prior to treatment and within the first week of cycle 2. This trial was activated in September 2012. The phase I cohort is now completed, and 8 patients have been enrolled in the phase II. The overall median age of study subjects is 49 (range 36-60) with a majority of squamous histology type (13/14 patients). A median of 3 cycles have been administered, and 12 patients have undergone pre- and post-treatment biopsies. Clinical trial information: NCT01693783.

**TPS5632 General Poster Session (Board #403B), Sat, 8:00 AM-11:45 AM**

**A phase III trial of adjuvant chemotherapy following chemoradiation as primary treatment for locally advanced cervical cancer compared to chemoradiation alone: Outback (ANZGOG0902/GOG0274/RTOG1174).** *Presenting Author: Linda R. Mileshkin, Peter MacCallum Cancer Center, Melbourne, Australia*

**Background:** Cervical cancer is a global health problem and the most common cause of cancer-related death among women in developing nations. Despite the recently developed cervical cancer vaccine, many women will continue to die from cervical cancer for many decades unless existing treatments can be improved. Unscreened women often present with locally-advanced disease that has a 5-year overall survival (OS) rate of 60% or less following standard chemo-radiation. Although some evidence suggests that adjuvant chemotherapy following chemo-radiation may be of value, its role remains controversial. **Methods:** OUTBACK is a randomised phase III Gynecologic Cancer InterGroup (GCIG) trial designed and led by the Australia New Zealand Gynaecological Oncology Group (ANZGOG) in collaboration with the NHMRC Clinical Trials Centre. Participating countries (groups) include Australia & New Zealand (ANZGOG), the USA (GOG, RTOG), Saudi Arabia, and Canada (RTOG). OUTBACK is suitable for women with locally advanced cervical cancer (FIGO stage $IB_1$ & node positive, $IB_2$, II, IIIB or IVA). The primary objective is to determine if the addition of adjuvant chemotherapy to standard cisplatin-based chemo-radiation improves OS. Women are randomized to either (A) standard cisplatin-based chemo-radiation or (B) standard cisplatin-based chemo-radiation followed by 4 cycles of carboplatin and paclitaxel chemotherapy. Secondary objectives are to compare progression-free survival, treatment-related toxicity, patterns of disease recurrence, quality of life and psycho-sexual health, and the association between radiation protocol compliance and outcomes. Blood and tumour samples are collected from consenting patients for future translational studies. 780 women will be enrolled to determine if the addition of adjuvant chemotherapy can improve the 5-year OS rate by $\geq$ 10%. OUTBACK opened in Australia & New Zealand in 2011 and in early 2012 the trial opened in the USA. 285 patients have been recruited from 145 active sites. The IDMC last reviewed the trial in September 2013 and recommended that the trial continue as planned. Clinical trial information: ACTRN12610000732088.

**6000 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**The *KRAS*-variant and cetuximab response in RTOG 0522.** *Presenting Author: Joanne B. Weidhaas, Yale School of Medicine, New Haven, CT*

**Background:** The *KRAS*-variant, a germ-line mutation in a microRNA-binding site in *KRAS*, predicts increased cancer risk and unique cancer biology for many cancers. RTOG 0522 is a phase III trial of cisplatin/radiation +/- cetuximab for patients with locally advanced head and neck cancer. Here we tested the hypothesis that the *KRAS*-variant would predict cetuximab response for these patients. **Methods:** Germline DNA was isolated from blood or buffy coat and tested for the *KRAS*-variant in Mira Dx's CLIA-certified laboratory. Hazard ratios (HR) were estimated by Cox model. Where proportional hazards assumption was invalid, models included time-dependent covariates. **Results:** 413/891 eligible patients on 0522 (46.4%) were tested for the *KRAS*-variant, and 70/413 were positive (16.9%). For progression-free survival (PFS) in the *KRAS*-variant group, there was a significant cetuximab benefit in year 1 (HR 0.31, p=0.04) and a significant interaction between treatment and time (p=0.02), confirming different effects in the first year and after. HR after year 1 was 1.76, but this did not reach statistical significance (p=0.29). The number of events in the *KRAS*-variant group (32) was too small for formal multivariate analysis, but HRs were stable after adjustment for single covariates (age, pack-years, Zubrod, site, p16, stage). In the *KRAS*-wildtype group, HRs for cetuximab effect were 1.00/1.07 with/without adjustment for covariates, similar to the overall trial (1.08). For overall survival (OS) in the *KRAS*-variant group there was a significant cetuximab benefit in years 1-2 (HR 0.19, p=0.03) and a significant interaction between treatment and time (p=0.02) confirming different cetuximab effects in years 1-2 and after. The HR after year 2 was 2.34, but this did not reach statistical significance (p=0.23). HRs were stable after adjustment for single covariates. In the *KRAS*-wildtype group, HRs for cetuximab effect were 0.90/0.93 with/without adjustment for covariates, similar to the overall trial (0.95). **Conclusions:** Our findings suggest that locally advanced head and neck cancer patients with the *KRAS*-variant appear to positively respond to cetuximab, resulting in better short-term PFS and OS. These results warrant further validation through a prospective study. Clinical trial information: NCT00265941.

**6001 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Impact of p16 status on the results of the phase III cetuximab (cet)/radiotherapy (RT).** *Presenting Author: David I. Rosenthal, MD Anderson Cancer Center, Houston, TX*

**Background:** This is a retrospective analysis of the phase III IMCL-9815 trial assessing the role of HPV status in LASCCHN patients (pts) receiving RT+cet or RT by measuring p16 status. **Methods:** The intent-to-treat (ITT) population (424 pts) was randomized to RT+cet or RT. p16INK4A status was determined by immunohistochemistry. **Results:** 312/424 (74%) of the ITT pts were p16 evaluable. Baseline characteristics in the ITT and p16 evaluable pts were similar. In both p16+ and p16- pts, the addition of cet to RT improved locoregional control (LRC), overall survival (OS), and progression-free survival (PFS) (Table). Univariate analyses showed a more pronounced treatment effect of RT+cet vs RT in p16+ pts across all endpoints in both the ITT and the oropharyngeal (OPC) populations; however, interaction tests for LRC, OS and PFS (ITT and OPC) did not demonstrate a significant interaction between p16 status and treatment effect. There were no new safety findings. **Conclusions:** p16 tumor status is strongly prognostic for pts with LASCCHN. Although the number of pts is small, these data showed that the pts benefit more from RT+cet compared with RT alone regardless of p16 status. HPV data are to be presented at the meeting. Observations in the OPC population are being evaluated in the RTOG 1016 trial. Clinical trial information: NCT00004227.

**6002 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Genomic profiling using targeted ultra-deep next-generation sequencing for prediction of treatment outcome after concurrent chemoradiation: Results from the German ARO-0401 trial.** *Presenting Author: Inge Tinhofer, Department of Radiooncology CCM/CVK, Charite University Hospital, Berlin, Germany*

**Background:** Genomic profiling using next-generation sequencing (NGS) has provided novel insights in the genomic landscape of squamous cell carcinoma in the head and neck region (SCCHN). This is the first report on its application within a phase III trial of concurrent chemoradiation in locally advanced SCCHN. **Methods:** Between 2004 and 2008, 364 patients with stage IV SCC of the oro- or hypopharynx were treated with hyperfractionated accelerated radiotherapy with cisplatin/5-FU or mitomycin C/5-FU. From 174 patients (48%) FFPE samples could be collected. HPV DNA PCR and p16 immunohistochemistry were carried out. From 106 cases (29%) targeted NGS was possible. Based on previous reports an SCCHN panel was designed comprised of 224 exons from 53 genes (mean coverage 3000-fold, minimum 370-fold). Only non-synonymous germline and somatic single-nucleotide polymorphisms (SNP) with an allele frequency of >5% were considered. SNP were classified according to a damage-score prediction algorithm. Kaplan-Meier-analysis, log-rank test and multivariate Cox regression analysis were performed. **Results:** The most frequent germline/somatic SNP were found in *TP53* (total 94%, disruptive mutations 22%) followed by *FAT1, PCDH15, KDR, PDGFRA* and *NOTCH1* (14%), with disruptive mutations in *TP53* and *NOTCH1* being almost mutually exclusive. Disruptive mutations in *TP53* were significantly associated with an HPV-negative status and correlated with reduced OS (HR 0.37, 95% CI 0.21-0.65, p=0.0005) and PFS (HR 0.39, 95% CI 0.23-0.69, p=0.001). In contrast, *NOTCH1* mutations were not related to HPV status, were significantly associated with improved OS (HR 2.4, 95% CI 1.1-5.7, p=0.039) and showed a trend to improved PFS (HR 2.1, 95% CI 0.9-5.1, p=0.07). Disruptive mutations in *TP53* and *NOTCH1* remained significant after correction for smoking, HPV and treatment. **Conclusions:** Targeted NGS revealed three SCCHN subgroups with distinct outcomes after chemoradiation. As discriminative factors we identified HPV, *NOTCH1* and disruptive *TP53* mutations. The functional relevance of *NOTCH1* mutations for radio-/chemosensitivity remains to be determined.

**6003 Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Randomized phase III trial of concurrent chemoradiation with or without neoadjuvant gemcitabine, carboplatin, and paclitaxel in locally advanced nasopharyngeal cancer.** *Presenting Author: Terence Tan, National Cancer Centre Singapore, Singapore, Singapore*

**Background:** The role of neoadjuvant chemotherapy in addition to concurrent chemoradiation (CRT) in locally advanced nasopharyngeal cancer (NPC) is unclear. This trial investigates the overall survival (OS), tumor control, toxicity and quality of life (QOL) in stage III-IVB NPC patients treated with this approach. **Methods:** Patients were stratified by N-stage and randomized to neoadjuvant GCP (gemcitabine 1000mg/m$^2$, cisplatin AUC 2.5 and paclitaxel 70 mg/m$^2$) on Days 1 and 8 every three weeks for 3 cycles followed by CRT (radiotherapy 69.96 Gy (RT) with weekly 40mg/m$^2$Cisplatin), or CRT alone. The accrual (total 172) was planned to detect a 15% difference in OS with a one-sided 5% significance level and 80% power. Kaplan-Meier survival curves were compared using Peto's method. Cox regression analyses were performed. **Results:** Between September 2004 and August 2012, 180 patients were accanded, and 172 (GCP 86, CRT 86; WHO type II 7%, type III 93% ) analyzed by intention to treat. The median follow-up was 3.25 years for GCP and 2.69 years for CRT. There was no significant difference in OS between the two arms: 5-year OS 74.8% (GCP) vs 77.6% (CRT); HR =1.05; one-sided p=0.494. No significant difference was seen in the disease-free survival (HR 0.77, 95% CI 0.44–1.35, p=0.362) and distant metastases-free survival (HR 0.80, 95%CI 0.38 – 1.67, p=0.547). Treatment compliance in the neoadjuvant phase was good with relative dose intensity (RDI) between 83-85% but the RDI for concurrent Cisplatin was significantly lower in the GCP arm (75% vs 84%, p=0.003). 98% of patients received RT by intensity-modulated RT or tomotherapy. All patients completed RT except for 1 CRT patient who died during treatment. Overall, the GCP arm had higher rates of grades 3 and 4 pancytopenia (58% vs 37%), neutropenia (66% vs 12%), thrombocytopenia (14%vs 0%) and fatigue (14% vs 2%) than the CRT arm. The global QOL scores were comparable in both arms. The statistical boundary for futility was crossed at this 5$^{th}$ interim analysis and is being reported early on the recommendation of the DSMC. **Conclusions:** Neoadjuvant chemotherapy with GCP did not improve survival in locally advanced NPC and concurrent CRT remains the standard of care. Clinical trial information: CDR0000657121.

**6004** **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Concomitant chemoradiation (CRT) or cetuximab/RT (CET/RT) versus induction Docetaxel/ Cisplatin/5-Fluorouracil (TPF) followed by CRT or CET/RT in patients with Locally Advanced Squamous Cell Carcinoma of Head and Neck (LASCCHN). A randomized phase III factorial study (NCT01086826).** *Presenting Author: Maria Grazia Ghi, Medical Oncology Department, Venezia, Italy*

**Background:** Platinum-based CRT is the standard treatment for LASCCHN. CET/RT is superior to RT alone and it is an alternative treatment to CRT. Induction TPF resulted to be superior to cisplatin/5fluorouracil but its efficacy when added to concomitant treatment is to be demonstrated. We designed this open-label multicenter 2x2 factorial study to assess 2 primary endpoints: 1) overall survival (OS) of induction vs. no induction; 2) Grade 3-4 in-field mucosal toxicity of CRT vs. CET/RT (already presented at ASCO 2013). **Methods:** 421 patients with LASCCHN of the oral cavity, oropharynx, hypopharynx, stage III-IV, ECOG PS 0-1 were randomized to one of four treatment options: Arm A1: CRT (cisplatin/5fluorouracil x 2 concomitant to standard RT fractionation); Arm A2: CET/RT; Arm B1: 3 cycles of TPF followed by the same CRT; Arm B2: 3 cycles of TPF followed by CET/RT. The superiority hypothesis of OS comparison of TPF induction vs. no induction (Arms B1+B2 vs. A1+A2), requires 204 deaths to detect a relative reduction of 33% with 2-sided 5% significance level for the log-rank test and a power of 80%. **Results:** 415 out of 421 patients (six major violations) were finally analyzed: 207 in induction and 208 in concomitant arm. By march 2014, at a median follow-up of 41.3 months (mos), 243 events for PFS and 201 deaths were observed. Radiological CR was 43.5% in induction and 28% in concomitant arm (p=0.002) Median PFS was 29.7 mos in induction vs 18.5 in concomitant arm with a 3-year PFS of 46.8% vs 36.7% (HR:0.73; 95%CI 0.57-0.94; p=0.015), respectively. Median OS was 53.7 mos in induction vs 30.3 in concomitant arm with a 3-year OS of 57.6% vs 45.7% (HR:0.72; 95%CI 0.55-0.96; p=0.025) respectively. Compliance to concomitant treatments was not affected by induction TPF. **Conclusions:** Induction TPF followed by CRT or CET/RT significantly improved PFS and OS (independently from the type of concomitant strategy) in LASCCHN patients without compromising compliance to the concomitant treatments. Clinical trial information: NCT01086826.

**6005** **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Final analysis: A randomized, blinded, placebo (P)-controlled phase III study of adjuvant postoperative lapatinib (L) with concurrent chemotherapy and radiation therapy (CH-RT) in high-risk patients with squamous cell carcinoma of the head and neck (SCCHN).** *Presenting Author: Kevin J. Harrington, Institute of Cancer Research and Royal Marsden Hospital, London, United Kingdom*

**Background:** Epidermal growth factor receptor (EGFR) and ErbB2 are overexpressed in up to 90% and 40% of SCCHN, respectively. L, a tyrosine kinase inhibitor (TKI) of both EGFR and ErbB2, demonstrates tumor responses in SCCHN. **Methods:** Patients with resected stage II-IVA SCCHN, with a surgical margin ≤5mm and/or extracapsular extension were randomized to CT-RT with either P or L. RT was 66Gy (2Gy per day, 5 days per week).100 mg/m$^2$of cisplatin was administered on days 1, 22 and 43 of RT. P or L 1500 mg/day was given for up to one week prior to CT-RT, during CT-RT and for up to 12 months as monotherapy maintenance. Patients were stratified by nodal status, primary tumor location, geographical region and ErbB1 expression. The study had 80% power to detect a 10% absolute difference in disease free survival (DFS) rate (55% to 65%). **Results:** 688 patients were in the ITT population, 346 L and 342 P. Treatment arms were well balanced for prognostic factors. Median total doses of cisplatin (266.5 and 280 mg/m$^2$, L and P respectively) and median doses and duration of RT were similar in both arms. At the time of unblinding, recurrence/death from any cause was seen in 35% in L and 32% in P by independent review committee (IRC): Median DFS (95% CI) L: 53.6 mo (45.8, Not Reached [NR]); P: NR (54.6, NR), HR (95% CI) = 1.10 (0.85, 1.43) 2-sided p value = 0.45. Investigator results confirmed the IRC assessment: HR 1.03 (0.81, 1.30), p=0.82. No significant differences were observed in DFS for any of the pre-specified subgroups, including HPV. Death occurred in 30% L and 32% P; HR (95% CI) = 0.96 (0.73, 1.25). At least one adverse event was seen in 99% L and 98% P (SAEs 48% L/40% P, fatal AEs 7% L/5% P). AEs seen more in L were those expected with a TKI: diarrhea 42% vs 12%, rash 49% vs 30%, vomiting 46% vs 35%. Decrease in left ventricular ejection fraction SAEs were noted in 10 (3%) subjects L vs 3 (<1%) P. **Conclusions:** In patients with resected SCCHN at high risk for recurrence, L, when added to standard therapy RT/CDDP, does not extend DFS. DFS in both treatment arms exceeded adjuvant CT-RT compared with historical randomized data. Clinical trial information: NCT00424255.

**6007** **Oral Abstract Session, Mon, 8:00 AM-11:00 AM**

**Randomized placebo-controlled trial (RCT) of erlotinib for prevention of oral cancer (EPOC).** *Presenting Author: William Nassib William, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Loss of heterozygosity (LOH) profiles predict oral cancer (OC) risk in patients (pts) with oral premalignant lesions (OPL). We conducted a randomized, multi-center, double-blind, placebo-controlled, personalized medicine trial of the EGFR inhibitor erlotinib in pts with OPLs defined as high risk by molecular criteria. Our primary hypothesis was that erlotinib would improve oral cancer-free survival (OCFS) in the high-risk, LOH+ population. **Methods:** Pts with histological evidence of an OPL (with or without a prior history of invasive OC) underwent LOH profiling at 3p14, 9p21, 4q, 8p, 11p, 13q, 17p. LOH+ pts were defined as those with prior OC and LOH at 3p14 and/or 9p21; or those without prior OC and LOH at 3p14 and/or 9p21 plus an additional chromosomal site. LOH- pts received no treatment. LOH+ pts were stratified by history of OC, then randomized (1:1) to erlotinib 150 mg po daily for 12 months or placebo and were assessed every 3-6 months for development of invasive OC. Primary endpoint was OCFS in the intent-to-treat (ITT) population. With a planned sample size of 150, the study had 85% power to detect a hazard ratio (HR) of 0.47 with a 5% 2-sided type I error rate (stratified logrank). **Results:** Of 375 pts evaluated for LOH, 254 were LOH+, of which 150 were randomized to erlotinib (N=75) or placebo (N=75). After a median follow up of 2.9 years, 44/179 LOH+ pts not randomized or randomized to placebo developed OC, versus 15/121 LOH- pts (HR=2.1, 95% CI 1.2-3.8, p=0.01). Among the randomized, LOH+, ITT population, 18/75 (24%) placebo-treated pts developed OC versus 22/75 (29%) erlotinib-treated pts. The HR for OCFS was 1.2 (95% CI 0.7-2.3, p=0.51) in the ITT population, 0.6 (95% CI 0.2-1.7) in 66 pts without prior OC, and 1.9 (95% CI 0.9-4.2) in 84 pts with prior OC (p=0.08 for interaction). Dose reductions were implemented in 34/75 and 1/75 erlotinib and placebo-treated pts, respectively, mostly due to expected, low-grade toxicities. **Conclusions:** EPOC is the first personalized RCT in cancer prevention and prospectively confirmed LOH as an OC risk marker. Erlotinib did not reduce OCFS in this high-risk population, although the trend of reduced OCFS in pts without prior OC suggests that the timing of this intervention may be important. Clinical trial information: NCT00402779.

**6009** **Clinical Science Symposium, Sun, 11:30 AM-1:00 PM**

**Correlation of T-cell inflamed phenotype with mesenchymal subtype, expression of PD-L1, and other immune checkpoints in head and neck cancer.** *Presenting Author: Vassiliki Saloura, University of Chicago, Chicago, IL*

**Background:** Immunotherapy with checkpoint blockade has shown encouraging activity in squamous cell carcinomas including a case report in tongue cancer (Herbst 2013). PD-L1 expression is common in HNC (Lyford-Pike 2013). In melanoma a T cell-infiltrated phenotype is common and correlates with immune inhibitory pathways. We interrogated the immune microenvironment in a large cohort of HNC in order to identify molecular correlates of an inflamed tumor microenvironment that may predict benefit from checkpoint blockade. **Methods:** We evaluated the presence of a T cell-inflamed tumor microenvironment in a cohort of 134 (Chicago HNC Genomics (CHGC)) and 424 TCGA HNC samples using a melanoma expression signature (Harlin/Gajewksi 2009). We evaluated multiple immune-related markers by IHC in a subset of CHGC tumors including CD8 tumor infiltrating lymphocytes (TIL)(N=73) and PD-L1 (N=55). Results were correlated with genetic and clinical information. **Results:** 47% of CHGC and 33% of TCGA tumors showed a T cell-inflamed phenotype (TCIP) similar to melanoma based on a gene expression signature (Harlin 2009). 75% of HPV(+) tumors showed a TCIP compared to 23% of HPV(-) tumors in both cohorts. Mesenchymal subtype (Keck 2014) strongly correlated with TCIP ($p<2.2x10^{16}$), and 90% of mesenchymal tumors showed TCIP including roughly equal numbers of HPV(+) and HPV(-) tumors in both cohorts. Basal and HPV-negative classical HNC tumors were TCIP negative. Based on IHC, 38% of CHCG tumors showed PD-L1 expression and 64% showed CD8+ TILs, both correlating with TCIP. Additional checkpoint molecules were universally co-expressed in the same TCIP tumors including CTLA4, LAG3, PDL-2, and IDO. Molecular processes enriched in non-TCIP tumors included EGFR/erbB signaling ($p=0.09$) characteristic of basal HNC, while multiple T-cell related signatures and the JAK/STAT pathway ($p<0.05$) characteristic of mesenchymal HNC were enriched in the TCIP tumors. **Conclusions:** 33-47% of HNC show a T cell-inflamed phenotype similar to melanoma. PD-L1 expression and TIL presence is common and strongly correlated with mesenchymal HNC in both HPV(+) and HPV(-) HNC and may benefit from immunotherapy.

**6010** **Clinical Science Symposium, Sun, 11:30 AM-1:00 PM**

**Distinct patterns of intratumoral immune cell infiltrates in patients with HPV-positive versus HPV-negative head and neck squamous cell carcinoma.** *Presenting Author: Simona Partlova, Department of Immunology, Charles University and University Hospital Motol, Prague, Czech Republic*

**Background:** Persistent human papillomavirus (HPV) infection is the most important etiologic agent of the oropharyngeal head and neck squamous cell carcinoma (HNSCC). Patients with HPV-positive HNSCC were reported to have a better clinical outcome than HPV-negative patients. However, little is known about the possible causes of the difference in the clinical outcome. In this study, we analyzed a detailed immune profile of tumor samples from HNSCC patients with respect to their HPV status. **Methods:** We studied the intratumoral immune cell infiltrates in 51 fresh HNSCC samples collected during the primary surgery. We analyzed the characteristics of immune cell infiltrates, including the frequency and distribution of antigen presenting cells, naïve and effector T cells, Th1/Th2/Th17 lymphocytes, regulatory T cells and cytokine and chemokine levels in the tumor tissue. **Results:** There was a profound difference in the extent and characteristics of the intratumoral immune cell infiltrates in HNSCC patients depending on their HPV status. In contrast to HPV-negative tumor tissues, HPV-positive tumor samples showed significantly higher levels of infiltrating IFN$\gamma$+ CD8+ T lymphocytes, IL-17+ CD8+ T lymphocytes, myeloid dendritic cells and proinflammatory chemokines. Furthermore, HPV positive tumors had significantly lower infiltration by exhausted CD8+ T lymphocytes characterized by high PD-1 and Tim-3 expression. **Conclusions:** The presence of strong intratumoral immune cell infiltrates might play a crucial role in the significantly better response of HPV-positive patients to standard therapy and their favorable clinical outcome. Additionally, characterization of the HNSCC immune profile may represent a valuable prognostic tool in addition to the HPV status and may help to identify novel targets for therapeutic strategies, including cancer immunotherapy.

**6011** **Clinical Science Symposium, Sun, 11:30 AM-1:00 PM**

**A phase Ib study of MK-3475 in patients with human papillomavirus (HPV)-associated and non-HPV–associated head and neck (H/N) cancer.** *Presenting Author: Tanguy Y. Seiwert, The University of Chicago Medicine and Biological Sciences, Chicago, IL*

**Background:** The PD-1 receptor-ligand pathway can be used by tumors to evade immune surveillance, thereby allowing neoplastic growth. MK-3475 is a highly selective, humanized IgG4/kappa isotype mAb designed to block PD-1 interaction with its ligands PD-L1 and PD-L2, to reactivate the immune system to eradicate the host tumor. **Methods:** Pts with recurrent/metastatic H/N cancer were enrolled in this multi-center, non-randomized trial in two cohorts (HPV and non-HPV associated). Pts were prescreened for PD-L1 expression by immunohistochemistry (22C3), and if positive allowed to proceed with treatment of single agent MK-3475 given intravenously at 10 mg/kg every 2 wks. Primary objectives are to determine (1) safety and tolerability and (2) anti-tumor activity of MK-3475 assessed by RECIST 1.1. Secondary objectives include progression-free survival, overall survival and response duration. **Results:** All results are based on preliminary, unaudited data as of Jan. 27, 2014. 77.9% of patients expressed PD-L1, defined as $\geq$1% of stained cells in the tumor microenvironment (Table). Of 60 patients (11 female, 49 male) enrolled in the study, 19 had an ECOG status of 0, and 40 had an ECOG status of 1 (1 unknown); 23 were HPV+ and 37 were HPV-; 9 had no prior systemic treatment, 10 had 1, 16 had 2, 13 had 3, and 7 had $\geq$4 prior regimens of treatment (5 unknown). Of the patients treated with MK-3475, 78.3% experienced $\geq$1 AE, and 46.7% reported a drug-related (DR) AE. The most common DR AEs reported were pruritis (6, 10%), fatigue (4, 7%), rash (4, 7%), and diarrhea (3, 5%). At least one Grade 3-5 AE was reported in 55.0% of patients, with 13.3% reporting a DR Gr 3-5 AE. Grade 3-5 AEs considered DR were hyponatremia, lymphopenia, rash, diarrhea, musculoskeletal pain, abscess (neck), and atrial fibrillation. Tumor shrinkage was observed in several patients, but protocol-specified efficacy analyses are not yet available. **Conclusions:** To date, treatment with MK-3475 has been well tolerated overall, with few serious DR AEs. Protocol-specified efficacy analyses are not yet available. Clinical trial information: NCT01848834.

**Induction chemotherapy followed by chemoradiotherapy versus chemoradiotherapy as treatment of unresected locally advanced head and neck cancer squamous cell cancer (HNSCC): A meta-analysis of randomized trials.** *Presenting Author: Wilfried Budach, University of Düsseldorf, Düsseldorf, Germany*

**Background:** Induction chemotherapy with docetaxel. cisplatin, and 5FU (TPF) before radiotherapy or chemoradiation (RT-CHX) has been shown to improve overall survival compared to induction chemotherapy with cisplatin and 5 FU in locally advanced HNSCC. Whether TPF induction before chemoradiation improves clinical outcome in comparison to chemoradiation is still a matter of debate. Recently, the results of 4 randomized trials addressing this question have become available. **Methods:** In the 4 trials of interest, in total 802 patients with locally advanced HNSCC were randomly assigned to receive either TPF induction chemotherapy followed by concurrent RT-CHX or concurrent RT-CHX. Platin or taxane based chemotherapy was used during radiotherapy (2x1.5 Gy and 1.8- 2 Gy in 30-35 fractions). 416 had oropharyngeal, 114 hyopharyngeal, 78 laryngeal, 143 oral cavity and 52 other HNSCC. Published hazard ratios and hazard ratios extracted from available survival curves for overall survival (OS) and progression free survival (PFS) were basis of the meta-analysis. Meta-analysis of the effect sizes on OS and PFS was performed using a random effects model based on parameter estimates of log hazard ratios in Cox models and their standard errors. **Results:** Additional induction chemotherapy with TPF before RT-CHX did not result in an improvement of overall survival (Hazard Ratio: 1.008, 95% confidence limits (CL) 0.816-1.246, p=0.940). A modest and statistically not significant benefit was observed in terms of PFS (Hazard Ratio: 0.881, 95% CL 0.723-1.073, p=0.207). **Conclusions:** Additional induction chemotherapy with TPF before RT-CHX does not improve overall survival in HNSCC.

**6013 Poster Highlights Session (Board #28), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Comparison of clinical primary tumor site (PTS) response to induction chemotherapy (IC) with APF (*nab*-paclitaxel, cisplatin, and 5-FU) or APF plus cetuximab (APF+Cetux) in patients with locally advanced squamous cell carcinoma of the head and neck (SCCHN).** *Presenting Author: Jessica C. Ley, Washington University School of Medicine in St. Louis, St. Louis, MO*

**Background:** Achievement of a favorable (> PR) response (particularly CR) at the PTS to IC predicts a higher likelihood of long-term disease control after definitive chemoradiotherapy (CRT) in SCCHN. Low T classification and p16 + oropharynx [OP]SCCHN associate with favorable PTS response to IC. Based on improved tumor response rate with cetuximab added to chemotherapy in the EXTREME trial, we hypothesized a higher PTS CR rate with the addition of cetuximab to APF given as IC before CRT. **Methods:** Two consecutive prospective phase II trials (APF and APF+Cetux) were performed with the primary objective to determine the response rates (CR, PR, <PR) at the PTS. 30 patients were treated with APF (weekly *nab*-paclitaxel 100 mg/m$^2$ and every 3 week cisplatin 75 mg/m$^2$ and 5-FU 750 mg/m$^2$/dayx3) and 30 patients were treated with APF+Cetux (APF + weekly cetuximab 250 mg/m$^2$). After two cycles of IC, PTS response assessment by clinical exam was performed by experienced oncologic otolaryngologists. Patients were then scheduled for a third cycle of IC followed by definitive CRT (with cisplatin). **Results:** After two cycles of APF or APF+Cetux, CR rates at the PTS were 76.7% (23 patients) and 53% (16 patients), respectively. PR and <PR rates at the PTS after two cycles of APF were 16.7% (5 patients) and 6.7% (2 patients) and after APF+Cetux were 47% (14 patients) and 0%, respectively. CR rates at the PTS were consistently higher with APF compared to APF+Cetux when stratified for T classification and p16 status (Table). **Conclusions:** Unexpectedly, the addition of cetuximab to APF did not increase the CR rate at the PTS even when stratified for T classification and p16 status. This observation is consistent with our historical experience of TPF+Cetux (Adkins et al ASCO 2011 #5560). Validation of these findings in a randomized trial is indicated. Clinical trial information: NCT01566435 AND NCT00736944.

**Cisplatin versus cetuximab plus concomitant radiotherapy in locally advanced head and neck cancer: A meta-analysis of published trials.** *Presenting Author: Sandro Barni, Department of Medical Oncology, Treviglio and Caravaggio Hospital, Treviglio, Italy*

**Background:** Concurrent chemoradiotherapy (CTRT) or RT + cetuximab (RT + CET) are both treatment options for the treatment of locally advanced head and neck cancer (HNC). The efficacy of these two treatment modalities for patients with locoregionally advanced or inoperable HNC however has never been compared. **Methods:** We conducted a systematic review and meta-analysis by searching in PubMED, EMBASE, SCOPUS, Web of Science and The Cochrane Register of Controlled Trials, to compare CTRT and RT + CET in locally advanced HNC. Risk ratios (RRs) with 95% confidence intervals (95%CIs) were calculated for pre-specified endpoints as 2-year overall survival (OS), 2-year disease free-survival (DFS), 2-year loco-regional relapse (LRR) and 2-year distant metastases (DM). Meta-analysis was performed using the fixed- or random-effects models. **Results:** 15 trials for a total of 1,808 patients, were included. Concurrent CTRT significantly improved 2-year OS (RR=0.66, 95% CI 0.46-0.94; P=0.02), 2-year DFS (RR=0.68, 95% CI 0.53-0.87; P=0.002) and 2-year LRR (RR=0.63, 95% CI 0.45-0.87; P=0.005) compared to RT + CET. The absolute risk differences were 12%, 17% and 10%. Risk of distant metastases was identical (RR=1.01, 95%CI 0.69-1.48; P=0.94). **Conclusions:** Platinum-based CTRT is associated with a better 2-year OS and locoregional control compared to RT + CET, and still remains the standard of care in locally advanced HNC until prospective trials can demonstrate equivalence.

| **Endpoint** | **CTRT** | **RT + CET** | **Risk ratio (95% CI)** |
|---|---|---|---|
| **2-yr OS** | 71 % | 60.7 % | 0.66 (0.46-0.94) P=0.02 |
| **2-yr DFS** | 61.7 % | 43.1 % | 0.68 (0.53-0.87) P=0.002 |
| **2-yr LRR** | 19.6% | 32.3% | 0.63 (0.45-0.87) P=0.005 |

**6015 Poster Highlights Session (Board #30), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Induction chemotherapy (IC) followed by radiochemotherapy (RCT) versus radiochemotherapy alone as treatment in advanced laryngeal (LC)/ hypopharyngeal cancer (HC): Phase IIb.** *Presenting Author: Rainald Knecht, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

**Background:** Recently published long term results of the RTOG 91-11(J Clin Oncol 31:845-852) have shown that locoregional control and larynx preservation is in favour to concomitant radiochemotherapy(RCT).However there have been no differences in survival between IC, RCT and RT. RTOG 91-11 didn't use novel IC regimens like the standard IC Protocol of TPF (Tax324,Lancet Oncol 2011;12:153-59).The aim of the study was therefore to answer the question(a) if the addition of the standard IC TPF protocol to the standard RCT of the 91-11 is able to enhance the treatment efficacy(b)if TuVol and molecular markers are able to predict the outcome. **Methods:** 278 UICC Stage III/IV patients have been treated according the RTOG 91-11 protocol (concomitant arm) +/- IC TPF Tax323 induction protocol.Objective response and adverse events were assessed trough the RECIST criteria and the NCI CTCAE v2.0.Tumor assessment(endoscopy,biopsy,MRI)and EORTC QLQ C30 HN35 survey were carried out at the end of ICT and CRT and during fixed intervals after therapy. Primary endpoint was TTF assuming a 15% difference in favour of IC . **Results:** 5year Results:TPF IC+RCT vs.RCT:Completion of therapy 75%/82%; ORR 94%/87%; local 77%/64%,regional 72%/60% control(p<0.05);larynx preservation 87%/79%;distant control 94%/81%(p<0.05);OS 61%/55%(n.s);DFS 46%/37%,significant in HC(p=0.03).TTF difference in favour of IC was accepted(p=0.048).No significant differences in Grade 3-4 toxicities with the exception of neutropenia.CR after IC and IC+RCT was associated with better survival with only IC being highly significant in multivariate analysis(p<0.001).TuVol correlated with response rate(p=0.003)as well as Ki67+ and vascular density in the tumor(p<0.05). **Conclusions:** The addition of the Tax 324 TPF IC protocol to the 91-11 RCT protocol may be an appropriate approach for advanced risk for local and distant failure.The dose of cisplatin during RCT should be limted to 200mg/m$^2$.

**6016^ Poster Highlights Session (Board #31), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Induction chemotherapy (IC) docetaxel (T), cisplatin (P), 5-fluorouracil (F) (TPF), or TP followed by concomitant boost radiotherapy (R) with or without cetuximab (E) for functional organ preservation (FOP) of resectable laryngeal and hypopharyngeal cancer (LHSCC): First results of the phase II randomized DeLOS-II study.** *Presenting Author: Andreas Dietz, University of Leipzig, Leipzig, Germany*

**Background:** The DeLOS-II trial is a German multicenter randomized phase II trial (IIT) investigating IC with or without cetuximab for patients with LHSCC, followed by R assessing FOP. **Methods:** Previously untreated patients (pts) with resectable stage III/IV LHSCC indicated for total laryngectomy were randomized to three cycles (TP both 75 mg/m² day 1 and F 750 mg/m²/day on days 1-5) without (arm A) or with (arm B) standard dose of cetuximab for 16 weeks. In case of non-response after the first cycle, the study therapy was terminated and salvage laryngectomy was performed. Three cycles of IC were followed by R (69.6Gy). In this first analysis, we report rates of 6-months survival with functional larynx (FOP). Secondary endpoints included feasibility and toxicity. **Results:** 180 pts were randomized (7/2007-9/2012), 174 fulfilled ITT criteria (85.1% male, 49.4% larynx, 87.4% T3/4N2bc, equally distributed both arms). Due to 4 therapy related deaths among the first 64 pts (3 arm A, 1 B), F was omitted from IC in 2/2009. Interim analysis for response and toxicity of 126 pts in 2011 showed no efficacy differences between TPF vs TP and no more treatment related deaths. Overall, in arm A 31 pts received TPF and 55 TP, in arm B 31 TPFE and 57 TPE IC. 66.7% of pts received complete IC (4.0% two cycles; 29.3% one cycle). Dose reduction (>10%) mainly due to toxicity occurred in 27.9% arm A and 98.9% B (30.7% T, 31.8% P, 18.2% F, 98.9% E). Main early toxicity grade 3/4 was hematotoxicity (81.4% in A, 85.2% B). Early response (CR, PR) after first cycle in arm A was 67.4% (95%-CI: 56.5-77.2) and in arm B 77.3% (67.1-85.5; p=0.15). 126 pts were early responders and suitable for the complete IC and R protocol. Overall response in this group was CR/PR 81.0/8.6% in A, 77.9/5.9% in B. Endpoint (loss of FOP, death) was reached in 31.4% vs. 17.0%, favoring arm B (HR 0.502 [0.267-0.944]; p=0.0289). **Conclusions:** IC with TPFE/TPE was feasible and more effective compared to TPF/TP for Larynx preservation. TPE was less toxic and similarly effective as TPFE. Clinical trial information: NCT00508664.

**6017 Poster Highlights Session (Board #32), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase II study comparing metronomic chemotherapy with chemotherapy (single-agent cisplatin), in patients with metastatic, relapsed, or inoperable squamous cell carcinoma of head and neck.** *Presenting Author: Vijay Maruti Patil, Tata Memorial Hospital, Mumbai, India*

**Background:** Cetuximab based regimen is the recommended palliative chemotherapy for head and neck squamous cell cancers. However, due to financial constraints, toxic intravenous chemotherapy with poor outcome is more commonly used in lesser developed countries. Retrospective studies have shown a role for oral metronomic therapy (MCT) in HNSCC especially in a resource poor setting. **Methods:** We conducted an open label, superiority, parallel design, randomized phase II trial comparing oral MCT [daily celecoxib (200 mg twice daily) and weekly methotrexate (15mg/m$^2$)] to intravenous single agent cisplatin (IP) (75mg/m$^2$) given 3 weekly. Patients with relapsed, metastatic and inoperable head and neck cancers meriting palliative chemotherapy,performance status 0-2, unaffordable for cetuximab and with adequate organ functions were eligible.. The primary end point was progression-free survival. The trial was powered to detect a 33% improvement in the median PFS, from 2.7 months for IP arm, with type 1 error of 5% and type 2 error of 80%. Univariate analysis of survival was performed using Kaplan Meier estimates with intention to treat analysis. Toxicity rates were compared using chi square test. **Results:** 110 patients were recruited between July 2011 to May 2013, 57 randomized to the MCT arm and 53 to the IP arm. Patients in the MCT arm had significantly longer PFS (median 101 days, 95% CI: 58.2-143.7 days) compared to the IP arm (median 66 days, 95% CI; 55.8-76.1 days) (log-rank p=0.014). The overall survival (OS) was also increased significantly in the MCT arm (median 249 days, 95% CI: 222.5 - 275.5 days) compared to the IP arm (median 152 days, 95% CI: 104.2 -199.8 days) (log-rank p=0.02). There were fewer grade 3/4 adverse effects wth MCT, which was nonsignificant.(18.9% vs. 31.4%, P = 0.14). **Conclusions:** Oral metronomic chemotherapy has significantly better PFS and OS than single agent platinum in the palliative setting. It is a viable and cost-effective treatment option in patients not affording cetuximab. Further studies are warranted to evaluate the benefit, schedule and combination of metronomic therapy. Clinical trial information: 2014/01/006359.

**6018 Poster Highlights Session (Board #33), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Cetuximab (C), fluorouracil (F), and cisplatin (P) alone or with docetaxel (D) for recurrent/metastatic (RM) head and neck cancer (HNSCC): First analysis of AIO trial # 1108.** *Presenting Author: Ulrich Keilholz, Charité Comprehensive Cancer Center, Berlin, Germany*

**Background:** This trial was based on the findings that D in addition to PF in induction treatment and C in addition to PF in RM disease both improved outcome in HNSCC. The question was, whether TPFC would be feasible and superior to PFC in patients with RM-HNSCC without limiting comorbidities. **Methods:** In an open-label randomized multicenter trial, 180 patients were assigned 1:1 to receive either (arm A) P 40 mg/sqm, D 40 mg/sqm, F 2000 mg/sqm days 1+8, C 400/250 mg/sqm days 1, 8, 15 q3w or (arm B) standard PFC (P 100 mg/sqm day 1, F 1000 mg/sqm days 1-4, C 400/250 mg/sqm days 1, 8, 15) q3w. Chemotherapy was continued for a maximum of 6 cycles in absence of disease progression or limiting toxicity, followed by C maintenance (500 mg/sqm q2w). Primary endpoint was PFS. **Results:** Accrual was completed in Nov 2013. A planned safety analysis had revealed excessive toxicity (gastrointestinal and infections) in arm A, necessitating an amendment with reduction of P to 30 and F to 1000 mg/sqm after 20 patients/arm. After the amendment, toxicity was similar in both arms, with a rate of grade 4 toxicities of 21.3% vs. 30.8% of patients in arms A vs. B. 11.2% vs. 6.6% potentially treatment related deaths were observed in arms A vs. B. Median PFS A vs. B was 5.5 vs. 5.0 mo (HR 0.78, p=0.375), and response rates 38.2% vs. 31.9%, respectively. Further follow-up is required to describe OS. **Conclusions:** Despite of the previously described advantage of both components D and C in treatment of HNSCC, the four-drug regimen was not associated with improved median PFS, the primary endpoint of the trial. There is a tail of the curve effect, which will require further follow up. Clinical trial information: 1108.

**6019^ Poster Highlights Session (Board #34), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase II trial of temsirolimus plus low-dose weekly carboplatin and paclitaxel for recurrent/metastatic HNSCC.** *Presenting Author: Matthew G. Fury, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** The PI3K/mTOR pathway is commonly altered in HNSCC, but single agent activity of mTOR inhibitors is modest. Following up on encouraging results of a phase I study of temsirolimus + low dose chemotherapy (PMID 22644799), we launched this prospective phase II study. **Methods:** This was a nonrandomized, prospective, phase II study at MSKCC main campus and regional network affiliates. Eligible patients (≤ 2 prior regimens for R/M disease) received paclitaxel (80 mg/m$^2$) + carboplatin (AUC 1.5) + temsirolimus (25 mg flat dose) by vein, on days 1 and 8 of a 21 day cycle for up to 6 cycles. After 6 cycles, patients without progressive disease had the option for temsirolimus monotherapy. The primary endpoint was objective response rate, as assessed by RECIST 1.0. **Results:** Between 1/11/2012 and 5/15/2013, 30 eligible subjects were enrolled (22 M/8 F): median age 59 (range, 30 to 85 years), median KPS 80 (range, 70 to 90). 15 patients had received at least one prior systemic therapy regimen for R/M disease. Primary tumor sites were larynx (10), oropharynx (9; HPV ISH status- 6 positive, 2 negative, 1 not done), oral cavity (8), neck node with occult primary (2), and hypopharynx (1). 17 patients had tobacco history of > 10 pack-years. The most common ≥ grade 3 AEs were lymphopenia (56%), leukopenia (37%), and neutropenia, dysphagia, and low hemoglobin (each 20%). The overall radiologic response rate was 43% (13/30) with 1 CR, 10 confirmed PRs, and 2 unconfirmed PRs (Figure 1). Overall survival was 12.9 months (95% CI, 12.3 – 13.5). Correlative studies on pre-treatment pathology samples are in progress to evaluate if p-eIF4E:p-4EBP-1 ratio is associated with efficacy. **Conclusions:** This low dose weekly chemotherapy regimen demonstrates clinical activity comparable to that of standard high dose combination chemotherapy regimens, and was well tolerated after first line therapy. Acknowledgment: This study was approved and funded by the National Comprehensive Cancer Network (NCCN) from generous research support provided by Pfizer. Clinical trial information: NCT01016769.

**6021^ Poster Highlights Session (Board #36), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Platinum-based chemotherapy (CT) plus cetuximab in recurrent or metastatic squamous cell carcinoma of the head and neck cancer (R/M-SCCHN): 5-year follow-up data for the extreme trial.** *Presenting Author: Jan Baptist Vermorken, Antwerp University Hospital, Edegem, Belgium*

**Background:** The EXTREME trial demonstrated that patients with R/M-SCCHN benefit significantly from the addition of cetuximab to first-line platinum-based CT in relation to overall survival, progression-free survival (PFS) and response rate. We report the 5-year follow-up data. **Methods:** The intent-to-treat (ITT) population comprised patients (pts) randomized to receive either platinum-based CT plus cetuximab (n=222) or CT alone (n=220) for 18 weeks (6 x 3-week cycles). **Results:** A total of 100 pts in the cetuximab arm who had at least stable disease received cetuximab monotherapy until disease progression or unacceptable toxicity, with a median treatment duration of 29.9 weeks. For 77% of these pts, the relative dose intensity (RDI) of cetuximab was ≥90% during this maintenance period. Thirty-one (14%) pts in the cetuximab arm and 25 (11%) in the CT arm of the ITT population were deemed long-term survivors (>2 years). Of these, 6 (22%) and 5 (23%) pts were p16+ and 11 (35%) and 10 (40%) pts had oropharyngeal tumors, in both arms respectively. At 5-years, 6 pts treated with CT plus cetuximab and 2 pts treated with CT alone were still in the study and known to be alive. In pts in the cetuximab arm, the frequency of severe (grade 3-4) adverse events (AEs) decreased from 81% to 49% during the cetuximab maintenance period compared with the previous treatment period with CT plus cetuximab. Grade 3 skin toxicity decreased from 9% when combined with CT to 5% during cetuximab maintenance and no grade 4 skin toxicity was observed.Twelve pts (5%) in the cetuximab arm of the ITT population were long-term responders (PFS>12 months) compared with 3 pts (1%) in the CT arm, with a median treatment duration of 67.7 weeks. The RDI of cetuximab was ≥90% for all long-term responders. **Conclusions:** The addition of cetuximab to first-line platinum-based CT significantly improves outcome for patients with R/M-SCCHN. Although there are notable differences in long-term responders favoring cetuximab, the 5-year survival figures are still extremely low for both arms of the study. Cetuximab maintenance therapy proved to be feasible with manageable skin reactions. Clinical trial information: NCT00122460.

**6022 Poster Highlights Session (Board #37), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Meta-analysis of chemotherapy in nasopharyngeal carcinoma (MAC-NPC): An update on 4,798 patients.** *Presenting Author: Pierre Blanchard, Institut Gustave Roussy, Villejuif, France*

**Background:** In a previous MAC-NPC individual patient data (IPD) meta-analysis, the addition of chemotherapy (CT) to radiotherapy improved overall survival (OS) in nasopharyngeal carcinoma (NPC; Baujat IJROBP 2006). There was an interaction between the timing of CT and treatment effect, with an OS benefit restricted to the concomitant (+/- adjuvant) timing. Since other trials have been conducted, this meta-analysis was updated. **Methods:** Trials of radiotherapy (RT) with or without CT in patients with non-metastatic NPC were identified and updated IPD obtained. Both Western and Chinese medical literatures were searched. OS was the main endpoint. The fixed-effect model was used. All analyses were pre-specified. **Results:** Overall 19 trials and 4,798 pts were included. One 2x2 trial was counted twice and 5,020 pts were analyzed. Patients characteristics were well balanced (60% < 50 years, 75% male, 60% PS 0, 90% stage III-IV and 96% WHO grade 2-3). Median follow-up was 7.1 years. There was a significant benefit in favor of CT regarding OS (hazard ratio (HR) [95% confidence interval]: 0.79 [0.72;0.86], p <0.0001; absolute benefit at 5 years=6.4%). There was a significant interaction between treatment effect on OS and the timing of CT (p=0.01) in favor of concomitant CT (without adjuvant CT: HR 0.79 [0.68;0.92]; with adjuvant CT: HR 0.65 [0.56; 0.76]) compared to induction CT (HR 0.96 [0.80;1.16]) or adjuvant CT (HR 0.93 [0.70;1.24]), which explained the statistical heterogeneity. Restriction of the analysis to trials with a control arm with RT alone led to similar results. The benefit of the addition of CT was consistent for all endpoints: progression-free survival (HR 0.76 [0.70;0.82], p<0.0001), loco-regional control (HR 0.74 [0.65;0.85], p<0.0001), distant control (0.68 [0.60;0.76], p<0.0001) and NPC related mortality (0.73 [0.66; 0.81], p<0.0001). There was no significant interaction between treatment effect on OS and patient covariate (age, sex, tumor stage). **Conclusions:** The addition of concomitant chemotherapy, with or without adjuvant CT, significantly improves survival in patients with locally advanced nasopharyngeal carcinoma. Supported by PHRC and LNCC

**6023 Poster Highlights Session (Board #39), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Comparison of concurrent chemoradiation therapy with 3-weekly versus weekly cisplatin in patients with locally advanced nasopharyngeal cancer: A multicenter randomized phase II noninferiority trial (KCSG-HN10-02).** *Presenting Author: Ji Yun Lee, Department of Medicine, Division of Hematology-Oncology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

**Background:** Concurrent chemoradiation therapy (CCRT) with every 3 week schedule of cisplatin is the standard treatment for locally advanced nasopharyngeal carcinoma (NPC), but concerns have been raised about treatment-related complications. We conducted a randomized phase II non-inferiority study of CCRT with three week versus weekly cisplatin to compare the efficacy and toxicity profiles. **Methods:** From September 2009 through August 2011, 111 patients with locally advanced NPC who have stage II-IVb were enrolled from 22 centers in Korea. Patients were randomized into treatment groups that either received cisplatin 100 mg/m$^2$ every 3 weeks for 3 cycles (arm A) or cisplatin 40 mg/m$^2$ weekly for 7 cycles (arm B) concurrently with RT. Subsequent adjuvant chemotherapy, cisplatin 80 mg/m$^2$ day 1 and fluorouracil 1,000 mg/m$^2$/day day 1-4 was administered every 3 weeks for a total of 3 cycles. **Results:** Of the 109 eligible patients, 56 were assigned to arm A, and 53 to arm B. The two arms were well-balanced in all prognostic factors and RT parameters. There was no significant difference in RT dose (67.28 Gy vs 68.30 Gy, p=0.559) or cisplatin dose (257 vs 249 mg/m$^2$, p=0.433) between two arms. About 90% of patients in both arms completed protocols of CCRT. However, 29% of patients in arm A and 45% of those in arm B received subsequent adjuvant chemotherapy (p=0.045). Overall tumor response was 97 % but no difference was noted in tumor response between two arms (96 vs 98%, p=1.000). Overall, the grade 3/4 toxicities were similar between the two arms. The most common grade 3/4 adverse events during CCRT were neutropenia (15% in arm A vs 28% in arm B), stomatitis (13% vs 15%), and nausea/vomiting (11% vs 8%). **Conclusions:** These results demonstrated that weekly regimen of cisplatin as CCRT is well tolerated and shows similar treatment efficacy compared with 3 weekly schedule of cisplatin in patients with locally advanced NPC. Longer follow-up is needed to evaluate the final results of progression free survival and overall survival.

**6024 Poster Highlights Session (Board #40), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Chemoradiotherapy regimens for locoregionally advanced nasopharyngeal carcinoma: A Bayesian network meta-analysis.** *Presenting Author: Marie Yan, University of Toronto, Toronto, ON, Canada*

**Background:** Concurrent chemoradiotherapy followed by adjuvant chemotherapy (CRT-A) is often the regimen of choice in locoregionally advanced nasopharyngeal carcinoma (LANPC). Many alternative regimens have been reported in the literature; however, it is unknown how effective these regimens are compared to each other due to the lack of direct comparisons. Our aim was to perform a network meta-analysis (NMA) to determine the relative survival benefits of these treatments in LANPC. **Methods:** We performed a systematic review following the Cochrane methodology, using MEDLINE, EMBASE, and CENTRAL to identify all randomized controlled trials (RCTs) that compared different chemoradiotherapy regimens in LANPC. Overall survival (OS) and progression-free survival (PFS) were the primary outcomes of interest. Hazard ratios (HRs) were extracted using the Parmar method. Bayesian NMAs with random effects were conducted using WinBUGS to compare all regimens simultaneously and improve precision. **Results:** Twenty-four RCTs (5,492 patients) were included in this review. All together, these trials compared seven different regimens: radiotherapy (RT), concurrent chemoradiotherapy (CRT), neoadjuvant followed by CRT (N-CRT), CRT-A, RT-A, N-RT and N-RT-A. All regimens that contained CRT performed significantly better than RT. The combined HRs for CRT-A vs. CRT were 0.96 (95% credible regions: 0.69–1.31) for OS and 0.86 (0.55–1.39) for PFS. For N-CRT vs. CRT, the HRs were 1.01 (0.65–1.46) for OS and 0.65 (0.34–1.18) for PFS. When CRT-A was compared against N-CRT, the resulting HRs were 0.96 (0.64–1.46) for OS and 1.33 (0.67–2.87) for PFS. CRT, CRT-A and N-CRT all had similar probabilities of being the best regimen (23%, 34% and 28% respectively) among all seven regimens based on OS. **Conclusions:** To our knowledge, this is the first NMA to study chemoradiotherapy regimens in LANPC. Contrary to common clinical practice, adjuvant chemotherapy does not appear to improve survival following CRT. The efficacies of CRT, CRT-A and N-CRT all appeared to be similar. Further studies are warranted to examine whether omitting additional chemotherapy phases can decrease side effects without adversely affecting survival.

**6025 Poster Highlights Session (Board #41), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**The correlation between the severity of cetuximab-induced rash and clinical outcome for patients with head and neck carcinoma treated with chemoradiotherapy (CRT) plus cetuximab: The RTOG experience.** *Presenting Author: Voichita Bar-Ad, Department of Radiation Oncology, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

**Background:** To evaluate the severity of cetuximab-induced rash and its correlation with clinical outcome and late skin toxicity. **Methods:** The analysis included patients who received definitive CRT on RTOG 0522 (70 Gy + cisplatin and cetuximab) or postoperative CRT on RTOG 0234 (60–66 Gy + cetuximab and either docetaxel or cisplatin). Patients had to have received the loading dose and at least one concurrent dose of cetuximab. **Results:** Six hundred two patients were analyzed: 406 on RTOG 0522 and 196 on RTOG 0234; 386 patients (64.1%) developed Grade 2-4 cetuximab rash. Patients with Grade 2-4 rash had younger age ($p<0.001$), fewer pack-years smoking history ($p<0.001$), were male ($p=0.03$) and had an oropharynx primary site ($p=0.002$). Combined across treatment groups, patients with Grade 2-4 rash, when compared to those with Grade 0-1 rash, had increased OS (HR 0.58 [95%CI 0.44-0.76)], $p<0.001$), increased PFS (HR 0.76 [95%CI 0.60-0.97], $p=0.03$), and reduced incidence of distant metastasis (HR 0.63 [95%CI 0.40-0.99], $p=0.04$), but no detectable difference in loco-regional failure (HR 0.80 [95%CI 0.58-1.10], $p=0.17$). After adjustment for prognostic factors (age, Zubrod PS, primary site, TNM stage): HR 0.69 [95%CI 0.51-0.92], $p=0.01$ for OS; HR 0.87 [95%CI 0.68-1.12], $p=0.28$ for PFS; HR 0.90 [95%CI 0.65-1.25], $p=0.55$ for loco-regional failure; and HR 0.67 [95%CI 0.42-1.06], $p=0.08$ for distant metastasis. Twenty-five percent of patients with Grade 2-4 acute in-field radiation dermatitis experienced Grade 2-4 late skin fibrosis vs 14% of patients with Grade 0-1 acute in-field radiation dermatitis (Odds ratio 1.92 [95%CI 1.23-3.00], $p=0.004$). **Conclusions:** Grade 2-4 cetuximab rash was associated with increased OS, that may be due to a reduction in incidence of distant metastasis. Grade 2-4 rash was not associated with increased PFS or decreased loco-regional failure. Grade 2-4 acute in-field radiation dermatitis was associated with higher risk of late Grade 2-4 skin fibrosis. This project was supported by RTOG grant U10 CA21661, and CCOP grant U10 CA37422 from the National Cancer Institute (NCI) and Bristol-Myers Squibb.

**6026 Poster Highlights Session (Board #42), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A multicenter international phase 2 trial of pazopanib in metastatic and progressive medullary thyroid carcinoma: MC057H.** *Presenting Author: Keith Christopher Bible, Mayo Clinic, Rochester, MN*

**Background:** Pazopanib is a small molecule inhibitor of kinases principally including vascular endothelial growth factor receptors (VEGFR)-1,-2, and -3, platelet-derived growth factor receptors (PDGFR)-$\alpha$ and $-\beta$; and c-Kit. We previously reported a tumor response rate of 49% in patients with advanced differentiated thyroid cancer and 0% in patients with advanced anaplastic thyroid cancer. The present report details results of pazopanib therapy in advanced medullary thyroid cancer (MTC). **Methods:** Having noted preclinical activity of pazopanib in MTC, patients with advanced MTC who had disease progression within the preceding 6 months were accrued to this multi-institutional international Phase II clinical trial to assess tumor response rate (by RECIST criteria) and safety of pazopanib given orally once daily at 800 mg until disease progression or intolerability. **Results:** From September 22, 2008 to December 11, 2011, 35 individuals (80% males, median age 60 years) were enrolled. All patients have been followed until treatment discontinuation or for a minimum of 4 cycles. Eight patients (23%) are still on study treatment. The median number of therapy cycles was 8. Five patients attained partial RECIST responses (14.3%; 90% CI: 5.8- 27.7%) with median progression-free survival and overall survival 9.4 and 19.9 months respectively. Side effects included treatment-requiring (new) hypertension (33%), fatigue (14%), diarrhea (9%) and abnormal liver tests (6%); three of 35 patients (8.6%) discontinued therapy due to adverse events. There was one death of a study patient after withdrawal from the trial deemed potentially treatment-related. **Conclusions:** Pazopanib has promising clinical activity in metastatic MTC with overall manageable toxicities. Supported by NCI CA15083 and CM62205. Clinical trial information: NCT00625846.

**6027 Poster Highlights Session (Board #43), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Axitinib treatment in advanced RAI-resistant differentiated thyroid cancer (DTC) and refractory medullary thyroid cancer (MTC).** *Presenting Author: Jaume Capdevila, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Multikinase inhibitors (MKI) have demonstrated significant activity in advanced thyroid cancer. Axitinib is a potent oral MKI targeting the three known receptors of VEGF. **Methods:** Patients (pts) with advanced RAI-refractory DTC or unresectable MTC in documented disease progression were included in a compassionate use program of axitinib 5 mg bid. Primary end point was response rate (RR) by RECIST, and secondary objectives included progression-free survival (PFS), toxicity profile and biomarker correlation analysis. The program was validated by regulatory authorities and all patients signed informed consent form. **Results:** 41 pts were enrolled (med age: 54; male: 51%; 29 DTC, 12 MTC). Axitinib was first-line MKI therapy in 39%, second-line in 36% and 24% in subsequent lines. One level dose reduction (5 mg qd) was required in 24% of pts to manage toxicity. Main side effects were grade 1-2, including fatigue (46%), mucositis (24%), diarrhea (24%) and hypertension (19%). Grade 3-4 side effects included anorexia, diarrhea and cardiac toxicity in less than 5% of pts. 32 pts were evaluable for efficacy. In DTC, RR was 41%, stable disease (SD) 18% and progression disease (PD) 41%. In MTC, RR was 30%, SD 40% and PD 30%. Regarding treatment lines, RR in first-line was 69% and SD 31%; in second and third-lines, RR was 20%, SD 30% and PD 50% ($p<0.05$). No differences in median PFS were observed between DTC and MTC ($p=0.509$). However, significant differences were found regarding treatment lines: first-line 12.6 months, second-line 8.6 months and successive lines 3.9 months. 15 pts were evaluated for biochemical response. The Kappa index correlation observed between biomarker reduction >30% and tumor growth control (RR + SD) was for thyroglobulin 0.21 (0.30-0.72), CEA 0.22 (0.19-0.64) and calcitonin 0.087 (-0.62-0.79). No correlation was observed in this small number of pts. **Conclusions:** Axitinib has showed meaningful activity and a safety toxicity profile in refractory and progressive thyroid cancer regardless tumor histology in first and second-line therapy. Efficacy significantly decreases in successive lines suggesting cumulative resistance to MKIs.

**6028 Poster Highlights Session (Board #44), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Interest of pretreatment quantification of anti-cetuximab IgE to prevent severe hypersensitivity reaction to cetuximab.** *Presenting Author: Benoit Dupont, University Hospital (CHU), Caen, France*

**Background:** Hypersensitivity reactions (HSR) are dreaded and relatively frequent adverse events associated with cetuximab (CTX). High pretreatment levels of anti-CTX IgE have been observed in patients (pts) who experienced a grade 3-4 reaction (NCI CTCAE v3.0) after CTX administration. We hypothesized that dosage of anti-CTX IgE prior to treatment in pts naive to CTX may be used for therapeutic decisions to reduce the incidence of severe HSR. Our main objective was to compare the incidence of severe HSR during the first injection of CTX among pts with low levels of anti-CTX IgE, compared to an incidence of 5.2% retrospectively observed among 213 pts previously treated in our centre. **Methods:** We conducted a multicentre prospective diagnostic trial among pts with a colon or head-and-neck cancer, candidate to a first treatment by CTX. The pre-treatment level of anti-CTX IgE was measured. An IgE level lower than 30 EAU (IgE Arbitrary Unit) did not interfere with the therapeutic decision whereas for pts with levels of 30 EAU or higher, CTX indication was either revised or maintained provided that the 2 first injections were done under closer medical monitoring. **Results:** 300 of 303 included pts were assessable. Median age was 60 years old, sex ratio was 4.3 and 77% had head-and-neck cancer. Prevalence of high levels of anti-CTX IgE was 22% (66 pts): 38 (58%) of which received CTX *vs* 208 (89%) among low level pts. Severe HSR during the first injection were noted in 8 pts (5 grade 3 and 3 grade 4). No death was observed following HSR. The incidence among low level pts was significantly lower than the retrospective one (1.4%, $p=0.03$). The incidence of severe HSR was significantly higher among pts with high levels of IgE rather than low levels (5/38 *vs* 3/208; odds ratio=10.4, $p=0.0027$) Pts with severe HSR had higher levels of anti-CTX IgE (median 45 *vs.* 5 EAU, $p=0.006$). No significant relation was noted between severe HSR and gender, age, history of allergies or tumor localization. **Conclusions:** Our findings support the role of an allergic mechanism in CTX reactions. Detection of anti-CTX IgE prior to treatment is a feasible and helpful strategy to predict HSR and adapt care. Clinical trial information: NCT01436617.

**6029 Poster Highlights Session (Board #45), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Single-nucleotide polymorphism (SNP) of excision repair cross complementation group 1 (ERCC1) in nasopharynx cancer (NPC): A companion biomarker study to Hong Kong NPC Study Group 0502 trial.** *Presenting Author: Edwin Pun Hui, Partner State Key Laboratory of Oncology in South China, Sir Y K Pao Centre for Cancer, Department of Clinical Oncology, Hong Kong Cancer Institute and Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, Hong Kong*

**Background:** Polymorphisms at ERCC1 has been linked to platinum sensitivity and treatment outcome. We hypothesized that ERCC1 SNP at codon 118 and C8092A is predictive of relapse free survival (RFS) in NPC, and correlates with ERCC1 protein/mRNA in paired tumor samples. **Methods:** 0502 is a multi-center prospective clinical trial to assess adjuvant chemotherapy in NPC pts with detectable plasma EBV-DNA (pEBV) following primary radiotherapy (RT) or cisplatin-RT (CRT) (NCT00370890). Eligible pts with biopsy proven NPC, AJCC stage IIB-IVB, no persistent locoregional disease or distant metastasis, ECOG 0-1, adequate organ function, were screened by pEBV at 6-8 weeks after completing RT/CRT. Post-RT pEBV -ve pts received no further treatment. pEBV +ve pts underwent work-up and randomization to adjuvant chemotherapy or observation. We tested our hypothesis using samples collected in the 0502 screening cohort. Primary endpoint is relapse free survival (RFS). ERCC1 genotyping was by TaqMan real time PCR. 450 pts is planned to detect a hazard ratio (HR) of 1.5 for the weaker ERCC1 SNP at 80% power and 2-side 5% alpha level. In subset with available tumor biopsies, we quantified ERCC1 protein expression by immunohistochemistry (IHC) or Western blot (WB) with mouse monoclonal antibody (clone 8F1), and ERCC1 mRNA by quantitative RT-PCR. **Results:** ERCC1 SNP was analyzed in peripheral blood lymphocytes from 478 pts. Median follow up was 3.61 years (90% C.I. 3.36-3.88). 31% pEBV +ve, 17% randomized. ERCC1 genotype distribution at codon 118: 54% CC, 39% CT, 7% TT; C8092A: 38% CC, 50% CA, 12% AA. There was no significant association of ERCC1 SNP with 3-year RFS or overall survival. No significant correlation was observed in ERCC1 SNP and tumor ERCC1 expression by IHC, WB or mRNA. In subset evaluated by ERCC1 IHC (n=79), pts with ERCC1+ve tumor (H-score > median) had worse RFS (HR 2.34, 95% C.I. 1.06-5.16, p=0.036). Multivariate analysis showed pEBV was the most significant adverse prognosticator for all clinical endpoints. **Conclusions:** We found no association of ERCC1 SNP with NPC survival. pEBV remained the most significant prognostic biomarker in NPC.

**6030 Poster Highlights Session (Board #46), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Proteomic profiling of HPV-positive head and neck cancer to identify new candidates for targeted therapy.** *Presenting Author: Lauren Averett Byers, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The incidence of oropharyngeal cancer (OPC) has increased 5% per year over the past decade due to a rise in human papilloma virus (HPV)-driven OPC. HPV+ OPC is clinically and molecularly distinct from HPV- head and neck squamous cell carcinomas (HNSCC). However, there are currently no validated therapeutic targets for HPV+ HNSCC. **Methods:** Reverse phase protein array (RPPA) was performed on HNSCC tumors from The Cancer Genome Atlas to measure cancer-associated pathways and targets. Differences in individual markers and proteomic pathway scores between HPV+ and HPV– tumors were assessed by t-test in the overall group and for the subset of OPC. **Results:** Significant proteomic differences were observed in 14 HPV+ and 186 HPV- HNSCC. Of 160 proteins, the top marker overexpressed in HPV+ HNSCC was p16, an established clinical biomarker of HPV status ($p<0.0001$). Other cell cycle proteins significantly dysregulated were p27; cyclins B1, E1 and E2; and E2F1 (higher in HPV+) and pRb (lower in HPV+) ($p<0.03$). In the OPC subset, several E2F1 targets were overexpressed in HPV+ cancers, including those involved in apoptosis (Bcl2, BIM) and DNA repair (PCNA, Chk2) ($p<0.05$). Despite frequent PIK3CA mutations, no significant PI3K pathway activation was observed in PIK3CA-mutated HPV+ tumors. Interestingly, total and pEGFR were expressed at lower levels in HPV+ tumors while pSTAT3, paxillin, and FAK were elevated ($p=0.04$). Finally, consistent with previous gene signature analyses showing less EMT in HPV+ HNSCC, they expressed higher levels of E-cadherin ($p=0.04$). **Conclusions:** Proteomic profiling of HPV-positive HNSCC identified potential therapeutic targets including DNA repair proteins and Src. These results are consistent with the known role of HPV E6/E7 oncoproteins in activating DNA damage response and of paxillin/FAK activation contributing to anoikis-resistance. The activation of Src substrates (STAT3/paxillin/FAK) despite inactive EGFR suggests an alternate mechanism of Src/STAT pathway activation that may have implications for response to EGFR inhibitors. Inhibitors of CDK2, Chk2, Bcl2, and Src are in clinical development suggesting that rapid translation to clinical practice could be achieved.

**Validation of two biologically distinct HPV-associated head and neck cancer subtypes and correlation with E5 expression.** *Presenting Author: Zhixiang Zuo, University of Chicago Medical Center, Chicago, IL*

**Background:** Human Papilloma Virus (HPV) is involved in the etiology of 60-80% of oropharyngeal head and neck cancers (HNC) in the US. HPV16 is the dominant HPV type present in 90% of HPV-positive HNC. We previously discovered the presence of two distinct HPV(+) HNC groups, based on gene expression profiling and consensus clustering. In this study we apply our classifier to TCGA data, and analyze viral gene expression. **Methods:** Using consensus clusteringbased on literature derived microarray gene expression profiles of 371 HNC samples we built a gene expression based classifier for HNC. We then applied the gene signature to RNA-Seq data of 424 TCGA samples and 134 Agilent array samples of the Chicago HNC Genomics Cohort (CHGC) using nearest centroid method.HPV status was determined by E6/E7 expression and confirmed with an HPV signature. We determined HPV type and the E5, E6 and E7 mRNA level for the TCGA samples using RNA-Seq data. **Results:** Three stable groups were obtained for the 371 cross-platform HNC samples. The signature for the three groups similarly classified 415 out of 424 TCGA samples, and all 134 samples in the CHGC cohort. Groups were named Mesenchymal (MS), Basal (BA), and Classical (CL), with HPV samples falling into two groups in both CHGC and TCGA cohorts supporting the presence of two distinct HPV subgroups: MS-HPV and CL-HPV. Out of 54 HPV16 positive CHGC samples, 26 were in MS group and 28 were in CL group; similarly, out of 47 HPV16 positive TCGA samples, 24 were in MS group and 23 were in CL group. MS-HPV was characterized by EMT, and high expression of immune related genes, CL-HPV by high expression of cell cycle genes. Furthermore, in the TCGA dataset, all 23 samples in MS-HPV group showed high expression level of E5, alongside E6 and E7, while all samples with low E5 fell into the CL-HPV. E5 expression differed significantly between the two groups ($P=7.763e-05$, Fisher exact test). **Conclusions**: In conclusion, we confirm the presence of two biologically distinct HPV subgroups – MS-HPV, and CL-HPV in two large, independent cohorts, with distinct biologic characteristics. Subtypes are characterized by differential E5 expression. Further study into the underlying mechanisms is indicated.

**6032 Poster Highlights Session (Board #48), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Review of pathologic diagnosis in head and neck cancer patients: Why do it?** *Presenting Author: Gefei Alex Zhu, Stanford University, Stanford, CA*

**Background:** Our hospital mandates review of outside pathology prior to treatment. Previous studies of inter-institution pathology consultations have demonstrated discordance rates of approximately 10%. We examined the overall rate of as well as predictors of discordant interpretations in patients seen at the Stanford Head and Neck Oncology program. **Methods:** The study cohort was identified using a retrospective search of the Stanford Cancer Center Research Database for head and neck cancer patients from 2005-2010 with outside pathology reviews. Discordance was manually assessed by a board-certified medical oncologist. We captured interpretation differences in histology, depth of invasion, margin positivity, presence of high-risk features, and results of special studies. The impact of tumor type (squamous, thyroid, or other), biopsy site, and type of specimen (cytology vs. histology) were assessed using chi-squared testing. **Results:** Of the 1,003 cases in the final cohort, 306 have been reviewed to date. There was an overall 18% discordance rate (56 cases), of which 68% (38 cases) were due to differences in histology. Discordance was associated with tumor type ($p = 0.004$), with lower rates for squamous (13%) and thyroid tumors (17%), and higher rates for other tumors (30%). Tumor biopsy site was also associated with discordance ($p = 0.011$), with lower rates in tumors of the oral cavity and lip (12%), oropharynx (12%), and hypopharynx (14%) and higher rates in those of the paranasal sinuses (42%), salivary glands (38%), and thyroid (26%). Fine needle aspiration specimens were not associated with discordant review ($p = 0.14$). **Conclusions:** Discordance rates of initial versus referral center diagnosis of head and neck tumor biopsies is substantial and clinically relevant. We could not identify any subset by site or initial histology where concordance exceeded 90%. Therefore we conclude that review is clinically relevant for all head and neck cancer patient specimens. Data for all 1,003 cases will be presented at the annual meeting.

**6033 Poster Highlights Session (Board #49), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Erlotinib, dasatinib, erlotinib-dasatinib versus placebo: A randomized, double-blind window study in operable head and neck squamous cell carcinoma (HNSCC).** *Presenting Author: Julie E. Bauman, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** The epidermal growth factor receptor (EGFR) and Src family kinases are upregulated in HNSCC. EGFR interacts with cSrc to activate oncogenic STAT3 signaling; dual targeting is synergistic in HNSCC cell lines. In preclinical models, phosphorylated cSrc (pSrc) mediates resistance to erlotinib (E), a small molecule EGFR inhibitor. Baseline overexpression of pSrc was associated with E resistance in our prior window trial. Here, we conducted a four-arm phase 0 trial of E; dasatinib (D), an ATP-competitive inhibitor of cSrc; E+D; vs. placebo (P). **Methods:** Patients with operable Stage II-IVa HNSCC were randomized 1:1:1:1 to 7-21 days of neoadjuvant E 150 mg daily (n=11), D 100 mg daily (n=13), E+D (n=15), or P (for E; n=14). Paired tumor specimens were collected pre- and post-treatment. The primary endpoint, percent change in RECIST-measurable index lesions, was compared among groups by 2-way ANOVA. We analyzed the relationship between tumor percent change and pharmacodynamic expression of EGFR and cSrc pathway constituents. Pre-defined, hypothesis-driven analytes included pSTAT3, pSrc, pMet, and pMAPK. **Results:** From Apr 2009-Dec 2012, 58 patients were consented, 55 randomized, and 53 treated. Rash was observed on E arms; GI toxicities were observed in all active treatment groups. There was a significant decrease in tumor size in the E arms (p=0.0014), and no additive or independent effect from D (p=0.24). Among E-treated patients, high baseline pMAPK expression was associated with reduction in tumor size (p=0.03). An E-treated patient experiencing complete clinical response harbored a somatic *MAPK1*$^{E322K}$mutation. Among D-treated patients, high baseline pSTAT3 was associated with tumor progression (p=0.03). **Conclusions:** Brief neoadjuvant treatment with E significantly decreased tumor size in operable HNSCC, with no independent or added effect from D. Baseline pMAPK expression and genomic *MAPK* alterations warrant further study as response biomarkers for anti-EGFR therapy. High basal pSTAT3 in HNSCC patients may be independent of cSrc, explain therapeutic resistance, and preclude further development of D in biomarker-unselected cohorts. Clinical trial information: NCT00779389.

**6034 Poster Highlights Session (Board #50), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Harvey ras (HRAS) mutations in head and neck cancer (HNC) and dependence on PI3K signaling and resistance to EGFR inhibition.** *Presenting Author: Katharina Endhardt, The University of Chicago, Chicago, IL*

**Background:** HRAS is significantly mutated in head and neck squamous cell carcinomas (HNC) and is a putative oncogenic driver. We studied the impact of HRAS mutations and signaling, which remains poorly defined for HNSCC. **Methods:** We evaluated HRAS expression, copy number changes, and hotspot mutations in HNSCC tumor tissues and cell lines (Chicago HNC Genomics Cohort (CHGC) (N=120), HNC TCGA (N=279), and HNC cell lines (N=50). MAPK, PI3K-AKT pathway signaling was interrogated by immunoblotting, and viability/apoptosis were determined in HRAS mutant and control cell lines (HN4(G12D), BB49(Q61L) and H357(G13S)) in presence of EGFR, and/or PI3K inhibitors. **Results:** Incidence of HRAS mutations was 4% in CHGC and TCGA cohorts, and 6.1% in HNC cell lines – with almost exclusively canonical HRAS mutations. Neither HRAS expression nor copy number aberrations were associated with mutations, and no high-level CN aberrations occurred. HRAS siRNA gene knockdown was extremely effective at inducing apoptosis and decreased viability in all three HRAS mutated cell lines, but largely ineffective in control cell lines. Interestingly immunoblotting revealed that mutant HRAS signals exclusively via PI3K-AKT and not via the MAPK pathway. EGFR inhibition had no visible effect on viability or apoptosis in these cell lines, and did not impact PI3K pathway activity. By contrast PI3K inhibition was highly effective and induced apoptosis. Combinations of PI3K and EGFR inhibition showed synergy only in wild-type cell lines. Lastly we developed HRAS mutation gene expression signature that confirmed PI3K signaling dependence. By contrast HRAS wildtype co-expression modules enrich for EGFR and MAPK signaling. **Conclusions:** Canonical HRAS mutations are strong oncogenic drivers and in-vitro associated with high-level EGFR-resistance. Unlike KRAS in other tumor types, HRAS in HNC signals exclusively via the PI3K pathway, and PI3K inhibitors are effective at inducing apoptosis and decreased viability.

**6035 Poster Highlights Session (Board #51), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Evaluation of computational tools to determine prognostic significance of *TP53* mutation in head and neck squamous cell carcinoma (HNSCC).** *Presenting Author: David Masica, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** *TP53* is the most commonly mutated gene in HNSCC. The specific mutations in *TP53* can be prognostic of patient survival. Thus, a framework to predict patient survival from previously uncharacterized mutation in *TP53* is valuable. There are many computational tools for predicting the phenotypic impact of genetic variation, but the overall clinical value of these algorithms remains unclear. **Methods:** Sixteen different models to predict HNSCC patient survival based on *TP53* mutations were assessed using the *TP53* mutation and clinical data from ECOG 4393 [Poeta, M. L., et al. NEJM (2007) 357(25) 2552-2561]. These models include: server-based computational tools SIFT, PolyPhen-2, and Align-GVGD; our in-house POSE and VEST algorithms; the rules devised in Poeta *et al.*[1] with and without considerations for splice-site mutations; location of mutation in the DNA-bound TP53 protein structure; and a functional assay measuring *WAF1* transactivation in *TP53*-mutated yeast. **Results:** We assessed model performance using overall survival (OS) and progression-free survival (PFS) from 420 HNSCC patients, of whom 224 had *TP53* mutations. Each mutation was categorized as "disruptive" or "non-disruptive". For each model, we compared the outcome between the predicted disruptive group vs. the non-disruptive group. The rules devised by Poeta *et al.* [1] (disruptive mutations: non-conservative mutations in the key DNA-binding domain, or stop codons vs. non-disruptive mutations: all mutations excluding the disruptive mutations) with or without our modification were observed to be superior to others. While the differences in OS (disruptive vs. non-disruptive) appear to be marginally significant (Poeta rule+modification, p=0.089; Poeta rule: p=0.053), both algorithms identified a disruptive group that has significantly worse PFS outcome (Poeta rule+modification, p=0.011; Poeta rule, p=0.027). **Conclusions:** In general, prognostic performance was low among the computational methods assessed here. Further studies are required to develop and validate computational models that can predict functional and clinical significance of *TP53*mutations in HNSCC patients.

**6036 Poster Highlights Session (Board #52), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Prevalence and outcome of mutations (mut) in the Fanconi anemia (FA) DNA repair pathway among head and neck cancer (H&N Ca) patients (pts).** *Presenting Author: Nooshin Hashemi Sadraei, University of Cincinnati Cancer Institute, Cincinnati, OH*

**Background:** Almost all survivors of FA, an inherited DNA repair deficiency syndrome, will develop H&N Ca. Preclinical data in H&N Ca cells harboring FA mut show increased sensitivity to chemo (CT) and radiation (RT) therapy. Little is known about prevalence and outcome of FA mut in general population of H&N Ca . **Methods:** Whole exome sequencing data from tumor samples of pts with H&N Ca were analyzed for 15 FA genes. Disease related characteristics and outcome data was collected. **Results:** A total of 124 pts were identified between 3/2003 - 5/2011 based on fresh frozen tissue availability. Overall, 21 (16.9%) pts had at least one mut in an FA pathway gene. For the entire cohort the median age was 59 (range 19-90), 77% were male, and 10% were HPV+ . Oral cavity was most frequent site (54%), followed by larynx (27%), oropharynx (10%), hypopharynx (8%) and sinonasal (1 %). Overall, T3-T4 and N1-3 was seen in 72% and 65%. PNI and ECS in 55% and 54%. RT was delivered in 68% and 71% received CT. Loco-regional recurrence occurred in 29 (23%). Median survival (OS) was 23 months (m) (2-89m) There were no significant differences in tumor characteristics (T, N, PNI, ECS) between FA mut and wild type pts (p> 0.48). However, recurrence occurred in only 2/19 ( 11%) HPV(-), FA mut pts compared to 34/92 ( 37%) HPV(-) wild type FA , p=0.02. No such difference was seen in the HPV(+) pts. Median OS was 22 m in the HPV + wild type vs 14 m in the HPV+FA mut pts ( p=0.1) (HR=3.4, p=0.1) **Conclusions:** Mut in FA pathway genes are detectable in a variety of H&N Ca. Recurrence and survival may be differentin FA mut and wild type H&N Ca depending on HPV status: In absence of HPV, these mut may result in a lower disease recurrence rate, which may reflect increased sensitivity to treatment. In the presence of HPV, the presence of an FA mut may negatively impact prognosis. These findings may suggest distinct biological consequences of FA mut in HPV (–) versus HPV (+) pts.

**6037 General Poster Session (Board #72), Sat, 1:15 PM-5:00 PM**

**GDF15 as a potential predictive biomarker for TPF induction chemotherapy in oral squamous cell carcinoma.** *Presenting Author: Lai-ping Zhong, Department of Oral & Maxillofacial-Head & Neck Oncology, Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

**Background:** Randomized trials have not shown major survival benefits when induction chemotherapy plus standard therapy is compared with standard therapy alone in patients with oral squamous cell carcinoma (OSCC). Induction chemotherapy is likely to be effective for biologically distinct subgroups and biomarker development may lead to identification of patients whose tumors are likely to respond to a particular treatment. **Methods:** We evaluated immunohistochemical staining for GDF15 in pretreatment biopsy specimens of 230 out of 256 OSCC patients who were treated in a prospective, randomized, phase three trial on induction chemotherapy including docetaxel, cisplatin and 5-fluorouracil (TPF). Relationship between GDF15 intervention and cell proliferation, migration, invasion, colony formation, and tumorigenicity was analyzed using *in vitro* and *in vivo* OSCC models. **Results:** LowGDF15 expression predicts a better survival in OSCC patients, especially overall survival ($P$=0.049, HR=0.597) and distant metastasis free survival ($P$=0.031, HR=0.562). Low GDF15 expression also predicted a better clinical response to TPF induction chemotherapy in comparison to high GDF15 expression ($P$=0.004). Decreased GDF15 expression in OSCC lines significantly inhibited cell proliferation, migration, invasion, colony formation, and tumorigenesis through increased phosphorylation of AKT and ERK1/2 ($P$<0.05). Likewise, overexpression of GDF15 significantly promoted cell proliferation, migration, invasion, and colony formation through decreased phosphorylation of AKT and ERK1/2 ($P$<0.05). **Conclusions:** GDF15 expression can be used as a prognostic biomarker for OSCC. A low GDF15 expression level predicts a high clinical response rate to TPF induction chemotherapy in OSCC patients. GDF15 promotes tumorigenesis and progression through phosphorylation of AKT and ERK1/2 in OSCC.

**6038 General Poster Session (Board #73), Sat, 1:15 PM-5:00 PM**

**Prognostic significance of multifocalty in papillary thyroid carcinoma: A multivariate analysis of prognostic factors.** *Presenting Author: Ivan Markovic, Institute of Oncology and Radiology of Serbia, Belgrade, Serbia*

**Background:** The incidence of multifocality in papillary thyroid carcinoma (PTC) was refered form 18 to 87,5%. The mechanisms of multifocal spreading, corelation with tumor size and histology variants of PTC, presence of lymph node metastases, as well as prognostic significance of multifocality has not yet been clarified. **Methods:** One hundred fifty three patients with PTC were surgicaly treated. Patients with locally invasive tumors (pT4) and initial distant metastases were excluded from study. Median age 42 years at diagnosis. Sex ratio: F/M-3.9/1. Total thyroidectomy (TT) was done in all 153 patients. Dissection of central and lower jugular lymph nodes of the neck for frozen-section histology was done in 117 (76.5%) patients and modifed radical neck dissection if positive. Statistics: Kapplan-Meier, Log Rank, Cox's multivariate regresion model. **Results:** Multifocal tumors were found in 43 (28%) thyroid gland specimens. The smallest focus was 2 mm. The incidence of multifocality was significantly higher in patients above 45 years at diagnosis (p<0.05) and in tumors greater than 4 cm in diameter (p<0.01). Multifocality was not significantely corelated with gender, histology variants of PTC or presens lymph node metastases (LNM). Incidence if LNM in patients with multifocal PTC was 29% vs. 44% in patients with solitary tumors. In a median follow up of 138 months (rang =2-229) regional relaps in not dissected lymph nodes occurred in 13 (8.4%) and distant metastases in 2 (1.3%) patients, while 8 (5.2%) patients died due to PTC. Incidence of relapse was significantly higher (p<0.01), and relapse free interval and survival significantly shorter (p=0.0095, p=0.0004, respectively) in patients with multifocal PTC. According to Cox's multivariate regrresion model, multifocality was independent prognostic factor for both relapse and survival in patients with intrathyroid papillary carcinoma. **Conclusions:** Due to high incidence of multifocality, higher relapse rate and worse survival, total thyroidectomy should be consider as optimal treatment in patients with PTC, in a goal to reduce relapse rate and improve disease free and overall survival.

**6039 General Poster Session (Board #74), Sat, 1:15 PM-5:00 PM**

**Risk factors predictive for poor outcomes in patients with human papillomavirus (HPV)-initiated oropharyngeal cancer (OPC).** *Presenting Author: Tobenna Igweonu Nwizu, Cleveland Clinic Foundation, Cleveland, OH*

**Background:** Studies have demonstrated better prognosis for patients (pts) with HPV-initiated OPC when compared to OPC caused by smoking. A small subset of pts however experience disease recurrence and have poor outcomes. We report our Cleveland Clinic experience with HPV-initiated OPC in an effort to identify determinants of a poor prognosis. **Methods:** We identified pts with stage III-IVb HPV-initiated OPC treated with definitive chemoradiotherapy between 2002 and 2012 from an IRB approved registry. HPV-initiated disease was determined by positivity for p16 by immunohistochemistry or HPV DNA by fluorescent in-situ hybridization. Radiation therapy was administered to a total dose of 70-74 Gy. Chemotherapy consisted of either cisplatin and 5-Fluorouracil, cisplatin or cetuximab. Kaplan-Meier estimates of disease-free survival (DFS) and overall survival (OS) were calculated. Univariate (UVA) and multivariate analyses (MVA) using Cox proportional hazards regression were performed to identify variables associated with inferior DFS and OS. **Results:** Of the 228 patients identified, 17% had T4 disease, 40% had N2c/3 disease, 51% had a smoking history (>10 pack years) while 31% were lifetime never smokers. Median follow up was 40 months. 3-year DFS and OS was 89% and 90% respectively. UVA revealed that DFS was inferior in pts with T4 (HR = 2.525; 95% CI = 1.089 to 5.848; P = 0.03) and N2c-N3 (HR = 2.364; 95% CI = 1.062 to 5.263; P = 0.04) disease. OS was also inferior in pts with T4 disease (HR = 2.123; 95% CI = 1.042 to 4.329; P = 0.04), and pts with a smoking history (HR = 2.475; 95% = CI 1.192 to 5.128; P = 0.02). On MVA, the most important predictors for an inferior DFS were smoking history, T4 and N2c-N3 disease. Patients with 2 or more of these risk factors had a significantly worse 3 –year DFS (77% vs. 94%; HR = 4.082; 95% CI = 1.828 - 9.091; P <0.001) and OS (83% vs. 93%, HR = 2.283; 95% CI = 1.193 - 4.367; P 0.01). **Conclusions:** Patients with HPV-initiated OPC and at least two high risk features, including T4, N2c/3, or >10 pack years of smoking, had significantly inferior DFS and OS. Such patients should not be considered for treatment de-intensification strategies.

**6040 General Poster Session (Board #75), Sat, 1:15 PM-5:00 PM**

**Minocycline for reduction of patient-reported symptoms during radiation therapy for head and neck cancer: First results of a randomized trial.** *Presenting Author: Gary Brandon Gunn, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background**: Local and systemic symptoms during radiation therapy (RT) may be exacerbated by dysregulated inflammation and its downstream toxic effects. Minocycline (mino) can suppress pro-inflammatory cytokine release. We conducted this study to investigate its potential to reduce patient (pt) reported symptom severity during RT for HNC. **Methods**: Eligible pts for this blinded, placebo-controlled trial were adults with oro- or nasopharyngeal carcinoma (T0-3, N-any, M0) dispositioned to intensity-modulated RT alone (no concurrent systemic therapy or prior resection). Participants were equally randomized to receive mino (100 mg twice daily) or placebo (P) during RT course. The primary endpoint was the area under the curve (AUC) of 5 pre-specified symptoms (pain, fatigue, sleep, appetite and swallowing) during RT course as assessed by the MDASI-HN (0-10 scale). As the overall goal of this study was to determine the potential signal/benefit of mino to inform future clinical trial design, we selected a modest power (70%) to detect a large standardized effect size (ES) of 0.70 (one-sided, 5% sig. level) on the primary endpoint, requiring 20 pts per arm. **Results**: From 8/10-7/13, 82 pts were approached and 47 were enrolled (safety analyses cohort); 7 withdrew and were replaced per protocol. 20 evaluable pts in each arm formed cohort used for symptom analyses. Pt characteristics and toxicity details will be presented. There were no grade 3+ potentially study medication-related AEs. There were 2 and 7 grade 1-2 AEs for P and mino arm respectively (p=0.53). All pts completed RT (66-70 Gy); there have been no recurrences to date. 5 pts in P arm required feeding tube during RT, versus 2 in mino arm (p<.21). The average daily AUC for the 5 preselected symptoms during RT were 3.7 (SD=1.7) and 3.1 (1.0) for the P and mino group (p<.16), respectively, and equivalent to an ES of 0.37. AUC ES comparisons for several individual symptoms and interference also favored mino but were not significant. **Conclusions**: Mino during RT for HNC is feasible and achieved a positive signal in terms of patient reported symptom severity and interference to justify and direct future trial design. Clinical trial information: NCT01173692.

**6041 General Poster Session (Board #76), Sat, 1:15 PM-5:00 PM**

**Preoperative window-of-opportunity (WOO) study of dacomitinib (Dac) in patients (Pts) with resectable oral cavity squamous cell carcinoma (OCC): Generation of a gene expression signature (DGS) as a predictor of Dac activity.** *Presenting Author: Irene Brana, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Dac is a potent, irreversible oral pan-HER tyrosine kinase inhibitor (TKI) with activity demonstrated in a multi-center phase II trial as first-line treatment in pts with recurrent and/or metastatic squamous cell carcinoma of the head and neck (SCCHN) (NCT01449201; Razak et al. Ann Oncol 2013). No predictive biomarkers currently exist for Dac. **Methods:** WOO is a single-center, investigator-initiated study which enrolled pts with untreated resectable OCC, ECOG 0-2, and adequate organ functions. Pts were randomized 2:1 to Dac 45 mg or placebo QD for 7-11 days prior to surgery. Pre- and post-treatment (surgical specimen) samples were collected. Study objectives: (1) to evaluate a gene expression signature as a predictor of response to Dac, (2) to assess Ki67 modulation by Dac on paired tumor samples. DGS generation and validation: Using pre- and post-treatment fresh tumor biopsies from 7 pts in the NCT01449201 study as a discovery set, DASL HT12 Illumina gene expression array was performed on RNA. Genes differentially expressed in two groups were identified: pre- vs. post-treatment samples and pts with short vs. long progression-free survival ($<$ 10 weeks vs. $>$ 10 weeks). Genes commonly deregulated in both groups defined the signature DGS. DGS was then applied to pre-treatment samples from the WOO study as a validation, blinded to clinical response. Euclidean distance was used for complete-linkage clustering. **Results:** 14 pts were enrolled in the WOO study with evaluable samples from 10 pts (Dac/Placebo 8:2; response: yes/no/unknown 4/5/1). In the discovery set, a signature of 47 commonly-deregulated genes was found to be capable of dividing patients as high- or low-expressers pre-treatment. Patients clustered as high-expressers were more likely to be good-responders after treatment (RR = 3.75, 95% C.I. 0.8-21.7). No difference was observed in pre- post-treatment Ki67 between pts on Dac or placebo, nor between responders and non-responders. **Conclusions:** DGS may identity a subgroup of SCCHN pts more likely to respond to Dac; further validation in other Dac-treated SCCHN pts is ongoing. Clinical trial information: NCT01116843.

**6042 General Poster Session (Board #77), Sat, 1:15 PM-5:00 PM**

**Adjuvant radiotherapy (RDT) plus cisplatinum (Cis) and cetuximab (Cet) in resected head and neck squamous cell carcinoma.** *Presenting Author: Frederic Peyrade, Centre Antoine Lacassagne, Nice, France*

**Background:** Adjuvant RDT-chemotherapy is the standard for resected head and neck squamous cell carcinomas (SCCHN) with adverse histological prognostic factors (AHPF). Despite this treatment, half of the patients will relapse. Cet can enhance radiotherapy activity for patients (pts) with unresectable SCCHN. Thus, we conducted a phase II clinical trial to investigate a combination of Cis, Cet and RDT in resected SCCHN with AHPF. **Methods:** Pts with resected M0 SCCHN and at least one of the following (positive margin and/or N+$>$1, and/or extracapsular extension and/or vascular embolisms and/or perineural disease) were enrolled. They received a radiotherapy (2.0 Gy per day, 5 days a week for 7 weeks) with Cet (400 mg/m2 at D- 8 before RDT followed by 250 mg/m$^2$ weekly for 7 weeks) and Cis 75 mg/m$^2$ every 3 weeks. The primary objective was Disease Free Survival (DFS). **Results:** From March 2008 through January 2011, 45 pts were included. The median follow-up was 27 months (95% IC: 26-34 months). The median age was 57 years (range 28 - 71). Tumor location was oral, oropharyngeal and hypopharyngeal in 47%, 45% and 8% respectively. All of patients had at least one adverse prognostic factor mainly $>$1 N+ (82% of cases). 71% of patient received the all treatment as planned. The 2-year disease free survival was 60% [95% CI: 46-77%]. Median DFS has not been reached yet. The two-year OS was 78.9% [95% CI: 67.5-92.1%]. 86 % of patients presented at least one toxicity $>$ Grade II according to NCI-CTCAE 3.0 classification. Grade 3-4 mucositis, dermatitis inside and rash outside radiotherapy fields were observed in 52%, 50% and 29% of pts respectively. 23 pts (52%) had a grade III/IV lymphopenia. Treatment was definitively discontinued because of toxicities in 6 cases. **Conclusions:** In patients with SCHNC with AHPF, the association of treatment with Cet, Cis and RDT appears to be safe and effective, comparing favorably with conventional RDT-Cis. Further protocols clinical investigations are justified to compare these two regimens in such a setting. Clinical trial information: NCT00875849.

**6043 General Poster Session (Board #78), Sat, 1:15 PM-5:00 PM**

**Clinical dosimetry analysis of radiation-induced temporal lobe necrosis in nasopharyngeal carcinoma patients treated with intensity-modulated radiotherapy.** *Presenting Author: Jin Yi Lang, Sichuan Cancer Hospital and Institute, Chengdu, China*

**Background:** Radiation induced temporal lobe necrosis(RITLN) is one of the late complications in nasopharyngeal carcinoma patients undergoing radiotherapy.This retrospective study aims to explore the clinical dosimetry characteristcs of radiation induced temporal lobe necrosis in nasopharyngeal carcinoma patients treated with intensity-modulated radiotherapy. **Methods:** This study enrolled the patients in Sichuan cancer hospital from January,2004 to November, 2008; diagnosised as nasopharyngeal carcinoma and treated primarily with intensity-modulated radiotherapy (IMRT). Magnetic resonance imaging ( MRI) was taken for all these patients in follow-up, RITLN was diagnosised based on the T1-weight with contrast. Dosimetry parameters of bilateral temporal lobe D1cc(the 1 cubic centimeter temporal lobe received the max dose), D2cc, D3cc, D5cc, D10cc, D15cc, D20cc,Dmean, Dmax were analysised . **Results:** MRI were assessed in a total of 148 patients primarily diagnosised with nasopharyngeal carcinoma treated by IMRT, 59 cases of RITLN were found. Univariate analysis showed that all the parameters demonstrated statistically significant results ($p<0.05$). Multivariate analysis showed that D1cc ($P= 0.026 <0.05$) and Dmax ($P=0.000 <0.05$) had statistically significant. The 5 years incidence of RITLN for D1cc$\leq$61Gy and Dmax$\leq$70Gy is less than 5%, the RITLN incidence has 3.3% increasing per Gy of D1cc beyond 60Gy and 4.6% increasing per Gy of Dmax over 69Gy. **Conclusions:** The incidence of radiation induced temporal lobe necrosis has closely relationship between the dose of temporal lobe and corresponding volume, temporal lobe D1cc less than 61Gy and Dmax less than 70Gy may be the restrict dose of temporal lobe for IMRT patients.

**6044 General Poster Session (Board #79), Sat, 1:15 PM-5:00 PM**

**Phase Ib/II study of the PI3K$\alpha$ inhibitor BYL719 in combination with cetuximab in recurrent/metastatic squamous cell cancer of the head and neck (SCCHN).** *Presenting Author: Albiruni R. A. Razak, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

**Background:** Preclinical data suggest that simultaneous inhibition of PI3K and EGFR leads to synergistic antitumor activity in SCCHN. BYL719 is a potent, oral inhibitor of the $\alpha$-isoform of class I PI3K. The Phase Ib dose-escalation part of this study used a Bayesian model to identify the recommended Phase II dose (RP2D) of BYL719 combined with standard weekly doses of cetuximab (EGFR inhibitor) in patients (pts) with platinum-resistant, recurrent/metastatic SCCHN (NCT01602315). **Methods:** BYL719 was administered QD in 28-day cycles using two methods: (1) as whole tablets (Arm A) or (2) as a drinkable suspension (crushed tablets) for pts with swallowing dysfunction (Arm B). **Results:** As of Oct 28, 2013, 32 pts were treated with either BYL719 300 mg QD (n=15) or 400 mg QD (n=5) in Arm A or BYL719 300 mg QD (n=12) in Arm B. At 300 mg (Arms A+B), 4 out of 27 pts had dose-limiting toxicities (DLTs; 2 mucositis, 1 hyperglycemia, and 1 PEG tube site infection). At 400 mg (Arm A), 2 out of 5 pts had DLTs (1 fatal tumor lysis syndrome and 1 esophageal ulcer). Other frequent drug-related AEs (any grade $>$15%) were similar across arms and included hyperglycemia (55%; G3/4, 20%), acneiform dermatitis (40%; G3/4, 5%), stomatitis (40%; G3/4, 5%), dry skin (25%; G3/4, 0%), hypomagnesemia (25%; G3/4, 5%), decreased appetite (20%; G3/4, 5%), diarrhea (20%; G3/4, 0%), fatigue (20%; G3/4, 10%), and paronychia (20%; G3/4, 0%) in Arm A. Exposures (AUC) and maximal concentrations (Cmax) were similar across arms and were consistent with the PK profile of single-agent BYL719. Best overall response per RECIST v1.1 in Arm A was 1 partial response, 3 unconfirmed partial responses, 5 stable diseases (SDs), and 1 unknown at 300 mg (10 evaluable pts); 1 pt had progressive disease (PD) and 1 pt had SD (2 evaluable pts) at 400 mg.No responses were observed in Arm B. The primary reason for discontinuation was PD (28%). The RP2D of BYL719 in combination with cetuximab was declared as 300 mg QD (whole tablets). **Conclusions:** Combined inhibition of PI3K-a and EGFR by BYL719 and cetuximab was tolerated and demonstrated encouraging antitumor activity. The Phase II part of the study comparing this combination with cetuximab alone is ongoing. Clinical trial information: NCT01602315.

**6045 General Poster Session (Board #80), Sat, 1:15 PM-5:00 PM**

**Phase 2 study of dalantercept in recurrent or metastatic squamous cell carcinoma of the head and neck.** *Presenting Author: Antonio Jimeno, University of Colorado Denver, Aurora, CO*

**Background:** Limited treatments exist for patients with recurrent or metastatic squamous cell carcinoma of the head and neck (RM-SCCHN) after platinum therapy. Activin receptor-like kinase 1 (ALK1) is a member of the TGF-$\beta$ superfamily involved in blood vessel maturation that is selectively expressed on activated endothelial cells. ALK1 binds to ligands bone morphogenetic protein (BMP) 9 and 10 and results in phosphorylation of Smad 1/5/8. Dalantercept (Dal) is an ALK1 receptor fusion protein and acts as a ligand trap. In Phase 1 testing Dal had clinical activity in pts with RM-SCCHN. This study sought to determine the activity of Dal monotherapy in pts with RM-SCCHN. **Methods:** 46 pts were enrolled and received Dal at 80 mg (n=2), 0.6 mg/kg (n=13) or 1.2 mg/kg (n=31) SC Q3W. Serum, archived, and optional biopsies were collected for pharmacodynamic (PD) studies. The primary endpoint was response rate per RECIST 1.1 and secondary endpoints included progression free survival (PFS) and overall survival (OS). Key eligibility: RM-SCCHN of mucosal origin, $\geq$1 one prior platinum regimen, ECOG $\leq$1, and no prior anti-angiogenic tx. **Results:** 41 pts were evaluable (1 at 80 mg, 13 at 0.6 mg/kg, 27 at 1.2 mg/kg). The median age was 60.5 yr, 85%M/15%F, ECOG: 0 (35%)/1(65%), HPV+ 41%, HPV- 33%, HPV unk 26%. Median number of prior tx was 4. 1 pt at 1.2 mg/kg (3.7%) achieved a PR and was on study for 9 mos. 23% (n=3) at 0.6 mg/kg and 37% (n=10) at 1.2 mg/kg had SD $\geq$ 3 cycles. Of those pts with SD or better (n=16), 62% were known to be HPV+. 17% (2 at 0.6 mg/kg and 5 at 1.2 mg/kg) pts. had SD for $\geq$ 6 cycles (4.5 mos.). The median OS (n=46) was 6.3 mos. (95% CI: 5.8-10.5) and 5 pts survived beyond 1 year. Common drug-related AEs were anemia, fatigue, peripheral edema, headache, hyponatremia, and pleural effusion. The frequency of grade $\geq$ 3 related AEs was 13% and the most common were hyponatremia (n=3) and pleural effusion (n=2). There were no thromboembolic or significant bleeding events. **Conclusions:** Dal is a novel anti-angiogenic agent that inhibits ALK1 signaling. In this heavily pre-treated RM-SCCHN population, Dal monotherapy demonstrated modest dose dependent activity and a favorable safety profile. Detailed safety, efficacy, and correlative PD data will be presented. Clinical trial information: NCT01458392.

**6046 General Poster Session (Board #81), Sat, 1:15 PM-5:00 PM**

**Boron neutron capture therapy in patients with recurrent head and neck cancers who have no other treatment options.** *Presenting Author: Itsuro Kato, Oral and Maxillofacial Surgery II ,Osaka University Graduate School of Dentistry, Suita, Japan*

**Background:** Boron neutron capture therapy (BNCT) is a targeted type of radiotherapy that has a number of significant advantages over conventional external beam photon irradiation, especially in that radiation can be selectively delivered to tumor cells. We had, first in the world, treated with BNCT for a patient with recurrent head and neck Cancers (HNC) in 2001. **Methods:** From December, 2001 to February, 2013, we have treated a total of 35 patients with recurrent HNC by means of 52 applications of BNCT. Histopathologically, there were 24 patients with squamous cell carcinomas (SCC), 7 with salivary gland carcinomas and 4 with sarcomas. All of them had received standard therapy and subsequently developed recurrent disease for which there were no other treatment options. All of the patients received intravenously either a combination of two boron containing drugs, sodium borocaptate (BSH, 5g) and boronophenylalanine (BPA, 250mg/kg) or BPA (500mg/kg) alone. In this report we will summarize the clinical results and outcomes of 35 patients with HNC who had received BNCT at either the Kyoto University Research Reactor Institute (KURI) or the Japan Atomic Energy Agency (JAEA) nuclear reactor. **Results:** All of the patients had advanced disease and 17 of 35 (49%) had regional lymph node metastases and 10 out of 35 (29%) had distant metastases at the time of treatment. (1) Boron concentration ratios of tumor/normal tissue (T/N ratio), as determined by $^{18}$FBPA-PET imaging were 1.8-7.0 for SCC, 2.5-4.0 for sarcomas and 2.5-3.7 for parotid tumors. (1) Regression rates were CR: 18 patients (51%), PR: 13 (37%), PD: 3 (9%), and not evaluated (NE):1patient. The overall patient response rate was 88%. (2) The Mean Survival Time was 24.2 months and the 4 year and 7-year OS rates were 42% and 36% , respectively. (3) Survival times following BNCT ranged from 1 to 95months. (4) BNCT improved QOL, PS and survival times. (5) The primary adverse events were brain necrosis, osteomyelitis and transient mucositis and alopecia. **Conclusions:** Our results indicate that we could make sure that safety and effectiveness of BNCT and BNCT represents a new and promising treatment modality in patients for whom there are no other treatment options.

**6047 General Poster Session (Board #82), Sat, 1:15 PM-5:00 PM**

**Impact of tumor metabolic response by PET/CT on the survival after salvage re-irradiation of head and neck cancers.** *Presenting Author: Tawee Tanvetyanon, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Re-irradiation (Re-RT) is a treatment option for recurrent, previously irradiated head and neck cancers. Nevertheless, most patients will still develop progressive disease after Re-RT. We sought to evaluate the predictive value of metabolic response by 18F-FDG-PET/CT (PET/CT) on the survival after Re-RT. **Methods:** Patients with locally recurrent squamous cell carcinoma of head and neck treated by Re-RT at our institution during 2005-2012 who had pre- and post-treatment PET/CT were identified. Their scans were re-analyzed by a nuclear medicine physician who was unaware of patient outcome. PET/CT analysis comprised qualitative analysis and measurement of maximum standardized uptake value (SUVmax) as a semi-quantitative index of relative tissue uptake. Complete metabolic response (CR) was defined as resolution of hypermetabolism without new lesion. **Results:** Fifty-five patients were analyzed: 41 patients (76%) had definitive Re-RT and 13 patients (24%) had adjuvant Re-RT. Median radiation dose delivered was 60 Gy (40-70 Gy). Concurrent chemotherapy was cisplatin in 28, carboplatin in 13, cetuximab in 10, and none in 3 patients. Median pre- and post-treatment SUVmax were 8.5 (range 3.3-18.9) and 4.3 (range 0-15.7), respectively. At a median of 13 weeks after Re-RT, the median metabolic response was 63% (range -80-100%), with 16 patients (30%) achieving CR. Median overall survival was 38.7 months among patients with CR vs. 12.2 months among those without CR ($p<0.0001$); Median PFS was 29.3 vs. 5.6 months ($p<0.0001$); and 5-year survival rates were 37% vs. 3%, respectively. Multivariate analysis adjusting for age, duration since previous radiation, comorbidity, organ dysfunction and sum of tumor sizes showed that achieving CR was a strong, independent predictor of survival, Hazard Ratio 5.52 (95% CI: 2.3-13.5). We found no significant difference in the survival of patients with partial metabolic response ($\geq$50% reduction of SUVmax) and those without response. For the prediction of 5-year survival, the negative predictive value of achieving CR by PET/CT was 97%. **Conclusions:** Failure to achieve a complete metabolic response after Re-RT is highly predictive of disease progression or death.

**6048 General Poster Session (Board #83), Sat, 1:15 PM-5:00 PM**

**Comparison of outcomes of locoregionally advanced oropharyngeal and non-oropharyngeal SCC over two decades.** *Presenting Author: Lauren Herman, The University of Chicago Medical Center, Chicago, IL*

**Background:** Human papillomavirus (HPV) has emerged as a causative agent and positive prognostic factor for oropharyngeal (OP) head and neck squamous cell cancer (HNSCC). This prompts inquiry into whether recent improvements in HNSCC outcomes are due to therapy improvements or the increasing incidence of HPV-related HNSCC. **Methods:** We performed a review of all patients treated for locoregionally advanced HNSCC with chemotherapy and radiation at the University of Chicago on a series of prospective institutional trials. Patients were divided into three groups according to the time period during which they were treated. Groups one, two, and three were treated between 1993-1998, 1999-2003 and 2004-2010 respectively. Trends were compared for OP and non-OP. **Results:** 422 patients were identified with OP (55.7%) and non-OP (44.3%) cancers. All patients had ECOG 0-2. Median age was 57 yrs. OP overall survival (OS) improved over time with 5 yr OS of 42.3% (group 1), 72.5% (group 2), and 78.4% (group 3), $p<0.001$. There was a trend towards improved 5 yr OS for non-OP patients with 51.0% (group 1), 58.8% (group 2), and 66.3% (group 3), $p=0.16$. Similarly 5 yr progression free survival (PFS) improved for OP groups from 42.3% to 68.4% to 75.8% ($p<0.001$). The respective increase in non-OP was from 42.9% to 53.6% to 61.7% ($p=0.094$). Five year distant failure free survival (DFFS) was 42.3%, 71.1%, and 77.8% ($p<0.001$) for OP and 46.9%, 57.1%, and 66.0% ($p=0.13$) for non-OP. Trends remained statistically significant for OP groups after adjusting for baseline covariates but were diminished in the non-OP group ($p=0.51$, $p=0.30$, and $p=0.38$ for OS, PFS, and DFFS respectively). **Conclusions:** Over the past two decades, OP HNSCC outcomes (OS, PFS, DFFS) have significantly improved while non-OP HNSCC outcomes have trended toward improvement. Although our patients are not specifically stratified by HPV, it is likely that improving OP outcomes are due to the increasing incidence of HPV-related HNSCC in the OP. These data further justify trial stratification for HPV status, investigations of novel approaches for patients with carcinogen-related HNSCC, and current de-intensification approaches for HPV-related HNSCC.

**6049 General Poster Session (Board #84), Sat, 1:15 PM-5:00 PM**

**A dose-finding study of nanoparticle albumin-bound paclitaxel plus cisplatin in patients with metastatic nasophyngeal carcinomas.** *Presenting Author: Li Zhang, Sun Yat-Sen University Cancer Center, Guangzhou, China*

**Background:** Nanoparticle albumin-bound paclitaxel (Abraxane, ABX), is a novel formulation of paclitaxel that has proved superior efficacy compared with conventional paclitaxel in the treatment of several metastatic cancers. We undertook this trial to determine the optimal dose and to preliminarily aseess efficacy of ABX plus cisplatin (DDP) in nasopharyngeal carcinoma (NPC). **Methods:** This was an open-label, nonrandomized study. Patients with metastatic NPC who were previously untreated or failed the standard treatment (radiochemotherapy or first-line chemotherapy) were enrolled sequentially into three cohorts (23 patients/cohort, N=69) to receive DDP 75 mg/m2 q3w plus ABX 260mg/m$^2$ q3w (cohort 1), or 140mg/m$^2$ d1, 8 q3w (cohort 2) or weekly ABX 100mg/m$^2$(cohort 3), respectively. Recruitment of any cohort would be deceased if more than one third of patients experienced dose-limiting toxicities (DLTs). **Results:** All clinical features were balanced among cohorts, including sex, age, histology, proportion of patients with different previous treatments, etc. All cohorts completed recruitment since DLT occured only in one case from cohort 1 and cohort 3 repspetively. The most common grade 3-4 adverse events were neutropenia (50.9%), leukocytopenia (43.6%), anemia (10.9%), fatigue (5.5%) and vomitting (5.5%). The proportion of patients experienced grade 3-4 toxicity is 65.5%, not differing in each cohort (cohort 1, 63.6%; cohort 2, 61.1%; cohort 3, 73.3%; $P$=0.74). The objecive response rates (ORR) were similar among all cohorts (70.0%, 66.7%, 66.7%, $P$=0.97). Notably, we observed that patients who had received not any prior chemotherapy (23.6%) had a significantly higher ORR than those who had ever experienced (100% vs. 56.8%, $P$=0.004), without difference in grade 3-4 toxicity ($P$=0.314). **Conclusions:** ABX-DDP is a safe and efficacious regimen for advanced NPC patients. ABX 260mg/m$^2$ q3w, 140mg/m$^2$ d1, 8 q3w or weekly ABX 100mg/m$^2$ showed equivalent response and toxicity. Taking convenience into consideration, we determined ABX 260mg/m$^2$ q3w as the standard dosage in the upcoming phase III randomized controlled trial. Clinical trial information: NCT01735409.

**6050 General Poster Session (Board #85), Sat, 1:15 PM-5:00 PM**

**Preliminary testing of a patient-reported outcome measure for recurrent or metastatic head and neck cancer.** *Presenting Author: Leanne Kolnick Jackson, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN*

**Background:** There are no patient reported outcome measures developed and tested in patients with recurrent-metastatic head and neck cancer (RMHNC). Symptom (sx) burden in RMHNC is poorly described. Available tools focus on acute and late effects of primary therapy and are hypothesized to lack content specific to RMHNC. We undertook development of the Vanderbilt Head and Neck Symptom Survey - Recurrent/Metastatic (VHNSS-RM) to assess tumor related sx, residual toxicity from prior therapy and side effects from current therapy. The tool contains 35 physical sx and 12 psychosocial issues scored on a 0 (none) to 10 (severe) scale (ASTRO abstract 46, 2014). We now report preliminary testing of the tool. **Methods:** A pilot trial with 39 patients was completed 6/2013 - 1/2014. Inclusion criteria: non-curable recurrent or metastatic HNC. The tool was administered online to all patients during clinic. **Results:** No barriers to completion of the tool via computer interface were noted. Patients found the tool acceptable, with high feasibility and readability. Completion time was $\leq$15 minutes for 92.4% of patients. A full range of scores was noted for 46 of 47 questions. VHNSS-RM includes 12 novel sx questions and 7 novel psychosocial issues. Novel sx include: diet change due to mouth swelling; tongue movement affecting speech/swallowing; swelling of face/neck; cramping in neck/jaw; bad breath; drooling; wound complications: drainage/pain/odor; nasal congestion/drainage; eyes watering; numbness of face/tongue/ear/scalp; headaches and confusion. Psychosocial issues include: perception of burden to family/friends; lost independence; fear; embarrassment; mood swings; stress and boredom. Overall, sx burden was high with moderate to severe symptoms (VHNSS-RM $\geq$5) identified in >30% of patients for 33/47 questions (70.2%), of those 48.5% had severe sx (VHNSS-RM $\geq$7). **Conclusions:** The VHNSS-RM is feasible and can be completed in a timely manner. Sx experienced by patients with RMHNC are often different than at initial presentation and during primary treatment. The 19 novel questions could aid in improved palliation to these patients. There are plans to validate the VHNSS-RM and analyze its role in assessment of treatment response and impact on overall sx burden.

**6051 General Poster Session (Board #86), Sat, 1:15 PM-5:00 PM**

**Internal lymphedema correlation with subjective and objective measures of dysphagia in head and neck cancer.** *Presenting Author: Leanne Kolnick Jackson, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN*

**Background:** Tumor/treatment-related external (EL) and/or internal lymphedema (IL) are associated with functional deficits and increased symptom burden in head and neck cancer (HNC) patients. We noted an association between EL/IL and patient-reported dysphagia using the Vanderbilt Head and Neck Symptom Survey (VHNSS) version 1.0. Consequently, we studied the relationship between EL/IL with subjective and objective measures of swallow function. **Methods:** 81 HNC patients completed: (1) the VHNSS version 2.0 which included 13 swallowing or nutrition related questions grouped into three clusters: swallow solids (ss), swallow liquids (sl), nutrition(nt); (2) physical assessment of EL using Foldi scale; (3) endoscopic assessment of IL using the Patterson scale (n=56); and (4) modified-barium videofluoroscopy (MBSS) rated by the Dysphagia Outcome and Severity Scale (DOSS) and in conjunction with a swallow evaluation, by the National Outcomes Measurement System (NOMS). Examinations were performed at varied time points to assess a spectrum of lymphedema, from baseline (n=15, 18.1%) to 18 months post therapy (n=20, 24.1%). **Results:** VHNSS swallow/nutrition items scores correlated with NOMS and DOSS ratings. The highest correlation was with the NOMS: ss (-.73; p<.001); sl (-.61; p<.001); nt (-.56; p<.001). VHNSS swallow/nutrition scores correlated with maximum grade of swelling for any single structure on the Patterson scale: ss (.43; p=.001); sl (.38; p=.004); nt (.41; p=.002). IL of the aryepiglottic and pharyngoepiglottic folds, epiglottis and pyriform sinus were most strongly correlated with VHNSS swallow/nutrition items and NOMS ratings. There was no correlation with VHNSS swallow/nutrition items or NOMS/DOSS ratings and EL. **Conclusions:** IL correlated with subjective and objective measures of swallow dysfunction. Longitudinal analysis of the trajectory and impact of IL/EL on dysphagia is ongoing. Clinical trial information: NCT01187173.

**6052 General Poster Session (Board #87), Sat, 1:15 PM-5:00 PM**

**Is there a survival benefit in patients with advanced squamous cell carcinoma of the head and neck under chemoradiotherapy or radiotherapy alone after surgery administration: A systematic review and meta-analysis.** *Presenting Author: Jinbiao Shang, Zhejiang Cancer Hospital, Hangzhou, China*

**Background:** The optimal treatment strategy for patients with operable advanced squamous cell carcinoma of the head and neck is uncertain. We performed a systematic review and meta-analysis to test the hypothesis that the addition of chemotherapy to radiotherapy after surgical resection could improve the locoregional control and survival compared with postoperative radiotherapy alone. **Methods:** A comprehensive search of PubMed for relevant studies comparing patients with advanced squamous cell carcinoma of the head and neck undergoing chemoradiotherapy or radiotherapy alone after resection was conducted using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) standards. The endpoints were local-regional control (LRC), disease-free survival (DFS) and overall survival (OS). Hazard ratios (HRs) were extracted from these studies to give pooled estimates of the effect of chemotherapy as an adjunct to postoperative radiation therapy on DFS and OS. **Results:** Data from a total of 1,054 patients from 5 randomized trials investigating chemoradiotherapy versus radiotherapy alone after surgery were included in a meta-analysis. The meta-analysis demonstrated significant benefits from adding chemotherapy to radiotherapy in LRC (risk ratio [RR]: 0.61, 95% confidence interval [CI]: 0.49 - 0.76, $p < 0.00001$), DFS (HR: 0.76, 95% CI: 0.65 - 0.88, $p = 0.0003$) and OS (HR: 0.77, 95% CI: 0.66 – 0.90, $p = 0.001$). The adverse effects occurred more frequently and severely in chemoradiation combined treatment, but there was no significant difference compared with radiotherapy alone. **Conclusions:** Postoperative chemotherapy adding to radiotherapy is superior to radiotherapy alone. Patients with chemoradiotherapy after surgical resection can achieve the higher LRC, longer DFS and OS. But the pronounced benefits of chemoradiation combined treatment need to be weighed against the potential toxicity of treatment.

**6053 General Poster Session (Board #88), Sat, 1:15 PM-5:00 PM**

**Quality of life of patients with locally advanced head and neck cancer (LAHNC) treated with docetaxel/cisplatin/5-fluorouracil (TPF) followed by cisplatin-containing chemoradiotherapy (CRT).** *Presenting Author: Chantal Driessen, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** The CONDOR study, a randomized phase II trial, investigated feasibility of TPF followed by conventional CRT with cisplatin 100 mg/m$^2$ on days 1,22,43 (cis100+RT) versus CRT with accelerated RT with weekly cisplatin 40 mg/m$^2$(cis40+ART) in LAHNC pts, PS 0-1, age 18-65. Here we report the analysis of health-related quality-of-life (HRQOL) and symptoms. **Methods:** HRQOL was assessed at baseline (BL), after 2 TPF, before start and at the end of CRT, and 1, 4, 8, and 12 months after completion of CRT using the EORTC QLQ-C30 and QLQ-H&N35. A change of >10 points on mean scores was considered clinically significant. BL scores were compared to EORTC reference values of LAHNC pts. **Results:** 62 pts started with TPF; 56 pts were randomized to cis100+RT (n=27) and cis40+ART (n=29). The study was terminated prematurely due to toxicity and inability to get the full dose of cisplatin: 22% (cis100+RT) and 41% (cis40+ART) of the pts could receive the planned cisplatin during CRT, respectively. The planned radiotherapy was given to 96% of the pts. Despite high toxicity rates, especially mucositis in cis40+ART, and not full dosed cisplatin 2-years overall and progression free survival were 72% and 65%, respectively. Compliance with the QOL questionnaires was 94% (59/62) at BL, and dropped to 61% (30/49) at 12 months. Mean global health score (GHS) at BL was 75.3 (SD 19.7) compared to the reference value of 63.1 (SD 22.4). GHS decreased after TPF, even more during CRT to 46.8 (SD 19.7) in both arms equally, but restored to BL level after approximately 12 months. Pain and swallowing dysfunction improved significantly during TPF, but deteriorated below BL levels during CRT, more in cis40+ART than in cis100+RT ($p<0.05$). Speech ameliorated not significantly during TPF, worsened during CRT below BL level, more in cis40+ART ($p<0.05$). All symptoms restored to BL within a year in both arms. **Conclusions:** The BL GHS appeared to be high in this population reflecting the good condition of these pts. After TPF, cis40+ART had a more negative impact on symptoms than cis100+RT, probably due to the ART. GHS and symptoms restored to BL levels within one year in both arms. Clinical trial information: NCT00774319.

**6054 General Poster Session (Board #89), Sat, 1:15 PM-5:00 PM**

**Gefitinib with concurrent chemoradiation in locally advanced head and neck cancers.** *Presenting Author: Charu Singh, S.M.S Medical College and Hospital, Jaipur, India*

**Background:** Squamous cell carcinomas of Head and Neck express EGFR receptors. We conducted a study to assess the efficacy and toxicity of Gefitinib along with concurrent chemoradiation in comparison to chemoradiation alone in management of locally advanced head and neck cancers. **Methods:** 86 previously untreated histologically proven patients of squamous cell carcinoma of head and neck cancer were divided into two groups- the study group (n=43) receiving gefitinib 250 mg OD along with weekly cisplatin 30 mg/m$^2$ and radiotherapy , and the control group receiving weekly ciasplatin 30mg/m$^2$along with radiotherapy. The radiotherapy dose was 70 Gy in 35 fractions, 2 Gy / fraction in both the groups. Inclusion criteria were- patients with locally advanced head and neck cancer, biopsy proven squamous cell histology, patients of both genders, between 18 and 70 yearsof age, ECOG PS 0 to 2, life expectancy of 6 months. Patients with poor performance status, known metastatic disease, uncontrolled intercurrent illness, deranged LFT, RFT and complete blood count, and histology other than squamous cell carcinoma were excluded from study. The patients were put on follow up for 6 months after completion of treatment. **Results:** The analysis was based on intent to treat. In the study group, 34 patients had complete response and 4 had partial response. Overall response was seen in 38 patients (88.37%, $p<.05$). While in control group 27 patients showed complete response and 3 patients had partial response. Overall response (CR+PR) was seen in 69.76% patients. The most common adverse affects were skin rashes and mucositis. The incidence of dermatitis was 51.16% in the study group and 39.53% in the control group , overall incidence of grade 3 dermatitis being 3%. The incidence of mucositis was 90.69% in the control group and 97.67% in the study group. **Conclusions:** Chemoradiation remains the mainstay of treatment for head and neck cancer patients. EGFR is most expressed receptor in squamous cell carcinoma of head and neck. The present study shows that targeted therapy with gefitinib and chemoradiation is well tolerated with some enhanced, but manageable toxicities and has shown to improve local control though further studies are needed.

**6055 General Poster Session (Board #90), Sat, 1:15 PM-5:00 PM**

**Surgery and definitive chemoradiation (CRT) for locally advanced oropharyngeal cancer and impact of transoral robotic surgery (TORS).** *Presenting Author: Charles Eric Wooten, University of Kentucky, Lexington, KY*

**Background:** TORS is an emerging modality for oropharyngeal cancer. However, many patients require adjuvant therapy based on high-risk pathologic findings. We compared control rates of TORS to CRT. **Methods:** A retrospective review was performed evaluating all consecutive patients treated in our department for oropharyngeal cancer from January 2010 through December 2013. All patients treated with definitive CRT or surgical resection with adjuvant RT +/- chemotherapy. **Results:** 103 total patients identified among whom 40 were resected (33/40 TORS). Majority of patients were stage IVA (86%). 92% (37/40) of patients in the surgery group were T1/T2 vs 36% (23/63) in CRT group. p16 associated with improved locoregional control (LRC) (91% vs 43%, p=0.035). 22/40 resected patients required adjuvant radiation with chemotherapy (trimodality) due to 16/40 with extracapsular extension, 5/40 with positive margins and 2/40 with both. TORS had decreased rate of positive margins (9.1%) vs radical resection (29%). T4a primaries (3/40) had significant risk of positive margins (p=0.038). At median follow up of 20 months (3 – 50), 4 year actuarial overall survival (OS) for entire cohort was 77%. 4 year actuarial OS for trimodality was 79% vs 74% with CRT. 4 year actuarial local control with trimodality was 94% vs 86% with CRT. Compliance was 79% in the surgical group and 100% in the CRT group. Non-compliance was associated with decreased LRC (p=0.049). Sites of first recurrence for surgical and CRT groups respectively were 2.5% vs 11% primary, 10% vs 7.9% regional and 7.5% vs 11% distant. OS was negatively associated with time from initial surgery to completion of adjuvant treatment (p=0.02). Distant failure was associated with retropharyngeal nodal involvement (p=0.0043). **Conclusions:** No significant difference in control between both groups despite greater percentage of advanced primary tumors with CRT. Compliance with adjuvant therapy in TORS population was lower.

**6056 General Poster Session (Board #91), Sat, 1:15 PM-5:00 PM**

**Degree of nephrotoxicity after intermediate or high-dose cisplatin-based chemoradiotherapy (CRT) in patients with locally advanced head and neck cancer (LAHNC).** *Presenting Author: Chantal Driessen, Department of Medical Oncology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** CRT with cisplatin 100 mg/m$^2$ on days 1, 22, 43 (cis100) is standard treatment for LAHNC and nasopharyngeal cancers (NPC) patients (pts). An alternative CRT schedule consists of cisplatin 40 mg/m$^2$ weekly during six weeks (cis40). A direct prospective comparison of these 2 schedules has not been performed, yet. Data on the influence of these schedules on cisplatin-based nephrotoxicity are scarce. This study compared the occurrence of cisplatin-induced nephrotoxicity between these 2 CRT schedules. **Methods:** All pts treated with CRT for LAHNC or NPC from 2003 until 2011 in the Radboud university medical center were studied retrospectively. One hundred forty-four LAHNC/NPC pts were included, of whom 40 received cis100 and 104 received cis40. Serum creatinine at baseline and maximal rise during treatment were collected. An increase of 25% was established as clinically relevant. Nephrotoxicity was scored according to both the CTCAE version 3.0 and version 4.03. **Results:** Baseline serum creatinine was equal in both groups. During treatment with cis40, 17.3% developed an increase of ≥25% serum creatinine versus 77.5% treated with cis100 ($p<0.05$). According to the CTCAE version 4.03, nephrotoxicity grade 1 occurred in 40% and 68%, grade 2 in 53% and 7%, grade 3 in 5% and 0%, and grade 4 in 2% and 0% ($p<0.05$) in cis100 and cis40 LAHNC/NPC pts, respectively. Scoring according to CTCAE v 3.0 showed grade 1 in 42% and 5%, grade 2 in 8% and 0%, grade 3 in 2% and 0% in cis100 and cis40 pts, respectively. In the cis100 group 3/40 pts developed chronic renal dysfunction, versus 0/104 in the cis40 group. Pts treated with cis100 were admitted to the hospital more often en needed more often extra hydration ($p<0.05$). **Conclusions:** Significantly less nephrotoxicity occurs in pts treated with cis40 CRT compared to cis100 CRT. We suggest that LAHNC/NPC pts with renal impairment are treated with cis40 CRT. The CTCAE v 4.03 is more appropriate in scoring nephrotoxicity than the CTCAE v 3.0. Until recently the CTCAE v 3.0 was used, which has lead to an underscoring of nephrotoxicity in studies using cisplatin-containing CRT schedules.

**6057 General Poster Session (Board #92), Sat, 1:15 PM-5:00 PM**

**Aggressive treatment and survival outcomes in *NUT* midline carcinoma (NMC) of the head and neck (HN).** *Presenting Author: Nicole Grace Chau, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

**Background:** NMC is a rare subtype of squamous cancer defined by rearrangement of the *NUT* gene. NMC is typically found in the thorax, although ~20% of cases arise in the HN. NMC is almost uniformly fatal. We report on a cohort of patients (pts) with HN NMC to identify disease characteristics, treatment and outcomes. **Methods:** A clinical database was established using demographic and outcomes data available on all known cases of HN NMC obtained from the International NMC Registry (www.NMCRegistry.org). Clinicopathologic variables were assessed for 40 pts, the largest cohort of HN NMC studied to date. Outcome data from 31 patients treated from 1990-2013 were available for survival analyses. **Results:** HN NMC incidence has increased annually since 2010. Median age was 21.9 years (range 0.1-81.7), male: female (%) was 45:55, sinonasal origin was 50%, and the *BRD4-NUT* fusion was found in 82%. At diagnosis, 36% had regional node metastases and 15% had distant metastases. Initial treatment was upfront surgery (S) +/- adjuvant chemoradiation (CRT) or adjuvant radiation (RT) (48%), upfront RT +/- chemotherapy (C) (21%), or upfront C +/- S or RT (31%). Median progression-free survival (PFS) was 7.2 months (range 6.3-8.7). Median overall survival (OS) was 9.8 months (range 6.6-15.6). The 2-year PFS was 27% (95% CI, 9-44). The 2-year OS was 31% (95% CI, 13-50). Upfront S +/- post-operative CRT or RT, and S with negative margins were significant predictors of improved PFS and OS. Initial RT or C, type of C regimen, and *NUT* translocation type were not significantly associated with improved outcome. **Conclusions:** HN NMC portends a poor prognosis. Aggressive initial surgical resection with or without post-operative CRT or RT may be associated with enhanced survival. C or RT alone is inadequate, and the development of targeted therapies is now underway.

**PFS and OS by treatment.**

| Treatment | | n | 2-year PFS (95% CI) | P value | 2-year OS (95% CI) | P value |
|---|---|---|---|---|---|---|
| Initial upfront strategy | S +/- CRT or RT | 14* | 55 (26-85) | 0.01 | 55 (26-85) | 0.01 |
| | RT +/- C | 6 | 0 | | 0 | |
| | C +/- S or RT | 8 | 0 | | 14 (1-27) | |
| Extent of surgical resection | None | 13 | 0 | 0.03 | 8 (0-24) | 0.03 |
| | Debulking | 4 | 33 (0-88) | | 33 (0-88) | |
| | Gross total | 6 | 40 (0-84) | | 40 (0-84) | |
| | Complete with negative margins | 5 | 75 (32-100) | | 75 (32-100) | |

* 12/14 had S then CRT, 1/14 had S then RT.

**6058 General Poster Session (Board #93), Sat, 1:15 PM-5:00 PM**

**Neck dissection for oral mucosal melanoma: Caution of nodular lesion.** *Presenting Author: Wei Guo, Department of Oral and Maxillofacial-Head and Neck Oncology, Shanghai Ninth Peoples Hospital, Shanghai, China*

**Background:** Oral mucosal melanoma (OMM) often metastasizes to cervical nodes. A great number of studies have been conducted to evaluate the efficacy of neck dissection in the treatment of OMM, but considerable controversy remains in this field. **Methods:** The clinical features, treatments, and outcomes of 254 OMM patients were retrospectively analyzed from Jan. 1998 to Jul. 2012. Multivariate analysis was performed to identify the variables related to overall survival (OS). **Results:** Tumor size greater than 4 cm ($p$=0.01) and nodular types ($p$<0.0001) were independent prognostic factors for OS. Patients with nodular melanomas were more likely to have distant metastases than those with macular melanomas ($p$<0.0001). 164 patients (65%) had CLN metastases. The multivariate analysis revealed that prophylactic neck dissection was an independent favorable factor for OS ($p$=0.0016) in patients with cN0 nodular melanomas; whereas radical neck dissection ($p$=0.03) in patients with positive CLN. Patients undergoing functional neck dissection were more likely to have neck recurrence (p <0.001). **Conclusions:** Nodular type is a dangerous signal to OMM. It is advisable for patients with cN0 nodular melanomas to have prophylactic neck dissection, close observation is recommended for patients with cN0 macular melanomas, and patients with positive CLN should undergo radical neck resection.

**6059 General Poster Session (Board #94), Sat, 1:15 PM-5:00 PM**

**A double-blind, randomized, placebo-controlled trial of l-glutamine for the severe oral mucositis induced by chemoradiotherapy in patients with locally advanced head and neck cancer.** *Presenting Author: Takae Tsujimoto, Department of Clinical Pharmacy, Faculty of Pharmaceutical Sciences, Kobe Gakuin University, Kobe, Japan*

**Background:** The incidence ofseveremucositis is high among patients with head and neck cancer receiving chemoradiotherapy, resulting in significant pain and impairment of quality of life. This study aimed to investigate whether L-glutamine (glutamine) decreases the severity of oral mucositis (OM) including an area of the pharynx and larynx induced by chemoradiotherapy. **Methods:** This double-blind, randomized, placebo-controlled trial included 40 untreated patients with squamous cell carcinoma of the nasopharynx, oropharynx, hypopharynx, or larynx between May 2010 and August 2013. The inclusion criteria of this study were that patients must be more than 20 years old, suitable for chemoradiotherapy with cisplatin and docetaxel. The exclusion criteria were the presence of serious liver and/or renal dysfunction, uncontrolled diabetes mellitus, and oral and/or throat soreness before study. Patients received 66 or 70 Gy of total radiation at the rate of 2 Gy per fraction daily and 5 fractions per week. Cisplatin (20 mg/m$^2$) and docetaxel (10 mg/m$^2$) were intravenously coadministered once a week for 6 weeks. Patients were randomized to orally receive either glutamine (group G: 20 patients) or placebo (group P: 20 patients) at a dose of 10 g 3 times a day throughout the chemoradiotherapy course. OM was assessed using the National Cancer Institute Common Terminology Criteria for Adverse Events version 3.0. The primary end point was oral mucositis severity. NCI CTCAE grade was analyzed using the Mann–Whitney $U$ test, and Fisher's exact test. The $p$ values were 2-sided, and a value of <0.05 was considered statistically significant. **Results:** OM developed in all patients. A maximal OM grade of G4 was observed in 0% and 25% group G and group P patients, respectively, while that of G2 was observed in 10% and 0% group G and group P patients, respectively($p$ = .023).Glutamine significantly decreased the maximal OM grade (group G: 2.9 ± 0.3, group P: 3.3 ± 0.4; $p$ = .005). **Conclusions:** Glutamine significantly decreased oral mucositis severity induced by chemoradiotherapy in patients with head and neck cancer. Clinical trial information: UMIN000003991.

**6060^ General Poster Session (Board #95), Sat, 1:15 PM-5:00 PM**

**Updated overall survival analysis of patients with locally advanced or metastatic radioactive iodine-refractory differentiated thyroid cancer (RAI-rDTC) treated with sorafenib on the phase 3 DECISION trial.** *Presenting Author: Marcia S. Brose, Department of Otorhinolaryngology: Head and Neck Surgery, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

**Background:** The phase 3 placebo-controlled DECISION trial established that sorafenib treatment significantly improves progression-free survival for patients with RAI-rDTC. Overall survival (OS) was immature at the time of primary analysis and possibly confounded by placebo crossing over to receive open-label sorafenib at progression. We report the OS results from a planned 9-month follow up as of May 31, 2013 and possible corrections for the crossover. **Methods:** Patients with locally advanced/metastatic progressive RAI-rDTC were randomized to receive sorafenib or placebo. Placebo patients were allowed to receive sorafenib open-label (OL) upon progression. OS data were analyzed using 2 correction methods for cross over: iterative parameter estimation (IPE) and rank preserving structural failure time (RPSFT). **Results:** A total of 417 patients were randomized (207 to sorafenib and 210 to placebo). Median OS had not been reached at the time of primary analysis (August 31, 2012) at which time 70% of placebo patients had started OL sorafenib and the difference across the two arms was not significant; HR: 0.80; 95% CI: 0.539, 1.194, p=0.138, one-sided. Correction for the effect of cross-over from the placebo to sorafenib treatment was performed using two methods: RPSFT (HR 0.61; 95% CI: 0.40, 0.94) and IPE (HR 0.70; 95% CI: 0.47, 1.04). As of the May 31, 2013 cutoff, 75% of placebo patients started OL sorafenib and there have been a total of 138 events (66 sorafenib and 72 placebo), with the median OS still not having been reached in the sorafenib arm and without statistically significant difference between arms; HR 0.88; 95% CI: 0.633, 1.236, p=0.2359. Correction for cross-over was performed using the RPSFT method (HR 0.69; 95% CI: 0.49, 0.99) and the IPE method (HR 0.79; 95% CI: 0.56, 1.11). **Conclusions:** The OS results from the DECISION trial are still immature 9 months following the primary analysis. OS analysis taking into account the crossover of placebo patients to the sorafenib arm are not conclusive, but nonetheless suggest that sorafenib may have an effect on OS. Long-term follow up of OS is on-going. Clinical trial information: NCT 00895674.

**6061^ General Poster Session (Board #96), Sat, 1:15 PM-5:00 PM**

**Population PK modeling and exposure-response analyses of sorafenib in patients with radioactive iodine-refractory differentiated thyroid cancer (RAI-rDTC) in the phase III DECISION trial.** *Presenting Author: Lars Bastholt, Odense University Hospital, Odense, Denmark*

**Background:** The recently reported phase III DECISION trial in patients with RAI-rDTC demonstrated a significant improvement in progression free survival (PFS) associated with sorafenib treatment. The purpose of this exploratory analysis was to evaluate sorafenib pharmacokinetics (PK) in RAI-rDTC and to examine the relationship between exposure and both PFS and adverse events (AEs). **Methods:** In DECISION, patients with locally advanced/metastatic RAI-rDTC who progressed in the prior 14 months were randomized to sorafenib 400 mg bid po or placebo. Plasma was collected on Cycle 2 Day 1 (steady state) and sorafenib concentrations measured using LC-MS/MS. Sorafenib AUC(0-12),ss were estimated using a population PK model developed from 10 sorafenib phase I-III trials, including DECISION. **Results:** Plasma samples from 156 patients randomized to sorafenib were valid for the analysis. Sorafenib mean AUC(0-12),ss (95.7 mg*h/L) was 103% higher in DTC compared to RCC and HCC, although the ranges of AUCs were overlapping. No specific mechanism for the elevated sorafenib levels has been determined. Analyses of sorafenib AUC vs. PFS were not significant, although patients with the highest exposure (Quartile 4) had a numerically longer median PFS (509 days [95%CI: 283-623 days]) than those in the low (Q1) or medium (Q2+Q3) exposure groups (median PFS 305 days [95%CI: 162-448 days] and 293 days [95%CI: 231-451 days], respectively). There was no correlation between sorafenib AUC and incidence or severity of AEs (e.g. any AE, any SAE, any drug-related AE, hypertension, diarrhea, and hand-foot skin reaction). **Conclusions:** Sorafenib exposure was higher in DTC patients compared to patients with RCC and HCC. There was no apparent correlation between sorafenib exposure and PFS or AEs in DTC patients. This analysis is limited by the small number of subjects in each exposure subgroup and the single measurement of sorafenib AUC on Cycle 2-Day1. Clinical trial information: NCT 00895674.

**6062^ General Poster Session (Board #97), Sat, 1:15 PM-5:00 PM**

**Safety and tolerability of sorafenib for treatment of locally advanced or metastatic radioactive iodine-refractory differentiated thyroid cancer (RAI-rDTC): Detailed analyses from the phase III DECISION trial.** *Presenting Author: Francis P. Worden, University of Michigan Comprehensive Cancer Center, Ann Arbor, MI*

**Background:** The phase III DECISION trial established that sorafenib treatment improved progression-free survival in RAI-rDTC patients. We report here on the incidence and prevalence of adverse events (AEs) by severity and treatment cycle and the dose modification patterns for patients treated on the DECISION trial. **Methods:** Patients with locally advanced/metastatic progressive RAI-rDTC were randomized and received sorafenib 400 mg bid po or placebo. AEs were recorded by cycle (C) and by grade (G) during the double-blind treatment period using NCI CTCAE v 3.0 or MedDRA v 15.1. **Results:** A total of 417 patients were randomized (207 to sorafenib and 210 to placebo). Hand-foot skin reaction (HFSR; 76% any grade/20% grade 3/ - grade 4), rash (50/5/0) and hypertension (41/10/0) tended to occur early in treatment (C1 and C2). G1-G3 HFSR occurred in C1, but was primarily G1 thereafter. Diarrhea (69/5/1) and fatigue (50/5/1) had a relatively constant onset across cycles and were predominantly G1. Weight loss (47/6/-) was primarily G1 and G2 with prevalence of G2 increasing with length of treatment. G1 TSH elevation (>0.5 mU/L) necessitating an increase in thyroxine replacement was observed in 33% of sorafenib patients and 13% of placebo patients. Hypocalcemia (19/6/3) was most likely to first occur in C2. Dose reductions in the sorafenib arm started early (35% of patients in C1 were on a reduced dose then ranged 50-60% thereafter). Dose interruptions were highest in C1 and C2 (37% and 26% of patients with dose interruption, respectively) and was <10% by C5. Most AEs decreased in severity or resolved following dose modification. Treatment discontinuation due to AEs occurred in 19% of sorafenib patients and were relatively evenly distributed after C1 (4% C1 and 0-2% C2-C9); 4% of patients in the placebo arm discontinued due to AEs. **Conclusions:** The incidence and prevalence patterns of AEs by severity and treatment cycle for RAI-rDTC patients treated with sorafenib demonstrated that the majority of AEs were Grade 1-2, occurred early during the treatment course, and were typically manageable over time. Clinical trial information: NCT 00895674.

**6063 General Poster Session (Board #98), Sat, 1:15 PM-5:00 PM**

**Pharmacokinetic and pharmacogenetic analysis in patients with advanced nasopharyngeal carcinoma (NPC) treated with 5-flurouracil (5-FU) and cisplatin.** *Presenting Author: Yuxiang Ma, Cancer Center, Sun Yat-sen University, Guangzhou, China*

**Background:** Many studies have demonstrated several pharmacokinetic and pharmacogenetic factors may affect the efficacy and toxicity of 5-FU. These factors include system drug exposure (area under the concentration-time curve, AUC), thymidylate synthase (TS) and dihydropyrimidine dehydrogenase (DPD). This study is to investigate correlation of these factors and efficacy and toxicity of 5-FU and Cisplatin in NPC patients. **Methods:** 122 NPC patients with measurable lesions were enrolled and received Cisplatin (80mg/m$^2$, day1) and 5-FU (4g/m$^2$, civ120h) regimen. The blood samples were collected at steady state of 5-FU infusion. AUC of 5-FU measurement was performed using an immune-based assay (MyCare). The 5-FU AUC target range was identified by Received Operating Characteristic Curve (ROC), based on 5-FU related mucositis and treatment response. Tumor tissues were also collected for evaluation the expression of TS, DPD by using immunohistochemistry (IHC). **Results:** 108 patients were analyzed (5 not assessable, 6 withdraw and 3 invalid sample). AUC of 5FU values ranged from 15 to 103mg·h/L. The optimal target range of 5-FU AUC was 31-37 mg·h/L. 20.4% of the patients were within the target range, while 39.8% was below and 39.8% was above. Within or above target range patients had better object response rate than those below target (75.4% vs 55.8%, P=0.033), within or below target range patients had lower toxicity rate (grade3/4) than those above target (6.2% vs 67.4%, P<0.001). A nomogram model based on AUC, DPD and TS expression for predicting treatment response shown that, all as independent variables, within the target AUC range, high-DPD or low-TS tumor had better response rate. **Conclusions:** The combination of pharmacokinetic and pharmacogenetic approach may be an innovative strategy for optimizing chemotherapy in patients with advanced NPC. These findings deserve confirmation in additional prospective studies.

**6064 General Poster Session (Board #99), Sat, 1:15 PM-5:00 PM**

**Association of young patient age with high-risk pathologic features and recurrence in papillary thyroid cancer.** *Presenting Author: Iris H. Wei, University of Michigan, Ann Arbor, MI*

Background: Certain histopathologic features may be risk factors for recurrent disease after resection of papillary thyroid cancer (PTC). Age is also an important prognostic factor, with higher mortality in patients over 45. Our objective was to determine whether age was associated with these pathologic features and rates of recurrence. Methods: A retrospective analysis was performed for PTC patients who underwent anatomically complete resection at the University of Michigan between 2006 – 2012. Patients with known distant metastases were excluded. Demographics, high-risk pathologic features (capsular or vascular invasion, extrathyroidal extension, lymph node metastases, extranodal extension), and disease recurrence were examined. Results: A total of 623 PTC patients were included in the analysis; 141 (23%) were men, 482 (77%) women. Median age was 49 years (range 10–87). Twenty patients had recurrent disease, and all recurred locoregionally in the central or lateral neck, with a mean time to recurrence of 1.2 years. One patient was treated with radioactive iodine, while the rest underwent reoperation. By Kaplan-Meier analysis, there was no difference in recurrence rates between patients <45 and ≥45 years ($p = 0.92$). However, additional subgroup analysis revealed that patients ≤25 had a higher rate of recurrent disease compared to those >25 years ($HR = 8.2$, $p = 0.02$). The tumors of young patients (≤25 years) were also larger ($p = 0.001$), with higher rates of extranodal extension ($p = 0.0004$), vascular invasion ($p < 0.0001$), capsular invasion ($p < 0.0001$), and lymph node metastasis ($p = 0.007$). Overall, the presence of any aggressive pathologic features was associated with an increased risk of recurrence ($HR = 18.5$, $p = 0.004$). Using a Cox proportional hazards model, the most significant risk factors were tumor size, capsular invasion, extrathyroidal extension, and lymph node metastases. **Conclusions:** PTC patients ≤25 years old have significantly higher rates of recurrence and reoperation despite being classified as AJCC Stage I. This may be in part due to larger tumor sizes and presence of aggressive histopathologic features. Patients with these factors should be monitored with close surveillance.

**6065 General Poster Session (Board #100), Sat, 1:15 PM-5:00 PM**

**Does age impact treatment of head and neck squamous cell carcinomas? A retrospective monocentric study about 107 patients age 75 and over.** *Presenting Author: Laurence Digue, Medical Oncology, CHU Bordeaux, Bordeaux, France*

**Background:** About 30% of head and neck carcinomas occur in patients over 70, and 10% in patients over 80. There is no standard of care for this population, which is under-represented in clinical trials. How are non-metastatic patients 75 and over treated in routine practice? **Methods:** Our study is a retrospective analysis based on 107 patients aged 75 and over (median 81.4 [75-94]) with non-metastatic squamous cell head and neck carcinomas treated in Bordeaux Academic Hospital between March 2007 and March 2012. We compared, for each patient, the standard treatment proposed to younger patients as described by international recommendations (NCCN, ESMO), the treatment recommended in multidisciplinary staff, and the treatment ultimately received. **Results:** Of the 107 patients, 69 (64.5%) were males and 38 (35.5%) females. 51.4% had an oral cavity cancer, 16.8% oropharyngeal, 15.9% laryngeal, 13.1% hypopharyngeal and 2.8% prevalent cervical lymph node without primary tumor. The standard treatment was proposed by multidisciplinary staff in less than 40% of patients, because of their deteriorating performance status (PS), chronological age and/or comorbidities. The treatment recommendedby multidisciplinary staff (with patients present in ¾ of the cases) was ultimately received in more than 80% of cases. In the others, the proposed treatment was not administered because of patient's deteriorating PS or their refusal. Only 15 patients had a geriatric assessment and none of them received the standard treatment. Treatment toxicities were acceptable and similar to those found in literature for younger patients. At 5 years, overall survival of our population was 14.5%, but specific survival was 74,5%. Our population passed away more from comorbidities than from their cancer after the first 2 annual follow-ups. **Conclusions:** We recommend the systematic completion, before treatment proposal, of at least one easy screening of geriatric fragilities in order not to under or over-treat these patients, and a prompt start of treatment after decision by multidisciplinary staff because of quick deterioration of PS. We also recommend that elderly patients can be included in clinical trials.

**6066 General Poster Session (Board #101), Sat, 1:15 PM-5:00 PM**

**Survival disparities and trend of head and neck cancer in the United States: A Surveillance, Epidemiology, and End Results (SEER) database study 1973-2010.** *Presenting Author: Shahzad Raza, Ellis Fischel Cancer Center, University of Missouri Health Care, Columbia, MO*

**Background:** Despite recent advances in the management of head and neck cancer (HNC), there is little evidence of improvement in 5-year overall survival (OS) over the last few decades. Ethnicity, age, and socioeconomic status have all been associated with outcomes in HNC. We examine the survival disparities and trends of HNC in major ethnicities using the largest population based database. **Methods:** Frequency, rate and survival sessions (Kaplan-Meier, age adjusted) on demographics and survival trends were performed and compared among Non-Hispanic-White (NHW), African-American (AA), Hispanics, Asians and Pacific-Islanders (A/PI) and Asian-Indian and Alaskan-Natives (AI/AN) with SEER*Stat using SEER 1973-2010 data. **Results:** A total of 247,310 HNC patients were reported from 1973-2010 in SEER database. The primary sites were lip (11%), Tongue (27%), floor of mouth (8%), gum and other parts of mouth (16%), tonsils (15%), oropharynx (4%), nasopharynx (7%), hypopharynx (9%) and others (3%). Overall, 71% patients were male. The incidence rates per 100,000 were reported highest in AA (16.4) compare to NHW (15.3), Hispanics (9.6), A/PI (9.7), and AI/AN (7.8). There were 40% stage IV cases which were equally distributed across all ethnicities. After adjusting for age, stage and year of treatment, AA has significantly ($p<0.05$) inferior 5-year OS (41.8%) compared to NHW (60.8%), Hispanics (59.3%), A/PI (62%) and AI/AN (50.2%).The OS rates in A/PI and AI/AN have improved by 17.5% and 14.6% ($p<0.05$) over last 37 years respectively. In contrast, the AA had 6.1% decreased OS ($p<0.05$) from 1973 to 2010. In subset analysis, OS for stage IV in AA is poor (21%) compare to other ethnicities ($p<0.001$). **Conclusions:** According to SEER analysis, the OS in AA has decreased significantly from 1973 to 2010 and they continue to have dismal prognosis. The underlying causes are largely unknown. However, biologic/genetic and epigenetic factors, access to health care, socioeconomic status may play a role. Prospective studies are needed to define these factors in AA and to formulate treatment strategies that would improve survival outcome in AA.

**6067 General Poster Session (Board #102), Sat, 1:15 PM-5:00 PM**

**Postsurgical erlotinib and cisplatin concurrent chemoradiotherapy (CRT) promotes favorable outcomes in high-risk locally advanced head and neck squamous-cell cancer (LAHNSCC): A GICOR Working Group trial.** *Presenting Author: Fernando Arias, Complejo Hospitalario de Navarra, Pamplona, Spain*

**Background:** The approach to LAHNSCC including surgery, radiotherapy(RT), and chemotherapy (CT) lacks of significant improvements in long-term survival. In an attempt to explore tolerance and potentially improve outcomes, the Spanish Clinical Research Group on Radiation Oncology (GICOR) designed a phase I/II study, with a dose-finding period to determine the maximum-tolerated dose (MTD) of daily erlotinib(E) administered in combination with cisplatin(C) and RT, followed by a phase II study to evaluate the therapeutic activity and safety of the selected dose combination. **Methods:** 13 patients(pts) were enrolled in phase I. The MTD was defined at C, 40 mg/m2 and E, 150 mg, based on G3 infection and mucositis in 2 out of 3 pts at dose level III. Phase II: 56 pts from 5 institutions were assigned to receive RT, 63 Gy (35 fractions over 7 weeks) combined with C, 30 mg/m2, on days 1, 7, 15, 22 and 29 of a 7-week radiation course, and E, 150 mg once daily on a continuous basis. The trial was designed to detect a 15% increase in disease free survival (45% to 60% at 2 years) with a 0.05 significance level, and a power of 0.8. **Results:** RT, C and E were completed on schedule in 87,5%, 64,3% and 80,4% of the cases, respectively. At a median follow-up (FU) of 40,6 months(mo), the 2-year DFI, locoregional DFI and OS was: 64,9%, 72,6% and 77,9%, respectively. High-risk criteria defined by involved surgical margins, extranodal extension and/or perineural infiltration were reported in 31 pts (55,4%). Treatment-related toxicity was generally mild to moderate: G-3/4 radiation skin changes included mucositis (n=33, 59%) and erithema (n=14, 25%). C-related G-3/4 toxicities were mucositis (n=15, 11%) and neutropenia (n=4, 7%). E-associated skin toxicity ≥G3 occurred in 14 (25%) pts. No toxic death occurred during the treatment. **Conclusions:** After surgery, CRT using conventional fractionated RT, with concurrent C and E promoted remarkable 2-year DFI, locoregional control rate and 2-year OS. The addition of erlotinib to cisplatin/RT is acceptably tolerated with a manageable side-effect profile. Clinical trial information: 2005-001506-29.

**6068 General Poster Session (Board #103), Sat, 1:15 PM-5:00 PM**

**Expressions of EGFR, HER2, and HER3 and their correlations with clinical characteristics in oropharyngeal squamous cell carcinoma (OPSCC).** *Presenting Author: Nabil F. Saba, Emory University, Atlanta, GA*

**Background:** Epithelial growth factor receptor (EGFR) is overexpressed in squamous cell carcinoma of the head and neck (SCCHN) and is a therapeutic target for this disease. Since other members of the HER receptor family may be valid therapeutic targets in SCCHN we examined the expressions of EGFR, HER2, and HER3 and correlated their expression with clinical patient characteristics. **Methods:** After IRB approval 96 patients with OPSCC had tissue and clinical information collected and analyzed. Tissue microarray stained by immunofluorescence (IHF) was used to evaluate HER receptor expression. High risk HPV status and p16 status were determined by HPV DNA *in situ hybridization* (ISH) and immunohistochemistry (IHC) staining, respectively. The correlation with clinical characteristics of each receptor and their effects on disease-free survival (DFS) or overall survival (OS) were assessed. **Results:** p16 status was inversely correlated with EGFR expression ($P$=0.012), whereas no significant association between p16 status and HER2 or HER3 expression was found ($P$= 0.563 and 0.635, respectively). Current smokers had the highest EGFR expression compared to never or former smokers ($P$= 0.006). Patients with T3 and T4 disease had a higher EGFR expression compared to T1 and T2 disease ($P$= 0.040). HPV negative smokers had a significantly higher HER2 ($P$ = 0.043) and HER3 expression ($P$ = 0.019) compared to non-smokers. Among patients with low EGFR expression, HPV negative patients had a higher HER3 expression compared to HPV positive patients ($P$ = 0.048). Patients with high EGFR expression were more likely to have disease progression (HR: 1.58; 95% CI: 1.13 – 2.20; $P$= 0.007) or death (HR: 1.30; 95% CI: 1.01 – 1.68; $P$=0.042). HER2 or HER3 expression were not related to DFS or OS in OPSCC. **Conclusions:** EGFR was a prognostic factor for worse DFS and OS in OPSCC. Among patients with low EGFR expression HER3 expression was higher in HPV negative patients. These findings may point to a role for combined EGFR and HER3 targeted therapy in HPV negative disease, but will need to be confirmed in other studies. (This study was supported by a grant from Merrimack Pharmaceuticals to NFS and GZC).

**6069 General Poster Session (Board #104), Sat, 1:15 PM-5:00 PM**

**Head and neck cancer (HN) characteristics and outcomes in a human immunodeficiency virus infected (HIV+) patient cohort: A 12-year experience of the Louisiana State University Health Sciences Center (LSUHSC) and Charity Hospital in New Orleans.** *Presenting Author: J. Nicholas Bodor, LSU Health Sciences Center, New Orleans, LA*

**Background:** HIV+ patients (pts) are typically excluded from enrollment on randomized clinical trials for head and neck cancer. Data regarding clinical characteristics and outcomes for HIV+ pts with HN are limited in the medical literature. Despite lack of data, pts with HN and HIV are managed at LSUHSC in a multidisciplinary fashion according to the standards of care established for HIV negative (HIV-) pts. **Methods:** 15 HIV+ pts with AJCC Stage I (33%), Stage II (0%), Stage III (20%) and Stage IV (47%) squamous cell carcinoma of the head and neck treated from 1/1999 to 6/2011 were retrospectively reviewed. Additional data collected included: tumor primary site, age at diagnosis, gender, ethnicity, time from confirmed HIV infection to HN diagnosis and characteristics of pts HIV status. End points analyzed were progression-free survival (PFS) and overall survival (OS). **Results:** Oral tongue (26%), tonsil (20%) and larynx (13%) were most common primary sites; mean age at diagnosis was 48 years (yrs) old; 86% of pts were male, 14% were female; 47% of pts were white and 53% were black. Mean time from diagnosis of HIV to HN was 69 months and mean CD4 count nadir at any point prior to HN diagnosis was 93 cells/mm^3. 60% of pts in the cohort had been diagnosed with acquired immune deficiency syndrome (AIDS) before the HN diagnosis; the diagnosis of AIDS occurred a mean of 16 months prior to HN diagnosis. PFS at 3 yrs was 80% and OS at 3 yrs was 40%; median overall survival was 2.1 yrs. **Conclusions:** A majority of HIV+ pts in this cohort had AIDS diagnosed preceding the HN diagnosis. However, outcomes of HIV+ pts diagnosed with HN treated at our institution are favorable compared to HIV- pts. Our experience would suggest that HIV+ pts be treated according to accepted standards of care with careful management by physicians with HIV expertise.

**6070 General Poster Session (Board #105), Sat, 1:15 PM-5:00 PM**

**Docetaxel (DOC) with concurrent radiation (CRT) and bevacizumab (BEV) or erlotinib (ERL) for locally advanced squamous cell carcinoma of the head and neck (LA-SCCHN).** *Presenting Author: Panayiotis Savvides, The James Cancer Hospital and Solove Research Institute, The Ohio State University, Columbus, OH*

**Background:** Cisplatin (CIS) may not be the optimal radiosensitizer when combined with targeted agents in CRT regimens. RTOG 0234, a randomized phase II trial of postoperative radiation (RT) plus DOC or CIS plus cetuximab for high-risk LA-HNSCC showed an impressive improvement in overall survival and disease-free survival of DOC versus CIS (79% versus 69% and 66% versus 57% respectively). DOC-based CRT backbone regimens are worth further study in the organ preservation setting. To facilitate and accelerate evaluation of additional targeted agents, we summarized our experience in DOC-based chemo-RT using two consecutive phase II clinical trials with either BEV or ERL. **Methods:** 73 patients with LA-SCCHN (stage III- IVb) treated with RT (70 or 70.2-72Gy, 1.8-2Gy/day), weekly DOC (20 mg/m$^2$) and targeted therapy [BEV (5 mg/kg/qow) or ERL (150 mg/day)] were included. DOC dose was based on a phase I clinical trial of RT + DOC + ERL (Savvides P. Phase I study of ERL, DOC and RT in LA-SCCHN. AACR 2007.). **Results:** Patients with a median age 57 (range 35-75), primary site of LA-SCCHN [oropharynx (n=49), larynx (n=17), hypopharynx (n=2) and oral cavity (n=5)]. Efficacy data have been previously presented separately for the 2 trials (Savvides P. Phase II study of ERL, DOC and RT in LA-SCCHN. AHNS 2010.), (Galanopoulos N. Phase II study of BEV, DOC and RT in LA-SCCHN. ASTRO 2011.). Delivery of planned treatment was achieved in both trials; median total radiation therapy dose 70 Gy, median duration 53 days. DOC median dose intensity (MDI) 20mg/m$^2$/qw, x8 doses; BEV MDI 5mg/kg/qow, x4 doses and ERL MDI 150mg/qd.No increased SAEs, compared to historical controls. BEV/ERL related events limited to 2 G4 bleeding episodes and 1 G3 episode of thrombosis (BEV); 4 G4 skin rash episodes and 1 G5 event (death not treatment related) (ERL). **Conclusions:** Weekly DOC at 20 mg/m$^2$/wk with RT and either BEV or ERL is feasible and safe for definitive treatment of patients with LA-SCCHN and should serve as the backbone for evaluation of novel targeted agents. Supported in part by Genentech, NIH grants CA62502 and M01 RR-000080. Clinical trial identifier: NCT00049283; NCT00281840.

**6071 General Poster Session (Board #106), Sat, 1:15 PM-5:00 PM**

**Patterns of distant metastases in HPV-positive head and neck squamous cell carcinoma.** *Presenting Author: Jennie York Law, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Patients with HPV-positive head and neck squamous cell carcinoma (HPV+HNSCC) demonstrate favorable outcomes compared to HPV-negative SCC. Despite loco-regional control distant metastases (DM) can occur. The pattern of DM in HPV+HNSCC is not clearly defined. **Methods:** 109 patients with HPV+HNSCC underwent treatment at our institution from 2010-2012 (HPV status not identified prior to 2010). Recurrence time and metastatic sites were compared to patients with high risk HPV-negative/unknown SCC (HR HPV-/unk) and intermediate risk HPV-negative/unknown SCC (IR HPV-/unk) from 2006-2012. **Results:** Group 1: 109 patients with HPV+HNSCC (10 never achieved initial disease control). 7/109 (6.4%) developed DM. Median time to metastases was 11 months (range 7-41 months, mean 16 months). Median follow up from diagnosis was 18 months. Predominant sites of metastases were lung (6), liver (1), bone (1), and brain (1). 5/7 patients with DM (out of 65 patients with a tobacco history and 44 without) had prior or current tobacco use. Primary sites of disease were base of tongue (4/49 total base of tongue sites), tonsil (1/27), glottis (1/9), and nasal cavity (1/1). Group 2: 546 high risk HPV-/unk patients (hypopharynx/larynx/glottis). 124 never achieved initial disease control. 25/546 (4.6%) developed DM. Median time to metastases was 15 months (range 6-52 months, mean 18 months). Median follow up was 25 months. Predominant sites of metastases were lung (10), bone (3), and CNS (3). Group 3: 839 intermediate risk HPV-/unk patients (oral cavity/oropharynx/hard palate/tonsil). 246 never achieved initial disease control. 34/839 (4.1%) developed DM. Median time to metastases was 9 months (range 3-54 months, mean 14 months). Median follow up was 24 months. Predominant sites of metastases were the lung (12), bone (2), and liver (2). **Conclusions:** At median follow up of 18-25 months, there was no difference in the overall rate of DM for HPV+HNSCC compared to HR HPV-/unk (p=0.21) and IR HPV-/unk (p=0.13) but there was a significant difference in the rate of DM to the lung in the HPV+HNSCC group compared to HR HPV-/unk (p=0.012) and IR HPV-/unk (p=0.002). In our data set, HPV+HNSCC showed a higher rate of DM to the lung compared to HPV-/unk HNSCC (p=0.002).

**6072 General Poster Session (Board #107), Sat, 1:15 PM-5:00 PM**

**Detection of novel HPV mutations and chromosomal number imbalance (CNI) in laryngeal cancer using next-generation sequencing (NGS).** *Presenting Author: Howard B. Urnovitz, Chronix Biomedical, Göttingen, Germany*

**Background:** We selected HPV-associated laryngeal papillomas and squamous cell carcinomas for genomic analysis of viral induced benign and malignant neoplasms. The nearly universal presence of HPV in Recurrent Respiratory Papillomatosis (RRP) and in certain squamous cell carcinomas provides an important model for the study of biomarkers and clinical outcomes as well as the generation of robust panels of viral and genomic mutation biomarkers that can be used to follow disease progression. **Methods:** DNA was isolated from biopsies of three patients and sequenced on a NGS Illumina HiSeq platform. The sequences were compartmentalized in 250kbp bins, normalized, and compared to the mean (+/- 3SD) of Chronix controls to identify regions of chromosomal number imbalance (CNI). Sequences were also compared to databases with known viral genomes. **Results:** Sample 1: an exophytic, focally invasive, HPV positive (PCR), squamous cell carcinoma from a never-smoker. The full genome of HVP16 was detected in low amount (~ 500 sequences/10 million sequences, average coverage=42 fold). Mismatches to the closest reference HPV16 strain isolate were found in protein (number of mismatches) E7 (1), E1 (2), E2 (4), E4 (1), L2 (3) and L1 (4). Sample 2: from a RRP patient, contained the full genome of HPV6, also in low amount (~300 sequences/10 million sequences, average coverage = 24 fold). Interestingly, the HPV long control region was a variant as yet undescribed. Sample 3: from a RRP patient whose papillomas slowly and spontaneously regressed, did not contain any detectable viral DNA. Only the HPV16 squamous cell carcinoma contained CNI with gains at chromosomes 3q and 8p, and losses at chromosomes 3p, 11q, 12p, and 21q consistent with a malignant transformation. **Conclusions:** NGS reveals the identity and copy number of viral genes directly from clinical samples. This approach has revealed new HPV mutations not described by current viral analytical procedures. The detection of novel HPV mutations and CNI analysis in a single NGS run on HPV-related diseases provides important information into viral-host dynamics while generating biomarkers that can be correlated with treatment outcomes.

**6075 General Poster Session (Board #110), Sat, 1:15 PM-5:00 PM**

**Comparison of three different induction regimen in nasopharyngeal cancer: CF versus DC versus DCF.** *Presenting Author: Neyran Kertmen, Hacettepe University Cancer Institute, Department of Medical Oncology, Ankara, Turkey*

**Background:** The standard treatment of local advanced nasopharyngeal cancer is chemoradiotherapy. There is no enough data about the induction therapy. In this study we retrospectively examined patients treated with induction therapy and chemoradiotherapy. **Methods:** Locally advanced nasopharyngeal cancers patients were included into the study who were treated between 1996-2013 in our clinic. Three different induction regimen were administered to our patients in different time periods; CF, DC and DCF. The dosage of the regimens as follows: CF regimen; cisplatin 50 mg/ m2 1-2 days , fluorouracil 500 mg/ m2 1-5 days, DC; docetaxel 75 mg/ m2 1.day, cisplatin 75 mg /m2 1.day and DCF; docetaxel 75 mg/ m2 1.day, cisplatin 75 mg / m2 1.day, 5-fu 750 mg/ m2 1-5 days. **Results:** One hundred fifty-four patients were included, 76% (n= 117) of the patients was male and 24% (n= 37) of them female. Median age at diagnosis was 47 (20-73). Most of the patients were at stage III (36.4%) and stage IV (51.7%). In terms of induction therapy, cisplatin-fluorouracil (CF) was administered to 24.7% (n= 38) of patients, docetaxel-cisplatin (DC) to 35.1% (n= 54) and docetaxel-fluorouracil (DCF) to 40.3% (n= 62). Median follow-up time was 50 months (2-201 months). Response rate to induction therapy in the CF group were 5.7% (n= 2) complete response, 82.9% (n= 29) partial response.In the DC group they were 11.4% (n= 5) complete response, 59.1% (n= 26) partial response and 10.6% (n= 5) complete response, 74.5% (n= 35) partial response in the DCF group. (p=0.20). 3- Year progression-free survival (PFS) levels was 79.3% and 5-year PFS of 72.4 % in all patients. 3-year overall survival (OS) rate were 87.4% and 5-year OS rate 76% in all patients. In terms of induction therapies, 3-year OS was 96.5% in the DCF group, 86.6% in the DC group and 76.3% in the CF group (p= 0.036). There was no statistically significant PFS difference according to the chemotherapy regimens. **Conclusions:** There was no significantly difference in response rate and PFS between three regimens. OS of the DCF group was significantly higher than the others. However, this study was retrospective and limited toxicity data were available, the findings need to be interpreted with care.

**6076 General Poster Session (Board #111), Sat, 1:15 PM-5:00 PM**

**Dynamic changes in epithelial to mesenchymal composition and prognostic relevance of circulating cancer cells (CTCs) in head and neck squamous cell carcinoma (HNSCC).** *Presenting Author: Elena Mihal Vagia, Attikon Hospital, National Kapodistrian, University of Athens, Athens, Greece*

**Background:** Epithelial-mesenchymal transtition (EMT) of adherent epithelial cells to migratory mesenchymal state has been implicated in tumor metastasis in preclinical models. To investigate its role in HNSCC, we characterized EMT in circulating tumor cells (CTCs) from HNSCC patients. **Methods:** We quantified by RT-qPCR EGFR, TWIST1, stem cell marker gene transcripts in immunomagnetically positively selected CTCs from 27 locally advanced HNSCC , 8 recurrent/metastatic HNSCC, and 20 healthy individuals. Patients with locally advanced disease were treated with cisplatin chemoradiotherapy +/- TPF induction chemotherapy. To assess the univariate differences of study parameters according to the expression of *EGFR*,*TWIST1* and $CD24^{-/low}/CD44^{+}$ and/or $CD24^{-/low}/ALDH1^{high}$ stem cell markers standard statistical procedures were used, as appropriate (Chi-square test for categorical data and Fisher's Exact test for categorical data with limited number of frequencies). Subsequently, survival curves were generated by Kaplan-Meier analysis and tested for significance using the Mantel-Cox log rank test. **Results:** Thirteen of 27 (48%) primary HNSCC and six of 8 (75%) metastatic HNSCC harbored CTCs in peripheral blood**.** Mesenchymal cells were highly enriched in CTCs. Significant correlations could be found for stem cell-like CTCs and TNM stage (p=0.046,Fisher's exact test). Detection of $EGFR^{+}$ CTCs at baseline in primary HNSCC was associated with recurrence or death (p=0.041,Fisher's exact test). **Conclusions:** These data support a role for EMT in cancer progression in human HNSCC. Liquid biopsies may identify patients at high risk for relapse in need for adjuvant therapy in locally advanced disease setting.

**6077 General Poster Session (Board #112), Sat, 1:15 PM-5:00 PM**

**Toxicities of tyrosine kinase inhibitors: Occurrence of hemoptysis and tracheo-oesophageal fistula in 150 patients with advanced thyroid cancer.** *Presenting Author: Livia Lamartina, Gustave Roussy Cancer Campus Grand Paris, Villejuif, France*

**Background:** Anti-angiogenic Tyrosine Kinase Inhibitors (TKI) represent the main systemic treatment for patients with refractory advanced thyroid cancer (TC), but may induce severe adverse events. **Methods:** The objective is to determine the incidence and risk factors of hemoptysis (H) or tracheo-oesophageal fistula (TOF) in TC patients during TKI treatment. Subjects and methods: A retrospective analysis of all advanced TC patients treated with TKI between 2004 and 2013 at Gustave Roussy, was performed. 150 patients were enrolled (94 M; median age at initiation of the first TKI treatment: 60 yr), 85 (57%) with medullary TC and 65 (43%) with differentiated TC (28 papillary, 20 follicular and 17 poorly differentiated). Total thyroidectomy was performed in 133 (89%) patients, and neck and mediastinum external beam radiation therapy (ERBT) in 44 patients (median dose 60 Gy). Tracheal invasion (TI) was present at initiation of TKI treatment in 32 (21%) cases and was evidenced in 7 patients by CT scan, in 3 by fibroscopy, in 10 with both techniques, and in 12 as an intra-operative finding. No patient disclosed H before initiation of TKI treatment (H within one month is an exclusion criteria in all trials). Patients received from 1 to 4 lines of TKI treatments (median 1). Median follow-up after the initiation of the first TKI treatment was 24 months. Occurrence of mild (grade 1 or 2) or severe (grade 3 to 5) H or TOF according to CTCAE v 4 were collected. Risk factors for H/TOF were investigated. **Results:** Grade 1-2 H occurred in 10 patients (7%) all aged ≥45 yr and was associated with TI in 7 [p 0.0008], EBRT in 7 [p 0.007], and differentiated TC in 9 [p 0.002]. Grade 3-5 events occurred in 3 (2%) patients (TOF in 1 case and fatal H in 2 cases), all with known TI. One fatal H and the TOF were preceded by grade 1-2 H. No significant relationship with age, gender, EBRT, surgery, pathology or number of TKI lines was found for grade 3-5 events. The rate of grade 3-5 event was 9% in patients with TI [p 0.0008]. **Conclusions:** Grade 3-5 H/TOF occurred during TKI treatment in 9% and grade 1-2 in 22% of patientswith known TI even in the absence of H prior to TKI treatment. This should lead to a careful use of TKI in these patients.

**6078 General Poster Session (Board #113), Sat, 1:15 PM-5:00 PM**

**Expression of interleukin-1$\alpha$ (IL1-$\alpha$) and risk of distant metastases (DM) in head and neck squamous cell carcinoma (HNSCC).** *Presenting Author: Antonio Lopez-Pousa, Hospital de La Santa Creu i Sant Pau, Barcelona, Spain*

**Background:** There is a lack of biologic predictive factors in HNSCC patients. Interleukin-1$\alpha$ is a cytokine that participates in the mechanisms of carcinogenesis in patients with HNSCC, through the induction of the expression of genes involved in angiogenesis process and metastases. The aim of our study was to evaluate the relationship between the levels of expression of IL-1$\alpha$ and clinical behaviour in patients with HNSCC **Methods:** In this retrospective study, we have included 157 consecutive HNSCC patients with complete remission after multimodal treatment, with a minimum 2-years follow-up. mRNA expression of IL-1$\alpha$ and $\beta$-actin was quantified by RT-PCR in tissue samples. Relative expression was expressed as IL-1$\alpha$/$\beta$-actin ratios. Multivariate analysis and a recursive partitioning analysis were performed. **Results:** During the follow-up period 46 p (29%) had a local failure, 23 (14.6%) regional failure and 18 (11.5%) DM. Frequency of DM in patients with low levels of IL-1$\alpha$ expression ( n = 103, 65.6%) was 5.1 %, and in patients with high levels (n = 54, 34.4%) was 23.5 . %. The 5-y DM free-survival was 93% vs 68.6% (low vs high expression). These differences are maintained regardless local and regional control. The only variables significantly associated with the risk of DM in the multivariate analysis were the presence of lymph node involvement at diagnosis (HR 3.1, 95% CI : 0.9- 9.6, p= 0.050), and elevated expression of IL-1$\alpha$ (HR 6.1 , 95% CI : 2.0-18.4, p=0.001). **Conclusions:** High levels of IL-1$\alpha$ expression is an independent factor associated with the risk of DM and survival. Although it should be validated prospectively, is a factor to be considered both clinically and in clinical trials.

**6079 General Poster Session (Board #114), Sat, 1:15 PM-5:00 PM**

**The effect of proteolytic enzyme-containing gargling agents on severe stomatitis caused by therapy for head and neck cancer.** *Presenting Author: Masatoshi Ohmae, Rinku General Medical Center, Izumisano, Osaka, Japan*

**Background:** Severe stomatitis is one of the most frequent and undesirable side effects of chemotherapy (CT) and chemoradiation therapy (CRT) for the treatment of head and neck cancer. It remarkably limits patients' quality of life, and in some cases, it becomes a dose-limiting factor. Such stomatitis is usually treated with oral care, anti-inflammatory agents, and analgesics. As for gargling agents, sodium gualenate hydrate, aspirin, and glycerin are widely used for oral care; however, they typically offer insufficient pain relief. Objective: To devise gargling agents to relieve pain and other related symptoms induced by CT or CRT for head and neck cancer. **Methods:** We focused on the necrotic tissue covering the inflammatory mucosa as an exacerbating factor for stomatitis, and we empirically applied a proteolytic enzyme to remove the necrotic coating and relieve the pain. We used 2 proteolytic enzymes, bromelain and pronase, as topical oral antiphlogistics, which are easily available as oral medicines, and established 3 gargling agent treatment groups: G, gualenate hydrate + glycerin; GB, G + bromelain; and GBP, GB + pronase. Bromelain is a general name for a family of sulfhydryl proteolytic enzymes. Thirty patients were included in this study and received CT or CRT. When they developed stomatitis during the course of CT or CRT, they were randomly assigned into 1 of the 3 above groups. Pain intensity was measured with a 100-mm visual analog scale (VAS) and degree of discomfort was estimated using the face scale (FS) at day 0 (just prior to treatment initiation) and at day 7. The effects of the gargling agents were evaluated by changes in the VAS and FS scores **Results:** The changes in the VAS score for groups G, GB, and GBP were −18, −20, and −42, respectively. The FS score for each group decreased by 1.5, 1.2, and 2.7 points, respectively. **Conclusions:** Proteolytic enzyme-containing gargling agents are beneficial for the treatment of severe stomatitis related to cancer therapy for the head and neck region.

**6080 General Poster Session (Board #115), Sat, 1:15 PM-5:00 PM**

**Molecular profiling of HPV-positive and -negative HNSCC.** *Presenting Author: Rebecca Anne Feldman-Moreno, Caris Life Sciences, Phoenix, AZ*
