## CONTENTS

### 2014 ASCO ANNUAL MEETING PROCEEDINGS

*continued on following page*

*Journal of Clinical Oncology* (ISSN 0732-183X) is published 36 times a year, three times monthly, by the American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Periodicals postage is paid at Alexandria, VA, and at additional mailing offices. Publication Mail Agreement Number 863289.

Editorial correspondence should be addressed to Stephen A. Cannistra, MD, *Journal of Clinical Oncology*, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Phone: 703-797-1900; Fax: 703-684-8720. E-mail: jco@asco.org. Internet: www.jco.org.

*Journal of Clinical Oncology*® is a registered trademark of American Society of Clinical Oncology, Inc.

**POSTMASTER:** ASCO members should send changes of address to American Society of Clinical Oncology, 2318 Mill Road, Suite 800, Alexandria, VA 22314. Nonmembers should send changes of address to *Journal of Clinical Oncology* Customer Service, 2318 Mill Road, Suite 800, Alexandria, VA 22314.

2014 annual subscription rates, effective September 1, 2013: United States and possessions: individual, $607 one year, $1,153 two years; single issue, $40. International: individual, $842 one year, $1,600 two years; single issue, $50. Institutions: bundled (print + online): Tier 1: $944 US, $1,310 Int'l; Tier 2: $1,089 US, $1,444 Int'l; Tier 3: $1,572 US, $1,914 Int'l; Tier 4: contact *JCO* for quote. Institutions: online only, worldwide: Tier 1: $807; Tier 2: $924; Tier 3: $1,334; Tier 4: contact *JCO* for quote. See www.jco.org/ratecard for descriptions of each tier. Student and resident: United States and possessions: $289; all other countries, $401. To receive student/resident rate, orders must be accompanied by name of affiliated institution, date of term, and the signature of program/residency coordinator on institution letterhead. Orders will be billed at individual rate until proof of status is received. Current prices are in effect for back volumes and back issues. Back issues sold in conjunction with a subscription rate are on a prorated basis. Subscriptions are accepted on a 12-month basis. Prices are subject to change without notice. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. *JCO* Legacy Archive (electronic back issues from January 1983 through December 1998) is also available; please inquire.

# 2014 Abstracts

## Descriptions of Scientific Sessions

***Plenary Session***
The Plenary Session includes abstracts selected by the Scientific Program Committee as having practice-changing findings of the highest scientific merit.

***Oral Abstract Sessions***
Oral Abstract Sessions include didactic presentations of abstracts of the highest scientific merit, as determined by the Scientific Program Committee. Experts in the field serve as Discussants and provide comprehensive themed discussions of the findings from the abstracts.

***Clinical Science Symposia***
Clinical Science Symposia provide a forum for science in oncology, combining didactic lectures on a specific topic with the presentation of abstracts. Experts in the field serve as discussants to place studies in the appropriate context and critically discuss the conclusions in terms of their applicability to clinical practice.

***Poster Highlights Sessions***
Poster Highlights Sessions feature selected abstracts of clinical research in poster format. The posters are grouped by topic and are on display for a specified time with opportunities for networking, followed by a discussion session in which experts provide commentary on the research findings.

***General Poster Sessions***
General Poster Sessions include selected abstracts of clinical research in poster format. The posters are grouped by topic and are on display for a specified time. Trials in Progress abstract presentations are presented within each track, and are designed to facilitate awareness of open, ongoing clinical trials of any phase.

***Publication-Only Abstracts***
Publication-only abstracts were selected to be published online in conjunction with the Annual Meeting, but not to be presented at the Meeting.

*All presented and publication-only abstracts are citable to this* Journal of Clinical Oncology *supplement. For citation examples, please see the Letter from the Editor.*

**This publication contains abstracts selected by the ASCO Scientific Program Committee for presentation at the 2014 Annual Meeting. Abstracts selected for electronic publication only are available in full-text versions online through ASCO.org and JCO.org. The type of session, the day, and the session start/end times are located to the right of the abstract number for scheduled presentations. To determine the location of the abstract session, refer to the Annual Meeting Program or the iPlanner, the online version of the Annual Meeting Program, available at am.asco.org.**

**Dates and times are subject to change.**
**All modifications will be posted on am.asco.org.**

The deadline for abstract submission for the 2015 Annual Meeting is
Tuesday, February 3, 2015, at 11:59 PM (EST).

# Letter from the Editor

The *2014 ASCO Annual Meeting Proceedings Part I* (a supplement to the *Journal of Clinical Oncology*) is an enduring record of the more than 2,900 abstracts selected by the ASCO Scientific Program Committee for presentation at the 50th ASCO Annual Meeting. Accepted abstracts not presented at the meeting are included in the online supplement to the May 20 issue of *Journal of Clinical Oncology* at JCO.org.

The majority of abstracts selected for presentation are included here in full and are categorized by scientific track. After the Annual Meeting, abstracts can be accessed online through ASCO University's Meeting Library (meetinglibrary.asco.org/abstracts). Online abstracts include the full list of abstract authors and their disclosure information.

Late-Breaking Abstracts are represented here by abstract title and presenting author only. The full-text versions of these abstracts will be publicly released through ASCO.org during the Annual Meeting. Late-Breaking Abstracts will also be included in the *2014 ASCO Annual Meeting Proceedings Part II*, an online supplement to the June 20 issue of *Journal of Clinical Oncology* on JCO.org. Print versions of these abstracts will be available onsite at the Annual Meeting in the *ASCO Daily News*.

All abstracts carry *Journal of Clinical Oncology* citations. The following are citation examples for print and electronic abstracts:

J Clin Oncol 32:5s, 2014 (suppl; abstr LBA1)

J Clin Oncol 32, 2014 (suppl; abstr e12000)

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

| Tier 3 $1,914 | $1,334 |
| Tier 4 Call for quote | Call for quote |

**Orders and Payments**
P.O. Box 37211
Baltimore, MD 21279-3211

**Important Tiers and Pricing Notes**
Additional rates along with tier descriptions are available online at www.jco.org/ratecard

1. Prices are in effect from September 1, 2013, through August 31, 2014. Prices are subject to change.
2. Print-only subscriptions or additional print subscriptions are available for $795 in the US and $1,150 outside the US.
3. Institutional online access, whether an online-only or bundled subscription, is for a single-site license, which allows an unlimited number of concurrent users from that site.
4. For multisite licenses, please contact the appropriate agent for a quote.
5. Subscribers outside the US, add $100 per print subscription for expedited delivery.
6. Single-issue price: $40 US, $50 international.
7. Prices quoted are in US dollars and payments must be made in US dollars.
8. Except on Tier 5 orders, the publisher allows for a 5% discount to recognized subscription agents.

Prices are subject to change without notice. Current prices are in effect for back volumes and back issues. Single issues, both current and back, exist in limited quantities and are offered for sale subject to availability. Back issues sold in conjunction with a subscription are on a prorated basis.

# ASCO Abstracts Policy

## Public Release of Abstracts

ASCO has implemented changes to its abstract distribution to ensure simultaneous public release of important scientific information. Please note the new release schedule.

The abstracts published in the *2014 ASCO Annual Meeting Proceedings Part I,* including those abstracts published but not presented at the Meeting, were publicly released by ASCO at 5:00 PM (EDT) on Wednesday, May 14, 2014. These abstracts are publicly available online through ASCO.org, the official website of the Society. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released according to the following schedule:

- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Friday, May 30, will be publicly released Friday, May 30, through ASCO.org at 2:00 PM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Saturday, May 31, will be publicly released Saturday, May 31, through ASCO.org at 7:30 AM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Sunday, June 1, will be publicly released Sunday, June 1, through ASCO.org at 7:30 AM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.
- Late-Breaking Abstracts presented in a press briefing or scientific presentation (whichever comes first) on Monday, June 2, or Tuesday, June 3, will be publicly released Monday, June 2, through ASCO.org at 7:30 AM (EDT). These abstracts will also be available in Section D of *ASCO Daily News* on the day of their scientific presentation.

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on ASCO.org.

## Abstract Notice

All abstracts presented at and published in conjunction with the Annual Meeting are included in online supplements to the *Journal of Clinical Oncology*. The abstracts released on May 14, 2014, are included in the May 20 (Vol. 32, No. 15S) issue (*2014 Annual Meeting Proceedings Part I*), and the Late-Breaking Abstracts, released on a daily basis during the Meeting, are included in the June 20 (Vol. 32, No. 18S) issue (*2014 Annual Meeting Proceedings Part II*).

# ASCO Conflict of Interest Policy and PI Exceptions

In compliance with standards established by the ASCO Conflict of Interest Policy (*J Clin Oncol*. 2006; 24[3]:519–521) and the Accreditation Council for Continuing Medical Information (ACCME), ASCO strives to promote balance, independence, objectivity, and scientific rigor through disclosure of financial and other interests, and identification and management of potential conflicts. According to the Society's Conflict of Interest Policy, the following financial and other relationships must be disclosed: employment or leadership position, advisory role, stock ownership, honoraria, research funding, expert testimony, and other remuneration (*J Clin Oncol*. 2006;24[3]:520).

The ASCO Conflict of Interest Policy requirements apply to all abstract authors. Per the ASCO Conflict of Interest Policy Implementation Plan for CME Activities, all Oral Abstract Presenters will be subject to the same disclosure review and management strategies as faculty who participate in ASCO CME activities.

For clinical trials that began accrual on or after April 29, 2004, the Conflict of Interest Policy places some restrictions on the financial relationships between a trial's Principal Investigator(s) (PI) and the trial's company sponsor (*J Clin Oncol*. 2006;24[3]:521). If a PI holds any restricted relationships, his or her abstract may be ineligible for placement in the 2014 Annual Meeting unless the Ethics Committee grants an exception. Exceptions are generally not granted for PIs who have employment relationships with their trial's company sponsor or stock in the company sponsor. Abstracts that receive exceptions will be subject to additional management strategies, including but not limited to additional peer review, advance slide review, and session audits. ASCO will collect information on accrual initiation date, financial relationships of the principal investigator, and National Institutes of Health (NIH) funding upon abstract submission. NIH-funded trials are exempt from the PI restrictions in the Conflict of Interest Policy. Abstracts for which authors have been granted an exception in accordance with ASCO's Policy are designated with a caret symbol ( ) in the *Annual Meeting Proceedings*.

For more information on the ASCO Conflict of Interest Policy, the Conflict of Interest Policy Implementation Plan for CME Activities, and the restrictions on PIs, please visit asco.org/rwc.

## SPECIAL AWARD LECTURE ABSTRACTS

### David A. Karnofsky Memorial Award and Lecture
### Saturday, May 31, 9:30 AM

**Understanding.**

*H. M. (Bob) Pinedo, MD, PhD; VUmc Cancer Center, Amsterdam, Netherlands*

Translational research assists us in taking treatments from bench to bedside, and vice versa, and in understanding at a molecular level what changes are taking place in our patients. In recent decades, clinical oncology has developed into a multidisciplinary profession with specialists working in harmony when treating the patient, but also when performing translational research. We are witnessing today that we can treat patients better by using the biologic and molecular properties of their cancer cells and their tumor. Sequential biopsies, modern imaging, proteomics, and genomics are becoming essential guides to personalized therapies. Society should get prepared for targeted treatment. Periods of heavy chemotherapy are being replaced with less onerous treatment, while cancer is becoming a chronic disease. Our translational research, conducted over the past decades, will be illustrated by reviewing biologic and molecular studies in various domains of cancer treatment, including drug resistance, angiogenesis, radiosensitization, epigenetics, and immunotherapy. Notwithstanding all these developments, the oncologist must know his or her patient. David Karnofsky is our example par excellence in understanding the disease and his patient, and being available day and night to guarantee continuity of care.

### Science of Oncology Award and Lecture
### Sunday, June 1, 1:00 PM

**Do some human cancers originate from infections transmitted from domestic animals?**

*Harald zur Hausen, MD; German Cancer Research Center, Heidelberg, Germany*

A number of viral, bacterial, and parasitic diseases originate from transmissions of these infections by contact with animals or their products, among them rabies, hemorrhagic fevers, borreliosis, brucellosis, and several helminth infections. Conversely, latent and persistent infections with several agents prevalent in human populations do not or only rarely cause symptoms in the human host. Some of them, however, such as the polyomaviruses BK and JC, specific types of adenoviruses, and Epstein-Barr virus are relatively effective inducers of malignant tumors in rodents or new world primates, commonly in species in which they are unable to replicate. This prompted the consideration of whether similar agents exist in our domestic animals, not tumorigenic in their native hosts, but potentially causing cancer in a nonpermissive host, specifically after infection of humans. This resulted in an analysis of human cancers linked to dietary habits. In particular, cancer of the colon stands out, being linked to the consumption of red meat and processed red meat. The global epidemiology suggests a remarkable geographic correlation of these dietary habits with the distribution of domestic cattle (*Bos taurus*). This will be discussed in more detail. Chemical carcinogens arising in the preparatory steps for meat consumption have been incriminated in the past, although they are also produced in similarly prepared poultry or fish. Long-time consumption of the latter two does not increase the risk for colon cancer. For this reason, a potentially oncogenic infectious factor was postulated in beef, probably interacting synergistically with some of the chemical carcinogens. This resulted in the analysis of sera from healthy cattle for the presence of infectious agents interacting with human cells. The available results will be presented.

### ASCO–American Cancer Society Award and Lecture
### Sunday, June 1, 8:00 AM

**Carpe diem: Time to seize the opportunity for cancer prevention.**

*Graham A. Colditz, MD, DrPH; Siteman Cancer Center and Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO*

The United States and other high-income nations have long developed a "cancer culture"—one marked by lifestyle profiles that together greatly increase cancer risk. There is immense potential to reduce the cancer burden by focusing prevention resources in a relatively small number of key areas. At least half of the roughly 1.6 million new cases of cancer diagnosed each year in the United States could be prevented using knowledge that we already have. Available strategies for cancer prevention include vaccination and safe sexual practices, smoking cessation, physical activity, healthy body weight, healthy diet, moderate or no alcohol intake, sun protection and avoidance of indoor tanning, and screening. Yet budget realities remain focused on areas other than prevention. To address the burden of cancer as effectively and efficiently as possible, prevention and control must become a true resource priority, with funding on par with other key areas. We need the political will to allocate resources, prioritize incentives and rewards, and implement regulations that reinforce behaviors that will prevent cancer.

## B. J. Kennedy Award and Lecture for Scientific Excellence in Geriatric Oncology
## Saturday, May 31, 4:45 PM

**Adventures in geriatric oncology: Inspirations, lessons learned, and hopes for the future.**
*Stuart M. Lichtman, MD, FACP; Memorial Sloan Kettering Cancer Center, New York, NY*

The field of geriatric oncology is now well within its third decade. B. J. Kennedy in his presidential address of 1988 laid out in great detail the importance of focusing on the older patient with cancer. He discussed the epidemiologic shift with the resultant aging of the population, the increased number of older patients with cancer, and relative shortage of physicians to address this need. The issues he anticipated have come true. Fortunately, he stimulated the interest of many to pursue this study. My adventures in geriatric oncology have paralleled the development of the field. The encouragement and foresight of the original investigators stimulated my interest. Inspiration came not only from colleagues, but also the older patients who provided their unique perspective on aging. Geriatric oncology in its infancy was a disparate group of clinicians, geriatrics, and investigators. In its adolescence there was the development of studies in the cooperative groups and a few institutions leading to the participation of national and international organizations. Our European colleagues, in particular, led this advance. Geriatric oncology now is not yet middle-aged. In this maturation of the field, there are thriving organizations (International Society of Geriatric Oncology, SIOG; Cancer and Aging Research Group), a unique journal: the *Journal of Geriatric Oncology,* and the strong commitment by ASCO. By witnessing and participating in this development, many lessons have been learned, which will be discussed. The current young investigators are leading the charge for geriatric oncology as an increasingly productive area of study, and they will help realize B. J. Kennedy's hope for the future to improve the care of the older patient with cancer.

## Pediatric Oncology Award and Lecture
## Saturday, May 31, 1:15 PM

**Childhood cancer survivors: A lifetime of risk and responsibility.**
*Leslie L. Robison, PhD; Department of Epidemiology and Cancer Control, St. Jude Children's Research Hospital, Memphis, TN*

Population-based statistics demonstrate that 83% of patients diagnosed with cancer in the first two decades of life survive five or more years. Among these five-year survivors, 95% are projected to be living 15 years following their cancer diagnosis. It is estimated that the prevalence of pediatric cancer survivors in the United States now exceeds 420,000. This growing population of cancer survivors represents a group at high-risk for experiencing long-term treatment-related morbidity and mortality. Results from large cohorts show that when compared to the general population, five-year survivors have an 8- to 10-fold increased risk of dying from a subsequent malignancy, cardiac event, or pulmonary cause. Clinical cohorts are now documenting that 80% of adult survivors of childhood cancer will have at least one serious/disabling or life-threatening chronic health condition by age 45. Knowledge relating to the prevalence of, and risk factors for, adverse health-related and quality-of life outcomes is increasing at a rapid rate with the expanding research base from established survivor cohorts. The challenge is to critically evaluate this information and rapidly translate it into clinical care guidelines for the long-term follow-up of childhood cancer survivors to facilitate early detection and treatment of therapy-related late effects, with the objective of minimizing excess morbidity and early mortality. Beyond the formulation and dissemination of clinical care guidelines, it is now important to also focus greater attention on translating knowledge from observational research to the development and the testing of intervention-based approaches, which are designed to avoid or ameliorate adverse outcomes. There is a role not only for researchers and health care providers, but also for survivors and their families, governing bodies, and advocacy groups in helping to understand and overcome the barriers that prevent survivors from receiving optimal care to minimize adverse health-related outcomes and to maximize quality-of-life outcomes.

**500** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Bevacizumab (Bv) in the adjuvant treatment of HER2-negative breast cancer: Final results from Eastern Cooperative Oncology Group E5103.** *Presenting Author: Kathy Miller, Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN*

**Background:** Bv improves progression-free survival (PFS) but not overall survival (OS) in MBC. E5103 added Bv to adjuvant therapy in patients (pts) with HER2- disease. **Methods:** Pts were assigned 1:2:2 to one of three treatment arms. In addition to doxorubicin and cyclophosphamide followed by wkly paclitaxel, pts received either placebo (Arm A – AC>T), Bv during chemo (Arm B - BvAC>BvT), or Bv during chemo -> Bv monotherapy for 10 cycles (Arm C – BvAC>BvT>Bv). Randomization was stratified and Bv dose adjusted for choice of AC schedule. Radiation and hormonal therapy were administered concurrently with Bv in Arm C. The primary endpoint was invasive disease free survival (IDFS) requiring 426 IDFS events across Arms C and A to detect hazard ratio (HR) of 0.75 with 80% power using a one-sided 2.5% (two-sided 5%) stratified log rank test. **Results:** 4,994 pts were enrolled. Median age 52; 64% ER+, 27% LN-; 80% received ddAC. Chemotherapy associated adverse events (AEs) including myelosuppression (Grade 4 neutropenia 17/20/21%) and neuropathy (Grade > 3 - 8/8/9%) were similar across all arms. Grade > 3 hypertension/thrombosis/proteinuria/hemorrhage was reported by 8/3/<1/<1% of Bv-treated pts. The cumulative incidence of clinical CHF at 15 mos. was 1.0/1.9/3.0%. Emergent unblinding was uncommon and similar among all arms (3/4/4% respectively) but Bv exposure was less than anticipated with ~24% of pts in Arm B and ~55% of pts in Arm C discontinuing Bv before completing planned therapy. With a median follow-up of 47.5 mos. and 430 IDFS events across Arms C and A, 5-yr IDFS (95%CI) was 77%(70.9%-81.2%/76%(71.5%-79.8%)/80%(77%-82.5%) respectively. **Conclusions:** Incorporation of Bv into anthracycline and taxane containing adjuvant therapy does not improve IDFS or OS in pts with high risk HER2- breast cancer. Bv did increase AEs but no unexpected AEs were encountered. Longer duration therapy is unlikely to be feasible given the high rate of early discontinuation due to all causes. Clinical trial information: NCT00433511.

| | C vs A HR (0.95 CI) | Two-sided P-value |
|---|---|---|

**501** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Arobase: A phase III trial of exemestane (Exe) and bevacizumab (BEV) as maintenance therapy in patients (pts) with metastatic breast cancer (MBC) treated in first line with paclitaxel (P) and BEV—A Gineco study.** *Presenting Author: Olivier Tredan, Département d'Oncologie Médicale, Centre Léon Bérard, Lyon, France*

**Background:** Combination of P+BEV significantly improves progression-free survival (PFS) in MBC pts, but is associated with adverse events (AEs), mainly neuropathy and fatigue worsening over time. Endocrine therapy (ET) combined to BEV has been proven tolerable and may be a option as maintenance therapy after P+BEV. **Methods:** in this prospective, randomized, open label, phase III study, pts with histologically confirmed ER+ HER2- locally advanced or MBC, who had not progressed after 16-24 weeks of 1st-line P+BEV therapy, were randomized to P+BEV continuation vs ET+BEV (Exe 25 mg/d+BEV 15 mg/kg q3w). Primary endpoint was PFS. To demonstrate an improvement in the 6-month PFS rate (PFS-6m) from 50% with P+BEV to 65% with ET+BEV (2-sided $\alpha$=5%) with 80% power, 141 events were requiered and 198 pts were planned. An interim analysis (IA) was planned after 40% of required events. Secondary endpoints included overall survival (OS) and toxicity. **Results:** At the cut-off date for the IA (May 2013), 113 pts were included, 98 were analyzable. Median age was 55 (range 35-86). ET was given as adjuvant therapy in 64% of pts and in the metastatic setting in 24%. Median follow up was 9.7 months (range 0.8-28.3). PFS-6m was 70% (95% confidence interval (CI) 54, 81.5) with P+BEV and 54% (95% CI 38.5, 67.2) with ET+BEV (HR 1.2, 95% CI (0.7, 1.9), p=0.56). Given these interim results, the probability to show statistically significant PFS at the end of the study was 7%. Deaths were reported for 11 pts in the P+BEV arm vs 6 pts in the ET+BEV arm (median OS not reached). Grade 3-4 AEs rates were lower with ET+BEV (fatigue: 4% of pts vs 14%); neuropathy: 0% vs 12%; pain: 2% vs 8%; neutropenia: 0% vs 12%), as well as serious AEs related to treatment (13% vs 24%). Based on both safety and efficacy results, the IDMC decided to definitely stop the enrollment and to keep patients under tretment in the protocol.Follow-up data will be updated for the final analysis. **Conclusions:** The efficacy hypothesis was not reached, despite a better safety profile of the ET+BEV maintenance therapy. Exploratory analyses are planned to identify potential subgroups benefiting from it. Clinical trial information: NCT01303679.

**502** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**A phase 1b study of trebananib plus paclitaxel (P) and trastuzumab (T) in patients (pts) with HER2+ locally recurrent or metastatic breast cancer (MBC).** *Presenting Author: Peter Andrew Kaufman, Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

**Background:** Trebananib (AMG 386) suppresses tumor angiogenesis by neutralizing the interaction between the Tie2 receptor and its ligands, angiopoietin-1 and -2. This study evaluated the tolerability and efficacy of trebananib plus P and T as first-line treatment in $HER2^+$ MBC. **Methods:** Pts in cohorts A1 and A3 received open-label trebananib (A1, 10 mg/kg; A3, 30 mg/kg) IV QW plus P 80 mg/m$^2$IV QW and T (loading dose of 8 mg/kg, then 6 mg/kg Q3W). If dose-limiting toxicity (DLT) criteria were not met, each cohort was expanded to 20 pts. A3 enrollment was initiated if DLT criteria were not met for A1. Results describing trebananib plus capecitabine and lapatinib will be reported elsewhere. Endpoints were the incidence of DLTs and treatment-emergent adverse events (AEs; primary); and efficacy and pharmacokinetics (PK). **Results:** Of 40 enrolled pts in A1 (n = 20) and A3 (n = 20), two DLTs occurred across A1 (grade 3 transient ischemic attack, n = 1) and A3 (grade 3 increased gamma-glutamyltransferase, n = 1). The most common (> 50%) AEs in A1/A3 were peripheral edema (n = 13/15), diarrhea (n = 13/14), alopecia (n = 13/13), fatigue (n = 15/9), nausea (n = 11/13), nail disorder (n = 12/7), and rash (n = 12/6). Grade ≥ 3 AEs occurring in > 10% of pts were peripheral neuropathy (n = 4/4), peripheral sensory neuropathy (n = 4/0), and dyspnea (n = 3/1). In evaluable pts (A1/A3, n = 20/17), confirmed objective response rates (ORRs) were 80% (complete responses [CRs], n = 0; partial responses [PRs], n = 16) in A1 and 88.2% (CRs, n = 3; PRs, n = 12) in A3. The median duration of response (DOR; 95% CI) was 12.6 (4.3 – 20.2) months in A1 and 16.8 (8.2 – not evaluable) months in A3. Median (95% CI) progression-free survival (PFS) was 14.5 (6.9 – 20.6) months and 18.7 (10.4 – not evaluable) months in A1 and A3, respectively. No apparent PK drug-drug interaction was observed. Trebananib exposure appeared dose proportional with intersubject variability of 40.5% and 28.6% in A1 and A3, respectively. **Conclusions:** In this phase 1b study, trebananib at 10 mg/kg and 30 mg/kg plus P and T appeared tolerable. The ORR, DOR, and PFS observed in this study suggest that further investigation of trebananib in this setting is warranted. Clinical trial information: NCT00807859.

**503** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Effect of obesity in premenopausal ER+ early breast cancer: EBCTCG data on 80,000 patients in 70 trials.** *Presenting Author: Hongchao Pan, Clinical Trial Service Unit and Epidemiological Studies Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom*

**Background:** Obesity (body mass index [BMI] ≥30 kg/m$^2$) is reportedly associated with worse prognosis in early breast cancer. But, this association could depend strongly on estrogen receptor (ER) positivity and ovarian activity (or young age). **Methods:** Through EBCTCG, anonymised information on each individual with early breast cancer in any trial is requested periodically, including BMI (at randomisation), ER status, menopausal status, age, treatment, recurrence and death. The global Steering Committee has requested analyses of the independent effects of BMI on outcome. Results are provided for 80,000 patients (in 70 trials) who had all these data items; most also had data on tumour diameter and nodal status. Mean follow-up was 8 woman-years. Cox regression (stratified for trial and treatment, and adjusted for age) assesses the relevance of BMI to mortality with recurrence (as a surrogate for the relevance of BMI to breast cancer mortality). Few had BMI <20 kg/m$^2$; the standard WHO cut-points define overweight (25-30 kg/m$^2$). **Results:** In 20,000 women with ER-poor disease there was little association of BMI with breast cancer mortality, and none after adjustment for tumour diameter and nodal status. In 60,000 with ER+ disease, BMI was positively associated with breast cancer mortality in pre/peri- and in post-menopausal women (each 2P<0.00001). But, after adjustment for tumour characteristics the association remained clearly significant only in 20,000 pre/peri-menopausal women with ER+ disease (breast cancer mortality rate ratio comparing BMI ≥30 versus BMI 20-25 kg/m$^2$ [RR] = 1.34, 95%CI 1.22-1.47, 2P<0.00001, with a steady trend between BMI <25, 25-30, 30-35 and ≥35 kg/m$^2$); little association remained in 40,000 post-menopausal women with ER+ disease (RR=1.06, 95%CI 0.99-1.14, 2P=0.12; heterogeneity between RRs 2P<0.0001). In analyses of ER+ disease subdivided by age (instead of menopausal status), obesity appeared importantly relevant only to age about 55 years. Findings were not materially altered by excluding the first 5 years of follow-up. **Conclusions:** In women with early breast cancer, obesity appears strongly independently related to breast cancer mortality only in pre/peri-menopausal ER+ disease.

**504** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Prognostic associations of 25OH vitamin D in NCIC CTG MA.21, a phase III adjuvant RCT of three chemotherapy regimens (EC/T, CEF, AC/T) in high-risk breast cancer (BC).** *Presenting Author: Ana Elisa Lohmann, Mount Sinai Hospital / University of Toronto, Toronto, ON, Canada*

**Background:** Low vitamin D (VitD) has been associated with poor outcomes in BC. We examined in MA.21 the association of VitD blood levels with relapse-free-survival (RFS) in all patients, and in BC subtypes. **Methods:** Fasting blood was collected pre-chemotherapy in 935/2,104 ((44.4%) of subjects (blood collection was initiated part-way through the trial); serum was frozen at -80C and shipped on dry ice to Mount Sinai Hospital (Toronto); it was analyzed for Vit D (radioimmunoassay, Diasorin) 25(OH)D (nmol/L). VitD underwent a $\lambda=0.5$ Box-Cox transformation for analysis to reduce asymmetry; data were back-transformed for reporting. VitD was assessed as a transformed continuous factor, and by quartiles and IOM categories (<40, [40-50), [50-125), >125 nmol/L). Univariate and multivariate (mv) assessments were with Cox models, adjusted for treatment, stratification factors, and imbalances in who had VitD assessed. **Results:** Median age was 47.8 years; most patients were white (91.6%), premenopausal (69.4%) with good performance status (PS) 0-1 (99.9%). The majority presented with grade III (52%), HER2 neg (66.6%), HER2 missing (22.9%), ER pos (61.9%), T1-2 (89.4%), N+ (72.7%) BC. 52.1% underwent mastectomy and 74.3% received adjuvant radiotherapy. Compared to the full MA.21 population, those with VitD levels were marginally (but significantly) more likely to be white, PS 1 or 2, to have undergone mastectomy and to have ER+, HER2 neg tumors. Mean Vit D was 69.7 nmol/L [95% CI (68.1-71.3)] nmol/L. The majority (752/935 = 80.5%) had levels > 50nmol/L (20ng/ml), considered adequate by the Institute of Medicine (IOM). In adjusted mv analyses, (continuous) VitD was not associated with RFS (HR 0.98, 95% CI (0.93-1.03); p=0.36) or categorical variable (between quartiles, p=0.20-0.43; between IOM categories, p=0.33-0.78). There were no significant differences in mean VitD levels or association of VitD with RFS in tumor subtypes (ER+, HER2- / any ER, HER2+ / ER-, HER2-; p=0.14-0.50). **Conclusions:** There is no evidence that VitD was associated with RFS in MA.21; the majority of subjects had adequate VitD levels at study entry. Clinical trial information: NCT00014222.

**LBA505** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Phase III trial (Prevention of Early Menopause Study [POEMS]-SWOG S0230) of LHRH analog during chemotherapy (CT) to reduce ovarian failure in early-stage, hormone receptor-negative breast cancer: An international Intergroup trial of SWOG, IBCSG, ECOG, and CALGB (Alliance).** *Presenting Author: Halle C. F. Moore, Cleveland Clinic, Cleveland, OH*

**The full, final text of this abstract will be available at abstracts.asco.org at 2:00 PM (EDT) on Friday, May 30, 2014, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2014, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Saturday edition of *ASCO Daily News*.**

**506** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Gene expression signatures in pre- and post-therapy (Rx) specimens from CALGB 40601 (Alliance), a neoadjuvant phase III trial of weekly paclitaxel and trastuzumab with or without lapatinib for HER2-positive breast cancer (BrCa).** *Presenting Author: Lisa A. Carey, Division of Hematology Oncology, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background:** Response to chemotherapy and HER2-targeting varies by molecular subtype. In C40601, 305 patients (pts) with stage II-III HER2+ BrCa were randomized to receive 16 weeks of preoperative paclitaxel and trastuzumab (TH), T and lapatinib (TL), or THL, and were followed for pCR. Primary data were reported previously. **Methods:** Gene expression by mRNA sequencing (RNAseq) was performed on 271 pre-Rx and 136 matched post-Rx samples. RNAseq was normalized to HER2+ tumors in The Cancer Genome Atlas Project, and genomic signatures applied including intrinsic subtype and immune cell features. **Results:** 60% of pre-Rx specimens were hormone receptor+. Overall, 30% were Luminal A, 31% Luminal B, 31% HER2-Enriched, 5% Basal-like, 2% Normal-like, and 1% Claudin-Low. In-breast pCR was 46%, which varied significantly by subtype: Luminal A 35%, Luminal B 36%, Basal-Like 36%, HER2-Enriched 69% (p<0.0001). Within HER2-Enriched, pCR rates by arm were: 50% TL, 71% TH, 80% THL. pCR also varied by risk of relapse score including proliferation genes (ROR-P): high 56%, medium 44%, low 33% (p=0.01). RNAseq on pre/post-Rx pairs revealed a change in subtype prevalence to: 43% Luminal A, 3% Luminal B, 2% Basal-like, 9% Claudin-Low, 5% HER2-Enriched, and 38% Normal-like. Excluding 49 normal-like tumors, which likely represent little tumor remaining after Rx, the most frequent subtype change among 84 paired non normal-like samples was to the Luminal A subtype, which occurred in 70% of baseline Luminal B, 20% of Basal-like, and 67% of HER2-Enriched tumors. Most (87%) had decreased ROR-P scores (p<0.0001). High expression of immune signatures, especially B-cell related, were significantly associated with pCR (IgG signature high 59%, low 32%, p=0.0002). **Conclusions:** HER2-Enriched had substantially higher pCR rates to chemotherapy + HER2-targeting than other subtypes. Residual disease was enriched for Luminal A and Normal Breast-like profiles. Among HER2-Enriched, taxane plus trastuzumab alone produced pCR rates in excess of 70%, which suggests that dual HER2-targeting or more aggressive chemotherapy may not be needed in this biologic subtype. Clinical trial information: NCT00770809.

**507** **Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**AVATAXHER: An open-label, randomized, multicenter study investigating the addition of bevacizumab (B) to neoadjuvant trastuzumab (T) plus docetaxel (D) in patients with early stage HER2-positive breast cancer (HER2+ BC) stratified according to PET change after one therapy cycle.** *Presenting Author: Bruno P. Coudert, Department of Medical Oncology, Centre Georges-Francois Leclerc, Dijon, France*

**Background:** T-based neoadjuvant chemotherapy achieves pCR rates of ~50% in HER2+ BC, enabling frequent conservative surgery. Pre-clinical and clinical data support the synergistic combination of B and T. The ph II AVATAXHER trial (EUDRACT 2009-013410-26) investigated whether adding B to neoadjuvant T+D improved pCR rates in tumors with a low likelihood of attaining pCR (predicted based on relative change in FDG tumoral uptake [ΔSUV] after one cycle of T+D). **Methods:** Patients were ≥18 yrs old with stage T2/3, N0/1 HER2+ BC. Patients received two 3-weekly cycles of T (8 mg/kg, then 6 mg/kg) and D (100 mg/m$^2$). Those with ≥70% ΔSUV in PET values between cycle 1 and 2 received four more cycles of T+D, one cycle of T, then surgery (standard arm). Those with <70% ΔSUV were randomized 2:1 to four cycles of T+D+B (15 mg/kg; arm a) or T+D (arm b), then one T cycle and surgery. The primary endpoint was pCR rate at surgery. The positive (PPV) and negative predictive value (NPV) of ΔSUV on pCR rate and safety were also investigated. **Results:** 152 patients were recruited at 26 sites (10 were withdrawn pretreatment; ITT=142). 37/69 (53.6%) patients in the standard arm achieved pCR, 21/48 (43.8%) in arm a and 6/25 (24.0%) in arm b. pCR rates in patients with hormone receptor –ve/+ve disease were: 69.0%/42.5% (standard arm), 57.9%/34.5% (arm a), and 40.0%/13.3% (arm b). Surgery (133 pts) was conservative in 84.8% of patients with surgery in the standard arm, 67.4% in arm a, and 62.5% in arm b. In patients without B, ΔSUV after one cycle predicted pCR with a PPV of 52.9% and a NPV of 75%. Toxicity was mild and included asthenia, myalgia, and increased lacrimation (all pts had ≥1 AE). Grade 3/4 AEs (in 31% of pts) included neutropenia (8.6% pts), febrile neutropenia (3.6%), myalgia (3.6%), asthenia (2.9%), and nail toxicity (2.9%). **Conclusions:** Adding B to neoadjuvant T+D, in tumors with a low likelihood of pCR predicted by PET ΔSUV, increased the pCR rate from 24.0% to 42.5%. PET ΔSUV, by selecting low responding HER2+ tumors, may be a useful tool for optimizing neoadjuvant therapy for HER2+ BC. Clinical trial information: 2009-013410-26.

**508 Oral Abstract Session, Sat, 3:00 PM-6:00 PM**

**Efficacy of adjuvant trastuzumab (T) compared with no T for patients (pts) with HER2-positive breast cancer and tumors ≤ 2cm: A meta-analysis of the randomized trastuzumab trials.** *Presenting Author: Ciara Catherine Maria O'Sullivan, National Cancer Institute, Bethesda, MD*

**Background:** Adjuvant T plus chemotherapy improves disease-free survival (DFS) and overall survival (OS) vs. chemotherapy alone for pts with early stage HER2-positive breast cancer. We conducted a meta-analysis to estimate DFS and OS for pts with small tumors (≤2cm) in the T arms from 5 of the 6 randomized adjuvant trastuzumab trials. Pts with tumors ≤2cm, with 0 or 1 positive lymph nodes, and hormone receptor (HR) positive disease had a 5-year DFS of 91% and a 5-year OS of 97% (O'Sullivan, SABCS 2013; abstract:1327). We now plan to conduct an additional meta-analysis to assess the efficacy of T compared with no T for pts with small tumors (≤2cm). **Methods:** Six randomized controlled trials (RCT) were identified by a Medline search from 2004-2013. Trial groups from 5 phase III RCTs provided data (HERA, NCCTG N9831, NSABP B31, PACS 04, and FinHER).In total, 11,200 pts were randomized in these 5 trials;4,220 of whom had ≤2cm tumors, and known number of positive axillary lymph nodes and HR status(2,588 randomized to T and 1,632 to no T). The individual pt meta-analysis will include pts with tumors ≤2 cm (T1a, T1b and T1c) and 0-1, 2-3 and ≥ 4 positive lymph nodes. Separate analyses will be performed for the two HR cohorts. This analysis will complement the published summary data-based Cochrane Review (Moja *et al.* 2012) by allowing a detailed investigation of the effect of disease characteristics, such as HR, on treatment effects. In addition to the standard Yusuf-Peto fixed effects model (Yusuf *et al.* 1985) we will investigate the impact of heterogeneity in study baseline hazards and study treatment effects by fitting random effect models.An intention to treat approach will produce a conservative effect estimate as substantial numbers of control-group pts 'crossed over' to the T arm after positive DFS results were reported. Methods to account for this 'selective crossover' are being developed; we plan to extend these methods to the meta-analysis setting to provide less conservative estimates. **Results:** Pending. **Conclusions:** A meta-analysis of 5 randomized adjuvant T trials focusing on pts with tumors ≤2cm will be performed and results submitted before the meeting.

**509 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM**

**Association of genomic analysis of immune function genes and clinical outcome in the NCCTG (Alliance) N9831 adjuvant trastuzumab trial.** *Presenting Author: Edith A. Perez, Mayo Clinic, Jacksonville, FL*

**Background:** Some 20-25% of patients with HER2+ disease relapse after adjuvant trastuzumab (H). We used a genomic approach to define biological processes that predict benefit from H. **Methods:** Whole genome DASL technology was used to identify genes associated with relapse-free survival (RFS) among 1,282 patients enrolled in the N9831 adjuvant H trial (NCT00005970). Cox proportional hazard ratios (HR), adjusted for significant clinical/pathological risk factors, were used to determine the association of each gene with RFS (median follow-up 6years, 11months) for 433 patients who received chemotherapy alone and 849 patients who received chemotherapy plus H. Functional ontology analysis and network modeling were used to identify key biological processes associated with RFS in patients who received chemotherapy alone or chemotherapy plus trastuzumab. **Results:** Using probes with HR $p<0.01$, 10/13 significantly enriched biological processes associated with increased RFS ($p<0.01$) were linked to immune functions. These 10 processes defined a cohort of 87 immune function genes. Patients defined as immune function positive based on the 87 genes experienced a favorable outcome when treated with H (HR=0.55, p=0.0005). Patients who did not exhibit immune function enrichment and were treated with H did not have better RFS than patients with immune function enrichment who were treated with chemotherapy alone (HR=0.93, p=0.72). Among patients who received chemotherapy alone, enriched immune function was not associated with increased RFS (HR=1.01, p=0.96). **Conclusions:** Improved RFS following treatment with adjuvant H appears to be associated with a heightened state of immunological function. This observation may define a significant biological process that is linked to the efficacy of HER2-targeted therapy, may provide a means of predicting probability of relapse following adjuvant trastuzumab, and suggests possible routes of therapeutic enhancement.

**510 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM**

**Expression of immunologic genes in triple-negative and HER2-positive breast cancer in the neoadjuvant GEPARSIXTO trial: Prediction of response to carboplatin-based chemotherapy.** *Presenting Author: Carsten Denkert, Charité-Universitätsmedizin Berlin, Institute of Pathology, Berlin, Germany*

**Background:** We have recently described tumor-infiltrating lymphocytes (TILs) as predictors of pathological complete response (pCR = ypT0ypN0) to neoadjuvant carboplatin-based chemotherapy in the GeparSixto breast cancer (BC) trial. To further dissect the immunological status in tumor tissue we have evaluated a total of 12 immunologically relevant genes, including T-cell markers, B-cell markers, chemokines and immunoregulatory factors, in 481 pretherapeutic FFPE samples. **Methods:** GeparSixto investigated the addition of carboplatin to a doxorubicin/taxane combination in HER2-positive (HER2+) or triple-negative (TN) primary BC. Trastuzumab and lapatinib were added for HER2+ disease and bevacizumab for TN disease. Expression of 12 immunologically relevant genes (CXCL9, CCL5, CD8A, CD80, CXCL13, IGKC, CD21, IDO1, PD-1, PDL1, CTLA4, FOXP3) was evaluated by quantitative RT-PCR in 481 core biopsies. **Results:** All immune mRNA markers showed a strong positive correlation with each other and with the stromal lymphocyte infiltrate. Hierarchical clustering revealed three different immune-subtypes of tumors with different expression of immunological genes and different amounts of tumor infiltrating lymphocytes. In the GeparSixto cohort all 12 immune markers were significantly linked to increased pCR rates in univariate analysis. 11 of the markers were also significant in multivariate analysis including clinical parameters. Some markers, such as CCL5, IDO1 and PDL1 provided predictive information even if controlled for TILs. CCL5, CD8A, CTLA4, IDO1 and PD1 showed a significant interaction with treatment (carboplatin vs. control) in the complete cohort. In TN disease CCL5 and CD8A provided predictive information for carboplatin response even after adjustment for TILs. **Conclusions:** Expression of immune marker mRNAs in BC is predictive for response to neoadjuvant chemotherapy. In GeparSixto, these immunological parameters can be used in addition to TILs to identify patients with increased response rates to carboplatin. The results should be validated in other breast cancer trials evaluating carboplatin therapy.

**511 Clinical Science Symposium, Sat, 1:15 PM-2:45 PM**

**Tracking tumor-specific mutations in circulating-free DNA to predict early relapse after treatment of primary breast cancer.** *Presenting Author: Nicholas C. Turner, The Royal Marsden NHS Foundation Trust, London, United Kingdom*

**Background:** Despite progress in the management of early breast cancer, a substantial number of patients relapse with metastatic breast cancer. Tumour-derived mutations can be detected in circulating free DNA (cfDNA) of patients with metastatic breast cancer. We assessed whether analysis of cfDNA can used to predict which patients will relapse following treatment of primary breast cancer. **Methods:** A cohort of 20 patients with primary breast cancer, all of whom received neoadjuvant chemotherapy (NAC) prior to surgery, had plasma samples for cfDNA extraction taken at baseline pre-NAC, post-surgery, and every 6 months in follow-up. Targeted next generation sequencing (NGS) was performed on the baseline tumour biopsy, and personalized tumour specific digital PCR assays were developed to track the identified mutations in cfDNA. **Results:** NGS identified at least one mutation in 60% (12/20) tumours. Mutation specific digital PCR assays were accurate and reproducible, with high correlation in tissue with NGS ($r^2=0.95$), and between mutation assays in cfDNA ($r^2=0.95$). Five patients relapsed at a median of 8.1 (5-16.6) months post-surgery, with the remaining patients disease free at a median of 11.5 months post-surgery. Tumour specific mutation was detected in 75% (9/12) of cfDNA samples at baseline, with no difference between patients who did, and did not, relapse early. In contrast, four patients had tumour specific DNA detectable in cfDNA in the first six months post-surgery, and all patients with detectable mutations in cfDNA relapsed. None of the patients who have not relapsed had a detectable mutation in cfDNA post-surgery (p=0.01), indicating clearance by the primary treatment. A patient with isolated relapse in the brain on trastuzumab, after a pathological complete response in the primary, did not have detectable mutations in cfDNA at relapse. **Conclusions:** We provide proof of principle that tracking tumour specific mutations in cfDNA can predict early relapse following treatment of primary breast cancer. Patients with detectable mutations in cfDNA post-primary treatment are at high risk of relapse, and may be suitable for therapeutic trials of novel agents.

**512 Poster Highlights Session (Board #1), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Obesity and menopausal status as determinants of procarcinogenic breast inflammation.** *Presenting Author: Neil M. Iyengar, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Chronic inflammation predisposes to several malignancies. We previously demonstrated an obesity → inflammation → aromatase axis in breast tissue. As obesity is a risk factor for postmenopausal (PoM) but not premenopausal (PreM) breast cancer (BC), we examined whether menopause and body mass index (BMI) independently impact breast white adipose tissue (WAT) inflammation. **Methods:** WAT was prospectively collected from patients (pts) from 04/10 – 08/13. WAT inflammation, detected by CD68 immunohistochemistry, was defined by the presence of dead/dying adipocytes surrounded by an envelope of macrophages known as crown-like structures of the breast (CLS-B). WAT area was measured with NIH Image J. Adipocyte diameter was measured with Canvas 11 Software. Endpoints: 1) CLS-B (+/-) and 2) CLS-B/cm$^2$. Clinicopathologic associations with CLS-B were analyzed by logistic regression and Fisher's exact test. **Results:** WAT (237 mastectomies, 13 abdominal reconstructions) was obtained from 238 women; median age 48 (range 22 – 90). CLS-B occurrence and number of CLS-B/cm$^2$ were greater in overweight/obese (BMI ≥25) and PoM pts compared to lean (BMI <25) and PreM pts (Table). In multivariable analyses, BMI and PoM state were independently associated with CLS-B presence (P<.01 and P=.04) and greater CLS-B/cm$^2$(P<.01 and P=.01). PoM pts had larger mean adipocyte diameter (105.2 +/- 14.0 $\mu$) than PreM pts (95.7 +/- 15.6 $\mu$; P<.01). In pts with bilateral breast WAT and abdominal WAT, concordant CLS status (+/-) was found in 49/63 (78%) and 10/13 (77%) pts, respectively. **Conclusions:** Breast WAT inflammation (both presence and severity), which we have previously linked to increased aromatase activity, is associated with both increased BMI and menopause. These findings can explain the increased risk of estrogen receptor-positive BC with obesity and PoM status and may also provide targets for rational therapies.

| Feature | CLS-B – N, (%) | CLS-B + N, (%) | P | CLS-B/cm$^2$Median, (range) | P |
|---|---|---|---|---|---|
| Lean (N=116) | 76 (66%) | 40 (34%) | | .27 (.06 – 4.37) | |
| Overweight (N=73) | 34 (47%) | 39 (53%) | | .26 (.05 – 51.85) | |
| Obese (N=48) | 5 (10%) | 43 (90%) | <.01 | .47 (.09 – 2.35) | .01 |
| Premenopausal (N=144) | 80 (56%) | 64 (44%) | | .26 (.05 – 5.49) | |
| Postmenopausal (N=93) | 35 (38%) | 58 (62%) | <.01 | .49 (.09 – 51.85) | <.01 |

**513 Poster Highlights Session (Board #2), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Association between visceral adiposity, BMI, and clinical outcomes in postmenopausal women with operable breast cancer.** *Presenting Author: Shalini Dalal, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** High body mass index (BMI), an indicator of excess body fat, has been shown to negatively impact clinical outcomes in breast cancer. Metabolic dysfunction associated with high visceral fat may be contributory. Since BMI provides no information on the anatomical distribution of stored fat, we conducted this retrospective study to examine the association between visceral adiposity parameters and clinical outcomes. **Methods:** 1,237 postmenopausal women with stage I-III invasive breast cancer, diagnosed between 1997 to 2012, and who received neoadjuvant chemotherapy (NC) were included. Computed tomography images were used to quantify visceral fat (VFA) and subcutaneous fat area (SFA). The VFA/SFA Ratio was used as a metric of regional fat distribution. We conducted univariate and multivariate analyses to examine the association between body composition parameters (VFA, SFA, VFA/SFA Ratio, BMI) and key outcomes (pathologic complete response [pCR], relapse-free [RFS], disease-specific [DSS] and overall survival [OS]), adjusting for demographics and known prognostic factors, including stage, tumor grade, receptor status and type of NC. **Results:** Median age was 58 years; 63% white. A majority were overweight (32%) or obese (44%). Median VFA was 110 cm$^2$, SFA 239 cm$^2$and VFA/SFA Ratio 0.41. In multivariate analysis, higher VFA (odds ratio [OR]=0.52; 95% CI, 0.36-0.75; p< 0.001) and lower SFA (OR=0.56; 95% CI, 0.39-0.81; p=0.002) were independently associated with lower likelihood of achieving pCR. Higher VFA/SFA Ratio was an independent predictor of lower RFS (hazard ratio [HR]=1.41; 95% CI 1.05-1.89; p=0.02), DSS (HR=1.71; 95% CI, 1.20-2.44; p=.003) and OS (HR=2.18; 95% CI, 1.52-3.13; p<0.001). **Conclusions:** Our study suggests fat-depot specific differences in breast cancer outcomes. Higher visceral fat and lower subcutaneous fat were independently associated with lower likelihood of pCR. Higher visceral to subcutaneous fat ratio predicted worse RFS, DSS and OS. The predisposition to accumulate fat viscerally versus subcutaneously may be a novel prognostic factor independent of BMI, absolute fat stores and tumor characteristics.

**514 Poster Highlights Session (Board #3), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Impact of insulin resistance (IR) on the prognosis of metastatic breast cancer (MBC) patients treated with first-line chemotherapy (CT).** *Presenting Author: Alessandra Gennari, E.O. Ospedali Galliera, Genoa, Italy*

**Background:** Higher insulin levels have been associated with a worse prognosis in early BC patients. However, the effect of higher insulin levels on MBC prognosis has not been explored so far. The aim of this study was to evaluate the influence of IR on the prognosis of HER2 negative, non-diabetic, MBC patients receiving first line CT. **Methods:** The relationship between IR, identified by HOMA index > 2.5 (fasting glucose [mmol/L] × insulin [mU/L]/22.5), and progression free (PFS) or overall survival (OS) was assessed in 87 MBC patients enrolled in a clinical trial of first line CT with non-pegylated liposomal doxorubicin 60 mg/sqm plus cyclophosphamide 600 mg/sqm Q21 days. PFS and OS were calculated by Kaplan-Meier estimation; multivariate Cox analysis was performed adjusting for age, PS, endocrine status, metastatic site and BMI. **Results:** Information on patient's IR status at baseline was available on 79 women. Median follow up was 15 months (IQR 9-21). Overall,48.4% patients wereclassified as insulin resistant (HOMA > 2.5), 41.0% were overweight (BMI 25-30) and 19.2% were obese (BMI > 30). Median age was 61 years (range 36-77); PS was 0 in 76.6% of the patients. Endocrine status was positive in 87.5% and visceral disease was present in 63.6%. Overall, median PFS was 9 months (IQR 5-18): median PFS was 14 months (IQR 8-18) in patients with HOMA index ≤2.5 and 8 months (IQR 2-17), in patients with HOMA index >2.5; HR=1.79 (95%CI: 1.01–3.18, p 0.04). By multivariate analysis, after adjustment for age, PS, endocrine status, visceral disease and BMI, a statistically significant higher risk of disease progression was detected in patients with HOMA Index > 2.5 (HR 2.28; 95%CI: 1.06 – 4.89, p = 0.035). **Conclusions:** In this study IR, indicated by an HOMA Index >2.5, was associated with a significantly worse prognosis; after adjusting for other acknowledged prognostic factors, the IR status was the only one to maintain its adverse prognostic effect. These data suggest that host metabolic status might influence the prognosis of MBC treated with CT and therefore additional alternative strategies, targeting host metabolism, should be considered in this unfavorable subset of patients.

**515 Poster Highlights Session (Board #4), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Inhibition of polo-like kinase 1 (PLK1) in endocrine-resistant ER+ breast cancer.** *Presenting Author: Valerie Malyvanh Jansen, Vanderbilt University, Nashville, TN*

**Background:** Estrogen receptor (ER)-positive breast cancers initially respond to antiestrogens but eventually become hormone-independent and recur. ER+ breast cancer cells resistant to long-term estrogen deprivation (LTED) exhibit estrogen-independent ER transcriptional activity and growth. Mechanisms of endocrine resistance remain to be fully characterized. **Methods:** A siRNA screen was used to identify kinases required for growth of MCF7/LTED cells. PLK1 RNAi oligonucleotides and the small molecule inhibitor volasertib were tested against ER+ LTED cells. Estrogen independent transcription and target genes were assessed with ER reporter assays and qRT-PCR, respectively. Volasertib and fulvestrant were used in ovariectomized athymic mice bearing MCF7 xenografts. Preclinical findings were correlated with RPPA and RNA-seq data from tumor biopsies of patients with ER+/HER2– breast cancer who received letrozole prior to surgery (NCT00651976). **Results:** A siRNA kinome screen identified Polo-like kinase 1 (PLK1) as one of the top RNAs required for MCF7/LTED cell growth. RNAi-mediated knockdown of PLK1 inhibited LTED cell growth and ligand-independent transcription of the ER-regulated genes PR, TFF1 and GREB1. Treatment with volasertib reduced ER expression, ER transcriptional activity and LTED cell proliferation. Volasertib in combination with fulvestrant reduced ER expression and inhibited growth of MCF7 xenografts more potently than either drug alone. A PCR array of ER regulated genes in MCF7/LTED cells showed that volasertib decreased expression of JUNB, FOS and BCL2L mRNAs. JUNB knockdown decreased ER transcriptional activity and ER expression suggesting that PLK1 affects ER via JUNB. Finally, in ER+/HER2– tumors from newly diagnosed postmenopausal patients, PLK1 protein and transcript levels positively correlated with resistance to letrozole as measured by high Ki67 levels in post-treatment biopsies (p=0.007; p<0.001). **Conclusions:** These data support a critical role of PLK1 in growth of antiestrogen resistant breast cancer cells. Targeting of PLK1 may abrogate resistance to endocrine therapy in ER+ breast cancer and is worthy of clinical investigation.

**516^ Poster Highlights Session (Board #5), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**SU2C phase Ib study of the PI3K$\alpha$ inhibitor BYL719 with letrozole in ER+/HER2– metastatic breast cancer (MBC).** *Presenting Author: Ingrid A. Mayer, Vanderbilt-Ingram Cancer Center, Vanderbilt University, School of Medicine, Nashville, TN*

**Background:** Mutations in *PIK3CA*, the gene encoding the p110$\alpha$ subunit of PI3K, have been associated with antiestrogen resistance in ER+ BC. In general, antiestrogen-resistant cancers retain ER and responsiveness to estradiol. This suggests that treatment of ER+ BC should include PI3K inhibitors plus antiestrogens. **Methods:** We conducted a phase Ib 3+3 dose escalation trial of letrozole (2.5 mg/day) with the PI3K$\alpha$ inhibitor BYL719 in post-menopausal patients (pts) with ER+/HER2- MBC refractory to previous endocrine therapies. BYL719 doses ranged from 300-400 mg/daily. Treatment continued until unacceptable toxicity or disease progression. Disease was assessed every 2 months. *PIK3CA* mutation status in archival tumor was obtained in all patients. **Results:** Twenty-one pts were accrued; 18 had progressed on an aromatase inhibitor (AI). Median age was 53 years (31-72); 76% of pts had bone and 61% had visceral metastases. Toxicities are summarized in Table 1. Rash was the dose limiting toxicity* at 350 mg/day dose. No pts had a complete response; 3 pts had a partial response; 6 patients had stable disease; 6 pts had disease progression; 6 pts have not yet had their first tumor assessment and 13 pts are still on treatment. Ten of 18 (56%) pts had a *PIK3CA* mutation; of these, two had a partial response, and two have been on treatment for >6 months. **Conclusions:** The combination of letrozole/ BYL719 is safe and tolerable in pts with AI-refractory ER+/HER2 MBC. The MTD and recommended dose for phase II trials of BYL719 in combination with letrozole was 300 mg/day. Grade 2-3 rash and hyperglycemia observed at this dose suggest inhibition of PI3K by BYL719. Clinical activity was not restricted to pts with *PIK3CA* mutant tumors. A correlation of *PIK3CA* mutations with clinical benefit cannot yet be fully established. Clinical responses and therapy duration will be updated at the meeting. Clinical trial information: NCT01791478.

**Monitoring *PIK3CA* mutant allele fraction (AF) in cell-free DNA (cfDNA) in metastatic breast cancer (MBC) patients treated with PI3K$\alpha$–inhibitor plus letrozole (L) or exemestane (E).** *Presenting Author: Mary Ellen Moynahan, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** In tumors that harbor activating mutations, tumor-derived cfDNA extracted from patient plasma can be serially quantified by droplet digital PCR (ddPCR). Mutant AF may be predictive of target-directed therapy for initial response and evolving resistance. We report results of a correlative aim assessing serial mutant AF in a phase I study of a PI3K$\alpha$-inhibitor, BYL719, with L or E in MBC. **Methods:** *PIK3CA* status was mutant/wild-type/unknown in 8/5/1 pts as determined by molecular analysis of tumor. Plasma samples were collected at baseline and on day 1 of each 28 day cycle while on protocol. cfDNA was extracted using QIAamp Circulating NA kit and quantified by KAPA hgDNA qPCR. Allele specific assays for *PIK3CA* E542K, E545K, H1047R and H1047L mutations were designed for quantification on BioRad QX200 Droplet Digital PCR System. Mutant AF is determined from the counts for mutant as compared to wild-type. The detection limit for each assay is calculated from the number of events detected. All sample runs are replicated. **Results:** 5/8 pts with *PIK3CA* mutation were evaluable by ddPCR having received treatment for at least 2 cycles with the PI3K$\alpha$-inhibitor. In the plasma of 4 pts, we identified a brisk decrease in *PIK3CA* mutant AF at cycle 2, day 1(C2D1) ranging from 91.8 - 99.6% decrease from baseline. All 4 pts had stable or responding disease as best response. In 1 patient, later determined to have disease progression there was a small change (19% decrease) in *PIK3CA* mutant AF at C2D1 with a 16X increase in mutant AF at C3. Ongoing responses result in a persistent low (>98% decrease) or undetectable mutant allele. In 1 patient, with a transient response, the marked decrease in mutant AF at C2D1 was followed by an increase at C3 predicting her clinical progression. **Conclusions:** Targeted therapies directed towards specific oncogene mutations may be assessed serially by ddPCR to confirm mutant target sensitivity. Assessment for early tumor resistance may allow a more rapid treatment change with real-time monitoring of target mutant alleles. Serial assessment may be helpful in the exploration of best and better tolerated dosing schedules. Clinical trial information: NCT01870505.

**518 Poster Highlights Session (Board #7), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**SAKK 24/09: Safety and tolerability of bevacizumab plus paclitaxel versus bevacizumab plus metronomic cyclophosphamide and capecitabine as first-line therapy in patients with HER2-negative advanced stage breast cancer—A multicenter, randomized phase III trial.** *Presenting Author: Christoph Rochlitz, University Hospital, Basel, Switzerland*

**Background:** Bevacizumab combined with chemotherapy has been shown to improve response rate and PFS in metastatic breast cancer. The aim of our study was to demonstrate decreased toxicity of metronomic chemotherapy/ bevacizumab when compared to paclitaxel/bevacizumab. **Methods:** In this multicenter, randomized phase III trial, we compared bevacizumab (10 mg/kg i.v. q 2 weeks) with either paclitaxel (90 mg/m2) i.v. on days 1, 8, and 15 of a 4 week cycle (arm A) or daily oral capecitabine (3x500 mg) and cyclophosphamide (50 mg) (arm B) as first-line treatment in patients with HER2-negative advanced breast cancer. Primary endpoint was the incidence of grade 3–5 adverse events (AE): febrile neutropenia, infection, sensory and motor neuropathy, mucositis and hand-foot-syndrome. Secondary endpoints included: objective response (OR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), other adverse events (AEs), and quality of life (QoL). **Results:** Between September 2010 and December 2012, 147 patients were included at 22 centers in Switzerland, 73 in arm A and 74 in arm B. The incidence rates of primary endpoint events were 25% (18/71; 95% CI 15–35%) for arm A and 24% (16/68; 95% CI 13–34%) for arm B (p=0.96). Objective response rates were 58% (42/73; 95% CI 0.46–0.69) and 50% (37/74; 95% CI 0.39–0.61) in arms A and B, respectively (p=0.45). Median PFS was 10.3 months (95% CI 8.7–11.3) in arm A and 8.5 months (95% CI 6.5–11.9) in arm B, p=0.90; other secondary efficacy endpoints (DCR, OS) were not significantly different between the two arms. Less hair loss in arm B was the only clinically and statistically significant difference in QOL. **Conclusions:** This trial failed to meet its primary endpoint of a reduced rate of prespecified grade 3–5 AEs of metronomic bevacizumab, cyclophosphamide and capecitabine but the combination could be an active, convenient treatment in HER-2-negative metastatic breast cancer. Clinical trial information: NCT01131195.

**519 Poster Highlights Session (Board #8), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Randomized phase 2 study of abiraterone acetate (AA) with or without exemestane (E) in postmenopausal patients (pts) with estrogen receptor–positive (ER+) metastatic breast cancer (MBC).** *Presenting Author: Joyce O'Shaughnessy, Texas Oncology-Baylor Charles A. Sammons Cancer Center and US Oncology, Dallas, TX*

**Background:** Androgen receptor (AR) signaling and/or incomplete inhibition of agonistic estrogen synthesis may contribute to MBC resistance to a nonsteroidal aromatase inhibitor (NSAI). Combined inhibition of the AR with AA and the ER with E may be of clinical benefit. We assessed the safety and efficacy of AA + prednisone (P) in postmenopausal pts with NSAI-pretreated ER+ MBC. **Methods:** 297 pts were randomized to receive 1000 mg AA + 5 mg P (AA + P) vs AA + P with 25 mg E (AA + P + E) vs 25 mg E alone (E); 293 pts were treated. The primary end point was progression-free survival (PFS). Secondary end points included overall survival (OS) and clinical benefit rate (CBR). **Results:** The median age was 63 (37-87); 64% (AA + P + E), 64% (AA + P), and 65% (E) of pts had prior NSAI for MBC while 70% (AA + P + E), 66% (AA + P), and 65% (E) had prior chemotherapy. AA + P enrollment was discontinued (n = 89) after the planned interim analysis. 181 pts had measurable disease at baseline by RECIST. There was no significant difference in PFS or CBR with AA + P or AA + P + E compared with E (Table). Median OS was not reached. Increased serum progesterone concentrations were observed in both AA arms but not with E. The grade 3 or 4 toxicities associated with AA included (AA + P + E vs E) hypokalemia (5.8% vs 2.0%), hypertension (5.8% vs 2.9%), AST increase (4.8% vs 3.9%), and ALT increase (2.9% vs 2.9%). Treatment discontinuation for treatment-emergent adverse events was uncommon and only included 6 (5.9%) in E and 10 (9.6%) pts in AA + P + E. **Conclusions:** Adding AA to E in NSAI-pretreated MBC pts did not improve PFS or CBR. Administration of 5 mg of P adequately suppressed AA-associated mineralocorticoid excess effects. AA-induced CYP17 inhibition may not suppress steroid hormone receptor signaling in ER+ MBC potentially due to AA-induced increased progesterone synthesis. Clinical trial information: NCT01381874.

**520 Poster Highlights Session (Board #9), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Evaluation of biomarker association with efficacy for abiraterone acetate (AA) plus prednisone (P) with or without exemestane (E) in postmenopausal patients (pts) with estrogen receptor-positive (ER+) metastatic breast cancer (mBCa) progressing after a nonsteroidal aromatase inhibitor (NSAI).** *Presenting Author: Weimin Li, Janssen Research and Development, Spring House, PA*

**Background:** AA treatment may suppress androgens and estrogens that stimulate BCa growth. We conducted a biomarker analysis of circulating tumor cells (CTCs) and formalin-fixed paraffin-embedded tissues (FFPETs) from a phase 2 study of the efficacy and safety of AA in postmenopausal ER+ BCa pts to analyze serum steroid concentrations and identify subgroups with AA sensitivity. **Methods:** Treatments: AA (1 g/d) + P (5 mg/d) vs AA + P + E (25 mg/d) vs E alone. FFPETs from diagnosis and blood samples collected at baseline, during treatment, and at the end of treatment were used for molecular characterization and serum endocrine marker analysis. Expression of androgen receptor (AR), estrogen receptor (ER), Ki-67, CYP17, CYP19, and other biomarkers was evaluated in CTCs and/or FFPETs. Cox regression analysis stratified by number of prior therapies and type of therapy was used to evaluate biomarker associations with progression-free survival (PFS). Statistical comparisons were performed for treatment effect in biomarker-positive and -negative subgroups using Cox regression to identify those with better PFS. **Results:** Serum testosterone, estradiol, and estrone were decreased by AA treatment. An increase in progesterone was observed in most pts (AA + P and AA + P + E) but was not associated with PFS. 104 pts had $\geq$ 3 CTCs (median age 62; prior NSAI in metastatic setting 66%). Individually, baseline expression of AR or ER in CTCs or FFPETs was not associated with PFS. However, there was a positive association for the combination of AR and ER expression in CTCs with PFS in favor of AA + P + E vs E (HR 0.41 [0.16-1.07], p = 0.070). In recent FFPETs obtained $<$ 1 yr prior to first dose (67 pts), AR expression suggested positive association with PFS (HR 0.56 [0.24-1.33], p = 0.191) for AA + P + E vs E. **Conclusions:** A positive pharmacodynamic effect of AA was shown by the decrease in serum estrogen and androgen and potentially by the increase in progesterone in most pts. Baseline AR and ER expression in CTCs and AR expression in recent FFPETs may predict improved PFS. Clinical trial information: NCT01381874.

**521 Poster Highlights Session (Board #10), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Comparison of breast cancer recurrence and outcome patterns between patients treated in 1986-1992 and 2004-2008.** *Presenting Author: Rachel Jorge Dino Cossetti, BC Cancer Agency, Vancouver, BC, Canada*

**Background:** Different patterns of breast cancer (BC) recurrence overtime have been reported according to estrogen receptor (ER) status. We report a change in BC recurrence patterns. **Methods:** Females with biopsy proven BC, stages I-III, treated at the BCCA 1986-1992 (cohort 1 – C1) and mid 2004-2008 (cohort 2 – C2), with known ER and HER2 status were eligible. Data was prospectively collected. C2 cases were matched to C1 by random case selection for grade and stage to adjust for imbalances. Endpoints were annual hazard rates of recurrence (HRR) and annual hazard rates of death (HRD). **Results:** After random sampling, 10,283 pts were included: 3672 in C1 and 6611 in C2. BC subtypes in C1 and C2 were, respectively, ER+/HER2-: 71.2 vs 64.8%; ER+/HER2+: 6.7 vs 11.7%; ER-/HER2+: 6.5 vs 8.2%; ER-/HER2-: 15.5 vs 15.3%. The HRR per yearly interval (up to year 9) for all subtypes have halved in C2. For ER+/HER2- BC, HRR in C2 was half of the HRR in C1. Differences in HRR between C1 and 2 were greater in the initial 5 intervals for HER2+ and triple-negative (TN) BC. The HRD have also decreased, but to a lesser extent. **Conclusions:** Outcomes have improved for all BC subtypes, but particularly for HER2+ and TN BC. The early spike in disease recurrence has markedly decreased. These contemporary hazard rates are important for treatment decisions and patient discussions, but also for planning of early BC trials.

**Emerging trends in type of chemotherapy (CT) received among patients (pts) with stage I breast cancer (BC).** *Presenting Author: Ines Maria Vaz Duarte Luis, Dana-Farber Cancer Institute, Boston, MA*

**Background:** We examined time trends of CT used and associations with pts characteristics in Stage I BC. **Methods**: Prospective cohort studyincluding pts with Stage I BC treated at a National Comprehensive Cancer Network center from 2000-09. We examined the proportion of pts receiving intensive vs. non-intensive CT over time.We defined an intensive regimen as: a combination of anthracyclines and taxanes (e.g. ACT ± H) or a combination of carboplatin and docetaxel (e.g. TCH), and non-intensive as: anthracycline-based (e.g. AC), taxane-based (e.g. TC) or similar. We evaluated factors associated with type of CT using multivariable logistic regression. Analyses were stratified by HER2 receptor status**. Results:** Of 8,907 pts, 33% received adjuvant CT. There was a dramatic increase of intensive CT: among HER2+ pts from 31% in 2000-05 to 63% in 2008-09 (including an increase in the use of TCH) and among HER2- from 15% in 2000-05 to 41% in 2008-09. Among non-intensive regimens there was an increase in the use of regimens such as TC with a parallel decrease in the use of regimens such as AC, in both HER2+ and HER2- groups. Characteristics which factored into CT decisions differed by tumor subtype, with significant center variations. **Conclusions:** Over time, there was an increase in use of intensive regimens among Stage I BC. CT use differed by HER2 status with striking center and temporal variations.

**Changing pattern for HER2 positivity due to updated ASCO/CAP guidelines for HER2 testing and its impact.** *Presenting Author: Mithun Vinod Shah, Mayo Clinic, Rochester, MN*

**Background:** ASCO/CAP guidelines for HER2 testing in breast cancer were published in 2007 and updated in 2013. HER2-directed therapies (HDT) should be recommended in patients who are deemed HER2 positive, while they are not recommended in HER2 negative patients. If HER2 testing is equivocal, the guideline suggests that HDT be considered. It is not known how implementation of updated guidelines will change clinical practice. **Methods:** After the implementation of the 2013 guidelines, 321 breast tumor samples were received by the Mayo Clinic Cytogenetics laboratory for FISH analysis of HER2 status. The prevalence of HER2 alterations in this cohort was analyzed using both 2007 and 2013 guidelines. We also retrospectively analyzed HER2 data from N9831 (Alliance), a prospective multicenter randomized trial that evaluated the use of trastuzumab in the adjuvant setting. The trial included 3,505 women with histologically confirmed node-positive/high-risk node-negative HER2 positive invasive breast cancer. US FDA criteria were used to define HER2 positivity in N9831. **Results:** Using 2007 guidelines, 44 (14%) of the Mayo clinical practice cases were HER2 positive, 262 (82%) negative, and 11 (3.5%) equivocal. Using 2013 guidelines, 80 (25%) were positive, 225 (70%) negative, and 12 (4%) equivocal. The interpretation changed in 48 (15%) cases (p$<$ 0.0001). In N9831 using 2007 guidelines, 2,878 cases were HER2 positive (80.7%), 607 negative (17%), and 80 (2.2%) equivocal. Using 2013 guidelines, 2,937 (82.4%) were positive, 538 (15.1%) negative, and 90 (2.5%) equivocal. The increase in the prevalence of positive cases was significant (p$<$0.0001). Preliminary analysis suggests no disease-free survival benefit in women who had change in classification when stratified by whether they received HDT or not. **Conclusions:** There is a significant increase in the proportion of HER2 positive cases when breast cancer specimens are assessed using the 2013 ASCO/CAP guidelines. The updated guidelines also result in more equivocal cases requiring reflex testing. Interpreting HER2 status using updated guidelines will result in an increase in the number of breast cancer patients eligible for HDT. Clinical trial information: NCT00005970.

**524^ Poster Highlights Session (Board #14), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Oncotype DX and proliferation response to short-term preoperative endocrine therapy for chemotherapy decision in early breast cancer: Biomarker data from the prospective multicenter phase II/III WSG-ADAPT trial.** *Presenting Author: Oleg Gluz, West German Study Group; Evangelic Hospital Bethesda, Moenchengladbach, Germany*

**Background:** WSG-ADAPT aims to optimize early breast cancer therapy within a genomically classified (by OncotypeDX) intermediate-risk group using individual endocrine sensitivity. **Methods:** WSG-ADAPT HR+/HER2- analyzes biomarker changes after 3 weeks of preoperative ET [aromatase inhibitors (AI) in postmenopausal, tamoxifen (Tam) in premenopausal women]. Overall, n=1760 patients (HR+/HER2-, pN0-1) with Recurrence Score (RS) 0-11 or RS 12-25 and post-Tx Ki-67<10% are treated by ET alone. Other RS 12-25 and all RS ≥26 patients are included in phase III CTx design (n=2200). **Results:** 1118 patients from 61 centers have been enrolled (01/2014); run-in phase analysis included 383 patients (median age 54 years, 175 Tam, 208 AI). RS distribution (≤11/12-25/≥26) was 23%/57%/20%; median relative Ki-67 decreases were 0.67/0.60/0.40 by RS groups (p=0.017). Median relative Ki-67 decrease was more pronounced in post- vs. premenopausal patients (75% vs. 38%; p<0.001). Mean PR (not ER) expression changes were also more pronounced in postmenopausal patients (-39.5 %- vs. -10.4%-units; p<0.001). Pre- and post-endocrine RS (n=187) are moderately correlated ($r_S$ =.70, p<.001); no significant RS change was seen (95% CI: -1.7 to 0.3). Absolute change in Ki-67 by IHC was correlated with change in RS proliferation ($r_S$= .62, 95% CI: 0.52 to 0.7). Median ER expression by RT-PCR was higher in post- than premenopausal patients (10.25 vs. 9.3, p<0.001); median PR expression by RT-PCR trended oppositely (7.7 vs. 8.1, p=0.01). Baseline ER expression by RT-PCR (not IHC) was associated with relative Ki-67 decrease ($r_S$=.29, p<0.001). Baseline Ki-67, menopausal status/endocrine agent, and RS were independent predictors for post-treatment Ki-67. **Conclusions:** Postmenopausal patients (mostly AI) and those with lower baseline RS showed stronger proliferation response to short preoperative endocrine therapy. The difference in outcome between early proliferation responders (>70%) treated with ET alone among pN0/N1 patients with RS 12-25 and those with RS<11 will be tested in the WSG-ADAPT HR+/HER2- main phase. Clinical trial information: NCT01779206.

**525 Poster Highlights Session (Board #15), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Prognostic score for Luminal A-like breast cancer patients.** *Presenting Author: Caterina Fontanella, German Breast Group, Neu-Isenburg, Germany*

**Background:** Luminal A breast cancer (BC) is considered a subtype with a good prognosis, but some poor prognostic factors can be identified, i.e. advanced stage and/or young age at presentation seem to be associated with higher risk of recurrence after neoadjuvant treatment (NAT). The importance of the progesterone receptor (PR) in Lum A BC prognosis has also been explored. **Methods:** We evaluated 2,248 patients with Lum A like BC (HER2-/estrogen receptor +/grade1-2) from 6 anthracycline-taxane based NAT trials (plus adjuvant endocrine therapy (ET) and radiotherapy if indicated). Combining tumor stage (AJCC Cancer Staging seventh), PR status, and age at baseline, we generated a score to divide Lum A like BC into 5 groups (Table). We used Kaplan Meier and uni/multivariate Cox regression analyses to explore the effect of the score on disease free (DFS) and overall survival (OS) and to evaluate its interaction with CPS+EG score (Mittendorf EA, JCO 2011), body mass index (BMI≤30/>30kg/m²), pCR (ypT0 ypN0), NAT density (conventional/dose-dense), and duration (24/18/≤12 weeks). **Results:** Mean DFS and OS decreased from score A to E (DFS: A 106.9 months, B 98.9, C 90.7, D 80.5, E 46.5; *p*< .001; OS: A 109.9 months, B 107.2, C 100.6, D 91.0, E 57.8; *p*< .001). Univar. analysis hazard ratios (HR) are displayed below. In multivar. analysis, our score independently predicted DFS (*p*< .001) and OS (*p*= .049). No interactions were observed (DFS: score*CPS+EG *p*= .440, s*BMI *p*= .347, s*pCR *p*= .462, s*density *p*= .350, s*duration *p*= .590; OS: s*CPS+EG= .734, s*BMI *p*= .784, s*pCR *p*= .999, s*density *p*= .870, s*duration *p*= .999). **Conclusions:** Using characteristics available in daily practice before treatment, we developed a score to identify Lum A like BC patients with poorer prognosis, despite NAT and ET, who are candidates for more aggressive NAT or additional postNAT in future studies.

**Phase II study of 3'-deoxy-3'-18F fluorothymidine PET/CT (FLT-PET) in the assessment of early response in locally advanced breast cancer (LABC): Preliminary results of ACRIN 6688.** *Presenting Author: Lale Kostakoglu, Department of Radiology, Mount Sinai Medical Center, New York, NY*

**Background:** FLT-PET imaging can be exploited as a marker of cellular proliferation and tumor (tm) therapy response. Our primary objective was to determine if early change in tm FLT uptake predicts pathologic complete response (pCR) to neoadjuvant chemotherapy (NAC) in primary tms in LABC pts. The secondary objective was to correlate standardized uptake values (SUVmax) with Ki-67 at baseline and after NAC. **Methods:** In this phase II study, 51 LABC pts [stage IIA-IIIC] were evaluable for primary objective analysis. NAC was according to standard of care; imaging was not used to change management. All 51 pts underwent FLT-PET imaging at baseline (FLT-1), and after one cycle (FLT-2);43 pts were imaged post-NAC (FLT-3). SUVmax's were averaged for multiple primary tms. The percent change in SUVmax (ΔSUVmax) between FLT-1 and FLT-2 was calculated. Pathologic response, Ki-67 assay and PET/CT were assessed at core labs. The predictive value of ΔSUVmax for pCR was determined by ROC; by area under the curve (AUC). Correlation between SUVmax and Ki-67 was assessed by the Spearman coefficient (R). **Results:** A pCR was achieved in 9 of 51 pts. At FLT-1, primary tm SUVmax range:0.9-11.8. FLT-1 uptake was not different between pts with pCR and non-pCR (p=0.59). NAC led to a significant ΔSUVmax (mean,36%;95%CI 28%-45%). AUC for ΔSUVmax in the prediction of pCR=0.68 [95%CI 48%-86%]. The best ΔSUVmax cut-off for predicting pCR was 51% (sensitivity 56%;specificity 79%). The difference in ΔSUVmax between pts with and without pCR was significant (20%;one-sided p=0.045). The correlation between FLT-1 SUVmax and Ki-67 was weak (R,0.29, p=0.04) but stronger at FLT-3 (R, 0.67%, p<0.0001). **Conclusions:** There was a significant difference in FLT ΔSUVmax in responders vs. non-responders after one NAC cycle, and FLT-PET was marginally predictive of pCR despite variable therapy. Post-NAC FLT uptake correlated with Ki-67. These data suggest that further work is warranted to define the clinical utility of FLT-PET in early evaluation of LABC therapy response. This project was funded in part with funds from the Department of Health & Human Services (DHHS); Grant#CA80098. Clinical trial information: NCT00572728.

**527 Poster Highlights Session (Board #17), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**A phase I trial of palbociclib and paclitaxel in metastatic breast cancer.** *Presenting Author: Amy Sanders Clark, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

**Background:** Palbociclib (Palb) is an oral CDK 4/6 inhibitor that is under development in breast cancer as a single agent and in combination with endocrine therapy. Preclinical studies suggest that Palb synergizes with paclitaxel (Pac) when given on an alternating schedule. We conducted a Phase I trial investigating the combination of weekly Pac and alternating Palb to synchronize the cell cycle in the tumors of patients (pts) with metastatic breast cancer. **Methods:** Pts with tumors expressing Rb protein, adequate organ function, and ≤3 prior cytotoxic metastatic regimens were eligible. Prior taxane was allowed. Palb was dose-escalated in a standard 3+3 design and taken on days 2-6, 9-14, 16-20 of each 28 day cycle. Pts received Pac 80mg/m2 weekly for 3 cycles; thereafter, Pac was administered on days 1, 8 and 15. After 6 cycles of therapy, pts had the option to drop the Pac and continue on Palb alone. Toxicity was assessed weekly and response was assessed every 2 cycles using RECIST 1.0. **Results:** The table below shows Palb dose level, enrollment, dose limiting toxicities (DLT), number of patients with Grade 3/4 neutropenia (NTP) and response (partial response (PR), stable disease (SD) or progressive disease (PD)). 8 patients had previously received a taxane. The only DLT was grade 3 AST and ALT (LFT). Among 11 pts with PR or SD, 8 pts continued on therapy >6 months and 4 >12 months. 11 pts are off study; 10 for PD, and one for toxicity (NTP in cycle 17) and 3 remain on study. Median time on treatment is 8 cycles. **Conclusions:** Combination Pac and Palb is safe and well tolerated. Prolonged tumor responses were seen. However, because uncomplicated grade 3/4 NTP was common and frequently led to dose reduction or dose interruption with 5-day Palb dosing, an additional Phase 1 expansion to examine Palb 100mg on a 3-day schedule (days 2-4, 9-11 and 16-18) is underway. Clinical trial information: NCT01320592.

**TBCRC 022: Phase II trial of neratinib for patients (Pts) with human epidermal growth factor receptor 2 (HER2+) breast cancer and brain metastases (BCBM).** *Presenting Author: Rachel A. Freedman, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Evidence-based treatments for metastatic, HER2+ breast cancer to the central nervous system (CNS) are limited. Neratinib is an irreversible inhibitor of erbB1, HER2, and erbB4 with promising activity in HER2+ disease. Preclinical evidence suggests it may cross the blood brain barrier. We evaluated neratinib in pts with HER2+ BCBM in a multicenter, phase II open label trial. We report the results of cohort 1 here. **Methods**: Pts with measurable BCMC (>/= 1 cm in longest dimension) who progressed after receipt of local CNS therapy were eligible. Pts received neratinib 240 mg orally once daily over 28 day cycles. Brain MRI and non-CNS imaging were obtained at baseline and every two cycles. Circulating tumor cell collections and neurocognitive evaluations were performed serially. The primary endpoint was composite CNS objective response rate (ORR). CNS ORR required all of the following: >/=50% reduction in volumetric sum of target CNS lesions, no progression of non-target lesions, no new lesions, no escalating steroids, no progressive neurologic signs/symptoms, and no non-CNS progression by RECIST 1.1. If patients progressed outside the CNS, the addition of trastuzumab was offered. We used a two-stage design to distinguish between ORR 6% vs 20% (responses in >/=1/18 pts to enter 2$^{nd}$stage; responses in >/=5/40 pts to be promising). **Results:** 40 pts were enrolled between 2/12-6/13; median age was 51. Most pts (80%) had received 2+ lines of therapy for metastatic disease, 85% had prior lapatinib, and 75% had prior WBRT. As of 1/10/14, 0 patients remain on protocol therapy and 22 patients have died. Three women experienced a response (CNS ORR=7.5%; 95% CI 2-27%). The median number of cycles received was 2 (range 1-15+); 6 women (15%) received 6+ cycles of therapy. The most common grade 3+ event was diarrhea (25%); this event decreased after an amendment mandated 2 mg loperamide prophylaxis once daily during cycle 1 (33% grade 3+ diarrhea pre-prophylaxis vs. 21% post-prophylaxis). **Conclusions:** Neratinib is associated with a low CNS ORR in pts with BCBM but provided durable disease control in some pts. Updated results will be presented at the meeting. Clinical trial information: NCT01494662.

**529 Poster Highlights Session (Board #19), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Patient-level meta-analysis of randomized trials of aromatase inhibitors (AI) versus tamoxifen (Tam).** *Presenting Author: John F. Forbes, University of Newcastle, ANZBCTG, Calvary Mater Newcastle Hospital, Newcastle, Australia*

**Background:** The optimal way to schedule AIs and/or Tam in the adjuvant treatment of early breast cancer remains uncertain. **Methods:** ITT meta-analysis of individual patient data on 36 889 post-menopausal women with ER-positive invasive breast cancers in randomised trials of [A] Continuous AI (5yrs) vs Tam (5yrs); [B] Sequential Tam then AI (2-3yrs of Tam then 2-3 yrs AI) vs Tam (5yrs); [C] Continuous AI (5yrs) vs Sequential Tam then AI (5yrs). **Results:** [A] Fewer women had breast cancer recurrence with Continuous AI than Tam (827/4,970 vs 964/4,915, p<0.0001) and fewer died of breast cancer: 504 vs 562; rate ratio (RR) 0.86 [0.76-0.97], p=0.014. Recurrence RRs were: 0.66 during yrs 0-1 [95%CI 0.54-0.80], 0.75 during yrs 2-4 [0.64-0.88] and 0.90 in yrs 5+ [0.79-1.04]. [B] Recurrence was also lower with Sequential Tam then AI than with Tam alone (753/5,909 vs 863/5,889, p=0.0001) as was breast cancer mortality (361 vs 428 deaths; RR 0.84 [0.73-0.97], p=0.015). Recurrence RRs were 0.56 during yrs 2-4 [0.46-0.67] and 0.97 in yrs 5+ [0.86-1.09]. [C] In trials comparing Continuous AI versus Sequential Tam then AI, recurrence was lower with AI than Tam during yrs 0-1; RR 0.75 [0.62-0.89], but similar during yrs 2-4 (0.99 [0.85-1.15]), when both groups received AI, and in yrs 5+ (0.96 [0.76-1.21]) after treatment completion; overall, there were fewer recurrences with Continuous AI than Sequential Tam then AI (705/6,422 vs 764/6,377, RR 0.90 [0.81-1.00]; 5yr recurrence 9.6% vs 10.7%, p=0.042) and fewer breast cancer deaths (395 vs 432; 0.89 [0.77-1.02], p=0.097). In the 3 comparisons, proportional recurrence reductions did not differ much by age, nodal status, tumour grade, or PR status and, overall, fewer endometrial cancers (0.2% vs 0.6%, RR=0.37 [0.27-0.51]) but more fractures (8.1% vs 5.9%, RR=1.40 [1.27-1.53]) were seen with AIs than Tam; non-breast deaths were similar. **Conclusions:** AIs, in either Continuous or Sequential regimens, are even more effective than Tam monotherapy in preventing recurrence and breast cancer death, despite substantial cross-over from Tam to AI in some studies. Recurrence reductions are seen mainly while treatments differ, hence somewhat fewer recurrences with Continuous AI than Sequential Tam then AI.

**530 Poster Highlights Session (Board #20), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**An immune-related signature for prediction of risk of late recurrences beyond proliferation and ER-related genes in ER-positive breast cancer.** *Presenting Author: Giampaolo Bianchini, San Raffaele Hospital, Milan, Italy*

**Background:** In ER+ tumors, a dentritic metagene (DM) predicts for lower risk of relapse (Bianchini G JCO 2010; Bianchini G ASCO 2012). We investigated if other immune metagenes provided additional prognostic information and their involvement in early and late (after 5 years) relapses. **Methods:** We evaluated public available Affymetrix-based gene expression profiles from ER+ untreated (n=599) and adjuvant tamoxifen (TAM)-treated pts (n=683). Four previously defined immune metagenes were evaluated: CD8, MHC1, STAT1 and interferon inducible (IF.I) (Gianni L SABCS 2012). Multivariate analyses were adjusted by estrogen-related genes, proliferation (Bianchini G Breast Cancer Res 2013) and HER2 status. Median cut-off points were used to define low and high expression groups. Outcome was assessed according to distant relapse. **Results:** In untreated breast cancer, adjusting for other markers only IF.I metagene retained independent prognostic value [HR 1.19 (1.00-1.41), p=0.043], with higher risk for higher expression value. This effect was driven by its prognostic value in the late period [HR 1.50 (0.99-2.28), p=0.057]. Low and high expression groups of DM and IF.I were combined. The lowDM/highIF.I group had a higher risk of recurrences in the overall period [HR 3.68 (1.96-6.91), p<0.0001], with a similar trend in the late period [HR 2.98 (0.85-10.5), p=0.08]. In tamoxifen treated patients, adjusting for other markers, IF.I was confirmed as prognostic in the overall period [HR 1.25 (1.05-1.49), p=0.01] with an even stronger time varying effect [late period: HR 1.51 (1.14-2.01), p=0.004 and early period: HR 1.12 (0.90-1.39), p=0.29]. From 5 to 10 years, the lowDM/highIF.I group had the highest risk [HR 7.26 (1.78-33.9), p=0.006] with a corresponding relapse rate of 22.8% compared to 3% in the highDM/lowIF group. **Conclusions:** In ER+ breast cancer, high expression of interferon inducible-related genes predicts for higher risk of late recurrences in untreated and tamoxifen-treated patients. Immune related-functions contribute to tumor dormancy and late relapses. Assessment of immune markers might contribute in tailoring extended adjuvant endocrine treatment.

**531 Poster Highlights Session (Board #21), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase I/II study of letrozole and sorafenib as first-line therapy of hormone-receptor positive (HR+) metastatic breast cancer (MBC).** *Presenting Author: Antoinette R. Tan, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

**Background:** Preclinical studies show that addition of an antiangiogenesis agent improves efficacy of aromatase inhibition in hormone-sensitive breast cancer. Sorafenib is a multitargeted kinase inhibitor of VEGFRs, PDGFRs, FLT3, c-kit, and RAF. In this phase I/II multicenter study, the addition of sorafenib to letrozole as first-line therapy of HR+ MBC was evaluated. We previously reported the phase II dose to be letrozole 2.5 mg daily with sorafenib 400 mg BID. **Methods:** Eligible patients (pts) were postmenopausal, had measurable or evaluable HR+ MBC, and no prior therapy for metastases. Prior adjuvant tamoxifen (TAM) or aromatase inhibitor (AI) was allowed. The primary endpoint was clinical benefit rate (CBR= PR + SD $\geq$ 6 mo). The trial planned to enroll 58 pts to detect a CBR of $\geq$ 67% in a single-stage phase II design (80% power, $\alpha$ = .05). Secondary endpoints were progression-free survival (PFS) and overall survival (OS). **Results:** 54 pts (median age 54 yrs, range 21-84; median ECOG PS 0, range 0-2) were treated (13 pts in phase I) between 8/2008 – 12/2012 at which time the study closed due to slow accrual. 44% had de novo MBC, 39% pts had prior adjuvant TAM, 11% had prior adjuvant AI, and 2% had both prior TAM and AI. Median no. of cycles was 9 (range 1-62). The median daily dose of sorafenib was 400 mg. Most common gr 1-3 toxicities (%) were hand-foot skin (HFS) reaction (35%), hypertension (33%), rash (26%), diarrhea (19%), joint pains (15%), fatigue (13%), and alopecia (13%). 3 pts had HFS reaction that led to discontinuation of therapy. 5 pts had grade 2-3 rash that led to dose interruption. Of 41 pts evaluable for response, 39% (16 pts) had PRs and 41% (17 pts) had SD $\geq$ 6 mo. The CBR was 80.5% (95% CI: 65.1 - 90.9%). Median PFS was 20.2 mo (95% CI: 12.4 - 54.5 mo) and median OS was 51.5 mo (lower 95% CI: 44.7 mo). 11 pts continue on study with a median duration of 26 mo (range 14 – 60) and the median daily dose of sorafenib for these pts is also 400 mg. **Conclusions:** Letrozole combined with sorafenib was active in the treatment of HR+ MBC, and produced durable clinical benefit in a subset of pts as first-line therapy. Treatment benefit was still observed in pts who received lower than the recommended daily dose of sorafenib. Clinical trial information: NCT00634634.

**532 Poster Highlights Session (Board #22), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Clinical impact of differential risk stratification by breast cancer index (BCI) versus recurrence score (RS) in HR+ early-stage breast cancer: A TransATAC study.** *Presenting Author: Ivana Sestak, Queen Mary, University of London, London, United Kingdom*

**Background:** BCI is a genomic signature that significantly predicts risk of both early (0-5y) and late (5-10y) distant recurrence (DR) in HR+, LN- breast cancer. Previous results from the TransATAC study showed that both BCI and Oncotype Dx RS added significant prognostic information for 10y DR risk. Here, pre-defined risk stratification with BCI vs RS and its potential clinical impact were comparatively evaluated. **Methods:** 665 HR+, LN- patients were examined. BCI and RS risk groups were determined using pre-defined clinical cut-points. Kaplan-Meier estimates of 10y risk of DR and log-rank tests were used to examine cross-stratification between BCI and RS. Likelihood Ratio (LR) tests were used to quantitate relative prognostic information beyond CTS. **Results:** BCI re-stratification of the RS-Intermediate (RS-I) and RS-Low (RS-L) groups significantly impacted risk of 10y DR ($P=0.003$ and $P<0.001$), whereas RS did not significantly re-stratify BCI risk prediction (Table). BCI identified a small subset (20 pts in RS-L) with a high risk of DR (23.3%). Furthermore, BCI identified a large (95 pts in RS-I) and smaller (34 pts in RS-I) subset with 7.1% and 27.8% 10y DR risk, respectively. BCI added significant prognostic information beyond CTS+ RS ($p=0.0009$), whereas RS did not provide additional prognostic information beyond CTS+ BCI ($p=0.1$). **Conclusions:** In this retrospective analysis evaluating individualized risk stratification, BCI identified subsets of RS-L and RS-I LN- patients with significant and clinically distinct rates of DR. BCI identified a small subset of RS-L and RS-I LN- patients that would potentially benefit from additional therapy.

**Risk stratification and 10-year distant recurrence rates (%).**

| No. of patients | | BCI risk groups | | | | |
|---|---|---|---|---|---|---|
| | | Low | Inter | High | Total | P value |
| RS risk groups | Low | 283 (3.9%) | 85 (12.2%) | 20 (23.3%) | 388 (6.6%) | <0.001 |
| | Inter | 95 (7.1%) | 49 (24.3%) | 34 (27.8%) | 178 (15.8%) | 0.003 |
| | High | 12 (10%) | 32 (25.4%) | 55 (31.5%) | 99 (26.9%) | 0.2 |
| | **Total** | 390 (4.8%) | 166 (18.3%) | 109 (29.0%) | 665 | |

**Phase Ib study of LEE011 and BYL719 in combination with letrozole in estrogen receptor-positive, HER2-negative breast cancer (ER+, HER2− BC).** *Presenting Author: Pamela N. Munster, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

**Background:** Postmenopausal women with advanced ER+ BC are usually treated with aromatase inhibitors (AIs) as first-line therapy but resistance eventually develops. Dysregulation of the PI3K pathway and cyclin D kinases 4 and 6 (CDK4/6) has been implicated in resistance to endocrine therapy. LEE011 (a selective CDK4/6 inhibitor) and BYL719 (an $\alpha$-selective PI3K inhibitor) demonstrate clinical activity in ER+ BC as single agents. In ER+ BC xenograft models, LEE011 has demonstrated enhanced antitumor activity when combined with BYL719 and letrozole versus each agent alone, suggesting this combination may optimize treatment in ER+ BC. In the ongoing Phase Ib part of this study (NCT01872260), two doublet combinations, LEE011 + letrozole (Arm 1) and BYL719 + letrozole (Arm 2), and the triplet combination of LEE011 + BYL719 + letrozole (Arm 3), are explored in patients with ER+ BC. **Methods:** Postmenopausal women with locally advanced/metastatic ER+, HER2− BC not amenable to curative treatment by surgery/radiotherapy receive escalating doses of oral LEE011 QD (3-wks on/1-wk off) or BYL719 QD (continuous) and a fixed dose of letrozole QD (2.5 mg, continuous) in 28-day cycles. The primary objective is to estimate the MTD and/or RP2D of each combination by assessing DLTs in Cycle 1 using an adaptive Bayesian Logistic Regression Model (BLRM) guided by the escalation with overdose control (EWOC) principle. Secondary objectives include safety, PK and preliminary efficacy assessments. **Results:** As of Jan 31, 2014, 6 patients have been treated in Arm 1 (LEE011 600 mg + letrozole), and 1 DLT (G4 neutropenia) has been reported. Five patients have started treatment in Arm 2 (BYL719 300 mg + letrozole). Preliminary PK data are consistent with that for the respective single agents, with no evidence of drug–drug interactions. **Conclusions:** AIs are recommended as first-line endocrine therapy in postmenopausal patients with advanced ER+, HER2− BC, but most patients develop resistance. This is the first trial evaluating an AI in combination with a PI3K and CDK4/6 inhibitor in ER+, HER2− BC. Phase II will compare the preliminary antitumor activity of the doublets vs. triplet combinations. Clinical trial information: NCT01872260.

**534 Poster Highlights Session (Board #24), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**LY2835219, a novel cell cycle inhibitor selective for CDK4/6, in combination with fulvestrant for patients with hormone receptor positive (HR+) metastatic breast cancer.** *Presenting Author: Amita Patnaik, South Texas Accelerated Research Therapeutics (START) Center for Cancer Care, San Antonio, TX*

**Background:** Cyclin-dependent kinases 4 and 6 (CDK4/6) act with D-type cyclins to enable cell proliferation. LY2835219, a small molecule inhibitor of CDK4/6, has shown antitumor activity in xenograft models of multiple cancers. In a cohort of 47 patients (pts) with metastatic breast cancer (MBC) treated with LY2835219, there were 8 confirmed and 3 unconfirmed partial responses (PRs) among 36 pts with HR+ MBC. Fulvestrant is an anti-estrogen used to treat HR+ MBC. Thus, we expanded the Phase I study to evaluate LY2835219 plus fulvestrant for pts with HR+ MBC. **Methods:** We conducted a Phase I study to evaluate the safety, pharmacokinetics, and antitumor activity of LY2835219 in 5 different tumor types. For breast cancer, there were cohorts for both LY2835219 in MBC (n=47) and the combination of LY2835219 plus fulvestrant in HR+ MBC (n=13). Patients in the HR+ MBC combination cohort received LY2835219 at 200mg orally every 12 hours on Days 1-28 of a 28-day cycle plus fulvestrant at 500mg IM once monthly. CTCAE v4.02 was used to grade adverse events (AEs). RECIST v1.1 was used to assess tumor response. **Results:** In the HR+ MBC combination cohort, 13 pts with a median of 4 prior systemic therapies (range 2-8) received LY2835219 plus fulvestrant. Among these pts, the most common possibly related treatment-emergent AEs across all grades were diarrhea (including 8% G3), fatigue (8% G3), neutropenia (31% G3), nausea (no G3), vomiting (no G3), and leukopenia (23% G3); there were no Grade 4 events. LY2835219 dose reductions from 200mg to 150mg occurred in 8 pts, including 2 pts for diarrhea and 1 pt each for fatigue and neutropenia. Importantly, febrile neutropenia was not observed and there were no discontinuations due to toxicity. No serious AEs or deaths were reported. In HR+ MBC, LY2835219 demonstrated clinical activity (8 confirmed and 3 unconfirmed PRs) and also acceptable safety in combination with fulvestrant. **Conclusions:** LY2835219 demonstrates single-agent activity in MBC. For patients with HR+ MBC, the combination of LY2835219 plus fulvestrant shows acceptable safety and merits further clinical investigation for efficacy. Clinical trial information: NCT01394016.

**535 Poster Highlights Session (Board #25), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Phase Ib/II study of LEE011, everolimus, and exemestane in postmenopausal women with ER+/HER2-metastatic breast cancer.** *Presenting Author: Aditya Bardia, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

**Background:** Aromatase inhibitors (AIs) are the recommended first-line endocrine therapy for postmenopausal (PM) patients (pts) with ER+/HER2– advanced/metastatic breast cancer (aBC). However, resistance develops over time. Activation of the PI3K/AKT/mTOR pathway and downstream cyclin D–cyclin-dependent kinase (CDK4/6) has been implicated in endocrine-therapy resistance. Combination of the mTOR inhibitor everolimus (EVE) with exemestane (EXE) significantly improved PFS of pts with ER+/HER2– aBC (BOLERO-2), and preclinical data suggest that combination of EXE, EVE, and the CDK4/6 inhibitor LEE011 may be even more effective in endocrine-resistant ER+/HER2– BC. **Methods:** During Phase (Ph) Ib, PM pts with ER+/HER2– aBC are being treated with escalating doses of LEE011 (3 wks on/1 wk off), EVE (continuous), and a fixed daily dose of EXE (25 mg/d; continuous; arm 1); or with a safety run-in of LEE011 (600 mg/d; 3 wks on/1 wk off) and EXE (25 mg/d; continuous; arm 2) to confirm the recommended Ph II dose (RP2D). The primary objective of the Ph Ib part of the study is to determine the maximum tolerated dose and/or RP2D in arm 1. Safety, tolerability, and PK will also be assessed. Dose escalation is guided by a Bayesian Logistic Regression Model (BLRM) with overdose control principle. **Results:** As of Dec 12, 2013, 6 pts have been treated in arm 1 with 200 mg/d LEE011, 2.5 mg/d EVE, and EXE, and among the 5 pts evaluable for dose determination, no DLTs were observed. AEs observed to date have been mainly hematologic (as expected with a CDK 4/6 inhibitor) and mild to moderate.Preliminary PK suggest that LEE011 exposure in the presence of EVE is similar to that of single agent, while for EVE there was a 2-fold increase in exposure at steady state.Pts are currently being treated in arm 1 cohort 2 (300 mg/d LEE011, 2.5 mg/d EVE, and EXE) and in arm 2. **Conclusions:** To the best of our knowledge, this is the first trial evaluating an AI in combination with an mTOR and a CDK4/6 inhibitor. Preliminary data suggest that the triple combination of LEE011 + EVE + EXE is feasible. The exposure of EVE is slightly increased. In Ph II of the study, pts will be randomized to receive LEE011 + EVE + EXE, LEE011 + EXE, or EVE + EXE, and safety and efficacy compared. Clinical trial information: NCT01857193.

**536 Poster Highlights Session (Board #26), Sun, 8:00 AM-11:00 AM and 11:30 AM-12:45 PM**

**Whole-exome sequencing (WES) of HER2+ metastatic breast cancer (MBC) from patients (pts) treated with prior trastuzumab (T): A correlative analysis of TBCRC003.** *Presenting Author: Nikhil Wagle, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Although several large sequencing studies have elucidated the spectrum of genomic alterations in primary, treatment-naïve HER2+ cancers, the genomic landscape in metastatic tumors after progression on anti-HER2 therapy remains largely unknown. **Methods:** We performed WES on baseline metastatic tumor biopsies from 57 pts enrolled on TBCRC003 (NCT00470704), a phase II study evaluating combined lapatinib (L) and T that included pts with varying degrees of prior T exposure. Tumors were analyzed for point mutations, insertions/deletions, and copy number alterations. **Results:** Across 57 tumors, the median depth of coverage was 99-fold (range 37-160). The median number of coding mutations per sample was 55 (Range: 1-716). Significant recurrently mutated genes were *TP53* (n=30; 53%) and *PIK3CA* (n=19; 33%). The incidence of mutant *TP53* and *PIK3CA* was not significantly different from 104 primary, treatment-naïve HER2+ tumors sequenced in the TCGA study (53% and 28%, respectively). Comparing the 40 pts who received prior T with the 17 pts who did not, there was no significant difference in the incidence of mutant *PIK3CA* (35% vs 29%, p=0.8) and *TP53* (53% vs 53%, p=1.0). Significant recurrent copy number alterations included amplifications in *FGFR1, MYC, CCND1,* and *MDM2* and deletions in *NF1,* also similar to TCGA data. In 3/40 pts who had received prior T (8%), we identified a HER2 L755S kinase domain mutation. HER2 mutations have been seen in ~2% of HER2-negative cancers and <1% of primary HER2+ cancers. HER2 L755S has been shown to be resistant to L and sensitive to irreversible HER2 inhibitors. 5 additional pts, 2 of whom received prior T, had uncharacterized HER2 mutations at low allelic fractions, including a novel kinase domain mutation in a pt who had received prior T. No HER2 kinase domain mutations were seen in T-naïve pts. **Conclusions:** We present the first genomic landscape of HER2+ MBC using WES data. WES of matched primary tumor tissue is underway. The presence of HER2 mutations in pts with HER2+ MBC treated with prior T suggests that these mutations may be involved in the development of resistance to T. Novel therapeutic approaches may be required for these pts.

**537 General Poster Session (Board #1), Mon, 8:00 AM-11:45 AM**

**Total estrogen blockade and chemotherapy in high-risk premenopausal early breast cancer (BC): Long-term follow-up of a phase II study.** *Presenting Author: Francesco Recchia, Medical Oncology, Civilian Hospital, Avezzano, Italy*

**Background:** Estradiol ($E_2$) mediates two important functions of premenopausal patients with BC: the induction of vascular endothelial growth factor (VEGF) and the expansion of T-Regulatory cells (T-Regs). Both these functions are fundamental for breast cancer development. We hypothesized that, decreasing plasma $E_2$, we could reduce VEGF and T-regs, and therefore, we could decrease the recurrence rate in premenopausal patients with high risk early breast cancer. Primary endpoint of this study was the evaluation of VEGF and T-Regs; secondary end points were the 5 and 15-year disease-free survival (DFS) and overall survival (OS) rates. **Methods:** Between June 1997 and June 2007, 200 premenopausal high risk early BC patients were entered into the study. After surgery and before starting the chemotherapy, an LH-RH analogue was administered to all patients. Chemotherapy was tailored to the biological characteristics of each patient, followed by radiation therapy, and by an aromatase inhibitor in ER+ patients. **Results:** Median patient's age was 43 years (range 26-45). Mean number of positive axillary nodes was 3.2 (range 1-25). Seventy-one percent of patients were ER+, 29% were ER -, and median KI-67 was 30% (range 15% -100%). After a median follow-up of 104 months (range 63-180), $E_2$ was suppressed to values < 40 ng/ml. A statistically significant decrease of VEGF ($P<0.0001$) and T-Regs ($P<0.0001$) were observed. Five-year DFS and OS rate were 89% and 96%, respectively, while the 15-year DFS and OS rate were 62%, and 73%, respectively. ER+ patients had a better DFS ($P<0.05$) with respect to ER- patients, while no difference was observed in OS. No recurrence after 5 years was observed in ER- patients who had late new primaries. ER+ patients had recurrences even after 15 years. The standard pattern of toxicity of chemotherapy was observed, while hot flashes and G1 osteopenia occurred after LH-RH analogue administration. **Conclusions:** $E_2$ deprivation with an LH-RH analogue is able to decrease T-Regs and VEGF and to improve the expected DFS and OS rate in premenopausal high risk ER+ and ER- BC patients, at the price of a moderate toxicity.

**538 General Poster Session (Board #2), Mon, 8:00 AM-11:45 AM**

**Phase 1b study of orteronel in postmenopausal women with hormone-receptor positive (HR+) metastatic breast cancer.** *Presenting Author: Murtuza M. Rampurwala, University of Wisconsin Carbone Cancer Center, Madison, WI*

**Background:** Endocrine therapies are the treatment of choice for HR+ metastatic breast cancer; novel drugs are needed due to resistance. Reducing both androgens and estrogens may circumvent resistance by reducing androgen receptor stimulation. Orteronel is a selective, reversible, nonsteroidal inhibitor of the 17, 20-lyase enzyme (which generates androgens and estrogens). We conducted a phase 1b study of orteronel in HR+ metastatic breast cancer; the primary objective was the recommended phase 2 dose (RP2D) of orteronel in women. **Methods:** Key inclusion criteria were postmenopausal status and evaluable or measurable HR+ metastatic breast cancer. Doses escalated via standard 3+3 design. Initial dose was 300 mg BID and escalated to 400 mg BID (the RP2D in men). Cycle length was 28 days. Patients were evaluated every 8 weeks for progression. Correlative studies assessing hormone levels via liquid chromatography-mass spectrometry were performed. **Results:** Seven patients enrolled (median 56 yo, range 47-71). Patients were heavily pre-treated: 6 had prior endocrine therapy for metastatic cancer (median 4 lines, range 0-5) and 5 had prior chemotherapy regimens for metastatic cancer (median 2, range 0-5). Four received 300 mg BID at dose level 1 (1 was not evaluable per protocol); 3 received 400 mg BID at dose level 2. Orteronel was well tolerated: no dose limiting toxicities were observed. Common adverse events at least possibly related to therapy were: grade 1 hot flashes (28%), grade 1-2 nausea (28%), grade 1 hypokalemia (28%), and grade 1 elevated AST (28%). 6 patients received 14 cycles of treatment. 2 patients remain on therapy with evidence of clinical benefit: 1 with stable disease for > 6 months (best response) and 1 with stable disease for 3 months. **Conclusions:** Orteronel 400 mg BID is well tolerated in post-menopausal women, and significantly suppresses serum estrogens and testosterone. Clinical benefit was seen among heavily pretreated patients. Clinical trial information: NCT01808040.

**Mean levels ± standard deviation prior to and after orteronel.**

**539 General Poster Session (Board #3), Mon, 8:00 AM-11:45 AM**

**Identification of patients with hormone receptor–positive breast cancer who need adjuvant tamoxifen therapy for more than 5 years.** *Presenting Author: Chiao-En Wu, Division of Hematology-Oncology, Department of Internal Medicine, Chang Gung Memorial Hospital at Linkou, Taoyuan County, Taiwan*

**Background:** Extended hormonal therapy with tamoxifen for more than 5 years has improved disease-free survival (DFS) and overall survival (OS) in hormone receptor (HR)-positive breast cancer patients. However, this strategy in patients with a low risk of recurrence is controversial, since the benefits should outweigh the risk of endometrial cancer or thromboembolic disease. Therefore, we attempt to identify risk factors for late recurrence after 5 years of adjuvant tamoxifen therapy. **Methods:** Between 1990 and 2004, 1,104 HR-positive breast cancer patients who had received tamoxifen treatment at our institution at some point and had been disease free for at least 6 years were included in this analysis. Univariate and multivariate analyses of prognostic factors for late recurrence were performed using the binary logistic regression model. **Results:** During a median follow-up period of 10.9 years after surgery, 70 patients died and 99 showed recurrence. Patients aged <40 years, those aged >65 years, those with stage T2–4 tumors, those with positive lymph nodes, and those with positive estrogen receptor (ER) status had significantly higher rates of recurrence. In multivariate analysis, age < 40 years (odds ratio [OR] = 4.21, $P < 0.001$) and lymph node metastasis (OR = 2.67, 3.77, 6.10 for N1, N2, N3 *vs.* N0, $P < 0.001$) were associated with higher rates of recurrence. We stratified patients into high-risk (age < 40 years or positive lymph node status, 536 patients) and low-risk (age > 40 years and negative lymph node status, 566 patients) groups. The recurrence rates were 14.6% and 3.5% in the high-risk and low-risk groups, respectively. Patients in the high-risk group had poorer DFS (estimated 15-year DFS rate: 78% vs. 92.3%, $P < 0.01$) and OS (estimated 15-year OS rate: 83.1% vs. 92.6%, $P = 0.01$) than those in the low-risk group. **Conclusions:** Our findings suggest that HR-positive breast cancer patients either aged <40 years or with positive lymph node status were justified in continuing with tamoxifen therapy for more than 5 years.

**540 General Poster Session (Board #4), Mon, 8:00 AM-11:45 AM**

**A simple, validated model for identifying cases that are unlikely to benefit from the 21-gene recurrence score (RS) assay.** *Presenting Author: Michele Maiko Gage, Walter Reed National Military Medical Center, Bethesda, MD*

**Background:** Predicting recurrence risk and chemotherapy benefit in breast cancer can be challenging, and Onco*type*Dx (ODX) is often used to gain insight. Using readily available clinical information, a simple model was created to identify high and low risk patients, saving the expense of ODX testing. **Methods:** Clinical-pathologic data from 221 hormone positive, HER2-negative invasive breast cancer patients was used to create a model with two simple rules: Low Grade and Positive PR tumors (LG+PR) are low risk, and High Grade or Low ER (ER<20%) tumors (HG/LER) are high risk. The TAILORx trial thresholds of RS≤10, where chemotherapy is of limited benefit, (TXNC) and RS≥26 supportive of chemotherapy (TXC) were used to judge model performance. The model was then validated on an independent second institution's set of 319 patients. **Results:** Most HG/LER were RS≥26, (84% on development set, 51% on #2 set), and most LG+PR were RS≤18 (83%, 74%, respectively). Refer to Table for distribution. Impressively, the 2-Step Errors for HG/LER (RS ≤10) were 0% and 2%, and for LG+PR (RS≥26) were 0% and 2.6%, showing it is very unlikely for HG/LER to have a low risk test result or for LG+PR to have a high risk test result.In the validation set, 28% of the indeterminate group result as high or low risk; this group may clinically benefit from ODX. **Conclusions:** In HG/LER and LG+PR, ODX is not clinically valuable because it consistently results in a RS in which benefit of chemotherapy is accepted or unknown for HG/LER, and benefit of chemotherapy is rejected or unknown for LG+PR. The equal hazard ratios of RS and high grade, as evaluated by a multivariate Cox model (using age, pathologic variables, and RS) (Paik et al. NEJM '04), further support the importance of grade when predicting risk. By identifying patients who are unlikely to benefit from ODX testing, expense will be spared.

**Changes in androgen receptor (AR) expression and its phosphorylated isoforms, in breast cancer (BC) patients treated with neoadjuvant letrozole.** *Presenting Author: Angel Guerrero, Medical Oncology. Instituto Valenciano de Oncología, Valencia, Spain*

**Background:** Most of BC express the AR, and this is considered to be a good prognostic factor. However, AR signalling has also been implicated as a possible mechanism to aromatase inhibitors (AIs) resistance. Cell line models suggest a switch from estrogen to androgen-dependent growth as they become resistant to estrogen deprivation therapies. The goal of this study is to examine, in vivo, changes in AR and its phosphorylated sepecies during AI therapy, and to assess its potential role in outcome. **Methods:** Eighty four, consecutive, postmenopausal women, stage II-III primary estrogen receptor positive BC, were treated, in the same institution, with preoperatory letrozole between 2005 and 2012. Pre- and post-treatment BC tissues were examined by inmunohistochemestry for total AR and the phosphorylation of AR at serine 213 (pAR-S213) and serine 650 (pAR-S650). **Results:** Letrozole decreased the expression of pAR-S213, that was positive (H-score≥10) in 65% of pre-treatment samples vs 30% of post-treatment samples (p=0.001). No changes were observed for total AR (90% pre- vs 88% post-) and pAR-S650 (39% pre- vs 41% post-). Only pAR-S213 positivity after treatment was associated with a decreased rate of relapse free survival at 55 months (post-pAR-S213 negative: 90% vs post-pAR-S213 positive: 60%, p=0.0004), and remained significantly associated in a multivariate analysis including classic prognostic factors (PEPI score, Ki-67, ypTNM, ER). **Conclusions:** High expression of pAR-S213 after treatment with letrozole is associated with poor outcome, which suggest the possibility of therapeutic intervention with antagonist of AR activation.

**542 General Poster Session (Board #6), Mon, 8:00 AM-11:45 AM**

**Vitamin B12 (Vit B12) biochemical (BCH) deficiency (DEF) in non-diabetic breast cancer (BC) patients on NCIC CTG MA.32: A phase III randomized adjuvant BC trial comparing metformin (Met) to placebo (Pl).** *Presenting Author: Mira F. Liebman, University Health Network, University of Toronto, Toronto, ON, Canada*

**Background:** Met, a drug used to treat type 2 diabetes, is being evaluated as an anti-cancer agent. Long-term use is associated with BCH Vit B12 DEF in up to 30%; a subset may develop symptomatic DEF. It is unknown if Vit B12 DEF is due to diabetes or Met use. We examined Vit B12 DEF in NCIC CTG MA.32, an RCT of adjuvant Met vs Pl in non-diabetic BC patients (pts). **Methods:** This was a DSMC approved central lab analysis in the first 492 (of 3649) high risk N0/N1-3 BC pts receiving standard therapy randomized onto MA.32 (Met 850 mg bid vs Pl bid for 5 years). VitB12 was analysed in baseline and 6 month (mo) fasting plasma; levels <181 pmol/L were DEF, 181 to 221 pmol/L borderline. Methylmalonic acid (MMA) and homocysteine (HC) (elevated in clinical Vit B12 DEF) were assayed in those with Vit B12 levels <222 pmol/L at either time. Hgb was measured locally. Analysis used Spearman's rank correlation coefficients and Wilcoxon signed rank test for continuous variables and Chi-square test for 2 by 2 tables. **Results:** Mean age was 52.4±9.7 yrs. 237 received Met and 255 Pl; arms were balanced for hormone receptors (73% +ve), BMI (mean 28.3 kg/m$^2$), adjuvant chemo (88%), stage, type of surgery/radiation. Median (Inter Quartile Range) baseline Vit B12 was 390 (281 to 556) and 370 (290 to 552) pmol/L in the Met and Pl arms respectively (p=0.97). 6 mo median levels were MET 320 (244 to 419) and Pl 380 (286 to 546) pmol/L (p=0.0001). 15 pts (11 Met and 4 Pl) had BCH Vit B12 DEF (<181 pmol/L) at diagnosis; 15 Met and 3 Pl at 6 mo (p=0.004). Mean Hgb was similar at baseline 130.1±9.1 (MET) and 131.0±9.9 g/L (Pl), p=0.38 and 6 mo 131.3±9.5 (MET) and 132.7±9.6 g/L (Pl), p=0.11); and in those +/- BCH Vit B12 DEF. Of the 74 with Vit B12 <222 pmol/L (45 Met, 29 Pl), MMA was normal in all pts at baseline; 2 had elevated HC (>15 umol/L). At 6 mo 1 Met pt had MMA >0.4 umol/L and 3 (2 Met, 1 Pl) had HC >15 umol/L. **Conclusions:** There was an increased rate of BCH, but not clinical, Vit B12 DEF after 6 mo of Met. This suggests that Met (not diabetes) lowers VitB12 and supports recommendations to monitor Vit B12 with Met use. Longer follow-up will evaluate clinical VitB12 DEF. Clinical trial information: NCT01101438.

**543 General Poster Session (Board #7), Mon, 8:00 AM-11:45 AM**

**Predictive factors for late (>5 years) distant recurrences in estrogen receptor (ER)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer patients: >20-year follow-up.** *Presenting Author: Jaskirat Singh Randhawa, Cleveland Clinic/Fairview, Cleveland, OH*

**Background:** ER+ breast cancer (BC) by virtue of tumor dormancy can present with delayed recurrences, frequently years after initial diagnosis. **Methods:** Over 2,500 charts of ER+/HER2 negative BC patients were reviewed. Patients with follow up < 5 years, recurrence within 5 years and all local recurrences < or > 5 years were excluded. 35 late distant recurrences with minimum follow up of 5 years were identified. Data was analyzed with 50 patients without recurrences during same period. Following factors were used for analysis: age at diagnosis, tumor diameter, smoking history, T- and clinical stage at diagnosis, lymph node involvement (LNI), tumor-grade, histology, progesterone receptor(PR) status, duration of adjuvant therapy and treatment modalities. Recurrence and time to recurrence were assessed. Wilcoxon rank sum, Kruskal-Wallis tests and Chi-square tests were used for univariate analyses. Multivariate analysis was conducted using logistic regression and proportional hazards models. **Results:** The median/mean age at diagnosis was 58/58.5 years and median/mean age at relapse was 63/65.5 years respectively. Tumor size, T-stage at diagnosis, and duration of adjuvant therapy were associated with late relapse (p≤0.025, p≤0.012, p≤0.037 respectively). T-stage at diagnosis was only independent predictor identified; with an estimated odds ratio of 2.62 (95% CI: 1.22, 5.64) and an estimated hazard ratio of 2.22 (95% CI: 1.32, 3.72). No other significant association was detected (age at diagnosis; p≥0.21, tumor-grade; p≥0.27, histology; p≥0.17, smoking history; p≥0.79, LNI; p≥0.08, PR status; p≥0.58). Of patients with recurrent disease, 40% showed identical receptor profile and 11.4% had receptors changed/different from their initial diagnosis. **Conclusions:** In univariate analysis, the tumor diameter, T-stage at diagnosis and duration of adjuvant therapy are associated with both recurrences and time to relapse. Patients who received adjuvant therapy ≥ 5 years had decreased rate of late recurrences. In multivariate analysis, T-stage at diagnosis is the only independent predictor.

**544 General Poster Session (Board #8), Mon, 8:00 AM-11:45 AM**

**IGF-1 receptor activation and intrinsic tamoxifen resistance in postmenopausal breast cancer patients.** *Presenting Author: Karin J. Beelen, Netherlands Cancer Institute, Amsterdam, Netherlands*

**Background**: Elevated insuline-like growth factor 1 receptor (IGF-1R) signaling activates the phosphatidylinositol-3-kinase (PI3K) and mitogen-activated protein kinase (MAPK) pathways and results in hormone indepedent cell growth in vitro, rendering cells resistant to anti-estrogens. The clinical validity of IGF-1R signaling to predict resistance to adjuvant anti-estrogen therapy has not been well established.We tested the predictive value of IGF-1R activation to predict adjuvant tamoxifen resistance in postmenopausal breast cancer patients. **Methods**: We collected primary tumor blocks from 563 ER$\alpha$ positive (stage I-III) postmenopausal patients who had been randomized between tamoxifen (1 to 3 years) vs. no adjuvant therapy (IKA trial). The median follow-up of patients without a recurrence event was 7.8 years. Immunohistochemistry was performed on a tissue microarray using monoclonal antibodies for IGF-1R and phosphorylated(p)-IGF-1R. Cytoplasmic p-IGF-1R and membranous IGF-1R intensity were scored (0-3). To assess IGF-1R activation the ratio p-IGF-1R/ IGF-1R was calculated. Multivariate Cox models including standard prognostic factors were used to assess hazard ratios (HRs) for recurrence free interval and the interaction between tamoxifen treatment and IGF-1R activation, using the median ratio as cutoff. In addition we tested the association between the ratio p-IGF-1R/ IGF-1R and downstream-activated proteins in the PI3K and MAPK pathways. **Results**: Patients with a tumor with a low p-IGF-1R/ IGF-1R ratio ($\leq$ 0.5) derived significant benefit from tamoxifen (HR 0.41, p=0.001), while patients whose tumor did express a high ratio did not (HR=1.47, p=0.53), p for interaction 0.05. Significant positive associations were observed between the p-IGF-1R/ IGF-1R ratio and p-AKT, p-ERK1/2, p-mTOR and p-p70S6K. **Conclusions**: In postmenopausal primary breast cancer patients, IGF-1R activation is associated with downstream PI3K and MAPK pathway activation and intrinsic tamoxifen resistance. A potential benefit from IGF-1R inhibitors in these tamoxifen resistant patients would be interesting to explore.

**545 General Poster Session (Board #9), Mon, 8:00 AM-11:45 AM**

**Enzalutamide plus exemestane: A pilot study to assess safety, pharmacokinetics, and effects on circulating estrogens in women with advanced hormone-positive breast cancer.** *Presenting Author: Lee Steven Schwartzberg, The University of Tennessee Health Science Center, Memphis, TN*

**Background:** Exemestane (EXE) is a commonly used aromatase inhibitor (AI) in patients (pts) with advanced ER/PgR+ breast cancer (BC). The androgen receptor (AR), expressed in the majority of ER/PgR+ BC, is believed to play a role in resistance to AI therapy. Enzalutamide (ENZA), a potent inhibitor of AR signaling, induces CYP3A4, an enzyme involved in the metabolism of EXE. We previously reported that the addition of ENZA (160 mg/day) to EXE 25 mg/day resulted in ~40% reduction in EXE exposure. The US product label recommends doubling the dose of EXE when administered in combination with a potent CYP3A4 inducer. This trial investigates daily ENZA 160 mg + EXE 50 mg. **Methods:** Postmenopausal pts with ER/PgR+ advanced BC received $\geq$14 days of EXE 50 mg/day prior to initiating ENZA 160 mg/day on Day 1 (NCT01597193). Prior EXE and non-measurable disease was allowed. Blood sampling occurred on Day -1 (no ENZA) and on Day 29 (+ ENZA) to assess PK interactions and effects on circulating estrogens (estradiol and estrone). Available tumor tissue was analyzed centrally for AR expression although AR+ disease was not required. Response assessments (RECIST 1.1) were performed approximately every 3 months. **Results:** As of 11 Dec 2013, data were available for 18 of the 24 pts enrolled. Median age/ECOG was 66/0; median number of prior hormonal therapies was 2.5. Common (>10%) treatment-related adverse events (AEs) included nausea, vomiting and fatigue. No treatment-related serious AEs or AEs $\geq$ Grade 3 have been reported. Preliminary data indicate that ENZA + EXE 50 mg achieves similar EXE exposure to EXE 25 mg alone (AUC=127$\pm$70 vs. 131$\pm$64 ng.h/mL) and maintains estrogen suppression for the majority of pts. Full data on PK, tolerability, estrogen levels and anti-tumor activity will be presented. **Conclusions:** To date, the combination of daily ENZA 160 mg + EXE 50 mg has been well tolerated. Doubling the dose of EXE appears to restore EXE exposure thereby maintaining the suppression of estrogens. An ongoing randomized double-blind, placebo-controlled phase 2 trial in ER/PgR+ advanced BC will determine if the combination of daily ENZA 160 mg + EXE 50 mg is more active than EXE 25 mg alone. Clinical trial information: NCT01597193.

**546 General Poster Session (Board #10), Mon, 8:00 AM-11:45 AM**

**Effect of multifocality and multicentricity on outcome in early breast cancer: A systematic review and meta-analysis.** *Presenting Author: Francisco Emilio Vera-Badillo, Princess Margaret Cancer Centre - University Health Network, Department of Medicine, University of Toronto, Toronto, ON, Canada*

**Background:** Women with multifocal or multicentric breast tumors (multifocality henceforth) have been reported to have greater probability of nodal metastasis and relapse and worse survival than women with unifocal tumors. However, these associations have been inconsistent and multifocality is not taken into account by staging guidelines and prognostic models. **Methods:** A systematic review of Medline and EMBASE (host: Ovid) from 1946 to July 2013 identified publications exploring the association between multifocality and overall survival (OS), disease-free survival (DFS), disease-specific survival (DSS) and loco-regional relapse (LRR). The hazard ratios (HR) for OS and DFS for multifocal compared to unifocal tumors were extracted from multivariable analyses and included in a meta-analysis. For studies not reporting multivariable analyses, odds ratios (OR) were estimated from Kaplan-Meier curves for all endpoints at 5 and 10 years. **Results:** Twenty-two studies comprising 67,557 women were included. Multifocality was reported in 9.5% of patients. Classical prognostic factors were well balanced between unifocal and multifocal populations. In multivariable analyses, multifocality was associated with significantly worse OS (HR=1.65, p=0.02), and a non-significant association with worse DFS (HR=1.96, p=0.07). Inter-study heterogeneity was significant (Cochran Q p<0.001 in both analyses). Similar results were observed for the odds of death or disease recurrence by 5 years (OR=1.39, p=0.02; OR=1.52, p=0.02, respectively). Additionally, multifocality was associated with worse DSS and a higher odds of LRR (OR=1.56, p=0.03; and OR=3.23, p=0.02, respectively). Similar estimates were observed at 10 years but statistical significance was only reached for DSS and LRR (OS: OR=1.40, p=0.07; DFS: OR=1.49, p=0.06; DSS: OR=1.69, p<0.001; LRR: OR=2.94, p=0.03). **Conclusions:** Multifocality appears to be associated with a worse prognosis. Substantial inter-study heterogeneity limits the precise determination of increased risk; however, the inclusion of multifocality as an independent prognostic factor appears warranted.

**547 General Poster Session (Board #11), Mon, 8:00 AM-11:45 AM**

**Association between androgen receptor (AR) expression, Ki-67, and the 21-gene recurrence score in early breast cancer.** *Presenting Author: Francisco Emilio Vera-Badillo, Princess Margaret Cancer Centre - University Health Network, Department of Medicine, University of Toronto, Toronto, ON, Canada*

**Background:** AR expression is a favorable prognostic factor in estrogen receptor (ER) positive and ER negative breast cancer. Here we explore the association between AR, Ki67, and the 21-gene recurrence score (RS). We hypothesized that ER-positive breast cancers with high AR expression will be associated with a low Ki67 and RS. **Methods:** Sequential patients with lymph node negative, ER positive and HER2 negative breast cancer who had surgery at Mount Sinai Hospital, Toronto between January 2010 and October 2013 and in whom the RS was requested were identified. Archival tissue was sectioned and stained for AR (AR441 clone, Dako) and Ki67 (MIB-1 clone, Dako) and then visualized by protein polymer (MACH4, Biocare) and DAB chromogen. AR was scored using the Allred system and Ki67 by manual count (using the Ki67 working group recommendations) by a single pathologist. Associations between RS and AR, age, grade, mitotic score, Ki67, and the extent of ER and progesterone receptor (PgR) expression were assessed using linear regression. Ki67 was assessed as a continuous and dichotomous variable (using a cut off of 14%). Statistical significance of this exploratory study was defined as p<0.10. **Results:** Seventy cases satisfied criteria for analysis. Median age was 59.5 years, mean tumor size was 1.8 cm (range 0.6-3.9 cm), 24% were grade 1, 66% grade 2 and 10% grade 3. Most tumors had high AR expression (median Allred score = 8, 97% had score $\geq$4). Median RS was 15 (range 1-53). AR expression showed a modest positive correlation with ER (R=0.37), but no correlation with PgR (R=0.09) or Ki67 (R=-0.18). In univariable analysis, AR (p=0.01), ER (p<0.001) and PgR (p<0.001) had significant negative associations with the RS. Ki67 had a non-significant positive association with RS (p=0.11 and p=0.16 for continuous and cut off analyses, respectively). Age (p=0.93), grade (p=0.40) and mitotic count (p=0.23) showed no association with RS. Multivariable analysis showed similar associations with RS (AR [p=0.07], ER [p=0.05], PgR [p=0.001]). **Conclusions:** AR is not associated with proliferative index (Ki67) but is associated with lower probability of disease recurrence (Low RS).

**548^ General Poster Session (Board #12), Mon, 8:00 AM-11:45 AM**

**First-line pertuzumab (P), trastuzumab (H), and taxane therapy for HER2-positive locally recurrent/metastatic breast cancer (LR/mBC): Interim safety results (N=704) from PERUSE.** *Presenting Author: Thomas Denis Bachelot, Département d'Oncologie Médicale, Centre Léon Berard, Lyon, France*

**Background:** Combining P with 1st-line H + docetaxel (DOC) in pts with HER2-positive mBC significantly improved progression-free survival (PFS) and overall survival (OS) in the randomized phase III CLEOPATRA trial. PERUSE is assessing the safety of 1st-line P + H + investigator's chosen taxane in routine oncology practice. **Methods:** In the ongoing multicenter single-arm phase IIIb PERUSE study, pts with HER2-positive LR/mBC, ECOG PS ≤2 and no prior systemic therapy for LR/mBC (except endocrine therapy) receive P (840→420 mg q3w), H (8→6 mg/kg q3w) and a taxane (DOC, paclitaxel [PAC] or nab-PAC) until disease progression (PD) or unacceptable toxicity. Pts will be followed until 45 mo after last pt enrollment. The primary endpoint is safety, including grade (G) ≥3 AEs. Secondary endpoints include PFS, OS, objective response rate and QoL. We report a prespecified interim analysis reviewed by the Independent Data Monitoring Committee. **Results:** As of 13 Sep 2013, 704 of the planned 1500 pts had completed ≥6 weeks' follow-up. Baseline characteristics: median age 55 y (range 26–87); 26% ≥65 y; 76% Caucasian; 61% ECOG PS 0; 32% stage IV at 1st diagnosis; 73% visceral metastases; 67% ER and/or PgR positive; 29% prior (neo)adjuvant H; 43% prior (neo)adjuvant chemotherapy. The initial taxane was DOC in 320 pts (45%), PAC in 331 (47%) and nab-PAC in 45 (6%). The median number of cycles was 9 (range 1–23) for P, 8 (1–23) for H and 6 (1–21) for each taxane; 81% of pts are still receiving ≥1 study therapy. Therapy was discontinued most often for PD (P 7%, H 7%, taxane 4%) and for AEs in 4% (each agent). **Conclusions:** The safety profile of P + H + investigator's choice of taxane in this interim safety analysis is consistent with previous clinical experience of P + H + DOC. No unexpected safety signals were seen. Safety data by taxane will be reported. Clinical trial information: NCT01572038.

**Combined IHC4 score and local recurrence in breast cancer.** *Presenting Author: Roopa Lakhanpal, Department of Radiation Oncology, The Canberra Hospital, Canberra, Australia*

**Background:** The immunohistochemical 4 (IHC4) score is a pathological prognostic score that is a quantative measurement of estrogen and progesterone receptor status, the her2 status and the Ki-67 score. Cuzick et al. created a prognostic model that integrates IHC4 with clinical parameters of nodal status, tumour size, grade and age that may be as useful prognostically as multiple gene expression profiling assays (Cuzick et al J Clin Oncol. 2011 Nov 10;29(32):4273-8.). The role of the IHC4 score in predicting local recurrence is evolving. This study explores the role of the combined IHC4 score and loco-regional recurrence in women who have had breast conservation surgery without radiotherapy. **Methods:** Women with invasive breast cancer treated with breast conservation surgery and no radiotherapy were selected from a prospective cohort of breast cancer patients enrolled in the Australian Capital Territory and South East New South Wales Breast Cancer Treatment Group (ACT&SE NSW BCTG) Quality Assurance Project from 1997-2010.The IHC4 parameters were scored using pathology reports, slide review, and conducting further IHC testing when data was missing. Clinical information was obtained from the database and combined scores were calculated using the formula described by Cuzick. A Cox regression model was used to assess the association between the combined score and the risk of loco-regional recurrence. **Results:** Fifty-nine women in whom all the IHC4 variables were quantified and who had breast conservation surgery, were ER positive and who did not have adjuvant radiotherapy or chemotherapy were used to test the model. Using the same cut-off points and patient selection criteria for the combined IHC4 score described by Cuzick for low, intermediate and high risk groups, the loco-regional recurrence rates were zero for the low risk group(n=34), 23.5% in the intermediate group (n=17), and 37.5% in the high-risk group (n=8). Local recurrence tended to occur within 5 years for the high-risk group and beyond 5 years in the intermediate group. **Conclusions:** The combined IHC4 clinical effectively defined a sub-group of women with breast cancer treated with breast conservation surgery without radiotherapy that had negligible local recurrence rates.

**550 General Poster Session (Board #14), Mon, 8:00 AM-11:45 AM**

**Comparison of test results and clinical outcomes of patients assessed with both MammaPrint and Oncotype DX with pathologic variables: An independent study.** *Presenting Author: David J. Dabbs, Department of Pathology, Magee Women's Hospital, Pittsburgh, PA*

**Background:** There are no comparisons between test results of MammaPrint and Oncotype DX. **Methods:** Oncotype DX (ODX) recurrence score (RS) on 437 patients with pathologically characterized ER+ tumors who had a minimum of 5 years follow-up from diagnosis was compared with MammaPrint (MP), BluePrint (BP) and TargetPrint (TP). **Results:** Of 301 MP low risk cases, 191 were low risk by ODX (63% agreement) and of 136 MP high risk, 63 were high risk by ODX (46%). Of ODX intermediate risk cases (161), 104 of were MP low risk (65%), 57 (35%) were MP high risk. Of BP low risk luminal tumors, 188/287(66%) were ODX low, 95/287 (33%) ODX intermediate, and 4/287 (1%) ODX high risk (Table). Tumor grade was significantly correlated at P<.0001 with risk assessment by both tests. BP class was correlated with ER, PR and HER2 results. Overall agreement between clinical ER, PR, HER2 (IHC+FISH) results with TP results were 92% (401/435), 85% (370/436), 95% (412/435), but percent positive agreement for HER2 was only 50% (20 of 40 unequivocally HER2 positive cases identified correctly by TP). Four percent of ODX low risk, 34% of intermediate and 77% of ODX high risk ODX patients received chemotherapy. There were 7 distant recurrences: 4 were MP high, 3 MP low; For ODX, 5 were intermediate, 1 high,1 low (Table). **Conclusions:** (1) There are real differences in risk assignments between MP and ODX that may affect treatment decisions. (2) There was close correlation between pathologic variables and MP and BP, but HER2 TP -FISH/IHC agreement is low. (3) Further follow-up of this cohort is required, along with prospective trials, to determine clinical utility of these tests compared to pathologic analysis.

* Distant recurrences.

**551 General Poster Session (Board #15), Mon, 8:00 AM-11:45 AM**

**Adjuvant denosumab for breast cancer: What efficacy in the D-CARE trial will translate into cost effectiveness?** *Presenting Author: Nathan William Dana Lamond, Department of Medicine, Dalhousie University, Halifax, NS, Canada*

**Background:** Bone targeted agents are important therapies in the treatment of metastatic breast cancer and have a potential role in the adjuvant setting. Several trials and metaanalyses have suggested that adjuvant bisphosphonates may reduce breast cancer recurrence rates by 15% or more in postmenopausal women. Adjuvant denosumab is currently being investigated in D-CARE, an ongoing phase III trial. The aim of the current study was to estimate the absolute disease-free survival (DFS) advantage that would have to be observed in D-CARE for adjuvant denosumab to be considered cost-effective in the Canadian healthcare system. **Methods:** A Markov model was developed to calculate cumulative lifetime costs and quality-adjusted life year (QALY) gains for adjuvant therapy with and without denosumab in a hypothetical cohort of women with early-stage breast cancer. Costs, utilities and probabilities were derived from the literature. A one-way sensitivity analysis (SA) was performed to explore the relationship between a range of DFS hazard ratios (HR) and incremental cost-effectiveness ratios (ICER) with all other parameters held constant. Further one-way and probabilistic sensitivity analyses were performed to explore the effects of changes to other model parameters including menopausal status. The model took a direct payer perspective with all costs and benefits discounted at 3%. **Results:** The one-way SA showed that the ICER for adjuvant denosumab was directly related to the HR for DFS. At an ICER threshold of $100,000/QALY, the corresponding DFS HRs were 0.94 and 0.89 for pre and postmenopausal breast cancer patients, respectively. The ICER also varied with changes to other model parameters, but was stable over reasonable ranges of uncertainty. **Conclusions:** This model suggests that adjuvant denosumab will be considered cost-effective by current North American standards, should it reduce breast cancer recurrence rates by more than approximately 10%. In the event of positive results from D-CARE of at least this magnitude, the current anticipatory analysis may help inform treatment choices, influence drug funding decisions, and provide patients with timely access to disease-modifying therapy.

**552 General Poster Session (Board #16), Mon, 8:00 AM-11:45 AM**

**Cardiology monitoring substudy in the PERSEPHONE trial: 6 versus 12 months of trastuzumab.** *Presenting Author: Louise Hiller, Warwick Clinical Trials Unit, University of Warwick, Coventry, United Kingdom*

**Background:** PERSEPHONE is a randomised trial comparing 6month (6m) to 12month (12m) of trastuzumab in patients (pts) with HER2-positive early breast cancer. The trial has recruited 3,166 of 4,000 pts. We report the results of the cardiology monitoring substudy, which the iDSMC reviewed in June 2013 and recommended we release. **Methods:** Left ventricular ejection fraction (LVEF) was measured prior to trastuzumab, and then 3-monthly for 12 months (x5). Low LVEF was defined as either <50%, or reported as 'low'. **Results:** 11,413 LVEF tests have been reported in 2,484 pts (see Table). Only 10% pts reported low LVEFs, similar across arms (p=0.19). In total, only 483 low LVEFs were reported. There was no difference in time to first low LVEF between treatment arms (log-rank p=0.49). On each treatment arm, there were statistically significant reductions in LVEF % at 6 and 12 months (all p<0.0001). Significantly more 12m pts reported delays (p=0.007) and discontinuations (p<0.0001) due to low LVEFs. **Conclusions:** Both PERSEPHONE arms are considered safe, with only small relative reductions in LVEF. Duration of treatment has no effect on numbers of pts reporting low LVEFs or time to first low LVEF. However the longer treatment suffers from more delays and discontinuation due to low LVEFs. Low LVEF may relate more to pt factors (e.g.pharmacogenetics), than length of treatment. The data support, and the iDSMC now recommend, less intensive cardiology monitoring during treatment. Clinical trial information: 52968807.

**A phase I study of the AKT inhibitor MK-2206 plus hormonal therapy in postmenopausal women with estrogen receptor positive (ER+) metastatic breast cancer (MBC).** *Presenting Author: Cynthia X. Ma, Siteman Cancer Center, Washington University School of Medicine, St. Louis, MO*

**Background:** Inhibition of the PI3K/AKT pathway synergize with hormonal therapy for ER+ BC in preclinical studies. We conducted a phase I trial of MK-2206 plus anastrozole (A) (Phase IA and IB) or fulvestrant (F) (Arm C) or A+F (Arm D) in postmenopausal women with ER+ MBC to obtain the recommended phase II treatment dose (RPTD). **Methods:** phase IA employed a 3+3 design to determine the maximum tolerated dose (MTD) of MK-2206. Pts treated at the MTD were eligible for Phase IB to determine RPTD based on first 3-cycle adverse events (AE). Arms C and D evaluated whether MK-2206 at the RPTD was tolerable when combined with F or A+F. Cycle 1 day 1 (C1D1) MK-2206 began after at least 2 weeks (wks) of A and/or 4 wks of F. FDG PET was performed in Phase IA on C1D1 prior to MK-2206 and C1D2. Tumor was measured every 3 28-day cycles. Baseline blood was assayed for PIK3CA E545K and H1047R mutations. **Results:** Thirty one pts, median age 55 (range 32-79) years, were enrolled (Table 1). MK-2206 was administered PO wkly, with A and/or F. Because grade (G)3 rash occurred in 3 of the first 8 pts, prophylactic prednisone was added subsequently. Treatment was well tolerated. G3 rash was the only dose limiting toxicity (DLT). The most common all-cycle AEs were rash (n=10), hyperglycemia (n=11), and hypophosphatemia (n=5). The MTD and RPTD of MK-2206, plus A and/or F, were 150mg PO wkly with prophylactic prednisone. Median SUV reduction was 14.5% (-58% to 19%) on C1D2 compared to C1D1. Twenty six pts, with a median of 1 (0-7) metastatic therapy, were evaluable for response. Eleven pts, 42% (95% CI 23% - 63%), derived clinical benefit, including 2 PR and 9 SD >= 6 months. Time to progression was significantly associated with prior adjuvant hormonal therapy (p=0.02), but not with circulating PIK3CA mutation or hyperglycemia. Tumor specimen analysis is ongoing. **Conclusions:** MK-2206 plus hormonal therapy was well tolerated with anti-tumor activity observed. Rash was common but incidence reduced with prophylactic prednisone. Clinical trial information: NCT01344031.

**Intracellular intermolecular relationships of LKB1 in breast cancer.** *Presenting Author: Binafsha Manzoor Syed, Liaquat University of Medical & Health Sciences Jamshoro, Jamshoro, Pakistan*

**Background:** The role of liver kinase B1 (LKB1), a serine/threonine kinase, has been described in the development of Peutz Jagher's syndrome, where a large proportion (45%) of patients have been reported to develop breast cancer in their life time. Cell line studies have also shown a link of LKB1 with the action of oestrogen, metformin and diabetes. This study aimed to analyse the intracellular molecular relationships of LKB1 in older women with early operable primary breast cancer. **Methods:** Between 1973-2010, a consecutive series of 1,758 older (≥70 years) women with T0-2 N0-1M0 breast carcinoma were managed in a dedicated facility. Of these 813 patients underwent primary surgery and 575 had good quality tumour samples available for tissue microarray construction. LKB1 was assessed by indirect immunohistochemistry using Ley37D/G6-ab15095/Abcam (primary antibody) and Envision method (secondary antibody). Tumours having 30% of cells with cytoplasmic expression were considered positive. **Results:** Positive LKB1 was seen in 318 (78.1%) patients. Such expression was significantly associated with high tumour grade (p=0.01), positive expression of HER2 (p=0.003), Ki67 (p=0.01), VEGF (p=0.002), HER4 (p=0.001), BRCA2 (p=0.01), MDM2 (p<0.001) and negative expression of CD44 (p=0.03). However there was no significant correlation with tumour size, axillary lymph node status, ER, PgR, p53, cytokeratins 5, 5/6, 14, 17, 18 and 19, bcl2, Muc1, EGFR, HER3, MDM4, E-cadherin, and BRCA1. **Conclusions:** LKB1 showed strong correlations with most biomarkers known to be associated with poor prognosis. Given the evidence from cell line studies mentioned, further studies are required to explore its relationship with clinical outcome and its role as a potential therapeutic target.

**555 General Poster Session (Board #19), Mon, 8:00 AM-11:45 AM**

**Estrogen receptor-positive (ER+) metastatic breast cancer (MBC) patients (pts) with extreme responses (ERs) to capecitabine having tumors with genomic alterations in DNA repair and chromatin remodeling genes.** *Presenting Author: Maren K. Levin, Baylor-Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX*

**Background:** We sought to understand the genomic alterations in tumors of MBC pts who had extreme durations of response to capecitabine (C). **Methods:** Following IRB-approved informed consent, targeted next generation sequencing (NGS) was performed on pts' FFPE primary breast cancer (n=4) or MBC (n=2) specimens at a CLIA-certified laboratory to characterize genomic alterations across 287 cancer-related genes. Reverse phase protein microarray (RPMA) was also performed. **Results:** Six postmenopausal pts with ER+/HER2- MBC and ERs with C were studied. Metastases comprised bone/lymph node (n=1) or liver (n=5; liver only, liver/bone, liver/bone/chest wall). Four pts had received ≥2 prior chemotherapy regimens for metastatic disease. Four pts received C + paclitaxel (mean 17 mos; range 4–57); three of these then continued C alone (mean 86 mos; range 59–118). Two pts received C monotherapy (54 and 91+ mos). C was discontinued after a mean of 66 mos in four pts (range 54–86); two pts remain on C (91+ and 122+ mos). On NGS, 50% (3/6) of pts' tumors had likely functional alterations in DNA repair and chromatin remodeling genes (Table) – a higher than expected prevalence in ER+ MBC. Three pts had variants of unknown significance (VUS) in these pathways. *PIK3CA* substitutions or amplifications of *AKT2, FGFR1, ZNF703*, as well as phosphorylation of HER family receptors and their downstream proteins on RPMA did not appear to preclude ERs to C. **Conclusions:** Three MBC pts with ERs to C (54–122+ mos) had genomic alterations in DNA repair pathways (double strand break response and homologous recombination) and in histone acetyl- and methyltransferase genes. We are exploring the potential function of the VUS in the other three pts. Preclinical data show that sensitivity to 5-FU is enhanced by deficiencies in chromatin remodeling and homologous recombination genes (Matuo, et al. Genet Mol Res, 2013), suggesting a strategy for pt selection for C.

**A phase II clinical trial of HDACi (vorinostat) and AI therapy in breast cancer with molecular imaging correlates.** *Presenting Author: Hannah M. Linden, University of Washington, Seattle, WA*

**Background:** Histone deacetylase inhibitors (HDACi) have shown preclinical promise in estrogen receptor-modulation and restoring sensitivity to endocrine manipulation in ER+ breast cancer. Vorinostat is an FDA approved HDACi for CTCL, and could have a beneficial role in restoring ER-signaling in endocrine-resistant tumors. [F-18]fluoroestradiol (FES) PET imaging may be used to monitor regional ER expression in patients with breast cancer. **Methods:** Patients with metastatic breast cancer with prior clinical benefit from endocrine manipulation and who progressed on AI therapy were eligible. In part A patients cycled between vorinostat for 2 wks, and AI for 6 wks. In part B (reflecting results of HDACi trials) patients were given vorinostat 400mg po daily 5/7 days 3/4 wks while AI was given continuously. Paired FES and FDG PET were performed at baseline, wks 2 and 8; clinical/radiologic assessment of disease was also performed at wk 8. Patients with clinical benefit (response or stable disease) continued on treatment until progressive disease or study withdrawal. Lesion-level analysis of the association between baseline FES uptake (logged) and FES/FDG ratio used generalized estimating equations (GEE). **Results:** 16 of 20 planned patients have accrued and treatment is well tolerated; one withdrew for toxicity. The majority of patients have longstanding, bone/soft tissue dominant disease, and were previously treated with multiple endocrine and chemotherapy regimens. Six patients have had clinical benefit (4/8 evaluable on part B), remaining on study treatment for >40, 29, >21, and >8 wks. FES and FDG uptake was analyzed in 101 lesions in 16 patients. FES uptake in general remained stable during treatment and FDG declined in responding patients. Two responding patients showed increase in FES with clinical benefit and two patients with clinical benefit had negligible pre-therapy FES uptake. **Conclusions:** HDACi therapy can be effective in hormone-refractory breast cancer. Molecular imaging in parallel with early studies indicate a heterogeneity of response patterns, suggesting that some patients benefit from AI plus vorinostat, and some may benefit from the HDACi alone. Clinical trial information: NCT01153672.

**557 General Poster Session (Board #21), Mon, 8:00 AM-11:45 AM**

**Patient-reported endocrine symptoms, sexual functioning, and quality of life (QoL) in the IBCSG TEXT and SOFT trials: Adjuvant treatment with exemestane (E) plus ovarian function suppression (OFS) versus tamoxifen (T) plus OFS in premenopausal women with hormone receptor-positive (HR+) early breast cancer (BC).** *Presenting Author: Juerg Bernhard, International Breast Cancer Study Group, Bern, Switzerland*

**Background:** Little is known about endocrine symptoms, QoL and sexual function in premenopausal women with BC receiving adjuvant endocrine therapy. TEXT and SOFT are the first trials providing patient-reported data in this population. **Methods:** From Nov 2003 to Apr 2011, 4096 premenopausal patients (pts) with HR+ BC were enrolled and included in the QoL analysis of the randomized phase III trials, TEXT and SOFT, to receive adjuvant treatment with 5 yrs E+OFS or T+OFS. Chemotherapy (chemo) was optional in both trials; received concurrently with OFS after randomization in TEXT and prior to randomization in SOFT, with women eligible if they remained premenopausal after completing chemo. Pts completed a questionnaire consisting of global and symptom-specific indicators at baseline, every 6 months for the first 24 months, and annually yrs 3 to 6. Differences in change of QoL from baseline between the two treatments were tested at short-, mid-, and long-term (6, 24 and 60 months post-randomization, respectively) for 3 global QoL and 5 symptom indicators using mixed models with repeated measures. **Results:** Pts on T+OFS were significantly more affected by hot flushes than E+OFS, with treatment difference persisting over time (each $p<.05$). The change of hot flushes from baseline improved over time for both treatments. Throughout treatment, pts on E+OFS reported more vaginal dryness and greater loss of sexual interest, while T+OFS reported more vaginal discharge (each $p<.0001$). The difference between treatments in bone/joint pain was most pronounced in the short-term in favor of T+OFS, but a difference persisted (each $p<.0001$). Changes of global QoL indicators (mood, physical wellbeing, and coping effort) from baseline were similar between treatments over the whole treatment period. **Conclusion:** Overall from a QoL perspective, there is no strong indication to favor either E+OFS or T+OFS. The differential effects of the two treatments on endocrine symptoms burden need to be addressed with patients individually. Clinical trial information: NCT00066783/NCT00066690.

**558 General Poster Session (Board #22), Mon, 8:00 AM-11:45 AM**

**SWOG S0307 phase III trial of bisphosphonates as adjuvant therapy in primary breast cancer: Comparison of toxicities and patient-stated preference for oral versus intravenous delivery.** *Presenting Author: Julie Gralow, University of Washington, School of Medicine, Seattle, WA*

**Background:** Bone metastases are a common site of distant recurrence in breast cancer. Evidence from randomized trials, including a recent meta-analysis, suggests that adjuvant bisphosphonates can decrease recurrence and death. SWOG S0307 compares efficacy of 3 bisphosphonates in early stage breast cancer. **Methods:** Patients with stage I-III breast cancer receiving adjuvant systemic therapy were randomized to receive 3 years of clodronate (CLOD) (1600 mg po qd), ibandronate (IBAN) (50 mg po qd) or zoledronic acid (ZA) (4 mg IV q month x 6, then q3 months x 2.5 years). The primary endpoint is disease-free survival. Overall survival, sites of first recurrence, and adverse events are secondary endpoints. **Results:** Between Nov 2005 and Feb 2010 6,097 patients were enrolled. Survival data are maturing with 50% of the expected events occurring to date. Annual interim analyses are being conducted. 5,752 patients are assessable for toxicity. Median age was 53. 78% of tumors were ER positive, 16% HER2 positive, 16% triple negative. 34% were stage I, 45% stage II, and 21% stage III. Planned adjuvant treatment included chemotherapy in 80%, endocrine therapy in 76%, and both in 56%. 25 (0.4%) and 494 (8.6%) patients experienced grade 4 or 3 toxicities, respectively. The most common adverse events were musculoskeletal, pain, gastrointestinal, metabolic/laboratory (creatinine, calcium), and constitutional symptoms (acute phase reactions). There have been 40 reported cases of osteonecrosis of the jaw (ONJ): ZA 24/2094 (1.15%), CLOD 6/2151 (0.28%), and IBAN 10/1507 (0.66%) ($p=0.003$). Fractures have been reported in 4.5% of patients in ZA arm, 4.8% in CLOD arm, and 4.1% in IBAN arm ($p=$ ns). Prior to randomization, 76% preferred oral medication versus 24% for intravenous if drugs proved equal in efficacy. Preferences changed little at completion of therapy, although some switched preference. **Conclusions:** Grade 3 and 4 toxicities were low in S0307. ONJ, a rare but serious complication, was statistically highest for ZA and lowest for CLOD. Fractures were equal across arms. The majority of patients indicated a preference for oral formulation. Clinical trial information: NCT00127205.

**559 General Poster Session (Board #23), Mon, 8:00 AM-11:45 AM**

**An estimation model for Oncotype DX recurrence score using routine histopathologic variables.** *Presenting Author: Hyunseok Kim, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** The gene expression profile assayOncotypeDx (ODX) is frequently used to guide adjuvant chemotherapy decisions for patients with estrogen receptor (ER)-positive, lymph node (LN)-negative breast cancer. We hypothesized that in cases where ODX is being considered, the observed recurrence score (RS) category can be accurately estimated using routinely available, less costly histopathologic variables. **Methods:** We retrospectively reviewed pathology reports between June 2006 and August 2012 from Johns Hopkins (JH) patients ($n=301$) with early stage ER-positive, LN-negative breast cancer, for whom ODX was ordered. We developed a linear regression model using routine histopathologic markers (ER and progesterone receptor [PR] expression, HER2 status, tumor grade, and Ki67) to calculate an Estimated Recurrence Score (ERS), and correlated it with the observed ODX RS assay result. This model was internally cross-validated in the JH cohort, and externally validated in a separate 326-patient cohort from three Maryland community settings. **Results:** In the JH cohort, 244 patients had an observed RS $\leq$ 25 (80%) and 57 patients had an observed RS above 25 (20%). When the ERS was $<21$ ($n=200$), we accurately classified 95% of them (191) who were found to have a low risk(observed RS $\leq$ 25). Similarly, 95% of those (18/19) with an ERS $>30$ fell into a high risk category with observed RS $>25$. An accuracy of 93% was observed in the external validation cohort (Table). **Conclusions:** We developed a clinical estimator of the ODX RS using cases in which the clinician chose to order ODX RS in routine clinical practice. For more than 80% of patients in the external validation cohort, ERS was estimated to be $<21$ or $>30$ and in this group, the Hopkins ERS model correctly predicted the observed RS category ($\leq 25$ or $>25$) in 93% of cases. Although further validation of this model is warranted, preliminary evidence supports use of ERS to reliably identify those patients most likely to benefit from including ODX RS results in therapeutic decision-making.

| JH cohort | ODX RS ≤ 25 | ODX RS > 25 | Total | External cohort | ODX RS ≤ 25 | ODX RS > 25 | Total |

**560 General Poster Session (Board #24), Mon, 8:00 AM-11:45 AM**

**Preclinical activity of MCLA-128, an ADCC enhanced bispecific IgG1 antibody targeting the HER2:HER3 heterodimer.** *Presenting Author: Cecile Geuijen, Merus, Utrecht, Netherlands*

**Background:** Amplification and dimerization of HER2 promotes growth and survival of malignant cells. Tumor responses to available therapeutic agents targeting HER2 are variable. Re-activation of the potent HER2:HER3 signaling dimer by up-regulation of the HER3 ligand heregulin (HRG) has recently been identified as an important resistance mechanism. Treatment of patients with tumors expressing HER2 could be improved with agents that specifically target and potently inhibit the HER2:HER3 heterodimer. **Methods:** Inhibition of HRG mediated cell growth and invasiveness was assessed by proliferation inhibition and high content imaging. ADCC activity was measured by standard PBMC assays and reporter cell lines. The trastuzumab-resistant, HER2 amplified JIMT-1 xenograft model was used to assess in vivo activity. Activation status of HER dimers was determined by specific phosphorylation readouts. **Results:** MCLA-128 is a human common light chain bispecific antibody targeting HER2 and HER3 selected from > 500 bispecific antibody candidates. MCLA-128 inhibits HER2:HER3 heterodimer phosphorylation. This molecular phenotype correlated with potent inhibition of HRG driven growth and invasiveness in BT474, SKBR3 and N87 cell lines [$IC_{50}$ 100 – 200 pM]. In contrast, HER3 antibodies, trastuzumab alone or combined with either pertuzumab or HER3 antibodies could not inhibit growth under these conditions even at concentrations two orders of magnitude higher. The ADCC activity of MCLA-128, a low fucosylated IgG1, was equivalent to trastuzumab when targeting $HER2^{hi}$ cell lines but significantly superior when targeting $HER2^{lo}$ cell lines and when low affinity FcgRIII effector cells were used. In vivo, weekly dosing of MCLA-128 at 25 mg/kg reduced tumor burden significantly compared to lapatinib or trastuzumab + pertuzumab treatment groups. **Conclusions:** MCLA-128 specifically and potently inhibits ligand dependent HER2:HER3 signaling resulting in suppression of tumor growth in vitro and in vivo. The unique functional profile of this novel full-length bispecific antibody, including its strong ADCC activity, supports further development and clinical evaluation in patients with HER2 positive tumors.

**561 General Poster Session (Board #25), Mon, 8:00 AM-11:45 AM**

**Does increasing the daily tamoxifen dose in patients with diminished CYP2D6 activity increase toxicity?** *Presenting Author: Daniel Louis Hertz, University of Michigan, Ann Arbor, MI*

**Background**: Tamoxifen treated breast cancer patients with diminished CYP2D6 activity have lower endoxifen exposure, which may lead to inferior treatment outcomes. Increasing the daily tamoxifen dose from 20 mg to 40 mg increases endoxifen in CYP2D6 poor (PM) and intermediate (IM) metabolizing patients. We previously reported that endoxifen exposure of an IM pt receiving 40 mg is similar to that of an extensive or ultra-rapid metabolizer (EM/UM) receiving 20 mg, while a PM at 40 mg continues to have lower exposure. Here we investigated whether increasing the dose to 40 mg/day in CYP2D6 PM and IM increases treatment toxicity. **Methods**: Patients receiving 20 mg tamoxifen for ≥ 4 months who were not taking a strong CYP2D6 inhibitor were genotyped for CYP2D6 using the Amplichip CYP450 test (Roche Diagnostics, Indianapolis, IN). PM and IM were increased to 40 mg for 120 days while EM/UM remained on 20 mg. Toxicity data was collected on the ordinal FACT-B Endocrine Subscale (0: "not at all" to 4 "very much") at enrollment and 120 days. The prevalence of patients reporting any toxicity ≥ 3 ("quite a bit") and the rating (0-4) of specific toxicities were compared across CYP2D6 phenotypes. **Results**: Of the 484 evaluable patients, 29 were PM, 293 IM and 162 EM/UM. At enrollment (all receiving 20 mg) there was a non-significant trend toward greater prevalence of toxicity as CYP2D6 activity increased (PM=55.2%, IM=57.0%, EM/UM=62.4%, p=0.25) with a significantly higher rating of vaginal dryness (PM=0.76, IM=0.84, EM/UM=1.06, p=0.03) but not hot flashes (p=0.80). After 120 days of 40 mg treatment there was a significant increase in the prevalence of toxicity in IM (change from baseline= +7.4%, p<0.001), but not PM (change=-11.7%, p=0.71). There was no significant increase in the rating of any toxicity (p>0.05). **Conclusions**: Increasing the daily tamoxifen dose in CYP2D6 IM, but not PM, is associated with a corresponding increase in global toxicity that cannot be attributed to any single toxicity. Analysis as to whether this impacts patients' QOL is ongoing. Given the absence of known impact on outcomes, increasing the tamoxifen dose should be discouraged in patients with diminished CYP2D6 activity. Clinical trial information: NCT00764322.

**562 General Poster Session (Board #26), Mon, 8:00 AM-11:45 AM**

**Competing risks of mortality by PAM50 intrinsic subtype: BC tamoxifen-treated cohort.** *Presenting Author: Judy-Anne W. Chapman, NCIC Clinical Trials Group, Queen's University, Kingston, ON, Canada*

**Background:** We previously showed that baseline patient/tumour characteristics, or prior treatment affected cause of death in NCIC CTG endocrine therapy trials (MA.14, MA.17, MA.27), in particular older age was associated with non-breast cancer death. We now examine whether PAM50 intrinsic subtypes were differentially associated with cause of death in a cohort of British Columbia tamoxifen-treated patients. **Methods:** Patients were 718 post-menopausal women, treated with tamoxifen, without adjuvant chemotherapy who had tumours which were Luminal A, Luminal B, Basal, or HER2 intrinsic subtype and known cause of death [cancer-specific (BrCa); other cause (OC)]. We tested whether intrinsic subtype and other patient and tumour characteristics were associated with 1) all cause mortality, and if so, 2) cause-specific mortality. We also fit step-wise forward cause-specific adjusted models. **Results:** Patients were followed a median of 11.7 years. In women <70 years of age, 138/425 (32% died of breast cancer) and 80/425 (19% died of other causes); 138/218 (63% of deaths were due to breast cancer). In those ≥70, 78/293 (27% died of breast cancer) and 133/293 (45% died of other causes); 78/211 (37% of deaths were due to breast cancer). Two factors were differentially associated with type of death: intrinsic subtype was associated with breast cancer death (p=0.001), while older age was associated with other causes of death (p<0.0001). Additionally, step-wise cause-specific models indicated larger tumour size (p=0.0002), higher number of positive number of lymph nodes (p<0.0001), and less PgR stain (p=0.03) were associated with worse breast cancer survival; higher number of positive lymph nodes (p=0.002) and no lymphovascular invasion (p=0.02) were associated with worse all cause mortality. Survival from breast cancer and other causes is provided by these factors at 5-, 10-, and 15-years, adjusted for the effects of other significant factors. **Conclusions:** Intrinsic subtype was associated with breast cancer death, and did not affect other cause mortality. Again, older age was associated with other cause mortality with the majority of women 70 or older surviving breast cancer.

**563 General Poster Session (Board #27), Mon, 8:00 AM-11:45 AM**

**The impact of intratumoral heterogeneity on the prognosis of ER-positive/HER2-negative breast cancer.** *Presenting Author: Masahiro Oikawa, Department of Breast Oncology, National Kyushu Cancer Center, Fukuoka, Japan*

**Background:** In this study, we assessed the clinical importance of minor HER2-amplified clones in ER-positive, HER2-negative breast cancer to demonstrate the impact of intra-tumoral heterogeneity on clinical outcome. **Methods:** We retrospectively mined clinical data from the National Kyushu Cancer Center (2008–2013) for surgically resected, primary invasive breast cancers, that were ER-positive and HER2 IHC 2+/FISH-negative (HER2:CEP17 signal ratio by FISH < 2.0). Samples were classified as minor clone (MC) (+) or MC (−) if they had minor clones with HER2:CEP17 ratios ≥ 3.0 or not, respectively. The clinicopathological findings including age, menopausal status, tumor size, lymph node metastasis, lymphatic invasion, PgR, Ki67 labeling index and chemotherapy were analyzed between the two groups by Fisher's exact test and the Wilcoxon rank-sum test. Survival curves were estimated using the Kaplan–Meier method and the significance of differences between survival curves was determined using the log-rank test. **Results:** Of the 149 cases, with mean follow-up period of 732 days, 87 cases (58.4 %) and 62 cases (41.6 %) were classified as MC (+) or MC (−), respectively. When comparing the clinicopathological findings between these two groups, the MC (+) group tended to have larger tumor size (mean size 20.6 mm vs. 18.9 mm, P = 0.078), had a significantly higher Ki67 labeling index (with mean of 36.2 % vs. 22.8%, P = 0.036), and a significantly higher ratio of receiving chemotherapy (59.8% vs. 41.9%, P = 0.045). The MC (+) group showed worse overall survival (OS) compared with the MC (−) group (P = 0.026), while the difference in disease-free survival (DFS) was not significant. **Conclusions:** Among ER-positive, HER2-negative invasive breast cancers, the subgroup with HER2-amplified minor clones showed more biologically aggressive features, which may have an impact on prognosis. Intra-tumoral heterogeneity should therefore be considered in breast cancer therapy, and further investigation is required.

**564 General Poster Session (Board #28), Mon, 8:00 AM-11:45 AM**

**Predictive value of angiogenesis-related gene profiling in patients with HER2-negative metastatic breast cancer (MBC) treated with bevacizumab and weekly paclitaxel (Bev-Pac).** *Presenting Author: Andrés Redondo, Hospital Universitario La Paz, Madrid, Spain*

**Background:** The combination of Bev-Pac significantly improved progression-free survival (PFS), compared with Pac alone in first-line treatment of HER2-negative MBC. To date only a few biomarkers relating to bevacizumab efficacy have been published, and none of them have been validated in prospective studies. The aim of this study is to build a profile predicting PFS in patients treated with Bev-Pac. **Methods:** 60 patients with Her2-negative MBC treated with Bev-Pac were included. RNAs were collected from formalin-fixed paraffin-embedded primary breast samples. Expression levels of 170 angiogenesis related genes were measured using quantitative real time PCR. Predictive models, genetic (G) and combined genetic-clinical (GC), were fitted by Lasso-penalized multivariate Cox proportional hazards modeling and validated by Leave One Out Cross Validation (LOOCV). Cross-validated Kaplan-Meier (KM) curves and time-dependent ROC curves were generated to estimate the predictive accuracy of the PFS models, and a log-rank permutation test was used to evaluate the statistical significance. **Results:** 49 patients had estrogen positive, and 11 had triple negative tumors. 60% received Bev-Pac in first line, and 40% in second or subsequent lines. Median PFS was 11.4 months. The multivariate clinical model generated with 5 variables (number of previous lines, disease free interval, estrogen receptor status, previous chemotherapy and metastatic locations) showed the last one ($<3$ vs $>3$ locations or liver metastasis) as the only clinical variable significantly correlated with PFS. An 11-gene profile (G model) was correlated with PFS. The G model and the GC model identified two groups of patients with different PFS, although the GC model was statistically more consistent across different time points (median PFS 17.9 months in favorable group vs. 7.4 months in the other). **Conclusions:** A molecular signature of 11 genes correlated with PFS in a series of patients treated with Bev-Pac. Better predictive accuracy was obtained by a combination of genetic and clinical variables.

**565 General Poster Session (Board #29), Mon, 8:00 AM-11:45 AM**

**Chromosomal copy number alterations (CNAs) for risk assessment of ductal carcinoma in situ (DCIS).** *Presenting Author: Anosheh Afghahi, Stanford University School of Medicine, Stanford, CA*

**Background**: Population-wide screening mammography has contributed to a significant increase in the diagnosis of DCIS, raising questions about over-diagnosis and over-treatment. We aimed to determine whether adding genomic variables to standard clinico-pathologic factors may identify low-risk versus high-risk DCIS, with an ultimate goal of tailoring therapy. **Methods**: Patient-level clinical and pathologic data were extracted from the electronic medical records of Stanford Cancer Institute and linked to demographic data from the population-based California Cancer Registry; results were integrated with data from tissue microarrays of biopsies revealing DCIS only versus concurrent invasive breast cancer (IBC) with DCIS. We used fluorescence in situ hybridization to investigate the predictive values of CNAs of 1q, 8q24 and 11q13 (reported by The Cancer Genome Atlas to be among the most frequent CNAs in IBC) in the DCIS component of the biopsies. Multivariable logistic regression analysis was performed to describe associations with concurrent IBC, adjusting for variables including CNA frequencies, age at diagnosis, race/ethnicity, hormone receptors and grade. **Results**: We studied 271 patients (120 with DCIS and 151 with IBC and DCIS), most of whom were diagnosed from 2000-2003, were of Non-Hispanic White race/ethnicity, and of top statewide quintile of neighborhood socioeconomic status. We observed no differences in standard clinico-pathologic factors, including hormone receptors and grade. Compared to DCIS only, patients with concurrent IBC had higher frequencies of 2 of 3 (34.8% vs. 18%) and all 3 (10.8% vs. 4.1%) CNAs amplified; on multivariable analysis, this was the only variable significantly associated with concurrent IBC, where having 2 of the 3 CNAs was associated with a risk of IBC that was 5.28 times that of having no CNAs, and all 3 CNAs was associated with a more than 7-fold risk ($P=0.0091$). **Conclusions:** This proof-of-concept study demonstrates the potential of CNAs to improve the identification of high-risk DCIS that is accompanied by IBC. Expanding and validating this approach may enable risk-adapted management of DCIS.

**566 General Poster Session (Board #30), Mon, 8:00 AM-11:45 AM**

**Does endocrine therapy in mucinous and tubular breast cancer improve outcome?** *Presenting Author: Nicola Jane Mitchell, Auckland City Hospital, Auckland, New Zealand*

**Background:** Mucinous and tubular breast cancer (ca) have better prognosis than infiltrating ductal carcinoma (IDC). Patients (pts) often receive adjuvant (adj) treatment as if their risk was standard but questions arise about which pts could safely avoid treatment. We aimed to establish the current local practices and assess outcomes. **Methods:** We identified pts with early-stage mucinous and tubular breast ca using prospectively collected data from the Auckland Breast Cancer Registry between June 2000 and June 2012. Pts were case matched with IDC according to size, grade, nodal status and age. Because endocrine therapy (ET) use increased with higher Nottingham Prognostic Index (NPI), survival outcomes were also analysed by NPI group. **Results:** 161 mucinous and 201 tubular ca were identified. Baseline characteristics and treatment received are shown below. ET was used more in IDC than mucinous (54% vs 40%) or tubular ca (23% vs 12%). Median follow up was 4.3 yrs for mucinous and 4.8 yrs for tubular ca. RFS was superior in mucinous cf matched IDC (HR 0.3, p=0.0012) as well as DDFS (HR 0.2, p=0.011). A trend towards improved OS with ET in mucinous ca was seen in the overall group (HR 0.3, p=0.056), despite ET use being more common in higher NPI groups. RFS (HR 0.7, p=0.38) and DDFS (HR 0.1, p=0.083) were similar in tubular cf matched IDC. Of 182 pts with EPG tubular ca, only 10 received ET with no improvement in OS (HR 2.8, p=0.21). **Conclusions :**In this study, mucinous ca has an inherently better survival than IDC but women at higher risk may still benefit from ET. The good prognosis in tubular ca appears to be due to low stage at presentation. No benefit of ET was seen in tubular or EPG mucinous ca, suggesting selected women may be safely spared the side effects and costs of treatment.

**Clinical outcomes of estrogen receptor (ER)-negative and progesterone receptor (PgR)-positive invasive breast cancer.** *Presenting Author: Melissa Chan, Princess Margaret Cancer Centre - University Health Network, Department of Medicine, University of Toronto, Toronto, ON, Canada*

**Background:** Hormone receptor (HR) expression has prognostic and predictive significance in breast cancer. Most HR-positive tumors are ER positive (ER+). In contrast, tumors that are ER negative (ER-) and PgR positive (PgR+) are uncommon and may represent an analytic artifact. We have previously shown that ER-/PgR+ tumors have been associated with younger age, higher grade, and Her2/neu over-expression suggesting a distinct biologic entity (Proceedings 103rdUSCAP Meeting). Here we evaluated clinical outcomes of ER-/PgR+ breast cancers. **Methods:** We retrospectively reviewed a well-characterized database comprising 816 sequential patients diagnosed with early stage invasive breast carcinoma in Salamanca, Spain. Outcomes of interest were time to relapse (TTR) and overall survival (OS). Multivariable Cox proportional hazards analysis was conducted to assess the association of ER-/PgR+ with TTR and OS in comparison to ER+ and to ER- and PgR negative (ER-/PgR-) tumors. **Results:** Fifty-six patients (7%) had ER-/PgR+, 624 (77%) had ER+ and 136 (17%) had ER-/PgR- phenotypes. For ER-/PgR+, ER+ and ER-/PgR- tumors, five-year relapse rates were 36%, 20% and 42%, and five-year OS was 92%, 93% and 66%, respectively. ER-/PgR+ showed annual hazards of relapse that were intermediate between ER+ and ER-/PgR- patients. Relapses occurred early in follow-up for ER-/PgR+ and ER-/PgR- tumors with few relapses beyond year 6. ER+ tumors showed a continuous risk of relapse throughout follow-up. Multivariable analysis for TTR is shown in the Table. Only nodal status and receptor group were associated with worse OS. **Conclusions:** ER-/PgR+ tumors are a rare, but defined subgroup. They have a higher risk of relapse than ER+ tumors, but lower than ER-/PgR- tumors. The timing of relapse more closely resembles ER-/PgR- disease, whereas overall survival more closely resembles ER+ disease. Further research on the role of PgR in breast carcinogenesis is warranted.

**568 General Poster Session (Board #32), Mon, 8:00 AM-11:45 AM**

**Enobosarm: A targeted therapy for metastatic, androgen receptor positive, breast cancer.** *Presenting Author: Beth Overmoyer, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The androgen receptor (AR) is the most highly expressed steroid receptor in breast cancer (BC) with 75-95% of estrogen receptor positive (ER+) and 50% of ER negative BCs expressing AR. Prior studies have shown that women with metastatic BC (MBC) who are progressing on tamoxifen subsequently respond to non-tissue-selective, synthetic androgens with overall response rates of 20-60%. Unfortunately steroidal androgens have unwanted virilizing effects which limit clinical use. Enobosarm, a nonsteroidal, tissue-selective, AR modulator (SARM), provides a novel targeted approach to exploit the therapeutic benefits of AR activation without virilization or estrogenic effects. **Methods:** A proof of concept, phase II study is examining efficacy and safety of enobosarm 9mg daily in 22 postmenopausal women with ER+ MBC who previously responded to adjuvant and/or salvage endocrine therapy. Treatment continues until disease progression (PD). Primary endpoint is clinical benefit response (CBR) by 6 months (m) defined as patients (pts) having a complete response (CR), partial response (PR), or stable disease (SD). CBR will be correlated with AR status of metastatic tumor biopsy. Serum prostate specific antigen (PSA) will be evaluated as a biomarker of AR activity. **Results:** Pt demographics: mean age 63.7 years, mean time from diagnosis 11 years, 68% prior chemo, 94% (15/16) AR+. After a median f/u of 85 days (d) (range 84-209d), preliminary results of 16 pts: 8 SD as best response, median duration 4.5m; 9 PD after a median 84d. Among pts who reached 6m, 3 are AR+ with SD and increased PSA. 7 have yet to reach 6m and no CR or PR has been observed. Enobosarm is well-tolerated, with no drug related serious adverse events. **Conclusions:** Enobosarm is well tolerated and demonstrates promise as a novel targeted therapy for AR+ MBC. The primary endpoint has been achieved, with 3/15 AR+ pts meeting statistical threshold for success. Serum PSA appears to be a surrogate marker for AR activity and disease response. Final analysis is due in June 2014. Clinical trial information: NCT01616758.

**569 General Poster Session (Board #33), Mon, 8:00 AM-11:45 AM**

**Phase 2 study investigating the safety, efficacy, and surrogate biomarkers of response to 5-azacitidine (5-AZA) and entinostat in advanced breast cancer.** *Presenting Author: Roisin M. Connolly, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background:** In breast cancer models, combination epigenetic therapy with a DNA methyltransferase inhibitor and a histone deacetylase inhibitor led to re-expression of genes encoding important therapeutic targets including the estrogen receptor. We conducted a multicenter phase II study of 5-AZA and entinostat in women with advanced breast cancer. **Methods:** Women with advanced HER2-negative (triple-negative [TNBC] or hormone-resistant [HR]) breast cancer received 5-AZA 40 mg/m$^2$ (SQ, ds 1-5, 8-10) and entinostat 7 mg (PO, ds 3,10) q28 ds. Primary endpoint: Objective response rate (ORR) in each cohort. Secondary endpoints: PFS, OS, safety. We obtained mandatory baseline and wk 8 tumor biopsies for gene methylation/expression, and blood samples for pharmacokinetics and pharmacogenetics. At progression, patients were offered optional continuation (OC) with the addition of endocrine therapy. We hypothesized that ORR would be >20% against null of 5% using Simon two-stage design. At least 1 response was required in 1$^{st}$ of 13 patients per cohort to continue accrual to 27 per cohort. Type I error 4%, power 90%. **Results:** TNBC data were presented at AACR 2013. From 08/2011-09/2013, 27 women enrolled in the HR cohort. Median age 55 ys (33-70), median prior endocrine and chemotherapies 3 each. Median cycles received 2 (1-16). Twelve women continued in OC phase and received median 2.5 additional cycles (range 1-9). We observed 1 partial response with epigenetic therapy alone (ORR 4%, 95% CI, 0-19%) and 1 in OC. At median follow up 6.3 ms, median PFS was 1.8 ms (95% CI, 1.7-1.9), and median OS 11.5 ms (95% CI, 5.5-16.3). In OC phase, median PFS was 1.9 ms (95% CI, 1.7-3.7) and median OS 15.6 ms (95% CI, 5.5-NA) vs PFS 1.8 ms (95% CI, 0.8-1.9) and OS 9.2 ms (95% CI, 2.3-16.3) for event monitoring. Therapy was well tolerated with few grade 3/4 events. We obtained 95% baseline core biopsies, and 58% matched samples. Correlative analyses will be presented. **Conclusions:** Combination epigenetic therapy was well tolerated but our primary endpoint was not met. OC results suggest that some women benefit from epigenetic therapy and/or reintroduction of endocrine therapy beyond progression. Clinical trial information: NCT01349959.

**570 General Poster Session (Board #34), Mon, 8:00 AM-11:45 AM**

**The impact of the Oncotype DX recurrence score pathology-clinical (RSPC) on the predicted recurrence risk for node negative breast cancer patients: A cancer center experience.** *Presenting Author: Barbara A. Wexelman, Massachusetts General Hospital, Boston, MA*

**Background:** The OncotypeDX 21-gene assay Recurrence Score (RS) is widely used to risk-stratify ER+, node negative breast cancer to determine the 10 year risk of distant recurrence (RR) and the potential benefit of chemotherapy. The OncotypeDX Recurrence Score Pathology-Clinical (RSPC) tool was recently developed to modify an individual's RR by incorporating clinical and pathological features (age, tumor size, grade, and type of endocrine therapy). We evaluated the impact of the RSPC on the predicted RR in a cohort of patients (pts) at our institution. **Methods:** A retrospective chart review of the last 250 consecutive pts (2012-2013) at our institution with OncotypeDX RS was performed. RSPC was calculated and compared to the RR. Patients were excluded from analysis for the following: DCIS only, node positive, or in-breast recurrence. Low, intermediate (int), and high risk cut-offs were based on published data using RS <18 (RR<12%), RS 18-31 (RR 12-20%) and RS >31 (RR>20%). **Results**: Of 250 RS obtained, 166 (66.4%) met inclusion criteria for this analysis. Mean tumor size was 1.6 cm, median grade=2, mean age=55.6, 49.4% started Tamoxifen, and 14.5% received adjuvant chemotherapy. The mean RS was 15.2 (SD 7.7, range 0-48). The mean 10-year RR compared to RSPC was 10.2% vs 8.6% (p<0.001). In addition, 71.1%, 24.1%, and 4.8% of tumors had a low-, intermediate- and high-risk RS, compared to 81.9%, 14.5%, and 3.6% after RSPC adjustment. RR shifted as 29/40 (72.5%) int-RR pts were reclassified as low risk by RSPC, and 12/118 (10.2%) low-RR pts were reclassified to int/high risk, leading to a 40% decrease in the number of int-risk tumors. Small tumors (T1a/b) had the greatest decrease in RR (-3.2%), while 22 (21.4%) of T1c tumors dropped from int to low RR. **Conclusions:** The RSPC tool modified the RR by a small but statistically significant decrease in the predicted 10 year RR for ER+ node negative breast cancer in a single institutional cohort, with most intermediate RR tumors shifting to low RR. Although RSPC does not alter the predicted relative benefit of chemotherapy, adjustment for the absolute RR may alter absolute chemotherapy benefit and impact treatment choice.

**571 General Poster Session (Board #35), Mon, 8:00 AM-11:45 AM**

**Breast cancer subtypes according to body mass index and insulin resistance.** *Presenting Author: Grazia Arpino, Medical Oncology, AOU Federico II, Naples, Italy*

**Background:** High body mass index (BMI) is considered a risk factor for breast cancer (BC) onset and is correlated with bad prognosis and resistance to endocrine therapy in BC patients. Obesity is also cause of insulin resistance (IR), often associated to resistance to anti human epidermal growth factor receptor (HER) inhibitors. The aim of the present study was to assess the association of BMI levels and IR with BC immunohistochemically-defined subtypes. **Methods:** One thousand consecutive post-menopausal patients with early BC were included in our study. Clinical, metabolic and tumor characteristics were prospectively collected at the time of diagnosis. IR was defined by the homeostatic model assessment (HOMA), with a cut off value to define IR ≥ 3,4. BMI was categorized as low: ≤25; intermediate: 26-30; high: >25. Data were analysed by logistic regression model. **Results:** Patients with luminal (A and B) BC were more likely to be overweight (BMI = 26-30) (OR=2.96 95% CI 1.53-5.74; p=0.006) although they had low HOMA scores (< 3.4) (OR=0.57 95% CI 0.35-0.93; p=0.02). In contrast, patients with HER2+ subtype were at increased risk for elevated HOMA score (OR= 2.36 95% CI 1.27-4.4; p=0.007), whereas the association with BMI was not statistically significant. In additional, no significant association was found between triple negative (TN) BC and anthropometric and metabolic variables. **Conclusions:** Our data suggest that high BMI may be associated with endocrine sensitive BC, whereas high HOMA score, may be more frequent in patients with HER2+ subtype. These findings support the hypothesis that high estrogen exposure of breast tissue in women with higher BMI may drive growth of luminal cancers while insulin an resistance environment may increase the risk of growth factor receptor-dependent BC. If further confirmed, our data suggests that body weight reduction and glycemic control, respectively in these two subsets of women may help to prevent cancer development.

**573 General Poster Session (Board #37), Mon, 8:00 AM-11:45 AM**

**Cremophor EL-free formulation of paclitaxel: A randomized, multicenter, safety, and efficacy study of nanosomal paclitaxel lipid suspension (NPLS) versus paclitaxel in women with metastatic breast cancer (MBC).** *Presenting Author: Ateeq Ahmad, Jina Pharmaceuticals, Libertyville, IL*

**Background:** The primary reason for the development of Lipid Based formulation of Paclitaxel is to improve the drug's safety profile by eliminating Cremophor EL (CrEL) and ethanol from Paclitaxel.The use of CrEL, a surfactant, has been associated with severe anaphylactoid hypersensitivity reactions, hyperlipidaemia, abnormal lipoprotein patterns, aggregation of erythrocytes and peripheral neuropathy in patients treated with Taxol. **Methods:** 120 MBC patients were enrolled in the study and the racial make-up was 100% Asian. They were administered NPLS (Arm A) or Paclitaxel (Arm C) at a dose of 175 mg/m$^2$ tri-weekly or NPLS (Arm B) at dose 80 mg/m$^2$weekly as per randomization schedule, by IV infusion at a ratio of 48 patients on Arm A: 45 patients on Arm B: 27 patients on Arm C. No pre-medication was given to the patients in NPLS groups. Safety and efficacy was determined for all treated patients. The efficacy was measured by Objective Response Rate (ORR = CR + PR) and Disease Control Rate ( DCR = CR + PR + SD). **Results:** (A) Efficacy - An independent radiologic review demonstrated clinically superior efficacy in terms of ORR, in MBC patients receiving the NPLS (175mg/m$^2$) or (80mg/m$^2$) versus the standard dose of Paclitaxel(175mg/m$^2$). The ORR was 36.4% (95% CI, 22.1 – 50.6%) for NPLS arm A, 46.5% (95% CI, 31.6 – 61.4%) for NPLS arm B and 20.8% (95% CI, 4.6 – 37.1%) for Paclitaxel arm C. The DCR was 86.4% for NPLS Arm A, 88.4% for NPLS Arm B and 80% for Paclitaxel Arm C. (B) Safety - A total of 450 adverse events (AEs) reported to 97 patients during the course of the trial. 157 AEs occurred to patients under NPLS Arm A, 239 AEs occurred to patients under NPLS Arm B and 54 AEs occurred to patients under Paclitaxel Arm C. **Conclusions:** In both Arm A and B, patients treated with NPLS showed higher ORR and DCR than patients receiving Paclitaxel (Arm C). The NPLS was well tolerated by patients. Majority of the post-dose AEs were resolved without any sequelae. The patients in NPLS treatment arms were not pre-medicated. Taken together, NPLS tri-weekly or weekly demonstrates clinical benefit versus Taxol for MBC patients. Clinical trial information: CTRI/2010/091/001344.

**574 General Poster Session (Board #38), Mon, 8:00 AM-11:45 AM**

**Prognosis of small tumors according to KI67 and IHC subtypes.** *Presenting Author: Antonella Ferro, Santa Chiara Hospital, Trento, Italy*

**Background:** The incidence of small ( ≤1 cm) node-negative breast cancers (BC) is increasing in mammography-screened populations. These tumors generally have good prognosis with low risk of distant and local recurrence. **Methods:** A retrospective review of 665 patients classified as having ≤1 cmN0 BC treated in our Institution from 1995 to 2008 was done. Clinical-pathological features and long term outcomes (EFS and OS) were analyzed according to KI67 LI, HER2 status, PR expression and intrinsic sybtypes (luminal A, B, HER2 luminal, HER2, Triple negative-TN). **Results:** Median age at diagnosis was 60 years (range: 23 to 86 ys).There were 30 T1mic (4.5%), 122 T1a (18.4%) and 513 T1b (77.1%) cancers. A higher proportion of pT1mic+T1a presented poor grading (G3) and had the HER2 and TN subtypes compared with pT1b BC. HER2 was over-expressed or amplificated in 89 (13.4%) of all cases. Chemotherapy with or without hormonal therapy was administered to 18 T1a (12%) and to 82 T1b (16%); hormonal therapy alone in 46 T1a (30%) and 252 T1b (49%). No one received adjuvant trastuzumab. At a 6,5 ys median follow up there were 29 (4.4%) loco-regional (LRR) or distant relapses (DR), 26 (3.9%) controlateral and 21 (31%) other tumors.Similar incidence of LRR, DR and BC related deaths between T1a and T1b was reported. High ki67 (defined as median value = 15%) confirmed its prognostic significance in term of OS, in particular T1b cases (p=0.015), but not in EFS.No difference was found between Luminal B and Luminal A subtypes for any of the outcomes analysed. TN and HER2 subtypes, but not HER2 luminals were correlated with a significantly increased BC related events if compared with the Luminal A subtype (TN 85.7%, HER2 79.4%, Her2 luminal 90.7%, Luminal A 93.7%, Luminal B 89.1%). **Conclusions:** Our experience confirms good prognosis of ≤ 1 cm N0 BC. However, tumors with more aggressive biological features (high Ki67, HER2 or TN subtypes) had higher incidence of relapses. In this "low stage but adverse biology" BC an intensive (aggressive?) adjuvant approach should always be considered.

**Relation of genes in estrogen and vitamin D signaling to bone mineral density loss in aromatase inhibitors treatment.** *Presenting Author: Sonia Servitja, Medical Oncology Department. Hospital del Mar, Barcelona, Spain*

**Background:** Bone mineral density (BMD) loss is a consequence of Aromatase Inhibitors (AI) therapy. This study aims to identify variants of genes in the vitamin D and estrogen signaling pathways associated with AI-related BMD loss in the B-ABLE cohort. **Methods:** B-ABLE is a prospective cohort of women recruited at the time they initiate AI therapy in a bone metabolism unit. Bisphosphonate users were excluded for these analyses. Selected single nucleotide polymorphisms (SNPs) were genotyped. Multivariate linear regression was used to test their association with relative lumbar spine (LS) and femoral neck (FN) BMD loss after 1 and 2 years of follow-up. All models were adjusted for age, body mass index, previous tamoxifen and chemotherapy. Further, potential confounding for baseline 25(OH)-VITD concentrationsand AI used was assessed. **Results:** 391 participants were included. For estrogen signaling, two SNPs in CYP11A1 (rs2959008 and rs7174179) for the association with FN BMD loss at both one ($P$=0.003 and $P$=0.012) and two years ($P$=0.004 and $P$=0.002) of follow-up were significant. For LS BMD lossthree SNPs in HSD3B2 (rs2854964), CYP2C19 (rs12248560) and CYP2C9 (rs28371674) were significantly associated at one year of follow-up ($P$=0.026, P=0.019 and $P$=0.011 respectively). Only rs12248560 remained also significant at 2 years of follow-up (P=0.014). Regarding vitamin D signaling genes, rs11907350 in CYP24A1 was associated with FN BMD loss at one year. As for LS BMD loss one SNP in GC (rs11907350) at one year of follow-up and one SNP in VDR (rs2544037) at two years of follow-upreached significant p-values (P =0.020 and P=0.024, respectively). Only the SNP rs7174179 in CYP11A1 for FN BMD loss association at 2 years of follow-up remained significant after Bonferroni correction. **Conclusions:** Several genes in estrogen and vitamin D signaling appeared involved in BMD loss in AI-treated women, suggesting a complex regulation of this outcome.

**576^ General Poster Session (Board #40), Mon, 8:00 AM-11:45 AM**

**Phase 2 trial of trastuzumab and/or everolimus in hormone-resistant HER2-negative metastatic breast cancer.** *Presenting Author: Amelia Bruce, Zelnak, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Increased signaling through growth factor receptor pathways, including HER2, has been demonstrated to play a role in resistance to endocrine therapy. Efficacy of inhibiting HER2 and mTOR in HER2-negative, hormone-resistant breast cancer has been previously demonstrated. We evaluated the ability of inhibition of HER2 with trastuzumab (TRAST) and/or mTOR with everolimus (EVER) to reverse resistance to endocrine therapy in patients with hormone receptor (HR)-positive HER2-negative metastatic breast cancer (MBC). **Methods:** Eligibility included HR-positive, HER2-negative (IHC 1+ or 2+ and/or FISH negative) MBC on metastatic biopsy and documented progression within 6-months of starting an endocrine agent in the metastatic setting. Patients continued on the endocrine agent they had experienced disease progression on and were randomized to receive TRAST (8mg followed by 6mg every 3-weeks) or EVER 10mg daily. At disease progression the other agent (TRAST or EVER) was added. Biopsies of metastatic lesions were obtained prior to study entry where possible. **Results:** To date 38 patients have been randomized to TRAST (n = 13) or EVER (n = 22), 3 patients not evaluable. All patients continued the endocrine agent on which they had most recently experienced disease progression. The median PFS is 1.5 (95% CI 1.5 to 4) and 6 (95%CI 4 to 15) months (mos.) for patients initially randomized to TRAST and EVER respectively. At disease progression 13 patients in the TRAST arm received EVER and 5 in the EVER arm received TRAST. The overall PFS for this group is 5.5 (95% CI 3 to 8) mos: 7 (95% CI 3 to 13) mos. for patients in the TRAST arm who then received EVER; and 4 (95% CI 1.5 to 7) mos. for patients in the EVER arm who received TRAST. There were no unexpected toxicities though 2 patients were taken off study for decreases in ejection fraction. Metastatic biopsies are available for 57% of patients. **Conclusions:** This trial demonstrates the efficacy of inhibiting mTOR alone or in combination with HER2 in patients with hormone-resistant HER2-negative breast cancer, suggesting that inhibition of this growth factor pathway may restore sensitivity to endocrine therapy. Updated results and correlative studies will be presented. Clinical trial information: NCT00912340.

**577 General Poster Session (Board #41), Mon, 8:00 AM-11:45 AM**

**Follicle stimulating hormone (FSH) as a surrogate parameter for the effectiveness of endocrine therapy with or without zoledronic acid in premenopausal patients with breast cancer: An analysis of the prospective ABCSG-12 trial.** *Presenting Author: Georg Pfeiler, Department of Gynecology and Gynecological Oncology, Medical University of Vienna, Vienna, Austria*

**Background:** Endocrine therapy is an effective, targeted therapy in patients with hormone receptor positive breast cancer (BC). However, in the adjuvant setting no indicator exists visualizing its effectiveness during therapy. In this analysis we test whether FSH serum levels during therapy might be a surrogate parameter for the effectiveness of adjuvant endocrine therapy. **Methods:** ABCSG-12 examined the efficacy of ovarian suppression using goserelin (3.6mgq4wSC) in combination with anastrozole or tamoxifen ± zoledronic acid (ZOL, (4mgIVq6mo) in premenopausal women with endocrine-responsive BC. Prospective collected data on FSH serum levels were used for the analyses. Disease-free survival (DFS), distant metastasis free survival (DMFS) and overall survival (OS) were calculated by Kaplan-Meier method, results were compared by using the log-rank test and Cox proportional hazard modelling. **Results:** Analyses are based on 503 patients with FSH levels at baseline, 562 patients with FSH levels during therapy and 641 patients with FSH levels during follow up. Mean FSH levels were significantly lower during therapy, when compared to baseline and follow up, respectively (4.87mIU/ml vs. 14.16mIU/ml vs. 22.28mIU/ml, $p<0.001$). Patients treated with anastrozole had significantly higher FSH levels during therapy compared to patients treated with tamoxifen (7.05mIU/ml vs. 2.45mIU/ml, $p<0.001$). Patients with FSH levels above the mean during therapy (4.87mIU/ml) had a worse outcome compared to patients with FSH levels below 4.87mIU/ml (DFS HR 1.347, $p=0.18$; DMFS HR 1.939, $p=0.035$; OS HR 2.208, $p=0.096$). This could be confirmed with borderline significance in the subgroup of patients treated with ZOL (DFS HR 1.886, $p=0.075$; DMFS HR 2.537, $p=0.077$; OS HR 1.306, $p=0.726$). BMI had no impact on FSH serum levels in any group during therapy. **Conclusions:** This study suggests that FSH serum levels during therapy might be a good surrogate parameter for the effectiveness of adjuvant endocrine therapy.

**578 General Poster Session (Board #42), Mon, 8:00 AM-11:45 AM**

**Breast cancer treatment with everolimus and exemestane for ER+ women: Results of the first interim analysis of the noninterventional trial BRAWO.** *Presenting Author: Diana Lueftner, Department of Hematology, Oncology, and Tumor Immunology, Charité University Medicine, Campus Benjamin Franklin, Berlin, Germany*

**Background:** BRAWO is a German non-interventional study of 3000 patients with advanced or metastatic, hormone-receptor-positive and HER2-negative breast cancer treated with Everolimus (EVE) and exemestane (EXE). Here we report the results of the first preplanned interim analysis (IA). **Methods:** BRAWO collects data on the routine clinical treatment with EVE 10mg/d and EXE 25mg/d at about 400 sites. Main objectives are to extend the knowledge on a) the impact of physical activity on efficiency and quality of life, b) prophylaxis and management of stomatitis in clinical routine, and c) the sequence of therapy, when EVE is used in usual daily care. This first IA focuses on objectives b) and c). **Results:** 866 patients (pts) at 253 active sites were analyzed, 53.2% of pts were ongoing at data cut-off. Baseline characteristics: Median age: 66 yrs; median BMI: 25.8. ECOC 0-1: 90%; visceral metastasis: 55.0%; bone only metastasis: 25.1%. 28.8% pts received EVE and EXE as first treatment (first line), 30.3% as second line, 18.0% as third line and 23.0% as forth or later line in the advanced setting. Comparing the first 200 with the most recent 200 documented pts the usage as first or second line treatment increased from 53.5% to 70.0%. Patients treated in first or second line were less likely to experience any adverse event (AE) (68.7% in first or second, 81.4% in later lines, $p<0.0005$). 18.1% of pts had received EXE earlier in their treatment history. Of 445 pts with at least 3 months follow-up 45.8% developed stomatitis: 26.6% grade 1, 16.9% grade 2, 2.7% grade 3. 87.2% of pts received recommendations regarding stomatitis prevention from their physician. QoL remained stable over the course of the treatment. No correlation could be seen between grade of stomatitis and QoL. Regarding global health status, pts without AEs reported better values than pts with AEs. Insights into dosing and therapy sequence will also be presented. **Conclusions:** This IA indicates that pts receiving EVE and EXE in earlier lines are less likely to experience AE. The majority of physicians recommend their pts to take prophylactic measures to prevent stomatitis. QoL remains stable over the course of the treatment.

**579 General Poster Session (Board #43), Mon, 8:00 AM-11:45 AM**

**Relative bone loss during aromatase inhibitors therapy: The B-ABLE cohort.** *Presenting Author: Sonia Servitja, Medical Oncology Department. Hospital del Mar, Barcelona, Spain*

**Background:** Estrogen deprivation induced by aromatase inhibitors (AI) leads to a rapid and prolonged bone loss and increased fracture incidence. The current study aims to evaluate AI-associated bone loss throughout the first two years of the treatment. **Methods:** B-ABLE is a prospective cohort of caucasian, postmenopausal women with early breast cancer, in adjuvant treatment with AI (according to the ASCO guidelines). Bone mineral density (BMD) and x-ray were measured at baseline and every year up to and 1 year after treatment completion. Paired t-tests were carried out to detect differences in lumbar spine (LS) and femoral neck (FN) BMD loss of 1 and 2 years of follow-up relative to baseline. Bisphosphonate users were excluded for these analyses. Women over 65 years old were also excluded from the analyses of LS BMD to avoid the underestimation of bone loss due to osteoarthritis. **Results:** Patients had mean rates of LS BMD loss relative to baseline of 1.98% ($n=241$) at 1 year and 3.51% ($n=182$) at 2 years of follow-up, ($P<0.001$). Mean rates BMD loss for FN were 1.24% ($n=381$) at 1 year and 2.07% ($n=257$) at 2 years, ($P<0.001$). Previous tamoxifen treated patients (40.7%) were younger and had a higher baseline BMD but experienced higher LS BMD loss rates at 1 (83%, $P<0.05$) and 2 (92%, $P<0.001$) years. FN BMD loss rates were also higher for those patients previously treated with tamoxifen at 1 (349%, $P<0.001$) and 2 years (177%, $P<0.01$). **Conclusions:** Rapid bone loss occurs in the first 2 years of AI treatment, especially in tamoxifen pre-treated women.

**580 General Poster Session (Board #44), Mon, 8:00 AM-11:45 AM**

**Gene expression profiling for identification of FYN in tamoxifen resistance and as predictor of early recurrence in patients treated with endocrine therapy.** *Presenting Author: Henrik Jorn Ditzel, University of Southern Denmark, Odense, Denmark*

**Background:** Development of resistance to tamoxifen is an important clinical issue in the treatment of breast cancer. **Methods:** To elucidate the molecular mechanisms of tamoxifen resistance in breast cancer, we performed gene array analyses and identified 366 genes with altered expression in 4 unique tamoxifen-resistant (TamR) cell lines vs. the parental tamoxifen-sensitive MCF-7/S0.5 cell line. **Results:** Most of these genes were functionally linked to cell proliferation, death and control of gene expression, and include FYN, PRKCA, ITPR1, DPYD, DACH1, LYN, GBP1 and PRLR. Treatment with *FYN*-specific small interfering RNA or a SRC family kinase inhibitor reduced cell growth of TamR cell lines, while exerting no significant effect on MCF-7/S0.5 cells. Moreover, overexpression of *FYN* in parental tamoxifen-sensitive MCF-7/S0.5 cells resulted in reduced sensitivity to tamoxifen treatment, while knockdown of *FYN* in the *FYN* overexpressing MCF-7/S0.5 cells restored sensitivity to tamoxifen, demonstrating growth- and survival- promoting function of FYN in MCF-7 cells. *FYN*knockdown in TamR cells led to reduced phosphorylation of 14-3-3 and Cdc25A, suggesting that FYN, by activation of important cell cycle-associated proteins, may overcome the anti-proliferative effects of tamoxifen. Evaluation of the subcellular localization of FYN in primary breast tumors from 2 cohorts of endocrine-treated ER+ breast cancer patients, one with advanced disease ($N=47$) and the other with early disease ($N=76$), showed that in the former, plasma membrane-associated FYN expression strongly correlated with longer progression-free survival ($p<0.0002$). Similarly, in early breast cancer patients, membrane-associated expression of FYN in the primary breast tumor was significantly associated with increased metastasis-free ($p<0.04$) and overall survival ($p<0.004$) independent of tumor size, grade or lymph node status. **Conclusions:** Our results indicate that FYN plays an important role in tamoxifen resistance, and its subcellular localization in breast tumor cells may be an important novel biomarker of response to endocrine therapy in breast cancer.

**581 General Poster Session (Board #45), Mon, 8:00 AM-11:45 AM**

**Bone turnover markers at 3 months of aromatase inhibitor therapy for prediction of 1-year bone mineral density loss: The B-ABLE cohort.** *Presenting Author: Ignacio Tusquets, Hospital del Mar, Barcelona, Spain*

**Background:** Most guidelines recommend bone mineral density (BMD) monitoring at 1-2 years of aromatase inhibitor (AI) therapy for women who do not need bisphosphonate therapy according to baseline assessment. Bone turnover markers (BTM) are sensitive to change in bone remodeling, and can be easily measured in clinic, offering an opportunity to anticipate BMD loss. We aimed to establish the association between changes in levels of BTMs at 3 months and 1-year BMD loss. **Methods:** The B-ABLE prospective cohort includes a consecutive sample of women with early breast cancer eligible for AI therapy. BMD is measured per protocol by DEXA at baseline and yearly, and BTMs (NTX and CTX in a subsample, Bone Alkaline Phosphatase (BALP) and Osteocalcin in all) at baseline, 3-months, and at yearly visits thereafter. Change in BTM levels (3-month minus baseline) was the main exposure and relative 1-year Lumbar Spine BMD loss (baseline minus 1-year over baseline) the main outcome of this study. Linear regression was used to establish the association between exposure and outcome. Multivariate models were adjusted for age, weight, and height. Adjusted standardized beta (ASB) coefficients are reported and must be interpreted as the mean increase in % BMD loss per each standard deviation of 3-month BTM change. **Results:** Data was available on 350 women starting on AI not on bisphosphonates according to ASCO guidelines. 138 and 149 had NTX and CTX data respectively. Changes in NTX (ASB 0.19, p=0.002), CTX (ASB 0.41, p<0.001), BALP (ASB 0.13, p=0.004) and Osteocalcin (ASB 0.21, p<0.001) at 3 months were associated with 1-year BMD loss. **Conclusions:** Changes in BTM (particularly CTX, with a strongest association) concentrations at 3 months of AI therapy can be used to target women with high BMD loss at 1 year. This strategy would identify high-risk women for closer monitoring/treatment.

**582 General Poster Session (Board #46), Mon, 8:00 AM-11:45 AM**

**Low cytolytic T-cell CD8 expression in mesenchymal triple negative (TN) breast cancers and overexpression of the adhesion protein CD24 in ER+ breast cancers that recur within 3 years of adjuvant chemotherapy.** *Presenting Author: Joyce O'Shaughnessy, Texas Oncology-Baylor Charles A. Sammons Cancer Center and US Oncology, Dallas, TX*

**Background:** The phase III trial USON 01062 (O'Shaughnessy J, et al Proc SABCS, 2010, abstract S4-2) showed that the addition of capecitabine to docetaxel following doxorubicin/cyclophosphamide adjuvant chemotherapy did not improve 5-year disease-free survival (DFS) (HR 0.84, p=0.125). We evaluated molecular biomarkers to identify genomic predictors of early recurrence in ER+ and TN breast cancers in USON 01062. **Methods:** 817 FFPE primary breast cancers had good quality gene expression data for PCR-based identification of *PIK3CA*somatic mutations (MT), as well as for Nanostring assessment of 800 breast cancer-related genes encompassing published breast cancer signatures and pathways. IHC for Ki67 and PTEN was also performed. **Results:** Intrinsic subtypes of the 817 cancers: 320 luminal A (Lum A); 124 Lum B; 296 basal (82% TN, 9% ER+ and 8% HER2+); and 69 HER2-enriched (60% HER2+, 33% TN, 7% ER+). Nonsignificant improvements in DFS with capecitabine were seen in the basal cancers with central Ki67 < 70%, and in luminal cancers with Ki67 > 25%. In Lum A pts, exons 9 or 20 *PIK3CA* MT predicted for favorable DFS; there was no difference in DFS outcome in Lum B *PIK3CA*MT vs wild type pts. CD24 and CDCA5 (which encodes the sister chromatid cohesion protein, sororin) were significantly overexpressed in ER+ cancers that recurred within 3 yrs of beginning adjuvant therapy (p=0.0086 and 0.045, respectively), and expression of ESR1 and its regulated genes such as RERG were associated with a low risk of recurrence. For the TNBCs, 42% were basal 1/2, 21% were immunomodulatory (IM), 15% were mesenchymal stem-like, 13% were mesenchymal and 9% were luminal AR. The mesenchymal subtype showed the highest rate of recurrence and low CD8 expression, while expression of IM genes including CD8 was associated with more favorable 5-year DFS outcome. **Conclusions:** Mesenchymal TNBC has low CD8 expression and a poor prognosis with adjuvant chemotherapy. Rapidly recurring ER+ breast cancers have low levels of ESR1 and overexpress CD24 which adheres to activated platelets and interacts with c-src/FAK to stimulate motility (Baumann P, Ca Res 65:10783, 2005).

**583 General Poster Session (Board #47), Mon, 8:00 AM-11:45 AM**

**Population-based evaluation of 21-gene assay in treatment decision making for early breast cancer in Ontario.** *Presenting Author: Mark Norman Levine, Ontario Clinical Oncology Group, McMaster University, Hamilton, ON, Canada*

**Background**: The OncotypeDX 21-gene assay (ODX) is used to aid in decision-making for chemotherapy (CT) in patients with breast cancer (BC). The province of Ontario, with a population of approximately 14 million, has a publically funded healthcare system. Funding of the ODX test by the Ontario Ministry of Health was conditional upon participation in a prospective cohort study by the Ontario Clinical Oncology Group to evaluate the test's impact on decision making. **Methods**: Subjects with node– ER+ Her2– BC who were considered for CT in addition to usual endocrine therapy (ET) were eligible. The oncologist's initial treatment recommendation based on the Adjuvant! Online (AO) result and classical factors (tumor size and grade) was recorded. Once the ODX recurrence score (RS) was available, the patient returned to clinic for final decision-making. Outcomes were the change in the oncologist's treatment recommendation, change in patient's treatment preference, and economics. AO relapse risk categories used in analysis were: low ≤ 25%, intermediate 26-36%, high ≥ 37%. **Results**: Between January 2012 and July 2013, 1,000 consecutive patients were recruited. Median age was 59 (26-88); median tumor size was 1.7cm (0.2-9.0); 24% were Grade I, 58% Grade II and 18% Grade III. Relapse risk groups for ODX (AO) in the 977 ODX tested patients were: 58% (55%) classified as low, 33% (15%) intermediate, and 9% (31%) high risk. The oncologist's recommendation was the same in 463 patients (48%), changed from unsure or CT to ET in 360 patients (37%), and from unsure or no CT to CT in 141 (15%). **Conclusions**: To our knowledge, the Ontario study is the largest population-based prospective cohort to assess the impact of ODX on treatment recommended and received. As expected, the ODX had a substantial impact on the CT plan; CT was avoided in up to 37% of patients and recommended in an additional 15%. Clinical trial information: NCT01423890.

**584 General Poster Session (Board #48), Mon, 8:00 AM-11:45 AM**

***ERP29* genetic polymorphism and breast cancer susceptibility and prognosis.** *Presenting Author: Gustavo Jacob Lourenco, Department of Internal Medicine, Faculty of Medical Sciences, University of Campinas, Campinas, Brazil*

**Background:** *ERP29*, a tumor suppressor gene, was related with the onset of tumors. The influence of *ERP29* c.*293A>G (rs7114) polymorphism in breast cancer (BC) risk and prognosis has never been performed before and was the aim of this study. **Methods:** We analyzed 742 BC patients and 742 healthy women. The BC patients were treated by conventional procedures. *ERP29* c.*293A>G genotypes were obtained from genomic DNA by TaqMan genotyping assays. The expression of *ERP29* mRNA was determined by quantitative PCR using total RNA from blood leukocytes of healthy individuals with distinct genotypes (12 individuals with AA, 15 with AG, and six with GG). Overall survival (OS) was obtained from date of first diagnosis until the date of death or last follow-up. The differences in frequencies of distinct genotypes in patients and controls were analyzed by logistic regression model, serving to obtain age, ethnic origin and adjusted crude odds ratios (ORs), considering a confidence interval (CI) of 95%. OS time was calculated using the Kaplan-Meier estimate probabilities and differences between survival curves were analyzed by the log-rank test. Statistical significance was established at a $P<0.05$. All computations analyses were done using the SPSS 21.0 software (SPSS Incorporation). **Results:** The frequency of *ERP29* AG+GG combined genotypes was higher in BC patients than in controls (36.6% versus 30.7%, P=0.03). Carriers of G allele were under a 1.33 (95% CI: 1.03-1.72)-fold increased risk for the tumor. The mean mRNA expression was lower in carriers of G allele than those with *ERP29* AA genotype (0.82 arbitrary units (AUs) versus 1.41 AUs; P=0.02). The median of observation of BC patients enrolled in the study was 54 months (1-325). OS of BC patients with the *ERP29* AG+GG combined genotypes was higher than that observed in those with the *ERP29* AA wild genotype (67.5% versus 59.0% at 120 months of follow up; $P=0.04$). **Conclusions:** Our data suggest, for the first time, that *ERP29* c.*293A>G polymorphism alters the risk and prognosis of BC possibly due to variation in the protein production.

**585 General Poster Session (Board #49), Mon, 8:00 AM-11:45 AM**

**Estrogen levels in premenopausal (prem) patients (pts) with hormone-receptor positive (HR+) early breast cancer (BC) receiving adjuvant triptorelin (Trip) plus exemestane (E) or tamoxifen (T) in the SOFT trial: SOFT-EST substudy.** *Presenting Author: Meritxell Bellet, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Optimal endocrine therapy for prem pts with early HR+ BC may depend on complete estrogen suppression with GnRH-A, and is crucial for those receiving concurrent aromatase inhibitors (AI). SOFT-EST is a prospective substudy of the phase III SOFT trial. Aims of SOFT-EST are to describe estradiol (E2), estrone (E1) and estrone sulphate (E1S) during monthly Trip + E or T and to assess if there is a group in E+Trip with suboptimal estrogen suppression (SES). **Methods:** All pts enrolled in SOFT from selected centers who consented, selected Trip as ovarian function suppression method and were randomized to E+Trip or T+Trip were enrolled in SOFT-EST until reaching the accrual goal (E=90;T=30 pts). Prem status for SOFT was based on local E2. Blood sampling timepoints (tp) were: 0, 3, 6, 12, 18, 24, 36 & 48 months (m). Serum estrogens were measured by GC/MSMS due to high specificity/sensitivity and no E cross-reactivity. SES for E+Trip for this first pre-planned (12 m) analysis was defined as E2 levels >2.72 pg/mL (10 pmol/L). **Results:** 116 pts (E/T=86/30) who started Trip and had ≥ 1 sample drawn constituted the analytic cohort. In E+Trip, median reductions from baseline in E2, E1 & E1S levels were >95% at all tp, and significantly lower than in T+Trip. 27 of 79 E+Trip pts with ≥1 post-baseline sample had E2 levels >2.72 pg/mL at least once (25%, 24% & 17% at 3, 6 & 12m, respectively); 2 had vaginal bleeding >3 m beyond start of E+Trip, 1 with SES. Baseline factors related to SES in E+Trip were no prior chemo (p=0.06), high BMI (p=0.05), low FSH & LH (p<0.01 for both), but not age (p=0.8). **Conclusions:** Most pts on E+Trip reached E2 below the defined threshold, consistent with postmenopausal pts on an AI, but some may be suboptimally suppressed. The clinical relevance will be further explored with the full 4-yrs of estrogen results and outcome data. Clinical trial information: NCT00066703/NCT00066690.

**Impact of 21-gene RT-PCR assay on adjuvant therapy for stage I breast cancer.** *Presenting Author: Fanny Le Du, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** A recurrence score (RS) derived from a 21-gene RT-PCR assay (Oncotype DX) stratifies patients (pts) with early estrogen receptor (ER)-positive, HER2-normal breast cancer (BC) into 3 groups based on risk of 10-year distant metastasis rate: low, intermediate, and high. High RS predicts benefit from chemotherapy follow-by hormonal therapy (CH-T); whether intermediate RS predicts benefit from CH-T is unknown. For Stage I, NCCN Clinical Practice Guidelines recommend use of RS for T1b BC with unfavorable features (angiolymphatic invasion, high histologic or nuclear grade) and T1c BC. However, data are limited on how RS influences treatment of stage I BC. We sought to define the impact of RS on treatment in pts with stage I BC. **Methods:** In 1057 pts with ER-positive, HER2-normal stage I BC with RS available, we assessed the interaction between RS and treatment by tumor category. Kaplan-Meier survival curves and log-rank tests were used to compare outcomes. **Results:** Pts with T1a, T1b, and T1c BC did not differ in the distribution of low, intermediate and high RS (P=0.53) (Table). In the T1b and T1c groups, 57% and 52%, respectively, of pts with intermediate RS did not receive chemotherapy. Median follow-up is 25.7 months. Among T1b pts with intermediate RS, disease-free survival did not differ between pts who received HT and those who received CH-T (P=0.84). Among T1b pts with intermediate RS, pts who received CH-T had higher RS than pts who received HT (median 23 vs 21, P<0.001). **Conclusions:** Less than 10% of patients with stage I had high RS.More than half of pts with stage I BC and intermediate RS received HT alone. Pts with higher RS were more likely to receive CH-T. Among pts with T1b BC and intermediate RS, pts who received HT alone had the similar DFS as those who received CH-T.

| | No. (%) of pts*** | | |
|---|---|---|---|
| **RS category and treatment** | **T1a (n=36)** | **T1b (n=296)** | **T1c (n=725)** |
| **Low** | 22 | 173* | 391* |
| **HT** | 22 (100) | 156 (90) | 345 (88) |
| **CH-T** | 0 | 7 (4) | 31 (8) |
| **Intermediate** | 13* | 98* | 269** |
| **HT** | 11 (85) | 56 (57) | 140 (52) |
| **CH-T** | 1 (8) | 37 (38) | 116 (43) |
| **High** | 1 | 25* | 65** |
| **HT** | 0 | 2 (8) | 10 (15) |
| **CH-T** | 1 (100) | 21 (84) | 52 (80) |

* DFS did not differ between HT and CH-T (P>0.05).
** DFS differed between HT and CH-T (P<0.05).
*** Percentages in some groups total less than 100% because 18 pts received no treatment and 29 pts had missing treatment data.

**587 General Poster Session (Board #51), Mon, 8:00 AM-11:45 AM**

**A randomized, double-blind phase II trial of exemestane plus MM-121 (a monoclonal antibody targeting ErbB3) or placebo in postmenopausal women with locally advanced or metastatic ER+/PR+, HER2-negative breast cancer.** *Presenting Author: Michaela Jane Higgins, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background:** Ligand-driven ErbB3 signaling has been implicated as a mechanism of resistance to conventional therapies across multiple malignancies, including endocrine resistant metastatic breast cancer (mBC). Here we present results of a trial evaluating MM-121 (M) or placebo (P) in combination with exemestane in postmenopausal women with ER/PR+ HER2-negative mBC. **Methods:** This study enrolled women with locally advanced or mBC who had failed adjuvant therapy or progressed in the metastatic setting. The primary endpoint was progression free survival (PFS) and the study was powered to detect a HR of < 0.5. Secondary and exploratory analyses included overall survival (OS), safety, and analyses of a pre-specified set of mechanistically-linked biomarkers ((BM), heregulin, betacellulin, EGFR, ErbB2, and ErbB3) in archived tissues. **Results:** 115 randomized and treated patients (56 (M), 59 (P)) were included in safety and efficacy analyses. Baseline demographics and disease characteristics were balanced. At the time of the analysis, 92 (80%) patients (78.6% (M), 81.4% (P)) had discontinued treatment, mainly due to progressive disease (66.1% (M), 76.3% (P)). PFS was analyzed after 84 events (38 (M), 46 (P)). The median PFS was 15.9 weeks (M) vs. 10.7 weeks (P), with a stratified hazard ratio (HR) of 0.772 (95% CI [0.496- 1.201]), p=0.249). OS data were immature at the time of the primary analysis (29 events: 11 (M), 18 (P)), with a stratified HR of 0.436 (95% CI [0.197 – 0.966]). In patients positive for two of the pre-specified BMs (31%: 17 of the 55 patients with BM data), the HR for PFS was 0.32 (95% CI [0.10-1.00]). Common adverse events (AEs, >20%) of any grade and causality (M vs. P), were diarrhea (50% vs. 23.7%), nausea (28.6% vs. 23.7%), fatigue (23.2 % vs. 23.7%), and arthralgia (17.9% vs. 20.3%). **Conclusions:** The addition of MM-121 to exemestane did not significantly prolong PFS in the unselected population, although the HR appears to favor the MM-121 arm. The biomarker findings were consistent with preclinical hypotheses, as well as an independently conducted Phase 2 study in platinum resistant ovarian cancer. Clinical trial information: NCT01151046.

**588 General Poster Session (Board #52), Mon, 8:00 AM-11:45 AM**

**Residual estrogen receptor availability during fulvestrant 500 mg therapy in patients with metastatic breast cancer.** *Presenting Author: Michel van Kruchten, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Fulvestrant competitively binds the ER and can decrease its expression. However, it is currently unknown whether the standard dose of 500 mg intramuscularly (days 1, 14, 28 and every 4 weeks thereafter) in metastatic breast cancer patients is sufficient for maximal ER downregulation. In a feasibility study we therefore evaluated whether fulvestrant 500 mg completely abolishes ER availability in patients with ER-positive metastatic breast cancer. **Methods:** Sixteen patients received fulvestrant and underwent positron emission tomography/computed tomography (PET/CT) before therapy initiation (scan 1), on day 28 (scan 2) and day 84 (scan 3) to monitor tumor [$^{18}$F]fluoroestradiol (FES) uptake. A relative decrease of <75% in the median (background-corrected) tumor FES uptake and a residual standardized uptake value ($SUV_{max}$) ≥1.5 was predefined as incomplete reduction in ER availability. Plasma fulvestrant levels were determined concurrently with the scans by liquid chromatography tandem mass spectrometry. **Results:** All patients had at least one FES-positive ($SUV_{max}$ ≥1.5) lesion before therapy initiation. A total of 131 FES-positive lesions were identified on FES-PET/CT (median $SUV_{max}$ in patients = 2.9 [range 1.7 - 6.5]). The relative change in tumor FES-uptake in patients during fulvestrant was -85% at scan 2, but varied widely across individuals (-99% to +60%). Median residual tumor $SUV_{max}$ was 1.7 (1.1 - 3.8) at scan 2 and remained stable at scan 3. Fulvestrant reduced tumor FES uptake incompletely at scan 2 in 6 of 16 patients (38%). Eight of nine patients with ≥75% decrease in median FES-uptake at scan 2 subsequently experienced clinical benefit from fulvestrant therapy, compared to only one of six with <75% decrease. Plasma fulvestrant levels were 33 (16 to 53) nmol/L at scan 2 and 27 (13 to 42) nmol/L at scan 3 and did not correlate with changes in tumor FES uptake. **Conclusions:** FES-PET showed significant residual ER availability in tumors during the first 3 months of fulvestrant therapy in 38% of patients, which was related to early progression. FES-PET may be used as an effect sensor for fulvestrant efficacy and may help to identify patients that could potentially benefit from a higher dose. Clinical trial information: NCT01377324.

**589 General Poster Session (Board #53), Mon, 8:00 AM-11:45 AM**

**The value of tamoxifen and trastuzumab in breast cancer treatment: A study based on uptake and use in Sweden.** *Presenting Author: Nils Erik Wilking, Karolinska Institutet, Stockholm, Sweden*

**Background:** Early breast cancer (EBC) and metastatic breast cancer (MBC) represents major health problems. Tamoxifen has since the late 1970s been a backbone in the treatment of hormone receptor positive (HR+) MBC and EBC, and lately also for primary prevention. Trastuzumab has since 2000 in the EU been the drug of choice for HER2+ MBC and from 2005 also in EBC. **Methods:** Sweden had in the end of the 1970s around 4500 and at present around 8000 new cases of EBC. Mortality has been stable over time with about 1500 patients dying annually. Tamoxifen was first introduced in the 1970s in the treatment of MBC. From 1985 and onwards it has been used extensively in EBC with adjuvant treatment times starting with a 1 year treatment period, which in the mid-1990ies was extended to 5 years. Trastuzumab was introduced in MBC in 2000 and became standard in the adjuvant setting in 2005-2006. We have calculated the value of the use of the two drugs from a societal perspective for two periods; 1979-2004 for tamoxifen (time of introduction of aromatase inhibitors as adjuvant treatment for EBC) and 2001-2011 for trastuzumab. We used outcomes from pivotal clinical trials and real world data on use of drugs from the National Pharmacy registry and the National Board of Health and Welfare. The value was estimated as the gains in QALYs and increased production net of costs for drugs and increased consumption in added years of life. **Results:** The gain from tamoxifen in EBC and MBC during 1979-2004 was 39 billion SEK; 32 from gains in QALY and 7 from added production. The cost was 1.1 billion SEK for drugs and 18 billion SEK for added consumption from improved survival. The gain from trastuzumab in EBC and MBC during 2001-2011 was 4.3-6.1 billion SEK from QALY gains and 5.3-7.2 billion SEK from added production. The cost was 2.0 billion SEK for drugs and 1.4 billion SEK for added consumption. (1 USD= 6.60 SEK). **Conclusions:** Tamoxifen and trastuzumab represent major gains in survival, quality of life and productivity of patients with breast cancer. Data showed a major surplus from a societal perspective for each SEK invested: for tamoxifen there was a return of 18 SEK from gains in QALYs and production; for trastuzumab the return was 3.2-5.0 SEK.

**590 General Poster Session (Board #54), Mon, 8:00 AM-11:45 AM**

**Clinical and pathologic correlation of the activated form of the androgen receptor (AR) in breast cancer (BC).** *Presenting Author: Philippe Jamme, Centre Oscar Lambret, Lille, France*

**Background:** The Androgen Receptor is present in BC, and ongoing studies are testing the activity of antiandrogens in BC. AR has been associated with a better prognosis in ER$\alpha$ positive tumors. AR has a nuclear biology dynamics common to the steroid nuclear receptors. In the absence of ligand, it is evenly distributed in nuclei; when exposed to androgens, it migrates to form sub-nuclear aggregates that can be detected by fluorescence microscopy. Thus, two distinct nuclear patterns, diffuse (D) or aggregated (A), correspond to two receptor functional states. Similarly to previous work on ER and PR (ASCO 2013 abstr # 11535 & 593), we have devised an immunohistochemical (IHC) method to characterize the nuclei patterns that may indicate whether AR is transcriptionally active or not in PEFF tissues. The goal of this study is to explore the AR biological or clinical relevance. **Methods:** As of February 4th, 662 archived BC biopsies have been obtained along with associated clinical data. Biopsies were analyzed for standard HES, ER, PR, AR and Ki67. AR positivity was determined with clone AR27 antibody (Novocastra). The A-AR (aggregated AR) and D-AR (diffuse AR) pattern were analyzed at x1000 magnification. **Results:** 490 cases have been analyzed to date. Mean Age: 57 (17-89). Histology: ductal 82%, lobular 15%, and other 3%; $ER\alpha^{pos}$ , 78%, $PR^{pos}$ 78%. Adj Chemotherapy 46% Hormonotherapy 85%. Stage I 44%, II 48%, III 8%. Grade I 25%, II 50%, III 25%. AR was positive ($AR^{pos}$) in 51%. AR status was diffuse (D-AR) in 66% and aggregated (activated, A-AR) in 34% of the $AR^{pos}$ biopsies. $AR^{pos}$ and D-AR were associated with lower Grade ($p < 0.04$, $p = 0.1$), ER$\alpha$ ($p < 0.000$,$= 0.03$), PR ($p < 0.000$, 0.1), but not HER2, Ki67, or Staging. Median follow up was 36 months (mo). Progressive disease (PD), local or distant, was 19%, and PD was not associated with A-AR ($p=0.25$). With DFS defined as time to PD or death (5 year cut-off), $AR^{pos}$was associated with a HR of 0.61 ($p = 0.08$) but not in a Cox model including both AR and ER positivity (HR for ER = 0.41, for AR 0.92, with $p = 0.006$ and 0.8 respectively). When added, grade was an independent predictor (HR= 0.44, $p = 0.004$). **Conclusions:** A-AR is associated with grade and other steroid receptors suggesting biological relevance.

**591 General Poster Session (Board #55), Mon, 8:00 AM-11:45 AM**

**A phase 1 study to assess the food effect on the pharmacokinetics (PK) of entinostat.** *Presenting Author: Denise A. Yardley, SCRI/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** Entinostat (ENT) is an oral, class 1 isoform selective histone deacetylase inhibitor shown to extend progression free and overall survival when combined with exemestane (EXE) in post-menopausal women with estrogen receptor positive (ER+) metastatic breast cancer (MBC) who have progressed on prior non-steroidal aromatase inhibitors (Yardley et al; JCO 31:2128;2013). Based on these results ENT was granted Breakthrough Therapy designation by the FDA for this indication. This Phase 1 study evaluated the effect of food on ENT PK in patients (pts) with MBC and advanced non-small cell lung cancer (NSCLC). **Methods:** A total of 17 pts (14 postmenopausal ER+ MBC and 3 NSCLC) were randomized 1:1 to receive ENT 10 mg administered Day 1 and 15 of a 28 day lead-in cycle, fasting and with food. Pts randomized to ENT with food on Cycle 1 Day 1 (C1D1) received ENT fasted on Cycle 1 Day 15 (C1D15); pts randomized to ENT fasted on C1D1 received ENT with food on C1D15. Blood samples were obtained pre-dose C1D1 and serially during C1 for PK and pharmacodynamic (PD) analysis. Following C1, ENT 10 mg was continued on D1 and 15 of a 28 day cycle in combination with daily EXE 25mg (MBC) or erlotinib 150 mg (NSCLC) until toxicity or disease progression. Tumor assessments (RECIST 1.1) were performed every 2 cycles. **Results:** Co-administration of ENT with food decreased its Cmax by 71% and overall exposure by 15-17%, as estimated by AUClast and AUCinf. The mean t1/2 of ENT was estimated at 140 hrs under fasted conditions and 178 hrs under fed conditions. Additional PK parameters along with protein lysine acetylation PD will be reported. ENT was well tolerated with no unexpected toxicities. 9 MBC pts experienced stable disease (n=8) or partial response (n=1) with 3 pts continuing beyond 10 cycles; one patient continues on study at cycle 19. Progressive disease was the best response in the 3 NSCLC pts. **Conclusions:** ENT $C_{max}$ and exposure as measured by $AUC_{last}$ and $AUC_{inf}$ were significantly reduced when co-administered with food, leading to recommended ENT dosing under fasted conditions. ENT 10 mg was well tolerated and clinical benefit was observed in MBC pts. A randomized, double blind, placebo-controlled phase 3 trial in ER+ advanced breast cancer is planned. Clinical trial information: NCT01594398.

**592 General Poster Session (Board #56), Mon, 8:00 AM-11:45 AM**

**Effect of age and tumor size on prognostic outcome of women with breast cancer.** *Presenting Author: Shaheenah S. Dawood, Dubai Hospital, Dubai, United Arab Emirates*

**Background:** Increasing tumor size is known to be associated with worse prognostic outcome. The objective of this study was to determine the prognostic impact of change in tumor size by age at diagnosis. **Methods:** Using the SEER registry we identified female patients with stage I to III breast cancer diagnosed between 1990 and 2006. Patients (pts) were divided into 4 groups according to age at diagnosis: a) 18 to 35 years, b) 36 to 50 years, c) 51 to 65 years, and d) > 65 years. Breast cancer specific survival (BCSS) was computed using the Kaplan-Meier method. 5-year BCSS were estimated for each tumor size within each age group. Next, the 5-year BCSS was modeled in a linear regression against tumor size as a continuous variable. **Results:** We identified 385,285 patients with following age distribution: 18-35 years =11,737 (3.05%) pts, 36-50 years = 99,442(25.81%) pts, 51-65 years = 130,011(33.74%)pts and >65 years = 144,095(37.40%) pts. The corresponding 5-year BCSS was 83%, 90%, 91% and 87% respectively ($p<0.0001$). 5-year BCSS among pts with T1, T2 and T3 disease was 96%, 84% and 67% respectively ($p<0.0001$). For pts aged 18-35 years, 36-50 years, 51-65 years and >65 years, a 1 cm increase in tumor size was associated with 4%, 4.1%, 4.4% and 5.3% decrease in 5-year BCSS respectively ($p<0.0001$ for difference between youngest and oldest age groups). Among pts with hormone receptor positive disease, a 1 cm increase in tumor size was associated in a significantly lower decrease in 5-year BCSS in the youngest (3.3%) compared to oldest (4.2%, $p <0.0001$) age groups; the corresponding decrease in 5-year BCSS among pts with hormone receptor negative disease was also significantly different ( 4.1% vs. 6.5%, $p<0.0001$). Similar results were obtained when the prognostic impact of tumor size in different age groups was analyzed by nodal status. **Conclusions:** Increasing tumor size has a significantly greater adverse prognostic impact in older compared to younger women and this result is consistent in subgroups defined by hormone receptor and nodal status. This observation could partly account for the greater impact of breast cancer screening in older compared to younger women.

**593 General Poster Session (Board #57), Mon, 8:00 AM-11:45 AM**

**Genes associated with serum estrone, estrone conjugates, and androstenedione concentrations in postmenopausal women with estrogen receptor-positive breast cancer.** *Presenting Author: Tanda M. Dudenkov, Mayo Clinic, Rochester, MN*

**Background:** Estrone (E1), the predominant estrogen in postmenopausal women, is synthesized from androstenedione (A) in the ovaries and adipocytes and can be converted to conjugates (E1Cs). Both circulating E1 and E1Cs are known risk factors for breast cancer; and E1C is present at concentrations up to 10 fold higher in breast cancer tissue than in serum. However, little is known regarding the genes that regulate serum A, E1 or E1Cs concentrations. **Methods:** In a cohort of 776 postmenopausal women with estrogen receptor positive breast cancer, we used a genome-wide association study (GWAS) to identify SNP signals associated with these concentrations. Serum levels of each hormone were measured using GC-MS/MS, and patients were genotyped at ~600,000 SNPs and another 7 million were imputed. Using linear regression models with additive genetic effects, a GWAS was conducted for each hormone level separately as well as the ratio of E1/A, E1Cs/A and E1Cs/E1. SNP effects were adjusted for BMI, population stratification and other relevant variables. **Results:** Multiple SNPs in *SLCO1B1*, a gene that encodes a transporter, were genome-wide significantly associated with E1C levels, E1Cs/E1 and E1Cs/A ratios. The variant allele of the top genotyped SNP rs4149056 (p value = $3.74x10^{-11}$) is a missense mutation that has an established association with statin-induced myopathy and sex hormone binding globulin levels. SNPs in *EMR2* ($p=1.39x10^{-07}$), *ELMO1* ($p=3.19x10^{-07}$), *LDB3* ($p=5.67x10^{-07}$) and *CYP11B1/2* ($p=6.65x10^{-07}$) genes were associated with androstenedione levels. SNPs downstream of *SYNJ2NP2/ARIP2* and upstream of the testis-specific gene *ADAM21* ($p=1.48x10^{-06}$) were associated with E1 levels, with a non-synonymous SNP in *ADAM21* showing suggestive association (rs45480894, $p=2.58x10^{-06}$). The ratio of E1/A was associated with a missense SNP in *ANO7* (rs74804606, $p=5.69x10^{-07}$). **Conclusions:** These results, particularly those for *SLCO1B1* that encodes a liver transporter of E1C, point towards mechanisms that may explain variation in these hormones that are associated with increased risk of breast cancer.

**594 General Poster Session (Board #58), Mon, 8:00 AM-11:45 AM**

**Impact of marital status on prognostic outcome of women with breast cancer.** *Presenting Author: Shaheenah S. Dawood, Dubai Hospital, Dubai, United Arab Emirates*

**Background:** The objective of this study was to examine the impact of marital status among patients with breast cancer. **Methods:** We searched the SEER registry to identify 549589 patients (pts) with stage I to IV breast cancer diagnosed between 1990 and 2010. Patients were divided into two groups depending on the marital status at diagnosis: a) married, b) unmarried (included never married, separated, divorced and widowed). Breast cancer specific survival (BCSS) was computed using the Kaplan Meier product limit method. Multivariable cox models were then fit to look at the association of marital status and BCSS adjusted for various pt and tumor characteristics. **Results:** Married pts accounted for 56.8% of the cohort. Married pts tended to be younger (median age of diagnosis 56 yrs vs. 65 yrs), have lower stage of disease, smaller tumor size, node negative disease and be of white/other race compared to unmarried pts. 5-year BCSS was 89% and 82% among married and unmarried pts respectively ($p<0.0001$). Among patients of either black or white/other race a 7% significant improvement in 5-year BCSS was observed among married compared unmarried pts. Among pts with stage I, II, III and IV disease a significant improvement in 5-year BCSS of 1%, 3%, 9% and 7% respectively was observed among married compared to unmarried pts. In the multivariable cox model unmarried pts had a higher risk of death from breast cancer compared to married pts (HR=1.2; 95%CI: 1.18-1.22; $p<0.0001$). An interaction term between marital status and age at diagnosis was significant, such that as age increases by one year unmarried pts had increasing risk of death compared to unmarried pts (HR 1.004, 95% CI 1.003-1.005, $p<0.0001$). **Conclusions:** Being married at the time of diagnosis of breast cancer improves survival regardless of pt and tumor characteristics. The impact of marital status appears to be greater among older pts compared to younger patients, which may be explained partly by a more aggressive biology generally seen among younger pts and the increasing need for a support system among older patients.

**595 General Poster Session (Board #59), Mon, 8:00 AM-11:45 AM**

**Breast cancer in young women: A single center study.** *Presenting Author: Joanna Rodriguez, Department of Medical Oncology, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

**Background:** Breast Cancer among young women is on the rise. It is estimated there will be up to 13,000 new cases this year in this age group. There are no screening guidelines in place for women younger than 40 years old. Breast cancer in this age group is associated with higher morbidity and mortality compared to older women, thus the impact of the disease is significant. **Methods:** We performed a retrospective chart review of women younger than 45 years old diagnosed and treated for breast cancer at Thomas Jefferson University from 1998-2012. Patients were stratified by age, stage, disease subtype (triple negative; HR+/Her2-;HR+/Her2 +; HR-/Her2+), race, and BMI. Descriptive analysis was performed. **Results:** Seven hundred and thirty three patients younger than 45 years old were reviewed from 1998-2012.The majority of patients were Caucasian (74%), followed by African American (14%), Asian (1.36%) and Hispanic (.13%). The analysis demonstrated that ER negative disease was found in 20% of patients, with the percentage increasing over the study period. From 1998-2006, 34% of patients were diagnosed with ER negative disease but from 2008-2012, 44.12% of patients were diagnosed with this type of breast cancer. This trend in incidence was not observed in the HER2 positive subtype set which remained stable at 21%. Moreover, the analysis found that there has been an increase in patients presenting with locally advanced disease (clinical stages III/IV). From 2007-2012 stage III/IV disease was documented in 29% of patients as compared to 13.5% of patients from 1998-2006. **Conclusions:** This retrospective study indicates that breast cancer diagnosed in women younger than 45 years is increasingly associated an aggressive clinical and molecular subtype. Delay in diagnosis has been a concern among this age group given the lack of screening guidelines. Furthermore, our data shows an increase in ER negative disease in recent years, suggesting a possible shift in tumor biology as well. More awareness and screening programs to both practitioners and young women should be implemented.

**596 General Poster Session (Board #60), Mon, 8:00 AM-11:45 AM**

**Characteristics of breast cancer in Ghana and prevalence of aggressive disease and high mortality.** *Presenting Author: Evelyn Mawunyo Jiagge, University of Michigan, Ann Arbor, MI*

**Background:** Breast cancer (BC) is now emerging as the most commonly diagnosed cancer among women in sub-Saharan Africa, surpassing cervical cancer. Although its incidence is relatively low in women in western Africa (approximately 28-35/1000,000), it carries 80% mortality, representing a massive public health problem. We hypothesized that the high mortality of BC is due to late diagnosis and to the high prevalence on estrogen receptor (ER) negative BC that is very aggressive and relatively unresponsive to existing therapies. The overarching objective of this work is to help focus research on the most pressing questions regarding the biological determinants contributing to high mortality from BC in sub-Saharan Africa. **Methods:** All the cancer cases that reported to Komfo Anokye Teaching hospital in Kumasi, Ghana diagnosed or treated at the facility between 2004 and 2011 were compiled and classified by age, stage, and receptor status, if available. The proportion of BC cases was further grouped by histologic type. **Results:** BC comprises nearly 25% of all cancers with male breast cancer accounting for 10% of BC cases. Of the female breast cancers, 50% are estrogen receptor negative. More than a third of the patients are younger than 45 years. The age specific incidence appears shifted to younger ages, after accounting for the population pyramid. **Conclusions:** BC in being increasingly diagnosed in Ghana; increased diagnosed burden may be due to increased awareness and/or to slowly increasing true incidence. BC in Ghanaian women exhibits phenotypic characteristics of younger age distribution, high proportion of ER- disease, high proportion of male breast cancer. These characteristics suggest specific early life exposures, hereditary factors, or both. Molecular genetics studies of tumors of differing ancestries may uncover hereditary factors that contribute to this spectrum of characteristics.

**597 General Poster Session (Board #61), Mon, 8:00 AM-11:45 AM**

**Factors influencing recurrence in long-term survivors with early-stage breast cancer of low risk.** *Presenting Author: Xerxes Pundole, The University of Texas Health Science Center at Houston, School of Public Health, Houston, TX*

**Background:** Approximately 60% of women with breast cancer (BC) are diagnosed with early stage disease with 5-year survival rates estimates of 84.4% to 98.6% depending on tumor type and extent of lymph node involvement. Despite high survival rates, many women experience recurrences after 5, 10 and even 15 years. Little is known about the influence of lifestyle and other 'host' factors and disease recurrence in 'long-term' survivors with low-risk disease. **Methods:** A retrospective case-only study of stage I-II BC patients, at The University of Texas M.D. Anderson Cancer Center from January 1, 1985 to December 31, 2000. The cases were disease free 5 years from diagnosis, and for whom baseline and follow-up information were available. We sought to compare epidemiologic and clinical factors among patients that had a late recurrence of their primary BC to those who did not. **Results:** A total of 2,468 patients were included in the original study from 1985 to 2000, of these 2,047 (83%) women were followed for >5 years. We obtained epidemiologic information on 1,057 (52%) women, of which 1,035 (98%) women were disease free and 22 (2%) had a recurrence after 5 years of being disease free. Multivariable analysis revealed that Hispanic women [Reference (Ref) Caucasian, (odds ratio (OR), 3.78, p =0.02] and heavy alcohol drinkers [Ref never drinkers, OR, 11.2, p=0.00] were significantly associated with recurrence in these patients with low risk disease, after adjusting for the year of diagnosis. No other clinical or histopathological characteristics at diagnosis or other epidemiologic factors (BMI, smoking, family history) were associated with recurrence in this sub cohort. **Conclusions:** Though limited by inherent bias of non-inclusion of women lost to follow-up and a small sample size, to our knowledge, this is the first evidence suggesting that alcohol consumption may increase the risk of late recurrence in an otherwise good prognosis group. Our results contrast published findings of no overall main effect of alcohol at baseline as a risk factor for BC recurrence and suggest a need to test the effect of alcohol consumption on late recurrence, where tumor biology is less likely to overwhelm modest but significant effects of lifestyle factors.

**598 General Poster Session (Board #62), Mon, 8:00 AM-11:45 AM**

**Phase I-II study of the histone deacetytase inhibitor vorinostat plus sequential weekly paclitaxel and doxorubicin-cyclophosphamide in locally advanced breast cancer.** *Presenting Author: Yifan Tu, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY*

**Background:** HDACs regulate chromatin remodeling and gene transcription. Vorinostat (V) is a panHDAC inhibitor that sensitizes breast cancer (BC) cells to taxanes and trastuzumab. **Methods:** 55 patients (pts) with clinical stage IIA-IIIC BC received 12 weekly doses of paclitaxel (P)(80 mg/m2) plus V on days 1-3 (200 mg BID [N=4], 300 mg BID [N=51]) of each P dose plus trastuzumab (if HER2-positive), followed by doxorubicin/cyclophosphamide (AC-60/600 mg/m2 every 2 weeks and pegfilgrastim), The trial was powered to detect an improvement in pathologic complete response (pCR) rate from 30% to 55% ($\alpha$=0.10, $\beta$=0.10) in stratum A (HER2+) and stratum B (triple negative), and from 15% to 40% in stratum C (ER+, HER2-). Immunohistochemistry was done on pretreatment core biopsies for HDAC6, p27, p21, Hsp70, and Ki67, and 3 pts had biopsies done before and after the third V dose for Western blot analysis. **Results:** There were no dose limiting toxicities at either V dose level. Breast/nodal pCR occurred in 13/24 evaluable pts in stratum A (54%, 95% confidence intervals [CI] 34%, 74%), 4/15 evaluable pts in stratum B (27%, 95% CI 95% CI 11%, 52%), and none of 12 evaluable patients in stratum C. Residual cancer burden (RCB) scores were 0-1 in 19 (79%, 95% CI 59%, 91%), 7 (47%, 95% CI 21%, 71%), and 1 (8%, 95% CI 0.4%, 35%) pts in stratums A, B, and C, respectively. Mean/median HDAC6 expression did not differ in each stratum or correlate with pCR. Mean P21 expression was higher in stratum A than B (p=0.03), and HSP70 expression was higher in stratum C than A (p=0.02). By Western blot, V suppressed HDAC6, increased acetylation of HSP90 and alpha-tubulin, and reduced levels of HSP90 client proteins (eg. HER2/neu, pAKT) in vivo. **Conclusions:** Combination of V with weekly paclitaxel and trastuzumab followed by AC induces higher than expected pCR rate in locally advanced HER2/neu-positive breast cancer. V induced biological effects in vivo that may enhance the antitumor effects of paclitaxel and trastuzumab and contribute to the efficacy of this combination. Clinical trial information: NCT00574587.

**599 General Poster Session (Board #63), Mon, 8:00 AM-11:45 AM**

**Differential effects of metformin on breast cancer proliferation according to insulin resistance and tumor subtype in a presurgical trial.** *Presenting Author: Andrea De Censi, E.O. Ospedali Galliera, Genoa, Italy*

**Background:** Treatment of diabetics with metformin decreases breast cancer risk in observational studies, but it is unclear if this drug has clinical antineoplastic activity. In a recent pre-surgical trial (Bonanni et al JCO 2012), we found a heterogeneous effect of metformin on Ki-67 depending upon insulin resistance (HOMA index). Here we determined the associations of additional biomarkers of insulin resistance, tumor subtype, and serum drug concentration with Ki-67 response to metformin. **Methods:** 200 non-diabetics were randomly allocated to either metformin (850 mg/bid) or placebo for 4 weeks prior to breast cancer surgery. Response was assessed by comparing baseline biopsy (Ki-67 and tumor subtype) and serum markers (HOMA, C-peptide, IGF-I, IGFBP-1, IGFBP-3, hsC-reactive protein, adiponectin) with the same measurements at surgery. For patients with a blood sample taken <24 hours from last drug intake, metformin level was measured. **Results:** Compared with placebo, metformin decreased Ki-67 in women with HOMA>2.8, bottom IGFBP-1 quintile, top IGFBP-3 quartile, CRP>2.5 mg/L, and HER2+ve tumors (table). When HOMA was>2.8, serum drug levels were positively correlated with Ki-67 decrease, whereas no trend was noted for HOMA<2.8 (p interaction=.07). **Conclusions:** At antidiabetic doses, the effect of metformin on tumor Ki-67 of nondiabetic breast cancer patients is modest and varies with host and tumor characteristics. These findings are relevant to clinical trials of metformin in breast cancer prevention and treatment. Clinical trial information: ISRCTN16493703.

**Median (IQR) Ki-67 changes (post-pre treatment) by arm and biomarker threshold.**

| Risk biomarker threshold | N | Placebo | Metformin | P interaction |
|---|---|---|---|---|
| HOMA index >2.8 | 53 | 0 (-2.0; 5.0) | 0 (-5.0; 2.5) | 0.03 |

**600 General Poster Session (Board #64), Mon, 8:00 AM-11:45 AM**

**Trastuzumab duration effects within patient prognostic subgroups in the PHARE trial.** *Presenting Author: Xavier B. Pivot, Institut Regional du Cancer en Franche-Comté - University Hospital, Besançon, France*

**Background:** At 42.5 months of median follow-up, PHARE failed to show that 6 was non-inferior to 12 month of adjuvant trastuzumab. From the results of PHARE questions remain regarding whether the magnitude of benefit derived from 1 year is sufficient to justify its systematic use for different patient subgroups. **Methods:** Treatment effects were evaluated according to various tumour characteristics, and multivariate Cox proportional hazards regression models were performed on metastatic disease free survival (M-DFS) in the 12 month control arm. A prognostic score was defined providing the identification of patient categories with similar risks. The 6 months arm was used as a validation set in order to test for heterogeneity. **Results:** A total of 261 M-DFS events were observed and 4 prognostic groups were defined: very low, low, intermediate and high risks. In the 12 month arm, the corresponding 3-year M-DFS rates were 98.3%, 95.8%, 90.4% and 78.4% in the 4 prognostic groups, respectively. In the 6 month arm, the 3-year M-DFS rates were 98.3%, 94.2%, 85.7%, and 74.8% in the 4 prognostic groups, respectively. **Conclusions:** In the very low risk and low risk groups, the potential absolute benefit of standard duration of trastuzumab was small enough to indicate that optimal standard treatment might be clinically questionable. On the other hand, the 3-year metastasis occurrence rates strongly support the need for a search of a more efficient treatment in the intermediate and high risk groups. Clinical trial information: NCT00381901.

**601 General Poster Session (Board #65), Mon, 8:00 AM-11:45 AM**

**Lapatinib or trastuzumab with taxane therapy as first-line treatment in metastatic breast cancer (MBC): A biomarker analysis in NCIC CTG MA.31.** *Presenting Author: Wendy R. Parulekar, NCIC Clinical Trials Group, Cancer Research Institute, Queen's University, Kingston, ON, Canada*

**Background:** Lapatinib (L) was associated with shorter progression-free survival (PFS) than trastuzumab (T) when combined with a taxane (Tax) as first line therapy for HER2+ MBC. We report the effects of 6 centrally reviewed biomarkers on efficacy. **Methods:** MA.31 accrued 652 patients with locally assessed HER2+ tumors of which 537 (82%) were HER2+ by central review. Protocol-mandated immunohistochemistry was conducted centrally for ER, PR, Ki67, EGFR, and CK5. The primary endpoint was progression free survival (PFS) defined as time from randomization to progression or death in the intention to treat (ITT) population. Stratified step-wise forward Cox models examined the multivariate (mv) effects of baseline characteristics and continuous biomarkers (% positive) on PFS in the ITT and centrally confirmed HER2+ populations. Predictive effects were investigated with cutpoints of >0% of any staining intensity for ER, PR, EGFR, CK5, and >geometric mean for Ki67 for both populations. **Results:** Assessments were completed for > 80% of patients. Median follow-up was 21.5 months. LTax/L demonstrated inferior PFS to TTax/T (ITT, $p<0.001$). Centrally confirmed HER2+ status conferred a positive prognostic effect on PFS ($p=0.005$). Patients whose tumors had higher % positive ER had longer PFS [stratified HR=0.996 (95% CI 0.993-0.999); ITT, $p=0.01$, HER2+, $p=0.003$]. In ITT, lower % positive CK5 had improved PFS [stratified HR=1.008 (95% CI 1.001-1.014); $p=0.03$]. However, treatment interactions with each of HER2, ER, and CK5 were not significant ($p>0.05$). EGFR had a quantitative interaction with treatment favoring TTax/T: ITT, $p=0.05$; HER2+, $p=0.06$. **Conclusions:** LTax/L therapy was associated with shorter PFS compared to TTax/T as first line therapy for HER2+ MBC. Centrally confirmed HER2+ and higher % positive ER were prognostic for longer PFS. Higher EGFR positivity indicated a better response to TTax/T. Clinical trial information: NCT00667251.

**602 General Poster Session (Board #66), Mon, 8:00 AM-11:45 AM**

**Transcriptional expression of Bcl-2 as predictive of response to neoadjuvant chemotherapy with trastuzumab in HER2-positive ER-positive breast cancer patients.** *Presenting Author: Maki Tanioka, Medical Oncology, Hyogo Cancer Center, Akashi, Japan*

**Background:** Several trials have confirmed that pathologic complete response (pCR) rates after neoadjuvant chemotherapy (NAC) are significantly lower in HER2+/ER+ patients (pts) than in HER2+/ER− pts. To elucidate this phenomenon, we investigated the association of anti-apoptotic Bcl-2, which is frequently overexpressed in ER+ tumors, with to NAC resistance. **Methods:** Pretreatment formalin-fixed tumor tissues were collected from 75 HER2+ pts receiving NAC comprising anthracyclines, taxanes, and trastuzumab. mRNA expression was detected by PCR amplificationand quantitative primer extension using MassARRAY (Sequenom, CA). The panel of 15 genes comprised EGFR, HER2, HER3, IGF1R, FGFR, PTEN, INPP4B, SRC-1, DUSP4, ESR1, PgR, FOXA1, PDL1, CTLA-4, and Bcl-2, whose expressions were dichotomized according to median values. PIK3CA mutations were detected using MassARRAY genotyping. ER, PTEN, and Bcl-2 protein expressions were scored from 0 to 3 according to the frequency and intensity by immunohistochemisty (IHC). The relationship between variables was assessed by Spearman's correlation. Logistic regression analysis was performed to detect predictors of pCR, which was defined as no invasive tumor in the breast or axilla. **Results:** Median age was 58 years; 97% were stage II–III, 47% were ER+, and 52% (40%/ 63% in ER+/ ER−) achieved pCR. Bcl-2 mRNA and protein expression were correlated ($r=0.66$, $p=.001$). In univariate analysis, pCR was associated with high mRNA levels of ESR1, PgR, IGF1R, HER2, CTLA4, PDL-1, and Bcl-2 ($p\leq.05$), but not with PIK3A mutations or PTEN loss by IHC. Bcl-2 expression was significantly correlated with ESR1 ($r=0.74$), PgR ($r=0.74$), and IGF1R ($r=0.68$); thus, PDL-1, CTLA4, HER2, and Bcl-2 were tested in the multivariate model. Bcl-2 retained the predictive value for pCR [$p=.022$; odds ratio (OR), 0.28 (0.10−0.84)]. In ER+ pts, median Bcl-2 levels were 2.2 times higher than in ER− pts, and pCR rates were 17% and 65% in pts with high and low Bcl-2 expression, respectively ($p=.006$; OR, 0.11). **Conclusions:** Our data suggests Bcl-2 expression is predictive of pCR and provides a rationale for the evaluation of Bcl-2 inhibitors in HER2+/ER+ BC pts.

**603 General Poster Session (Board #67), Mon, 8:00 AM-11:45 AM**

**Long-term cardiac safety analysis of NCCTG (Alliance) N9831 adjuvant trastuzumab (H) trial.** *Presenting Author: Pooja Prem Advani, Mayo Clinic, Jacksonville, FL*

**Background:** Significant improvement in disease-free and overall survival has been established with the addition of H to adjuvant chemotherapy. However, H may increase risk of cardiac dysfunction (CD) and warrants long-term evaluation. **Methods:** N9831 compared adjuvant doxorubicin and cyclophosphamide (AC) followed by weekly paclitaxel (T) (Arm A) vs. ACàTàH (Arm B) or ACàTHàH (Arm C) in operable HER2+ breast cancer. Cumulative incidence of cardiac events (CE) (symptomatic CHF and definite/probable cardiac death) and left ventricular ejection fraction (LVEF) assessed by MUGA/ECHO were evaluated in women who proceeded to post-AC therapy. Risk factors for H-related CD were identified by Cox regression models. **Results:** 977 women with clinical and LVEF data beyond 5 years (yr) from study enrollment were included (Arm A=304; Arm B=346 and Arm C=327); median follow up: 6.6 yr. Median age: 50 yr (range, 22–82). Median LVEF at 6 yr: 61% (Arm A); 61% (Arm B) and 60% (Arm C). Absolute median LVEF decrease from baseline: 3.0% (Arm A), 2.5% (Arm B) and 3.0% (Arm C). 6-yr cumulative incidence of CE: 0.6%, 2.8% and 3.4% in Arms A, B and C (minimal difference from CE at 3 yr: 0.5%, 2.6% and 3.4%). Suspected cardiac deaths: 4 (Arm A); 1 (Arm B); 1 (Arm C). There was a statistically significant increase in risk of CE in Arms B (HR 2.6; 95% CI: 1.1–6.2) and C (HR 3.4; 95% CI: 1.4–8.0) vs A ($P = 0.019$). Associated with increased risk of CE in Arms B and C were age > 60 yr (HR 3.2; 95%: CI 1.5-6.8, $P = 0.0019$), LVEF (50-55%) at registration (HR 3.3; 95% CI: 1.1-9.6, $P = 0.030$), and use of antihypertensive medications (HR 2.3; 95% CI: 1.2-4.4, $P=0.015$). Race ($P = 0.318$) and BMI 25-29.9 ($P = 0.1038$) and >30 ($P = 0.0735$) were nonsignificant risk factors. **Conclusions:** 6-yr cumulative incidence of CE was higher by 2.8% in the H-containing arms vs control arm. We noted minimal difference in the cumulative incidence of CE beyond 3-yr (Perez, JCO 2008), suggesting that late development of CE with H is infrequent. Hence, H (in context of anthracycline and taxane-based therapy) continues to have a favorable benefit-risk ratio (5-yr absolute OS benefit: 3.5%; DFS benefit: 12.7%). Older age, lower registration LVEF and antihypertensive medication use were predictive of increased risk of CD with H.

**604^ General Poster Session (Board #68), Mon, 8:00 AM-11:45 AM**

**Phase I/II study of neoadjuvant eribulin mesylate, carboplatin, and trastuzumab (ECH) for operable HER2 positive (HER2+) breast cancer.** *Presenting Author: Lee Steven Schwartzberg, The West Clinic and ACORN Research, LLC, Memphis, TN*

**Background:** Docetaxel, carboplatin (C) and trastuzumab (H) yields substantial pathologic complete response (pCR) in operable HER2+ breast cancer (BC). Eribulin mesylate (E) is a tubulin inhibitor shown to improve overall survival in pretreated advanced BC. This Phase I trial was designed to determine the maximum tolerated dose (MTD) of ECH as neoadjuvant therapy in HER2+ BC with a planned follow-on Phase II component with pCR as the primary endpoint. **Methods:** This was a multicenter open-label single arm trial. Eligible patients (pts) had operable stage IIA – IIIB HER2+ BC, ECOG 0-1, normal LVEF, QTc < 480 msec, < grade 1 neuropathy and no history of invasive cancer within 3 years. Phase I planned up to 18 pts to 1 of 3 E dose cohorts, with pts treated at the MTD also evaluable for the Phase II extension. Starting dose of E was 1.1 mg/m$^2$ with escalation to dose level +1 at 1.4 mg/m$^2$. ECH was given IV for six 3-week cycles with E d1 and d8; C AUC 6 d1; and H 8mg/kg loading dose d1c1 and 6mg/kg d1c2-c6. C1 dose limiting toxicities (DLTs) were defined as: grade 4 thrombocytopenia (TP), anemia, or neutropenia (N) lasting > 5 days; any grade 3-4 non-hematologic toxicity attributable to E, C, H, or the combination; or inability to deliver all three agents at assigned dose and schedule during cycle 1. Standard 3+3 dose escalation design was used. **Results:** 5/6 patients at 1.1 mg/m$^2$ and 4/6 at 1.4 mg/m$^2$ completed 6 cycles of ECH. The MTD of ECH was not determined. At 1.1 mg/m$^2$ E, Grade 3/4 hematologic toxicity: anemia 4 pts, TP in 2 pts, and N 4 pts, and at 1.4 mg/m$^2$ E, anemia 1 pt, TP in 2 pts and N in 5 pts. 8 of 12 (67%) pts required PRBC transfusions (range 2-12 units) and 2 pts required platelet transfusions (range, 4-12 units). 11 of 12 (92%) pts required dose reduction of E. At surgery, 10 pts (83.3%) achieved partial response and 2 (16.7%) had pCR. **Conclusions:** In this Phase I study, the ECH regimen was associated with levels of hematologic toxicities and transfusion requirements not observed in other eribulin-carboplatin studies. This combination is not planned to undergo further Phase II development in the HER2+ neoadjuvant setting. Clinical trial information: NCT01388647.

**605 General Poster Session (Board #69), Mon, 8:00 AM-11:45 AM**

**Relationship between tumor biomarkers (BM) and efficacy in TH3RESA, a phase 3 study of trastuzumab emtansine (T-DM1) versus treatment of physician's choice (TPC) in HER2-positive advanced breast cancer (BC) previously treated with trastuzumab and lapatinib.** *Presenting Author: Sung-Bae Kim, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

**Background:** T-DM1, an antibody–drug conjugate comprising trastuzumab, DM1 (microtubule inhibitor), and a stable linker, is approved for patients (pts) with HER2-positive metastatic BC previously treated with trastuzumab and a taxane. In two phase 3 studies, T-DM1 prolonged progression-free survival (PFS; EMILIA, TH3RESA) and overall survival (EMILIA) v control arms. Here we examine the relationship between tissue BM related to the HER2 pathway and PFS in TH3RESA (NCT01419197). **Methods:** Pts had prior taxane therapy and ≥2 HER2-directed regimens, including trastuzumab and lapatinib, and were randomized 2:1 to T-DM1 (3.6 mg/kg q3w) v TPC. qRT-PCR for HER2, HER3, and G6PDH (ref) mRNA was performed with available pt tumor tissue. Analyses of tumor DNA for PIK3CA mutations (exons 1, 4, 7, 9, 20) and cytoplasmic PTEN expression by IHC were performed as optional research. PFS was analyzed for each BM subgroup using the Kaplan-Meier method and a Cox regression model. **Results:** Overall, median HER2 mRNA, HER3 mRNA, and PTEN levels and PIK3CA mutation status were consistent across arms and with previous results. For all BM subgroups, median PFS was longer with T-DM1 v TPC (Table). Relative risk reduction for PFS was numerically greater for T-DM1 v TPC for >median HER2 mRNA levels than ≤median levels but similar within HER3 mRNA, PIK3CA, and PTEN (not shown) subgroups. **Conclusions:** Similar to previous results, T-DM1 prolonged PFS in all BM subgroups analyzed with a greater benefit observed for pts with tumors expressing >median HER2 mRNA levels. Although PIK3CA mutation status was not associated with decreased PFS in the control arm, benefit was seen with T-DM1 regardless of mutation status. Clinical trial information: NCT01419197.

**Trastuzumab emtansine (T-DM1) plus capecitabine (X) in patients with HER2-positive MBC: MO28230 TRAX-HER2 phase 1 results.** *Presenting Author: Karen A. Gelmon, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** T-DM1, an antibody–drug conjugate composed of trastuzumab, the microtubule inhibitor DM1, and a stable linker, is a newly approved therapy for HER2-positive MBC. Two phase 3 studies have shown significant efficacy in patients previously treated with trastuzumab and a taxane. HER2-directed therapies in combination with X have shown improved efficacy in patients with MBC, and preclinical data show enhanced activity with T-DM1 + 5-fluorouracil. Thus, T-DM1 + X may have increased antitumor activity in patients with HER2-positive MBC. **Methods:** TRAX-HER2 (NCT01702558) is a phase 1/2 study of T-DM1 + X in patients with HER2-positive MBC (IHC 3+/ISH+) or metastatic gastric cancer. Key inclusion criteria are progression on ≥1 trastuzumab + chemotherapy regimen, ≥1 measurable lesion (RECIST v1.1), and LVEF ≥50%. The primary phase 1 objective for MBC was to evaluate the maximum tolerated dose (MTD) of X with T-DM1 (3.6 mg/kg q3w) using a 3 + 3 design. Safety, tumor response, and PK were also assessed. **Results:** As of the data cutoff (1/17/14), 7 patients were enrolled in the T-DM1 + X 750 mg/m$^2$ cohort (a 7th patient replaced one that had not met the stable liver enzymes eligibility criterion). Of the 6 DLT-evaluable patients (follow-up: 3.7–13.2 mos), 2 had a DLT (1 grade 3 vomiting, 1 grade 3 elevated ALT and AST, which prohibited start of cycle 2 at 100% dose). After the DLT evaluation period, 2 patients had grade 3 AEs: 1 elevated ALT, 1 keratitis. No grade ≥4 AEs or SAEs were reported. As of the cutoff, 4 of the 6 patients remain on treatment. The best confirmed overall response was a partial response in 4 patients and stable disease in 1 patient; 1 patient was not evaluable (had only 1 assessment). The T-DM1 PK profile was comparable with that observed in single-agent T-DM1 trials; PK of X was similar ± T-DM1. Due to the 2 DLTs, the next cohort was opened with a de-escalated dose of X (700 mg/m$^2$). Three patients have been enrolled (follow-up: 0.5–1.2 mos); no DLTs or grade ≥3 AEs have yet been observed. **Conclusions:** T-DM1 + X 750 mg/m$^2$ showed encouraging activity. However, due to DLTs, a dose de-escalated cohort (T-DM1 + X 700 mg/m$^2$) was opened. Complete results from this cohort (n=6) will be available at the time of presentation. Clinical trial information: NCT01702558.

**607 General Poster Session (Board #71), Mon, 8:00 AM-11:45 AM**

**Survival among elderly breast cancer patients by receipt of human epidermal growth factor receptor 2-targeted therapy: A matched analysis of national registry data.** *Presenting Author: Jaqueline Willemann Rogerio, Novartis Pharmaceuticals Corporation, East Hanover, NJ*

**Background:** Few studies have examined survival among elderly breast cancer (BC) patients by receipt of human epidermal growth factor receptor 2 (HER2)-targeted therapy. **Methods:** Women aged 65+ with an incident diagnosis of BC (index) and no history of other cancer were identified from 2006-2010 linked Surveillance, Epidemiology, and End Results (SEER) and Medicare data. Women with BC were classified by receipt of HER2-targeted therapy (trastuzumab or lapatinib) or not, each matched 1:1 to a non-cancer comparison cohort by demographics. Patients had one year of continuous enrollment prior to index and were followed through the earliest of disenrollment, death, or the end of the data. Mortality and time to death were evaluated for all cohorts, by stage, age and race. One Cox model for each disease stage (I-IV) was constructed, with indicators for BC with HER2-targeted therapy and BC without such therapy, using the pooled non-BC comparison cohorts as the reference group. **Results:** We identified 1,746 BC patients with and 35,114 without HER2-targeted therapy. Patients with and without HER2-targeted therapy had similar mortality (13.0% versus 14.2%; P = 0.18) during follow-up (mean 28 versus 27 months; P = 0.03). Among patients who died, patients with HER2-targeted therapy experienced longer time to death (median 17 versus 13 months; P < 0.01). Among patients with HER2-targeted therapy, increased age (P<0.01) and later stage (P<0.01) were associated with higher mortality. In the Stage IV Cox model, both BC with HER2-targeted therapy and BC without HER2-targeted therapy (vs. no BC) were associated with significantly higher mortality (hazard ratio [HR] = 2.46 and 5.24, respectively; both P < 0.01). BC without HER2-targeted therapy was also a significant predictor of increased mortality in the Stage III model (HR = 1.37; P < 0.01). Significant predictors of increased mortality across the four models included older age (75+) and baseline Charlson comorbidity score >2. **Conclusions:** BC patients with and without HER2-targeted therapy had similar mortality, with longer time to death among the former. Mortality and time to death also varied by stage, age, and race.

**608 General Poster Session (Board #72), Mon, 8:00 AM-11:45 AM**

**Association of basal marker expression with outcome and trastuzumab resistance in HER2-positive breast cancer.** *Presenting Author: Alice P. Chung, Cedars-Sinai Medical Center, Los Angeles, CA*

**Background:** Herceptin resistance is a significant challenge in the treatment of Her2-positive (Her2+) breast cancer. A subset of Her2+ breast cancers are known to express basal genes (basal Her2). We investigated the effect of basal gene expression on cell viability and Herceptin response in Her2+ breast cancer cell lines and on prognosis in patients with Her2+ breast cancer who received Herceptin. **Methods:** We selected 4 cell lines to represent basal Her2 (HCC1569, HCC1954) and non-basal Her2 (BT474, SKBR3) breast cancer based on their basal gene signature in microarray analysis, and treated each with vehicle, Herceptin (H), Paclitaxel (P), and H + P. Cell viability was assessed by MTT assays. Her2 pathway suppression was compared between groups using immunoblotting with anti-Her2, p-AKT, p-ERK antibodies. Expression of CK5/6, CK14, and EGFR was evaluated after immunohistochemical staining in paraffin-embedded tissue of 88 patients with Stage 1-3 Her2+ breast cancer treated with chemotherapy and Herceptin. Groups with and without basal gene expression were compared with respect to clinicopathologic parameters and survival. **Results:** All cell lines expressed similar levels of Her2. Both H and P alone inhibited proliferation of non-basal cell lines, and H + P had an additive cytotoxic effect. Basal cells were resistant to H, P inhibited proliferation, but H + P had no additive cytotoxic effect on cell growth in basal cells. Immunoblotting showed a significant decrease in p-Akt levels after treatment with H or H + P in non-basal cells but not in basal cells. No alterations were observed in p-ERK levels in the 4 cell lines when treated with H and H + P. Of the Her2+ patients, 33/88 (37.5%) expressed at least one basal gene. Basal Her2 tumors were associated with higher grade (p=0.04) and more ER/PR-negativity (p<0.01). CK14 expression correlated with worse overall survival by log-rank test (p=0.02), while EGFR showed a similar trend (p=0.06). **Conclusions:** Basal Her2 cell lines are resistant to Herceptin. This resistance is associated with Herceptin refractory PI3K/Akt activity. CK14 expression is predictive of worse prognosis in Her2+ breast cancer patients treated with Herceptin.

**609 General Poster Session (Board #73), Mon, 8:00 AM-11:45 AM**

**Retrospective analysis of toxicity in patients (pts) with liver metastases (mets) from phase 3 studies of trastuzumab emtansine (T-DM1) in pts with metastatic breast cancer (MBC).** *Presenting Author: David Miles, Mount Vernon Cancer Centre, London, United Kingdom*

**Background:** In two phase 3 studies in pts with HER2-positive MBC, treatment with the antibody–drug conjugate T-DM1 resulted in increased progression-free survival (PFS) and overall survival (EMILIA) and PFS (TH3RESA) v control arms. T-DM1 is associated with grade (gr) ≥3 elevations of hepatic transaminases. We examined the association between the presence of liver mets at baseline (with/without abnormal transaminases) and toxicity, as well as efficacy in pts from these 2 studies. **Methods:** EMILIA and TH3RESA data were analyzed separately. Analyses included the rates of any grade adverse events (AEs), gr ≥3 AEs (including AEs identified with hepatotoxicity), selected AEs of interest for T-DM1, ORR, and PFS. Comparisons were pts with/without liver mets at baseline in the absence or presence of abnormal (>1× upper limit of normal [ULN]) alanine aminotransferase (ALT). **Results:** Overall, the rate of gr ≥3 AEs was lower with T-DM1 v controls (Table). In pts with liver mets and elevated ALT at baseline, the incidence of gr ≥3 AEs was higher with T-DM1, with the highest incidence in the "investigations" category, which includes laboratory data such as increased transaminases (EMILIA, 18.2% v 0%; TH3RESA, 17.4% v 10.5%). Reduction in risk of progression with T-DM1 was similar in all subgroups and comparable with the overall randomized populations (Table). **Conclusions:** This retrospective analysis suggests that in the presence of liver mets (with/without elevated ALT at baseline), the clinical efficacy benefit of T-DM1 is maintained. The AEs observed with T-DM1 in pts with liver mets and elevated ALT were primarily laboratory-based. Clinical trial information: NCT00829166 and NCT01419197.

**Barriers to the use of trastuzumab for HER2+ breast cancer and the potential impact of biosimilars: A physician survey in the United States and emerging markets.** *Presenting Author: Philip Edward Lammers, Meharry Medical College, Nashville, TN*

**Background:** Biologics, such as trastuzumab, are an important part of oncology treatment paradigms, although access to such therapies is a challenge in emerging markets and in certain areas of more developed countries such as the United States (US). Biosimilars have the potential to increase access to biologic therapies by offering a comparable but more affordable alternative relative to the innovator biologic. This study examined access to trastuzumab and identified barriers to its use in HER2+ breast cancer patients in the US, Mexico (MEX), Turkey (TUR), Russia (RUS), and Brazil (BRZ). The study also examined whether availability of a biosimilar to trastuzumab would improve access to, and use of, HER2 monoclonal antibody therapy. **Methods:** Medical oncologists (N=500) completed a blinded survey examining their use of trastuzumab. **Results:** Across all countries, oncologists reported "not so often", "rarely", or "never" using trastuzumab in a neoadjuvant (27%), adjuvant (8%), or metastatic (8%) setting. Common barriers to the use of trastuzumab were related to insurance coverage, drug availability, cost to the patient, treatment guidelines, and patient comorbidities. Oncologists also reported having had to cancel or delay treatment with trastuzumab due to reimbursement issues (Overall=31%, US=10%, BRZ=48%, MEX=37%, TUR=16%, RUS=76%). Overall, 45% of oncologists reported that they would increase the use of HER2 monoclonal antibody therapy if a lower cost biosimilar to trastuzumab was available, including 29% of US oncologists. This percentage was higher in BRZ (53%), MEX (63%), and RUS (81%). Oncologists reported that use would increase across all treatment settings. **Conclusions:** The availability of a trastuzumab biosimilar may increase use of HER2 monoclonal antibody therapy in the breast cancer arena across all treatment settings in the US and, to an even greater extent, in the emerging markets of RUS, MEX, and BRZ. A biosimilar could provide benefit to patients who currently do not receive trastuzumab, or receive less than optimal treatment, due to insurance coverage or cost issues related to such treatment. Sponsored by Pfizer Inc.

**611 General Poster Session (Board #75), Mon, 8:00 AM-11:45 AM**

**Long-term population-based outcomes of adjuvant trastuzumab in HER2-positive early breast cancer: The British Columbia experience.** *Presenting Author: Stephen K. L. Chia, British Columbia Cancer Agency, Vancouver, BC, Canada*

**Background:** The use of adjuvant trastuzumab in women with HER2 positive early breast cancer also receiving adjuvant chemotherapy became standard of care in British Columbia in 2005. As the randomized clinical trials continue to update on the long-term efficacy of adjuvant trastuzumab, we have also recently updated our longer term outcomes from a population based publicly funded health care perspective. **Methods:** The British Columbia Cancer Agency (BCCA) Breast Cancer Outcomes Unit database includes all referred patients to the BCCA since 1989. Only patients with stage I-III HER-2 positive breast cancer diagnosed from July 2004 – Dec 2008 were included in the analysis. Demographic, pathologic and treatment data were reviewed. 5 year relapse free survival (RFS), distant relapse free survival (DRFS) and overall survival (OS) rates were calculated by Kaplan-Meir method. **Results:** 1,413 patients were identified, of which 953 were treated with adjuvant trastuzumab with a median follow-up of 5.4 years. 226 Stage I HER-2 positive breast cancers were treated with chemotherapy and trastuzumab. Of the 64 T1a-bN0 cases, 63% were ER-; while in the 162 T1cN0 cases, only 37% were ER-. **Conclusions:** 5-year population based clinical outcomes in the era of adjuvant trastuzumab are favorable, especially in node negative disease. Our 5 year RFS in T1cN0 HER2+ breast cancers treated with chemotherapy and trastuzumab is 100%. Future adjuvant clinical trials with new or multiple anti-HER 2 agents should only focus on node positive patients.

**Identification and targeting of M-phase progression downstream of HER2 in trastuzumab-sensitive and -resistant breast cancer cell lines.** *Presenting Author: E. Aubrey Thompson, Mayo Clinic, Jacksonville, FL*

**Background:** It is generally accepted that therapeutic response to HER2-targeted therapy involves both immunological and cell autonomous (signaling) events. We have used a genomic approach to define signaling processes that occur downstream of HER2 in trastuzumab-sensitive and –resistant human breast cancer cells in culture, with a view towards defining downstream effectors that could be exploited as potential therapeutic targets in tumors that are resistant to inhibition of HER2 signaling. **Methods:** RNA-seq analysis was carried out with trastuzumab-sensitive cell lines (BT474 and SKBR3), resistant variants selected from such cells, and cells that exhibit de novo resistance (MDAMB453 and HCC1954). Changes in mRNA abundance were quantified after trastuzumab treatment and after shRNA-mediated knockdown of ERBB2. Network analysis was carried to define biological processes associated with abrogation of HER2 signaling. Both pharmacological and genetic knockdown were used to test candidate downstream effectors of trastuzumab. **Results:** A prominent cohort of M-phase progression genes was consistently downregulated in sensitive but not resistant cells. These genes included PLK1, AURKB, ECT2, MCM10, BUB1, and PBK. Knockdown of PLK1 inhibited growth of both sensitive and resistant cultures. Since both PLK1 and paclitaxel inhibit process associated with the mitotic spindle, we tested for synergy between paclitaxel and the PLK inhibitor BI2536 in sensitive and resistant cell lines. At EC50 concentrations, both inhibitors significantly reduced culture growth rates. However, when both drugs were combined at EC50 concentrations, culture growth was completely obliterated. **Conclusions:** Regulation of M-phase progression is a significant component of ERBB2 signaling in HER2+ breast cancer cells. Combined therapy with low concentrations of drugs that target mitotic spindle formation by different mechanisms appears to provide a potential mechanism to target HER2+ tumors irrespective of sensitivity to HER2-targeted therapy.

**613 General Poster Session (Board #77), Mon, 8:00 AM-11:45 AM**

**Comparison of recurrent and nonrecurrent breast cancer patients undergoing AE37 peptide vaccine therapy.** *Presenting Author: Erika J Schneble, San Antonio Military Medical Center, San Antonio, TX*

**Background:** We are conducting a Phase II clinical trial of the HER2 peptide vaccine AE37 (MHC Class II binding) for the prevention of breast cancer recurrence in disease-free, node-positive or high-risk node-negative patients (pts). In this analysis, we compare disease features and immunologic responses (IR) between vaccinated recurrent (vR) pts and vaccinated non-recurrent (vNR) pts. **Methods:** After completion of standard of care therapy, pts with any level of HER2 expression (IHC1-3$^+$) who were randomized to the vaccine group received AE37+GM-CSF in 6 monthly intradermal inoculations during the primary vaccine series (PVS) followed by four boosters every 6 months. Ex vivo IR was measured by T-cell proliferation using thymidine incorporation and expressed in mean counts per minute (cpm) ±SEM at R0 and as the average of multiple time points after the PVS and throughout the booster series (R). In vivo IR was measured by delayed type hypersensitivity (DTH) immediately before (R0) and after the PVS (R6). Data was compared using student's t-test and Fisher's exact as appropriate. **Results:** Of 298 enrolled and randomized pts, 153 have been vaccinated. For this analysis, 5 patients were excluded for second malignancies leaving 14 vR and 134 vNR available for analysis. Demographics between vaccinated pts were compared with vR exhibiting a higher percentage of node positive (85.7% v 61.9%, p=0.07) disease. vR pts displayed significantly weaker proliferation than nVR pts (R0: 912±254 v 1954±350, p=0.02; R: 4463±764 v 6803±391, p=0.01). DTH between vR and vNR revealed a significantly lower initial DTH response (R0: 1.09±0.78 v 2.80±0.71mm, p<0.05), but similar post PVS DTH (R6: 33.3±9.1 v 28.9±2.0mm, p=0.68). **Conclusions:** Comparison of vR and vNR pts demonstrates that vR have more advanced disease as well as a consistently weaker intrinsic anti-HER2 immunity as measured in vivo and ex vivo at baseline. The factors responsible for the diminished endogenous immune response and reduced amplification in these pts will require further studies in larger patient populations. Of particular interest would be the response in HER2 non-overexpressing and triple negative pts, both of which appear to derive a greater benefit from AE37. Clinical trial information: NCT00524277.

**614 General Poster Session (Board #78), Mon, 8:00 AM-11:45 AM**

**Preliminary results from TRASTYVERE study: A retrospective analysis of HER2-positive (HER2) metastatic breast cancer (MBC) patients treated in Spain with lapatinib (L) plus trastuzumab (T).** *Presenting Author: Joaquin Gavila, Instituto Valenciano de Oncología, Valencia, Spain*

**Background:** Dual blockade with L and T in heavily pretreated HER2 MBC patients obtains impressive survival gain (Blackwell, 2012), yielding to the EMA approval for the HR-negative subgroup. Nevertheless, the benefit of the combination is unknown in L pretreated patients. **Methods:** We conducted a retrospective, post-authorized, multicenter study including patients treated in Spain by compassionate uses for the combination of T-L. The inclusion criteria were (1) HER2-positive metastatic or locally advanced MBC; (2) progression on at least one prior line of trastuzumab for advanced disease; and (3) T-L treatment started before DEC/2012. Concomitant endocrine therapy for HR-positive patients was allowed as well as patients with brain metastasis. Combinations with cytotoxic agents were excluded. A total of 111 patients were predefined for the primary objective: Clinical Benefit rates (CBR). In JAN/2014 independently monitored data from 72 patients was confirmed. **Results:** The median age was 59 years (39 - 83); Mean number of prior T lines 4 (range 1-13); 72% previously treated with L; 58% HR-positive; 78% visceral disease; 35% CNS involvement; 44% 3 or more organs involved. A total of 31 patients (43%) achieved a CBR (95% CI 31% – 54%); 1 CR, 12 PR and 18 SD lasting >24 weeks. The median time to progression (TTP) was 5.5 months (95% CI 4.63 – 6.54) and the median overall survival (OS) was 14.5 months (95% CI 9.69 – 17.64). The CBR was independent of L exposition: (50% L naïve vs. 40% L pretreated; p=0.46) or HR-status (HR-positive 43% vs. HR-negative 41%; p=0.86). No significant trends were observed in any pre-specified condition for ORR, TTP or OS. No cardiac toxicity occurred and less than 10% of G3 or G4 toxicity were recovered during the T-L treatment. **Conclusions:** The combination of T-L is active in heavily pretreated patients. Benefit was independent of previous treatment with L and HR-status. Future research may focus on the potential synergism of endocrine therapy in HR-positive patients.

**615 General Poster Session (Board #79), Mon, 8:00 AM-11:45 AM**

**Phase I/II study of adoptive T-cell therapy following in vivo priming with a HER2/neu vaccine in patients with advanced-stage HER2$^+$ breast cancer.** *Presenting Author: Mary L. Disis, University of Washington, Seattle, WA*

**Background:** We have reported that infusion of ex vivo expanded T cells derived from previously HER2-vaccine-primed PBMC is safe and able to mediate an anti-tumor response in patients with HER2$^+$ breast cancer (Disis 2013). In this study, we evaluated the safety and clinical efficacy of infusion of HER2 specific T cells after rapid HER2 vaccinations in patients with advanced stage HER2$^+$ breast cancer. **Methods:** 19patients were vaccinated three times weekly with a HER2 peptide based vaccine. HER2 specific T-cells were expanded 2 weeks after 3$^{rd}$ vaccine. The patients received 2-3 escalating doses of T-cells given at 7-10 day intervals. Cyclophosphamide was administrated before the first dose of T- cells. One patient underwent indium-111 labeling of T-cells for SPECT/CT scanning. **Results:** All patients received at least two doses of HER2 specific expanded T-cells. The infused T-cell products were >98% of CD3$^+$ with an average of 43% CD4$^+$ and 54% CD8+ T-cells. The total number of T-cells infused was 0.3x10$^9$ – 57.1x10$^9$ (median 17.5x10$^9$). Subjects tolerated the infusions well with 95% of adverse events of grade 1 or 2. There were no complete or partial responses. 59% had stable disease (SD) 1-3 months after infusion and 41% of the patients demonstrated progressive disease (PD). The frequencies of HER2 specific T-cells in the infused products were significantly higher in patients with SD than that in PD (p=0.039). The percentage of CD4$^+$ cells in products was positively correlated with HER2 specific T-cells (p=0.017). HER2 immunity was generated in vivo and augmented in magnitude after infusion and was maintained 3-9 months post infusion in the majority of patients. SPECT/CT of In-111 labeled T-cells demonstrated cell trafficking to all sites of metastatic disease. **Conclusions:** Adoptive transfer of HER2 specific T-cells generated from PBMC after rapid immunization is feasible and safe. Clinical outcome is associated with the frequency of HER2 specific CD4 T-cells present in the infusion product. Clinical trial information: NCT00791037.

**616 General Poster Session (Board #80), Mon, 8:00 AM-11:45 AM**

**A phase I trial of the safety and immunogenicity of a DNA-based vaccine encoding the HER2/neu (HER2) intracellular domain in subjects with HER2+ breast cancer.** *Presenting Author: Mary L. Disis, University of Washington, Seattle, WA*

**Background:** Vaccination with the intracellular domain (ICD) of HER2 in pre-clinical models is both immunogenic and protective against the development of mammary tumors. This study was designed to examine the safety and immunogenicity of a DNA-based vaccine encoding the HER2 ICD in subjects with HER2$^+$ breast cancer. **Methods:** Sixty-six patients with stage III or IV breast cancer in remission were enrolled sequentially into three vaccine arms: 1 (10$\mu$g), 2 (100$\mu$g) and 3 (500$\mu$g). Vaccines were admixed with 100$\mu$g GM-CSF and administered i.d. monthly for three immunizations. Endpoints included safety and immunogenicity (optimum dose). Toxicity and HER2 specific IFN-gamma immune responses were evaluated and DNA persistence at the vaccine site was assessed. **Results:** Sixty-four of the 66 (97%) patients enrolled completed all vaccinations. Vaccination was associated with minimal toxicity. All three doses of vaccine were able to significantly induce or boost HER2-specific T cell responses to ICD, however the incidence of subjects with augmented immunity was greatest in Arm 2 (14/22, 64%) when compared to Arm 1 (9/17, 53%) and Arm 3 (8/22, 36%). Patients in Arms 2 and 3 had immune responses to HER2 ICD of higher magnitude than patients in Arm 1, however, only patients in Arm 2 retained immunity at 1 year after vaccination. DNA persistence in the vaccine site was related to dose being found most frequently in Arm 3 patients. DNA persistence was associated with a decrease in magnitude of HER2 ICD response and long term immunity. At a median follow-up of 68 months after vaccination, patients in Arm 2 demonstrate superior overall survival (p=0.02) as compared with patients in arm 3. **Conclusions:** Immunization with a DNA-based HER2 ICD vaccine is safe and can generate robust T-cell responses in treated patients. The resulting immune response is dose-dependent, with 100$\mu$g as the optimal dose. Higher vaccine doses may have a detrimental effect on the long term retention of immunity. Clinical trial information: NCT00436254.

**617 General Poster Session (Board #81), Mon, 8:00 AM-11:45 AM**

**Effect of serum HER2, TIMP-1, and CAIX on outcome in HER2+ metastatic breast cancer patients treated in first line with lapatinib or trastuzumab combined with taxane: NCIC CTG MA.31.** *Presenting Author: Diep Ho, Penn State Hershey Medical Center, Hershey, PA*

**Background:** The lapatinib-taxane combination led to shorter PFS than trastuzumab-taxane in HER2+ metastatic breast cancer. We investigated the prognostic and predictive effects of pretreatment serum HER2, CA IX, and TIMP-1. **Methods:** MA.31 accrued 652 patients; 537 (82%) were centrally-confirmed HER2+. Biomarkers were categorized for univariate and multivariate predictive investigations with a median cut-point, ULN cut-points (15 ng/ml for HER2; 506 pg/ml for CAIX; 454 pg/ml for TIMP-1), and custom cut-points (30 and 100 ng/ml for HER2). Stratified step-wise forward Cox multivariate analysis used continuous and categorical biomarkers for PFS in the ITT and central HER2+ populations; central HER2+ biomarker results are shown. **Results:** Serum was banked for 472 (72%) of 652 patients. Higher serum HER2 (>median; >15; >30; or >100 ng/ml; p=0.05-0.002); higher CAIX (>median; >506 pg/ml; p=0.02; p=0.001); and higher TIMP-1 (>median; >454 pg/ml; p=0.001; p=0.02) had worse univariate PFS. In multivariate analysis, higher continuous TIMP-1 was associated with significantly worse PFS: HR=1.001 (95% CI=1.000-1.002; p=0.004). Continuous serum HER2 and CAIX were not significantly associated with PFS. HER2 of 15 ng/ml or higher had shorter PFS (p=0.02); higher categorical CAIX had worse PFS (p=0.01-0.08). The interaction terms of HER2, CAIX, and TIMP-1 with treatment were not significant. Multivariate PFS categorical serum results (Table). **Conclusions:** Higher levels of serum TIMP-1, CAIX, and HER2 were significant prognostic biomarkers of shorter PFS. No serum biomarker was predictive of differential response to lapatinib vs. trastuzumab. Evaluation of TIMP-1 and CAIX targeted therapy in addition to HER2 targeted therapy is warranted in patients with elevated serum levels of these biomarkers.

**Correlation of $^{64}$Cu DOTA-trastuzumab positron emission tomography (PET) imaging with HER2 status by immunohistochemistry (IHC).** *Presenting Author: Joanne E. Mortimer, City of Hope, Duarte, CA*

**Background:** We have developed $^{64}$Cu-DOTA-trastuzumab for PET imaging of HER2-positive breast cancer. We have determined that administering trastuzumab (45 mg) prior to $^{64}$Cu-DOTA-trastuzumab sharply reduces liver uptake of the radiotracer. We are now testing whether tumor uptake of $^{64}$Cu-DOTA-trastuzumab correlates with variable IHC staining in women with advanced breast cancer. **Methods:** Eligibility criteria included biopsy confirmation of metastatic disease that was HER2 1+, 2+, or 3+ by IHC, no anti-HER therapy within the prior 2 mo, and at least 1 non-hepatic site of metastasis > 20 mm outside the biopsy site. Staging workup included $^{18}$F-FDG PET-CT. Patients received 45 mg of cold trastuzumab prior to $^{64}$Cu-DOTA-trastuzumab. PET-CT scans were obtained at 21-25 h (Day 1) and 47-48 h (Day 2) over axial fields of view chosen in reference to $^{18}$F-FDG. Uptake in prominent lesions was measured in terms of maximum single-voxel SUV ($SUV_{max}$) . Lesions identified on CT and judged to have image intensity > adjacent tissue by an expert radiologist were considered positive on PET. **Results:** Seventeen women (median age 59, range 35-75 y) have undergone imaging. HER2 status by IHC was 3+ in 7 pts., 2+ in 6 and 1+ in 4. Three women with IHC 2+ disease were FISH+. In the patients considered clinically HER2 positive (IHC 3+ or 2+, FISH+), $^{64}$Cu-DOTA-trastuzumab sensitivity was 75 and 90%, respectively, on Days 1 and 2, compared with 94% for $^{18}$F-FDG. Tumor uptake of $^{64}$Cu-DOTA-trastuzumab was also readily visualized in HER2-negative patients (measured detection sensitivity 78 and 80% on Days 1 and 2, respectively). There were 2 false positive findings with $^{64}$Cu-DOTA-trastuzumab. Lesion uptake of $^{64}$Cu-DOTA-trastuzumab was higher in HER2+ than in HER2- patients ($SUV_{max}$mean ± sem: Day 1 8.9±0.6 vs 4.2±0.2; Day 2 9.9±0.8 vs 4.9±0.2, $p < 0.001$). **Conclusions:** $^{64}$Cu-DOTA-trastuzumab PET visualizes HER2 1+, 2+ and 3+ metastatic breast cancers with high sensitivity and specificity. Tumor uptake of $^{64}$Cu-DOTA-trastuzumab-PET in IHC 1+ and 2+, FISH- patients implies possible benefit from anti-HER2 therapies for individuals whose cancers are currently considered HER2 negative. Research Support. DOD BC095002. Clinical trial information: NCT01093612.

**619^ General Poster Session (Board #83), Mon, 8:00 AM-11:45 AM**

**Phase II study of neoadjuvant weekly paclitaxel and carboplatin with lapatinib in HER2+ breast cancer.** *Presenting Author: Andrea Li Ann Wong, National University Health System, Singapore, Singapore*

**Background:** The optimal neoadjuvant regimen in HER2+ breast cancer is undefined. We evaluated the efficacy and tolerability of weekly paclitaxel/carboplatin with lapatinib. **Methods:** HER2+ stage I-III breast cancer patients received 4 cycles of 3 weekly PCL [IV paclitaxel (P) 80mg/m$^2$ (days 1, 8, 15), carboplatin (C) AUC 2 (days 1, 8), oral lapatinib (L) (750mg daily)] followed by surgery. Lapatinib dose reductions were not allowed. Patients with pCR (ypT0N0) received 2 cycles of adjuvant PCL; those without received 4 cycles of doxorubicin/cyclophosphamide. All received 1 year of adjuvant trastuzumab and at investigators' discretion, concurrent lapatinib 1000mg/day for 52 weeks (neoadjuvant + adjuvant). Primary endpoint was pCR; secondary endpoints were clinical CR/PR, toxicities and DFS. **Results:** 36 patients were recruited (Chinese/Malay/Others: 52.8/36.1/11.1%). Median age at diagnosis was 51 (29-78) years. 69.4%, 63.9%, 80.6% and 61.1% had cT3/4, cN+, grade 3 and hormone receptor positive tumors. 63.9% achieved CR/PR after 2 cycles. At surgery, 33.3% were ypN0, and 11.1% achieved pCR, which was limited to patients with cN0 tumors (n=8; 50% pCR). At 21 month median follow-up, 2 year DFS was 83.3%. G3/4 non-hematologic toxicities occurred in 19.4%, mainly from non-neutropenic infections (11.1%) and gastrointestinal toxicities (8.3%). None developed cardiac dysfunction. Patients with G3/4 non-hematologic toxicities had lower mean relative dose intensity of all 3 drugs (P: 0.61 + 0.33 *vs* 0.91 + 0.16, $p$=0.002; C: 0.65 + 0.30 *vs* 0.95 + 0.14, $p$=0.001; L: 0.62 + 0.34 *vs* 0.97 + 0.10, $p$<0.01) and lower clinical CR/PR rates (40% *vs* 90.3%, $p$=0.024) than those without. Dose interruptions (P: 37.1%, C: 34.4%, L: 11.4%) and reductions (P: 16.7%. C: 19.5%) were common. Serial samples from 5 patients without pCR showed general progressive decline in circulating tumor cells with treatment but remained measurable before surgery. **Conclusions:** While the low pCR rate was contributed by advanced tumors, PCL dose intensity was difficult to maintain and its efficacy/toxicity ratio not favorable in unselected patients. Tumor immunohistochemistry and pharmacogenetic studies are ongoing to select patients most likely to benefit. Clinical trial information: NCT01309607.

**620 General Poster Session (Board #84), Mon, 8:00 AM-11:45 AM**

**Prognostic significance of interferon regulating factor 4 (IRF4) in node-negative breast cancer.** *Presenting Author: Marcus Schmidt, Department of Obstetrics and Gynecology, Johannes Gutenberg University, Mainz, Germany*

**Background:** The transcription factor IRF4 (interferon regulating factor 4) regulates immunoglobulin class switch recombination as well as plasma cell differentiation. We examined the prognostic significance of IRF4 mRNA expression in node-negative breast cancer. **Methods:** Microarray based gene-expression data for IRF4 (204562_at) were analysed in four previously published cohorts (Mainz, Rotterdam, Transbig, Yu) of node-negative breast cancer patients not treated with adjuvant therapy (n=824). A meta-analysis of previously published cohorts was performed using a random effects model. Prognostic significance of IRF4 on metastasis-free survival (MFS) was examined in the whole cohort and in different molecular subtypes: luminal A ($ER^+$/$HER2^-$/aurora kinase A [AURKA]$^{low}$, luminal B ($ER^+$/$HER2^-$/$AURKA^{high}$), basal-like ($ER^-$/$HER2^-$), $HER2^+$. Independent prognostic relevance was analysed using multivariate Cox regression. **Results:** Higher RNA expression of IRF4 was related to better MFS in a meta-analysis of the whole cohort (HR 0.49, 95% CI 0.35-0.69, P<0.0001). Prognostic significance was most pronounced in the $HER2^+$ positive molecular subtype (HR 0.18, 95% CI 0.06-0.55, P=0.0008) as compared to luminal A (HR 0.75, 95% CI 0.36-1.53, P=0.425), luminal B (HR 0.39, 95% CI 0.20-0.76, P=0.0044) and basal-like (HR 0.55, 95% CI 0.32-0.94), P=0.0279) carcinomas of the breast. IRF4 showed independent prognostic significance (HR 0.394, 95% CI 0.249-0.621, P<0.0001) in multivariate analysis. In addition to IRF4, only histological grade of differentiation (HR 2.591, 95% CI 1.604-4.187, P<0.0001) and tumor size (HR 1.791, 95% CI 1.135-2.825, P=0.012), but neither age nor HER2 status nor hormone receptor status retained an independent prognostic association with MFS. **Conclusions:** The transcription factor IRF4 has independent prognostic significance in node-negative breast cancer. Higher expression of IRF4 is associated with improved outcome. The prognostic impact differs between diverse molecular subtypes and is most pronounced in $HER2^+$ breast cancer.

**621^ General Poster Session (Board #85), Mon, 8:00 AM-11:45 AM**

**Phase Ib study of BEZ235 plus either paclitaxel (PTX) in advanced solid tumors (aST) or PTX plus trastuzumab (TZ) in HER2+ breast cancer (BC).** *Presenting Author: Jordi Rodon Ahnert, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Preclinical data suggest BEZ235 (BEZ; dual PI3K/mTOR inhibitor) may enhance the activity of PTX ± TZ in pts with advanced cancers. In this 4-arm study (NCT01285466), BEZ or buparlisib (pan-PI3K inhibitor) were investigated in combination with PTX in pts with aST or with PTX + TZ in pts with HER2+ BC. Here, we report the BEZ arms only. **Methods:** Pts with aST or HER2+ BC who were candidates for PTX ± TZ were eligible. The primary objective was to define the MTD in each arm by assessing dose-limiting toxicities (DLT) in Cycle 1. Dose escalation was guided by a Bayesian logistic regression model with overdose control. Pts with PI3K-pathway alterations were enrolled in a BEZ + PTX safety expansion cohort. **Results:** (2 Apr 2013): BEZ + PTX: 35 pts received BEZ at 400–800 mg/d and PTX at 70–80 mg/m$^2$/wk. Median number of prior regimens was 3 (range: 1–10). DLT occurred in 5 pts: in 1 out of 4 pts at 600/80 and in 4 out of 26 pts at 800/80. The MTD was declared as BEZ 800 mg/d + PTX 80 mg/m$^2$/wk. Median exposure was 11 wks. Study drug-related Grade 3/4 AEs (>10%) included diarrhea (17%), fatigue (20%), and asthenia (11%). 29% of pts discontinued due to AEs and 63% due to progressive disease. The median $AUC_{0-24}$of BEZ at the MTD on C1D8 was 11000 (range: 1730–39000) h*ng/ml. The PK of PTX were unaffected by BEZ. Per RECIST, there were 3 PRs (ORR = 9%) and 18 SD. BEZ + PTX + TZ: 11 pts received BEZ + PTX (80 mg/m$^2$) + TZ (2 mg/kg/wk) at 2 BEZ doses: initially at 600 mg/d (5 pts) and then at 400 mg/d (6 pts). Median number of prior regimens was 4 (range: 1–10). DLT occurred in 2 pts (600 mg/d). The MTD was declared as BEZ 400 mg/d + PTX 80 mg/m$^2$/wk + TZ 2 mg/kg/wk. Median exposure was 19 wks. Study drug-related Grade 3/4 AEs (>10%) included neutropenia (27%), neurotoxicity (18%), and lymphopenia (18%). The median $AUC_{0-24}$of BEZ at the MTD on C1D8 was 3590 (range: 2190–12200) h*ng/ml. Per RECIST, there were 2 CR, 4 PR (2 with prior PTX/TZ in metastatic setting; ORR = 55%) and 3 SD. **Conclusions:** BEZ + PTX ± TZ has a challenging safety profile and substantial interpatient variability in PK parameters. However, encouraging signs of clinical activity suggest that PI3K-pathway inhibition in combination with PTX ± TZ is a promising approach for treating pts with aST. Clinical trial information: NCT01285466.

**622 General Poster Session (Board #86), Mon, 8:00 AM-11:45 AM**

**Preclinical in vitro and in vivo evaluation of antitumor activity of poly (ADP-ribose) polymerase inhibition and trastuzumab combined therapy in HER2-overexpressing breast cancer.** *Presenting Author: Ignacio Tusquets, Hospital del Mar, Barcelona, Spain*

**Background:** PARP inhibitors have provided promising results in BRCA deficient breast cancer, but not in unselected patient populations. Two lines of research in this field are needed: identification of novel subsets of patients that could potentially benefit from PARP inhibitors and the discovery of suitable targeted therapies for combination strategies. **Methods:** We tested PARP inhibition, alone or combined with the anti-HER2 antibody trastuzumab on HER2 positive breast cancer. We used two PARP inhibitors in clinical development, olaparib and rucaparib, as well as genetic downmodulation of PARP-1 for in vitro studies. DNA damage was studied by the formation of γH2AX foci and comet assay. Finally, in vivo anti-tumor effect of olaparib and trastuzumab was examined in subcutaneously implanted BT474 cells in nude mice. **Results:** In a panel of four HER2 overexpressing cell lines, but not in non-HER2 overexpressing breast cancer cell lines, both olaparib and rucaparib significantly decreased cell growth and enhanced anti-tumor effects of trastuzumab. Similar results were observed in cells with genetic downmodulation of PARP-1. Combined treatment with olaparib and trastuzumab resulted in increased DNA damage in vitro. In in vivoexperiments using the HER2 overexpression BT474 xenograft model, the combined treatment resulted in enhanced growth inhibition, as well as reduced tumor cell proliferation, increased DNA damage and apoptosis. **Conclusions:** Taken together, our results show that in HER2 overexpressing breast cancer, PARP inhibition has antitumor effects and significantly increases trastuzumab activity, which makes this novel combination a promising strategy for further development.

**623 General Poster Session (Board #87), Mon, 8:00 AM-11:45 AM**

**A multicenter randomized study comparing 6 versus 12 months of trastuzumab in combination with dose-dense docetaxel following FEC as adjuvant treatment of women with axillary node–positive or high-risk, node-negative breast cancer overexpressing HER2.** *Presenting Author: Dimitrios Mavroudis, Hellenic Oncology Research Group (HORG), Athens, Greece*

**Background:** Adjuvant trastuzumab in combination with chemotherapy improves outcome of women with HER2 positive early breast cancer. However, the optimal duration of treatment remains unknown. In this study we compared 6 versus 12 months of adjuvant trastuzumab. **Methods:** Axillary node positive or high risk node negative women with HER2 overexpressing or amplified early breast cancer were randomized following surgery to receive either 6 (arm A) or 12 (arm B) months of adjuvant trastuzumab in combination with dose dense G-CSF-supported Docetaxel (75mg/m$^2$ every 14 days for 4 cycles) following FEC (5FU 700mg/m$^2$, epirubicin 75mg/m$^2$, cyclophosphamide 700mg/m2 every 14 days for 4 cycles). The primary endpoint of the study was the 3-year disease-free survival (DFS). **Results:** Four hundred eighty one patients were randomized; 240 on arm A and 241 on arm B. Of them 83 (34%) and 100 (41%) were premenopausal, 200 (83%) and 180 (75%) were node positive, 165 (69%) and 156 (65%) were hormone receptor positive in arm A and B, respectively. Chemotherapy was completed in 98% and 99% of patients while trastuzumab therapy in 96% and 100% of patients in arm A and B, respectively. After a median follow up of 43.5 and 42 months there were 26 (10.8%) and 15 (6.2%) (p=0.07) disease relapses and the median DFS has not yet been reached (p=0.08) while the 3-year DFS rate was 92.4% and 95.1% for arm A and B, respectively. **Conclusions:** Preliminary results of this study in terms of disease relapse and DFS are in favor of 12 months of adjuvant trastuzumab administration. Clinical trial information: NCT00615602.

**624 General Poster Session (Board #88), Mon, 8:00 AM-11:45 AM**

**Long-term results on trastuzumab (T) in elderly patients (EP) with locally advanced or metastatic HER2-positive breast cancer (BC).** *Presenting Author: Christian Jackisch, Sana Kliniken Offenbach, Offenbach, Germany*

**Background:** In a prospective, non-interventional observation study, routine T treatment in advanced, HER2-positive BC was evaluated in a total of 1,843 patients (pts) enrolled between 2001 and 2010. With a follow-up duration of up to more than 11 years (y), this report focuses on the relatively large subgroup of EP (> 65 y). **Methods:** Pts were enrolled by 223 institutions in Germany. HER2-positivity was defined as 3+ staining in immunohistochemistry or a positive fluorescence in situ hybridization (FISH) test in case of 2+ staining. All types of pretreatments were acceptable. Detailed information on study treatment, its safety and the course of disease was collected for at least 1 y. Thereafter, long-term outcome data were additionally retrieved at specified follow-up time points. **Results:** The median age of the total observation group was 59.5 y (range: 21–95), with 505 pts being > 65 y (28%), 257 pts > 70 y (14%), and 58 pts even 80 y or older (3%). The percentage of EP constantly increased over the 10 y recruitment period. In EP, the proportion receiving T in combination with chemotherapy was 69% compared to 74% in younger pts (YP). Correspondingly, EP more often received T in combination with endocrine therapy only (19% vs 13%). With 11%, T monotherapy was not given more frequently in EP, but this proportion increased clearly in the cohorts > 70 y (14%) and ≥ 80 y (29%). Univariately, progression-free survival was almost identical for EP and YP (medians: 11.4 vs 10.7 months; p=0.99). Overall survival (OS) was shorter in EP with borderline significance (28.4 vs. 33.4 months; p=0.072). In multivariate analysis of OS, higher age retained its significance (HR=1.23; p= 0.022). Cardiac toxicity incidence was 2.3% overall (all grades; no grade 4 event), but distinctly higher in EP (4.2% vs 1.5%). **Conclusions:** To the best of our knowledge, our database comprises the largest population of EP with information on the longest follow-up period reported on T treatment in this disease setting. The antineoplastic efficacy of T seems to be independent of age, while the multivariately independent moderate impact of age on OS simply appears to reflect the higher background mortality of the older population.

**625 General Poster Session (Board #89), Mon, 8:00 AM-11:45 AM**

**Evidence of *PIK3CA* and *TP53* co-mutation in breast cancer identification on next-generation sequencing (NGS) of *ERBB2* (*HER2*)-amplified residual disease following preoperative anti-HER2 therapy.** *Presenting Author: Frankie Ann Holmes, Texas Oncology, US Oncology, Houston, TX*

**Background:** Understanding the molecular alterations in residual, treatment-refractory HER2-positive breast cancer (BC) following preoperative trastuzumab (H), lapatinib (L) or both (HL) in combination with chemotherapy may help identify patients at risk for not achieving pathologic complete responses as well as genomic alterations (GA) to target to overcome therapy resistance. Here we summarize the GA present in 21 pts' residual BC following preoperative anti-HER2 therapy. **Methods:** 100 pts with stage 2/3 HER2+ BC were randomized to treatment with H vs L 1250mg vs HL (L 750-1000mg) along with preoperative 5-fluoruracil, epirubicin, cyclophosphamide followed by weekly paclitaxel (Holmes F. BMC Res Notes 6:507, 2013). Following IRB-approved informed consent, targeted NGS was performed on 21 pts' FFPE residual disease (RD) after preoperative therapy at a CLIA-certified laboratory to characterize all classes of genomic alterations across 287 cancer-related genes. **Results:** 3 of 21 pts with RD were HER2-negative (1 with *TP53* mutation and *EGFR* amplification; 1 with *PIK3CA* mutation). Of the 18 HER2+ RD (5 ER- and 13 ER+), 13 (72%) had *TP53* mutations; 8 (44%) had *PIK3CA* mutations, always co-mutated with *TP53* (3 ER- and 5 ER+). Although prevalence of *TP53* and *PIK3CA* mutation was only modestly higher than published estimates for HER2+ primary BC (55% and 32% for *TP53* and *PIK3CA*, respectively - Stephens P. Nature 486:400, 2012), prevalence of co-mutations appeared significantly higher – 44% vs. 18%, $p<0.1$). Of the 4 RD post-HL, 3 were ER+, all had *TP53* mutations, 2 with *PIK3CA* mutations. Other prevalent alterations in checkpoint-related genes included truncations in *ATM* and *BRCA1*, and amplification of *EMSY*, *MDM2* and *MDM4.* Ampifications of *CCND1* and *CDK4* were also present. **Conclusions:** The enrichment of *PIK3CA* and *TP53* co-mutations in BC pts' HER2-amplifed RD following preoperative H or L or HL plus chemotherapy may predict for high sensitivity to PI3K inhibitors (Kim N, Int J Cancer 131:2456, 2012; Daemen A. Genome Biol 14:R110, 2013), and provides evidence for potentially actionable targeted treatment.

**626 General Poster Session (Board #90), Mon, 8:00 AM-11:45 AM**

**Toward clinical development of SYD985, a novel HER2-targeting antibody-drug conjugate (ADC).** *Presenting Author: Gijs Verheijden, Synthon Biopharmaceuticals BV, Nijmegen, Netherlands*

**Background:** SYD985 is a HER2-targeting ADC based on trastuzumab and vc-seco-DUBA, Synthon Biopharmaceuticals proprietary cleavable linker-duocarmycin payload. This paper describes the direct comparison of SYD985 to T-DM1 (ado-trastuzumab emtansine) in vitro and in vivo. **Methods:** Cell survival was tested in 96-wells plates using the CellTiter-Glo luminescent assay kit (Promega); cell line-based and breast cancer patient-derived tumor-based xenograft experiments were done in SPF athymic nu/nu mice (n=8 per group). A polyclonal rabbit anti-human HER2 (DAKO) antibody was used in the IHC analysis. In vitro data analysis comprised the sigmoidal dose-response equation with variable slope in GraphPad Prism. **Results:** In vitro, SYD985 and T-DM1 were compared head-to-head in a panel of 8 cell lines expressing different levels of HER2. In cell lines with high HER2 expression (HER2 3+), both SYD985 and T-DM1 show similar potencies and activities. In cell lines with low HER2 expression (HER2 2+ and 1+), SYD985 was a factor 3- to over 50-fold more potent than T-DM1. In vivoanti-tumor activity was assessed in a series of cell line and patient-derived breast cancer xenograft studies with varying HER2 levels, including FISH-positive / IHC-HER2 3+ and FISH-negative / IHC-HER2 2+ and 1+ models. Both SYD985 and T-DM1 showed anti-tumor activity in the FISH-positive / IHC-HER2 3+ models, although SYD985 appeared to be somewhat more active. Whereas SYD985 showed very potent anti-tumor activity in the FISH-negative models that were either IHC-HER2 2+ or 1+, T-DM1 was not active, indicating superior anti-tumor activity of SYD985 over T-DM1. The data are corroborated by similar results in gastric cancer models. **Conclusions:** The preclinical profile of SYD985 enables extending the target population of breast and gastric cancer patients that may respond to this treatment modality to include FISH-negative / IHC-HER2 2+ and 1+ patients. Early phase clinical trials with SYD985 in breast and gastric cancer patients with this tumor profile, besides the classical FISH-positive and/or IHC-HER2 3+ indication, appear justified and warranted.

**627^ General Poster Session (Board #91), Mon, 8:00 AM-11:45 AM**

**Phase Ib study of buparlisib (BKM120) plus either paclitaxel (PTX) in advanced solid tumors (aST) or PTX plus trastuzumab (TZ) in HER2+ breast cancer (BC).** *Presenting Author: Cristina Cruz, Vall d'Hebron University Hospital, Barcelona, Spain*

**Background:** Preclinical data show PI3K-pathway inhibition can enhance the efficacy of anticancer therapy, such as PTX or TZ. In this 4-arm Ph Ib study (NCT01285466), buparlisib (pan-PI3K inhibitor) or BEZ235 (dual PI3K/mTOR inhibitor) was combined with PTX in pts with aST or PTX + TZ in pts with HER2+ BC. Here we report the buparlisib arms only. **Methods:** Pts with aST or HER2+ BC eligible for PTX ± TZ received oral buparlisib qd + PTX (70−80 mg/m$^2$ IV) qw ± TZ (2 mg/kg IV) qw in 28-day cycles. The primary objective was to define the MTD in each arm by assessing dose-limiting toxicities (DLT) in Cycle (C) 1. Dose escalation was guided by a Bayesian logistic regression model with overdose control. Pts with PI3K-pathway alterations were enrolled in a buparlisib + PTX safety expansion cohort. **Results:** (2 Apr 2013) Buparlisib + PTX: buparlisib doses from 40−120 mg/d were tested in 53 pts, including 36 pts at 100 mg/d. Median no. prior regimens was 3 (1−12). DLT occurred in 5 pts: 3 at 120 mg and 2 at 100 mg. MTD was declared as buparlisib 100 mg qd + PTX (80 mg/m$^2$ IV) qw. Drug-related G3/4 AEs (>10%) were neutropenia (13%) and hyperglycemia (11%). Median exposure was 15 wks. Primary reason for discontinuation was PD (68%). Buparlisib exposure was lower than in the single-agent study, especially at 100 mg. Buparlisib did not modify the PK of PTX. Per RECIST, there was 1 CR, 8 PR, and 27 SD (ORR = 17%). 3 pts are ongoing. Buparlisib + PTX + TZ: all 11 pts received buparlisib at 100 mg/d. Median no. prior regimens was 4 (1−10; prior taxane, 82%; prior TZ, 100%). DLT occurred in 2 pts. MTD was declared as buparlisib 100 mg qd + PTX (80 mg/m$^2$ IV) qw + TZ (2 mg/kg IV) qw. Drug-related G3/4 AEs (>10%) were neutropenia (27%) and diarrhea (18%). 1 pt developed G4 psychosis in C2, resolving after discontinuation. Median exposure was 17 wks. Primary reason for discontinuation was PD (64%). PK of PTX and TZ were in the expected range. Per RECIST there were 3 PR (1 with prior PTX/TZ in metastatic setting) and 5 SD (ORR = 27%). 2 pts are ongoing. **Conclusions:** Buparlisib can be combined with PTX and TZ in pts with aST or HER2+ BC at the single-agent MTD, with early indications of activity, thus establishing the feasibility of PI3K blockade combined with PTX + TZ. Clinical trial information: NCT01285466.

**628 General Poster Session (Board #92), Mon, 8:00 AM-11:45 AM**

**Predictive value of CTCs biomarkers status in patients with metastatic breast cancer (MBC) receiving anti-HER2 therapy.** *Presenting Author: Zefei Jiang, Hospital Affiliated to Academy of Military Medical Science, Beijing, China*

**Background:** The value of circulating tumor cells (CTCs) enumeration has been widely accepted, but the predictive value of enumeration and the detection of HER-2 expression in CTCs (CTCs-HER2) in patients with HER2 positive disease treated with HER-2 targeted therapy has still not been prospectively demonstrated. **Methods:** One hundred one HER-2 positive (IHC HER2+++ or FISH+) patients were enrolled from Oct 2010 to Nov 2013. All of the patients received a new line of treatment with chemotherapy plus trastuzumab or lapatinib. CTC isolation, enumeration and characterization were performed by using the CellSearch technology. HER2 expression intensity in CTC was given a score of 0, 1+, 2+, or 3+, according to the trial we have conducted previously, the CTCHER2 positive criterion was defined as >30% of CTCs over-expressing HER2 (3+). Hormone receptor positive(HR+) was defined as ER or PR positive and hormone receptor negative(HR-) was defined as ER or PR negative. **Results:** 56(55.4%) out of 101 patients were detected with CTC≥1. For the patients who detected CTC, 29(51.8%) patients were CTCHER2-positive, 27(48.2%) were CTCHER2-negative. There was a statistically difference in PFS between the groups of CTCHER2-positive and the CTCHER2-negative (P=0.014). For the patients with ≥5 CTC, HR- patients benefit a longer PFS compared with HR+ patients (7m vs 4m). The PFS for CTCHER2-positive and hormone receptor negative patients versus CTCHER2- negative and hormone receptor positive patients were 8.5 months versus 2.5 months(P=0.003). **Conclusions:** This analysis demonstrates that the baseline enumeration of CTC for HER2 positive MBC patients with different HR statuses who received chemo plus anti-HER2 therapy lacks of predictive value, whereas the detection of baseline CTCHER2 status is associated with significant prediction of therapeutic benefit. Moreover, the CTCHER2 positive and HR- patients can benefit most from chemo plus anti-HER2 therapy. Routine CTCs biomarkers assessment should be prospectively evaluated in patients candidates for molecularly targeted therapies.

**629^ General Poster Session (Board #93), Mon, 8:00 AM-11:45 AM**

**Clinical effects of prior anthracycline or taxane use on eribulin as first-line treatment for HER+/- locally recurrent or metastatic breast cancer (BC): Results from two phase II, multicenter, single-arm studies.** *Presenting Author: Stefan Gluck, Sylvester Comprehensive Cancer Center, University of Miami, Miller School of Medicine, Miami, FL*

**Background:** Eribulin mesylate, a novel nontaxane microtubule dynamics inhibitor, has demonstrated an overall survival benefit relative to other commonly used agents in pts with at least 2 prior MBC therapies. Primary data presented from 2 phase 2 trials, Study 206 (eribulin in HER2- pts) and Study 208 (combination eribulin + trastuzumab [TRAS] in HER2+ pts), showed clinical activity and acceptable tolerability profiles as first-line therapy (tx). Here we present prespecified efficacy data for both trials based on prior anthracycline (A) and taxane (T) use. **Methods:** In both studies, pts received eribulin mesylate 1.4 mg/m$^2$IV on Days 1 and 8 of each 21-day cycle. Pts in Study 208 (HER2+ pts) also received initial TRAS (8 mg/kg IV/Day 1), followed by 6 mg/kg/Day 1 of each subsequent cycle. Response, progression-free survival (PFS), and tolerability were assessed. **Results:** In Study 206 (N=56), 48% and 46% received prior A and T, and in Study 208 (N=52), 21% and 44% received prior A and T, respectively. Objective response rates (ORRs), the primary endpoint, were similar in pts, regardless of prior A or T tx, except in pts w/o prior T in Study 208 whose ORR trended higher (table). In both studies, clinical benefit rate (CBR), PFS, and duration of response (DOR) were either similar or trended higher in pts w/o prior A or T. PFS was higher in HER2+ pts receiving eribulin + TRAS who had not received prior A or T compared with those who had. Grade (G) 3-5 AE rates were similar or lower in pts who had not received prior A or T. **Conclusions:** As first-line therapy, eribulin in HER2- pts and eribulin + TRAS in HER2+ pts were effective and well tolerated, regardless of prior A or T tx. However, in HER2+ pts receiving eribulin + TRAS, the lack of prior A or T tx may be a predictor of longer median PFS. Clinical trial information: NCT01268150 and NCT01269346.

**Prognostic, predictive, and surrogate value of HER2 extracellular domain (ECD) for progression-free survival (PFS) in advanced breast cancer treated with lapatinib (lap): A meta-analysis.** *Presenting Author: Chee Lee, NHMRC Clinical Trials Centre, Sydney, Australia*

**Background:** We performed a meta-analysis to determine the clinical utility of HER2 ECD in advanced breast cancer patients undergoing lap therapy. **Methods:** Data from Phase 3 clinical trials (EGF30001, EGF30008, EGF100151) of patients randomized to receive lap-containing or control treatments were analyzed. Baseline HER2 ECD (bECD) and tissue HER2 status were examined for associations with PFS. We also performed a landmark analysis to quantify the association between ECD change, as measured at 10 weeks post-randomization, with PFS, and assessed the extent ECD change predicted lap benefit. **Results:** Levels of bECD were higher in HER2+ (n=378) than HER2- (n=1060) patients (61.59 vs 14.25ng/ml, p<0.0001). The effectiveness of lap was significantly associated with bECD (joint treatment-biomarker interactions P=0.001[bECD], P=0.02[HER2 tissue status]). At 10 weeks post-randomization, there was a mean 4.23ng/ml reduction in ECD with no significant difference between treatment arms (lap: 4.33ng/ml, control: 4.12ng/ml; P=0.92). In the control arms, change in ECD was prognostic for PFS (P<0.0001). The median PFS from landmark (mPFS) were 9.8 and 2.9 months for those with low ECD (≤15ng/ml) and high ECD (>15ng/ml), respectively. mPFS were 3.3 and 5.7 months for patients with ECD increase to >15ng/ml and ECD decrease to ≤15ng/ml, respectively. Similar finding was observed in the experimental arm (P<0.0001). In both treatment arms, there was 4% increase in risk of disease progression for every 10 unit ECD increment after adjustment of bECD and other factors (P<0.0001). Lap improved PFS over control (HR 0.83, P=0.002). Adjustment for ECD change yielded a similar result (HR 0.80, P<0.001), indicating that change in ECD did not explain the treatment effect of lap. **Conclusions:** Baseline HER2 ECD was predictive of lap benefit. ECD increase during lap and non-lap therapies was associated with a shorter PFS. Change in ECD had additional prognostic information in addition to baseline ECD, but was not a valid surrogate marker for lapatinib benefit as the treatment effect of lap was largely independent of ECD change. Clinical trial information: NCT00075270, NCT00073528, and NCT00078572.

**631^ General Poster Session (Board #95), Mon, 8:00 AM-11:45 AM**

**Efficacy of eribulin in patients (pts) with metastatic breast cancer (MBC): A pooled analysis by HER2 and ER status.** *Presenting Author: Chris Twelves, Leeds Institute of Cancer and Pathology, and St James's Institute of Oncology, Leeds, United Kingdom*

**Background:** Eribulin (E) has been assessed in 2 phase 3, open-label trials in pts with locally recurrent or MBC progressing after an anthracycline (A) and taxane (T). E significantly increased overall survival (OS) compared with treatment of physician's choice (TPC) in 1 study and there was a non-significant trend for improved OS with E vs capecitabine (cape) in the other. We present an unplanned pooled analysis of these data. **Methods:** In the EMBRACE trial, women had received 2-5 lines of chemotherapy for advanced disease. In this ≥ third-line setting, pts were randomized 2:1 to E mesylate (1.4 mg/m$^2$ iv on days 1 and 8 every 21 days) or TPC. In study 301, pts who had received 0–2 prior chemotherapies for advanced disease were randomized 1:1 to either E (as above) or cape (1.25 g/m$^2$orally b.i.d. days 1–14 every 21 days). We analysed OS by 2-sided stratified log-rank tests and Cox regression in the overall intent-to-treat population and in the HER2–, triple negative (TNBC) and HER2+ subgroups. **Results:** In total 1,864 pts (median age 54 yrs) were included, most treated in the second (31.5%) or third-line (32.7%) MBC settings. Overall, E provided significantly improved OS vs control; this benefit was also significant in HER2− and TNBC, but not HER2+ pts (Table). E improved progression-free survival overall (4.0 vs 3.4 months, HR = 0.90, 95%CI = 0.81, 0.997, $p$ = 0.046), in HER2– (3.7 vs 3.0 months, HR = 0.84, 95%CI = 0.74, 0.95, $p$ = 0.006) and TNBC pts (2.8 vs 2.6 months, HR = 0.78, 95%CI = 0.63, 0.96, $p$= 0.018). As reported before, the E safety profile was similar in the studies. **Conclusions:** E significantly improved OS vs standard therapies in MBC pts with HER2− and TNBC in this pooled analysis; in pts with HER2+ disease the difference did not reach statistical significance but numbers were smaller. Clinical trial information: NCT00337103 and NCT00388726.

**632 General Poster Session (Board #96), Mon, 8:00 AM-11:45 AM**

**Randomized phase II trial of capecitabine and lapatinib with or without cixutumumab in patients with HER2+ breast cancer previously treated with trastuzumab and an anthracycline and/or a taxane: NCCTG N0733 (Alliance).** *Presenting Author: Paul Haluska, Mayo Clinic, Rochester, MN*

**Background:** Crosstalk between the insulin-like growth factor (IGF) and HER2 pathways in multiple preclinical models suggest a mechanism of resistance to HER2-targeted therapy. Cixutumumab (CIX, IMC-A12), an anti-IGF-1 Receptor monoclonal antibody, was investigated in combination with capecitabine and lapatinib (cape/lap) to determine if the addition of an IGF target agent would improve PFS compared to cape/lap in unselected HER2+ metastatic breast cancer (mbc) patients (pts). IGF binding protein (IGFBP) levels may be important in predicting tumor dependence on IGF signaling and are potential biomarkers. **Methods:** Following an initial safety cohort, this open label phase II study randomized (2:1) pts to cape/lap with CIX (Arm B) or cape/lap (Arm A). Primary endpoint was progression-free survival (PFS) with 144 pts planned for a target hazard ratio of 0.56. PFS was estimated using Kaplan-Meier and compared using Cox regression. Secondary endpoints included assessing the overall survival and treatment tolerability. Correlative studies included assessments of IGFBPs 1-6 using a Luminex multiplex assay on pt serum. **Results:** 64 evaluable pts were accrued, including 8 to the safety cohort. The most common grade 3 events were diarrhea, fatigue and mucositis. Dose reductions in the safety cohort for 6 of 8 pts prompted a dose reduction of cape/lap in Arm B of the randomized portion. The randomized portion of the study was closed early at 56 pts due to slow accrual. Median PFS by in Arm A was 6.0 mo vs. 4.9 mo in Arm B (p= 0.89). Median overall survival (16.8 vs 14.7 mo, p=0.93), time to treatment failure (TTF) (4.6 vs 4.4 mo, p=0.66), and duration of response (4.8 vs 6.9 mo, p=0.26) were not different between arms. In Arm B, increase in IGFBP5 correlated with poor PFS (1.4 vs 9.9 mo, p= 0.02) and high IGFBP5 correlated with improved TTF (9.9 vs 3.9 mo, p= 0.03). **Conclusions:** CIX is reasonably tolerated in combination with cape/lap following a dose reduction, but does not improve PFS in unselected pts with HER2+ mbc. IGFBP5 may be an important determinant of benefit from IGF targeted therapy and warrants further investigation. Clinical trial information: NCT00684983.

**633 General Poster Session (Board #97), Mon, 8:00 AM-11:45 AM**

**Phase II feasibility study of paclitaxel (T) with trastuzumab (H) and lapatinib (L) for node-negative, HER2-positive breast cancer (BC).** *Presenting Author: Neil M. Iyengar, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** We previously demonstrated that weekly T + HL after anthracycline based therapy was not feasible due to high incidence of grade (G) 3 diarrhea, which led to modification of the ALTTO trial. Previous data showed that L could be given more safely with every (q) 3 week than weekly T. Given the low and similar diarrhea rates between T dosed q 2 versus 3 weeks (CALGB 9741), we studied dose dense (dd) T + H + full dose L (THL). **Methods:** This is a single center, phase II feasibility study of dd T + HL. Eligible patients (pts) had HER2+ BC (IHC 3+ or FISH amplified ≥ 2.0) with negative nodes (micrometastasis allowed) and tumor size ≤ 3 cm. Pts received T 175 mg/m$^2$ x 4 q 2 weeks (w), H 4 mg/kg load → 2 mg/kg qw with T, and L 1000 mg daily. Pts received pegfilgrastim after each T, during the THL phase. Afterwards, H (6 mg/kg q 3 w) + L were continued x 1 year. Left ventricular ejection fraction (LVEF) monitoring was done at baseline, months 2, 6, 9, 12, and 18 by an echocardiogram. Primary endpoint was feasibility defined as ≥ 80% of pts who completed THL without dose delay or reduction. Allowable rate of G 3 diarrhea was set at 20% and cardiac event (symptomatic heart failure or cardiac death) at ≤ 4%. **Results:** From 05/13 – 11/13, 20 of 55 planned pts were enrolled; median age 49 (range 34 – 74 years). Overall, 17/20 (85%) had ER+ tumors. Tumors were T1a (20%), T1b (30%), T1c (40%), and T2 (10%). 1 pt had immediate T hypersensitivity and was deemed inevaluable. Only 12/19 (63%) evaluable pts completed the THL phase without dose delay/reduction or unacceptable toxicities. Diarrhea rates were: all G-16/19 (84%) and G 3-3/19 (16%). Rash rates were high: all G-18/19 (95%), G 2-7/19 (37%), G 3-1/19 (5%). Other G3-4 toxicities include: lymphopenia, 2/19 (11%); anemia, 1/19 (5%); cellulitis, 1/19 (5%); transaminases, 1/19 (5%); dehydration, 1/19 (5%). There were no cardiac events and LVEF was well preserved. The study was stopped early in November 2013 due to excess toxicity. **Conclusions:** The combination of full dose L with dd T and H was not feasible. There was an unexpected high incidence of rash. G 3 diarrhea incidence was acceptable. This important negative study provides additional feasibility data as we await the release of data from ALTTO. Clinical trial information: NCT01827163.

**634 General Poster Session (Board #98), Mon, 8:00 AM-11:45 AM**

**Racial/ethnic (RE) differences in the occurrence of HER2 and hormone receptor (HR)-defined breast cancer (BC) in California (CA).** *Presenting Author: Scarlett Lin Gomez, Cancer Prevention Institute of California (CPIC), Fremont, CA*

**Background:** RE disparities in the occurrence and mortality of BC are long-standing and persistent. Examining differences in the occurrence of molecularly-defined BC subtypes by RE can inform reasons for its unequal burden and point to better targeted strategies for prevention.Objective: To describe BC subtype occurrence by RE in a contemporary, population-based cohort. **Methods:** We examined demographic and clinical factors associated with prevalence of 4 BC subtypes (HER2Neu, HR [based on estrogen and progesterone receptor status]) by RE among all female CA residents diagnosed with primary invasive BC between 1/1/2005 and 12/31/2011 in the California Cancer Registry. **Results:** A total of 131,450 BC pts (59.0% HR+/HER2-, 10.4% triple-negative (TN), 9.9% HR+/HER2+, 5.0% HR-/HER2+, and 15.6% unclassified) were identified. TN BC was substantially more likely to be diagnosed among Blacks and Hispanics (19.8% and 12.9%, respectively) than Whites and Asians/Pacific Islanders (API) (9.2% and 8.5%, respectively). However, HER2+ BC was more likely to be diagnosed among APIs than other RE groups (19.4% vs. 13-18%). TN and HER2+ BC were more common among women living in lower socioeconomic status (SES) neighborhoods (Table 1). These associations persisted in multivariate polytomous regression analysis adjusted for year, age, stage, grade, histology, marital status, and insurance status. **Conclusions:** The distribution of breast cancer subtypes vary markedly by RE and SES, with minority RE and low SES populations being more likely to have subtypes associated with worse survival.

**Clinical effects of prior trastuzumab on combination eribulin mesylate plus trastuzumab as first-line treatment for HER2+ locally recurrent or metastatic breast cancer (MBC): Results from a phase II, single-arm, multicenter study.** *Presenting Author: Shannon Puhalla, Magee Womens Hospital, Pittsburgh, PA*

**Background:** Eribulin mesylate, a novel nontaxane microtubule dynamics inhibitor in the halichondrin class of antineoplastic drugs, is indicated for women with MBC who previously received ≥2 chemotherapy regimens in the metastatic setting. Primary data from a phase 2 trial on first-line combination eribulin + trastuzumab (TRAS) in HER2+ patients (pts) showed a 71% objective response rate (ORR) and tolerability consistent with the known profile of these agents. Here we present prespecified endpoint data for this study by prior TRAS use. **Methods:** Pts with HER2+ MBC who had not received prior chemotherapy for MBC received eribulin mesylate 1.4 mg/m$^2$IV on days 1 and 8 of each 21-day cycle and initial TRAS (8 mg/kg IV/day 1), followed by 6 mg/kg/day 1 of each subsequent cycle. Response, progression-free survival (PFS), and tolerability were assessed in patients who had and had not received prior TRAS treatment. **Results:** The 52 pts (median age, 59.5 years) received combination eribulin + TRAS, for a median treatment duration of ~30 weeks; 40% (n=21) were previously treated with TRAS in the neo-adjuvant / adjuvant setting. There was median of 23 months since completion of adjuvant treatment prior to retreatment with eribulin + TRAS for first-line MBC.Efficacy, assessed by ORR, clinical benefit rate (CBR), PFS, and duration of response (DOR), was largely consistent in pts who received prior TRAS relative to pts who had not received prior TRAS (see table). Overall, Grade (G) 3-5 adverse events (AEs), treatment-related AEs (TRAEs), and discontinuations (d/c) were similar between groups (Table). **Conclusions:** In this phase 2 single-arm trial in pts with HER2+ MBC, eribulin + TRAS demonstrated activity and was well tolerated as first-line treatment, irrespective of prior (neo) adjuvant TRAS treatment. Clinical trial information: NCT01269346.

**Anti-HER2 CD4 T helper type 1 response in breast cancer: Is there a role for immunorestoration?** *Presenting Author: Jashodeep Datta, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA*

**Background:** Tumor microenvironment infiltration of IFNγ-producing CD4 T helper 1 (Th1) cells is linked to improved prognosis in invasive breast cancer (IBC). We investigated circulating anti-HER2 CD4 Th1 response (Th1resp) involved in breast tumorigenesis, and compared Th1resp prior to after chemotherapy/trastuzumab (C/T) treatment or dendritic cell vaccination in HER2$^+$ IBC pts. **Methods:** Th1resp were compared in healthy donors (HD; n=21) and pts with benign breast biopsy (BD; n=9), HER2$^{neg}$ IBC (n=11), HER2$^+$ DCIS (n=31), and HER2$^+$ IBC (n=14). Th1resp of pts enrolled in neoadjuvant immunization trials for HER2$^+$ DCIS and found to have Stage I IBC at surgery (n=11) were analyzed pre/postimmunization, and compared with HER2$^+$ IBC pts after C/T (n=34). Th1resp were generated from PBMC pulsed with 6 HER2 MHC class II peptides, by measuring IFNγ via ELISPOT. Th1resp metrics were (1) anti-HER2 response rate, (2) # of reactive peptides (repertoire), (3) cumulative response across 6 peptides (SFC/10$^6$ cells). Contribution of regulatory T cells ($T_{reg}$) to immune profiles was assessed by IL-10 production via ELISPOT. **Results:** Stepwise decrements in response rate (100% vs 100% vs 100% vs 84% vs 21%; p<0.0001), repertoire (5.2 vs 4.6 vs 3.9 vs 2.0 vs 0.4; p<0.0001), and cumulative response (259.9 vs 218.7 vs 191.2 vs 125.2 vs 33.0 SFC/10$^6$, p<0.0001) were observed among HD, BD, HER2$^{neg}$ IBC, HER2$^+$ DCIS, and HER2$^+$ IBC cohorts respectively. HER2$^+$ DCIS and -IBC pts differed in response rate (p<0.001), repertoire (p=0.001), and cumulative response (p<0.001). HD, BD, and HER2$^{neg}$ groups did not vary significantly. After immunizing HER2$^+$ IBC pts, improvements were seen in response rate (91% vs 18%, p=0.004), repertoire (3.7 vs 0.3, p<0.0001), and cumulative response (162.8 vs 29.7 SFC/10$^6$, p<0.0001). C/T treated and untreated IBC patients did not differ significantly. IL-10 production, as well as CD4$^+$Foxp3$^+$ cell ($T_{reg}$) proportions by flow cytometry, was similar between HD, HER2$^+$IBC, and C/T treated pts. **Conclusions:** Anti-HER2 Th1resp is progressively lost in breast tumorigenesis, and is $T_{reg}$-independent. Vaccination – but not targeted therapies – restores Th1resp in IBC, providing rationale for immunization to prevent subsequent breast events.

**637 General Poster Session (Board #101), Mon, 8:00 AM-11:45 AM**

**New graded prognostic index for breast cancer patients (pts) with brain metastases (BCBM).** *Presenting Author: Manmeet Singh Ahluwalia, Cleveland Clinic, Cleveland, OH*

**Background:** Diagnosis-Specific Graded Prognostic Assessment (DS-GPA) is frequently used for prognosis for BCBM. We evaluated DS-GPA plus other potential prognostic factors for overall survival (OS) in BCBM pts treated at a single tertiary care institution in a contemporary cohort (Preliminary data was presented at ASCO 2013). **Methods:** With IRB approval, the Cleveland Clinic's database was used to identify BCBM pts treated between 2000 and 2010. OS from the diagnosis of BCBM was the primary end point.Cox proportional hazards models with stepwise variable selection were used for data analysis. **Results:** 371 female patients were included for this analysis. Karnofsky performance scale (KPS) was 90-100 in 142 patients (42%), 70-80 in 146 (43%) and <70 in 48 (15%) patients. Median OS for the entire group was 11.9 months (95% C.I. 9.8-13.6). Median OS in Luminal B, Her 2, Luminal A and basal groups of pts was 23.3, 13.7, 11.9 and 6.0 months respectively (using Sperduto e.t al. 2012 criteria to define the subgroups). DS-GPA for BCBM is based on KPS, age at diagnosis, and subtype. Overall it was prognostic for OS (p<.0001) however separation between groups was variable. Using DS-GPA as a starting point, the number of extracranial metastases (ECM) present, control of the primary, and leptomeningeal metastases (LEP), were found to be additional independent prognostic factors (Table). Combining these factors a revised DS-GPA with 3 groups was defined: unfavorable (total points <6), intermediate (6-8 points), and favorable (>8 points) with median OS of 4.3, 11.9, and 23.4 months, respectively. **Conclusions:** A revised DS-GPA for BCBM based on the conventional GPA, and 3 additional factors is proposed.

**638 General Poster Session (Board #102), Mon, 8:00 AM-11:45 AM**

**Primary analysis of the prospective, randomized, single-blinded phase II trial of AE37 vaccine versus GM-CSF alone administered in the adjuvant setting to high-risk breast cancer patients.** *Presenting Author: Elizabeth Ann Mittendorf, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** AE37 is the Ii-Key hybrid of the HER2 peptide AE36 (HER2 aa:776-790). It is a MHC class II epitope capable of stimulating $CD4^+$ helper T-cells. We have completed accrual to a prospective, randomized, multi-center, phase II trial of the AE37 vaccine for prevention of breast cancer recurrence. Here the planned primary analysis of disease free survival (DFS) is presented. **Methods:** The trial randomized clinically disease-free, node positive or high-risk node negative patients (pts) with any level of HER2 expression to receive AE37 + GM-CSF (VG) or GM-CSF alone (CG) following standard of care therapy. Pts received 6 monthly intradermal inoculations during the primary vaccine series (PVS) followed by four boosters administered every 6 months. Statistical analysis was performed in the following groups: intention-to-treat (ITT) as the entire randomly assigned trial population, HER2 non-overexpressing (nOE) pts with IHC $1/2^+$ or $FISH^-$ tumors regardless of ER/PR status, and triple negative breast cancer (TNBC) pts with HER2 nOE and ER/$PR^-$tumors. **Results:** With 298 pts (VG= 153, CG= 145) enrolled, there are no differences between groups with respect to age, rate of node positivity, tumor grade, tumor size, ER/PR status, and HER2 over-expression (all p > 0.05). The vaccine is safe and well tolerated with no grade 3 local toxicities and 1 pt experiencing grade 3 systemic toxicity. DFS analyses by Kaplan Meier demonstrated a 12% relative reduction in recurrence (RRR) in the ITT population (19/153 v 20/145 events; HR(CI) 0.89 (0.47, 1.66), p=0.70), a 40% RRR in HER2 nOE pts (10/76 v 14/78 events; HR(CI) 0.60 (0.26, 1.35), p=0.21), and 60% in TNBC pts (4/25 v 9/25; HR(CI) 0.40 (0.12, 1.32), p=0.12). **Conclusions:** AE37 + GM-CSF is a novel vaccine that is safe and well tolerated with minimal toxicity. The primary analysis of this prospective, randomized, single-blinded phase II trial demonstrates benefit in patients with HER2 nOE tumors, especially those with triple negative tumors. These data justify a phase III trial evaluating AE37 administered in the adjuvant setting to a HER nOE or specifically TNBC population. Clinical trial information: NCT00524277.

**639 General Poster Session (Board #103), Mon, 8:00 AM-11:45 AM**

**Immunohistochemical (IHC) prediction of lapatinib efficacy in HER2-positive advanced breast cancer patients.** *Presenting Author: Renata Duchnowska, Military Institute of Medicine, Warsaw, Poland*

**Background:** Molecular mechanisms of resistance to lapatinib are not well understood. We analyzed retrospectively expression of six potentially useful biomarkers and correlated their status with clinical efficacy of lapatinib. **Methods:** Study group included 199 HER2-positive advanced breast cancer patients treated with lapatinib and capecitabine after progression of trastuzumab-based therapy. Expression of MAP-K, pAMPK alpha2, HIF-2 alpha, p-P70S6K alpha, cyclin E and PTEN in tumor samples of primary tumor was investigated by IHC using tissue microarray technology and industrial kits. Staining H-score was calculated for all markers as percent of stained tumor cells x average staining intensity graded from 0 to 3, resulting in a score value between 0 and 300. The most discriminative cut-off values (Cox regression) were subjected to multivariate analysis considering other predictive variables. **Results:** Median duration of lapatinib therapy was 6 months (range 0-52). In 82% of patients lapatinib therapy was discontinued due to disease progression. Using best discriminative values, expression of p-P70S6K alpha ($P$=0.014) and cyclin E ($P$=0.05) was predictive for progression free survival (PFS), the primary endpoint, and their predictive value was confirmed in the multivariate analysis (HR 0.44; 95%CI 0.24-0.80; $P$=0.007 and HR 1.87; 95% CI 1.09-3.21; $P$=0.024, respectively). PFS was also associated with the presence of brain metastasis (HR 1.79; 95% CI 1.28=2.49; $P$=0.001). Overall survival (OS) was associated with expression of cyclin E (p=0.015), p-P70S6K alpha ($P$=0.021), PTEN ($P$=0.034) and pAMPK alpha2 ($P$=0.020), of which cyclin E and MAP-K were confirmed in multivariate analysis (HR 3.66; 95%CI 1-55-8.81; $P$=0.003 and HR 1.59; 95%CI 1.12-2.27; $P$=0.010, respectively). Another independent determinant of OS was the presence of brain metastasis (HR 1.69; 95% CI 1.17-2.40; $P$=0.005). **Conclusions:** Clinical efficacy of lapatinib is associated with activity of downstream signaling pathways – PI3K/AKT/mTOR and MAPK, that seem to play opposite roles. Further investigation may indicate potential role of combining lapatinib with MAP pathway inhibitors.

**640 General Poster Session (Board #104), Mon, 8:00 AM-11:45 AM**

**Survher: A retrospective multicenter study comparing demographic and tumor characteristics of clinical trials versus clinical practice patients with HER2-positive breast cancer.** *Presenting Author: Grazia Arpino, Medical Oncology, AOU Federico II, Naples, Italy*

**Background:** Several clinical trials (CT) have shown remarkable efficacy of trastuzumab-based adjuvant therapy in human epidermal growth factor receptor 2 (HER2)-positive breast cancers (BC). However, CT patient population may not always be representative of patients routinely seen in clinical practice (CP). The aim of this study was to compare clinical and tumoral features between CT and CP patients with HER2 positive BC. **Methods:** From January to December 2012, 696 consecutive patients with HER2+ early BC, treated in 36 Italian Hospitals were enrolled in our study. Age, treatment information, tumor size (T), nodes (N), grade (G), estrogen receptor (ER) and progesterone receptor (PgR) status, were prospectively collected in CP patients. In parallel, the same data were extracted from the adjuvant trastuzumab trials FNCLCC-PACS-04, BCIRG-006, FinHER, HERA, NSABP B31-NCCTG N9831 and pooled using the random-effects model of DerSimonian and Laird. CT and CP groups were compared by using the Cochran Q statistics. **Results:** Compared to CT patients, CP patients were more likely to be older than 50 years (65% vs 48%, respectively, p<0.0001) and have ER positive (71% vs 51%, p<0.0001) and PgR positive (60% vs 39%; p<0.0001) BC and were less likely to have tumor bigger than 2 cm (T ≥2 cm 39% vs 59%; p<0.0001), with positive N (47% vs 89%, p<0.0001) and high G (61% vs 67%, p=0.0241). Additionally, CP patients received more frequently adjuvant endocrine therapy (70% vs 57% p<0.0003) and less frequently adjuvant chemotherapy (97% vs 99.7%; p<0.0001). Among chemo-treated patients there was no difference in the type of administered chemotherapy. **Conclusions:** Most tumor and clinical characteristics significantly differed among CP and CT patients. These data raise doubts about the applicability of CT results to the CP patient population. Therefore, assessing the efficacy and tolerability of anti-cancer treatments also in a clinical scenario closer to the routine CP may be needed to further validate CT results.

**641 General Poster Session (Board #105), Mon, 8:00 AM-11:45 AM**

**Long-term follow up (FU) of patients with durable complete response (DCR) after chemotherapy (CT) and HER2-targeting systemic therapy (HER2-Tx) for HER2+ metastatic breast cancer (MBC).** *Presenting Author: Giuseppe Gullo, St Vincent's University Hospital, Dublin, Ireland*

**Background:** CT-induced DCR of MBC is reported only anecdotally. The addition of HER2-Tx to conventional CT results in increased response rates and prolonged survival for pts with HER2+ MBC. We previously reported that a minority of pts with HER2+ MBC can achieve prolonged CR but their long-term outcome remains unclear. **Methods:** We conducted a systematic retrospective review of all pts with HER2+ MBC treated at our Institution with any CT+HER2-Tx and identified DCR. DCR was defined as a complete response according to RECIST 1.1 criteria lasting >36 months. **Results:** Between January 2000 and December 2010 168 consecutive pts with HER2+ MBC were commenced on CT+HER2-Tx. We identified 17 pts (10%) who met criteria for DCR. Their characteristics are: median age: 53yrs (range 30-65), oestrogen receptors (ER): neg 53%/pos 47%, sites of distant metastases: visceral 47%/lymph nodes only 35%/bone and soft tissues 12%, unknown 6%. All pts received trastuzumab (T). Chemotherapy regimens were: docetaxel+carboplatin 64%/docetaxel+lapatinib 18%/single agent taxane 6%/capecitabine 6%/unknown 6%. Metastatic disease was biopsy-proven in 9/17 pts (53%). All pts received maintenance HER2-Tx after completion of CT. Median FU is 6.5 yrs (range 3.4-13.6). Median duration of HER2-Tx is 61 months (41-127+). Two pts (12%) had MBC relapse while on maintenance T, 1 pt had a second HER2+ primary BC and underwent curative surgery. At database cut-off date (1/2/2014) 15 pts (88%) are alive and disease-free. Their characteristics are: all 1st-line therapy, ER neg 53%, single site of distant metastases 73% (lymph nodes 40%, liver 33%). **Conclusions:** To our knowledge this is the largest series analyzing long-term outcome of HER2+ MBC pts with DCR after CT+HER2-Tx. Our mature results show that a subgroup of pts can achieve a very prolonged CR thus prompting speculations that they have been cured from HER2+ MBC. These pts are usually treated in the 1st-line setting, have more frequently ER-negative disease and limited metastatic disease. Prolonged HER2-Tx could play a role in maintaining DCR. We are currently investigating the molecular profile of this subset of pts.

**642 General Poster Session (Board #106), Mon, 8:00 AM-11:45 AM**

**Projecting the cost-effectiveness of pertuzumab with trastuzumab and docetaxel in the neoadjuvant treatment of HER2-positive, locally advanced, inflammatory or early breast cancer.** *Presenting Author: Joseph B. Babigumira, University of Washington, Seattle, WA*

**Background:** The NeoSphere trial (Gianni et al. [2012]) compared the following regimens for neoadjuvant treatment in HER2+, locally advanced, inflammatory or early breast cancer: 1) trastuzumab and docetaxel (TH) 2) pertuzumab, trastuzumab and docetaxel (THP), 3) pertuzumab plus trastuzumab (HP), and 4) pertuzumab plus docetaxel (TP). The pathological complete response (pCR) rates were 29.0% for TH, 45.8% for THP, 16.8% for HP, and 24.0% for TP. THP significantly increased the pCR rate. We performed a cost-effectiveness analysis of THP compared to other treatment regimens in the neoadjuvant setting based on the pCR results from NeoSphere. **Methods:** We constructed a combined decision-analytic (decision tree) and partitioned survival (area under the curve) model with three health states: disease-free (DF), progressive disease (PD), and death. The decision tree modeled the probability of pCR and the partitioned survival model projected life expectancy of patients who did or did not achieve pCR. Utility data for health states were assigned to calculate quality-adjusted life years (QALYs). We estimated the cost of early breast cancer systemic therapy, drug administration, drug monitoring, clinical management of adverse events, and progressive disease (PD). We performed univariate and probabilistic sensitivity analyses. **Results:** See Table. The incremental cost-effectiveness ratios (ICERs) comparing THP to TH were $34,700/LY and $38,500/QALY, THP to HP, $33,000/LY and $36,900/QALY, and THP to TP, $16,100/LY and $17,800/QALY. The ICERs (THP vs. TH) were most sensitive to pCR difference between THP and TH and the cost of pertuzumab. **Conclusions:** Pertuzumab combined with trastuzumab and docetaxel is projected to be cost-effective in the neoadjuvant setting. This study suggests that this regimen, in addition to being clinically effective, would be favorable from an economic standpoint in the U.S.

**Summary of results.**

| Treatment regimens | Lifetime cost ($) | Life years (LYs) | Quality-adjusted life years (QALYs) |
|---|---|---|---|
| **THP** | 143,000 | 18.41 | 16.51 |
| **TP** | 132,000 | 17.69 | 15.86 |
| **TH** | 124,000 | 17.85 | 16.01 |
| **HP** | 112,000 | 17.45 | 15.65 |

**643 General Poster Session (Board #107), Mon, 8:00 AM-11:45 AM**

**Trastuzumab (T) and pertuzumab (P)-mediated antibody-dependent cell-mediated cytotoxicity (ADCC) in tyrosine kinase inhibitor (TKI)-treated breast cancer (BC) cell lines.** *Presenting Author: Denis Collins, National Institute for Cellular Biotechnology, Dublin City University, Dublin, Ireland*

**Background:** Monoclonal antibody (mAb) therapy and TKI combinations are under investigation for the treatment of HER2-positive (HER2 gene amplification/IHC 3+/2+) BC. A further ~50% of BCs can be described as HER2-low (IHC 1+/2+/non-amplified). The HER2-targeted TKI lapatinib (LAP) can modulate HER2 levels and potentiate T-mediated ADCC in pre-clinical models. This study compares the effects of three HER2-targeted TKIs, LAP, neratinib (NER) and afatinib (AFAT) on HER2 levels in HER2-positive SKBR3 and HER2-low MCF-7 cells and examines the associated effects on T and P-induced ADCC in vitro. **Methods:** MCF-7 and SKBR3 were treated with LAP, NER or AFAT (0.2, 1 and 2$\mu$M, 48 hr). Membrane HER2 protein levels were determined by high content analysis (HCA) using an extracellular domain (ECD)-targeted antibody. A flow cytometry-based ADCC assay utilized TKI pre-treated SKBR3 and MCF-7 (2$\mu$M TKI, 48 hr) and healthy volunteer CD56+ NK cells or PBMCs. **Results:** LAP treatment increased HER2 in SKBR3 and MCF-7. Following LAP treatment, T and P-induced ADCC was increased in MCF-7 and reduced in SKBR3 using PBMCs.Using NK cells, T-induced ADCC was reduced in both LAP-treated cell lines.NER decreased HER2 expression in both cell lines but reduced T-related ADCC in MCF-7 only. AFAT reduced HER2 levels in SKBR3 cells only, but did not significantly reduce ADCC response in SKBR3 cells. (Table, *p< 0.05 relative to DMSO control). **Conclusions:** ADCC optimal TKI/mAb combinations may differ between HER2-positive and HER2-low models, and PBMC sub-populations other than NK cells may be required as mediators. Further pre-clinical assessment is required to elucidate the mechanisms of ADCC modulation by TKIs.

**Effect of adjuvant trastuzumab (T) among patients treated with neoadjuvant T-based chemotherapy.** *Presenting Author: Mariana Chavez-Mac Gregor, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Neoadjuvant T-based chemotherapy is commonly used in the treatment of invasive HER2-positive breast cancer. Pathological complete response (pCR) is a surrogate of improved long-term outcomes; the impact of adjuvant T among patients achieving a pCR is unknown. Among patients treated with neoadjuvant T-based chemotherapy we evaluated the impact of completion of adjuvant T. **Methods:** Patients with primary HER2-positive breast cancer treated with T-based neoadjuvant chemotherapy at our institution between 2001-2012 were included and categorized according to adjuvant T administration and pCR (no invasive residual tumor in the breast and ipsilateral axillary lymph nodes). Descriptive statistics and Cox proportional hazard models were used. **Results:** 589 patients were included. 203 (34.5%) achieved a pCR. 109 (18.5%) did not receive adjuvant including 53 (26.1%) that achieved a pCR and 56 (14.5%) that did not achieve a pCR. Median follow up was 45 months. The 5 year-OS for patients who did and did not receive adjuvant T was 91% vs 93% (p=0.97) and the 5-year RFS was 92% vs 85% (p=0.33). Among patients that achieved a pCR, the 5-year OS was 96% vs 100% (p=0.23) and the RFS was 93% vs 100% (p=0.06) for patient that did and did not receive adjuvant T. Among those without a pCR, the 5-year OS was 92% vs 83% (p=0.28) and the RFS was 81% vs 84% (p=0.67) for patients that did and did not receive adjuvant T. In the multivariable analysis after adjusting for pCR, adjuvant T had no impact on outcome (HR=0.85 p=0.68 for OS and HR 1.05 p=0.9 for RFS). Among patients with pCR, adjuvant T did not improve OS or RFS (HR=2.7 p=0.35 and HR=8.02 p=0.93), the benefit of adjuvant T in OS and RFS did not achieve statistical significance among patients without a pCR (HR=0.64 p=0.3 and 0.76 p=0.44). **Conclusions:** Our data demonstrates that patients treated with neoadjuvant T-based chemotherapy that achieve a pCR, have excellent outcome regardless of whether they received or not adjuvant T. Among patients not achieving a pCR, the use of newer agents should be studied in order to further improve outcomes. Our results are relevant as our field evaluates the appropriate duration, therapeutic index, and cost of additional targeted therapies.

**645 General Poster Session (Board #109), Mon, 8:00 AM-11:45 AM**

**Meta-analysis of stomatitis incidence in everolimus (EVE) clinical studies and its relationship with efficacy.** *Presenting Author: Hope S. Rugo, University of California San Francisco Comprehensive Cancer Center, San Francisco, CA*

**Background:** Stomatitis is a common adverse event with EVE. This meta-analysis of individual patient (pt) data assessed the incidence, severity, and potential impact on outcomes of stomatitis and related events in EVE pts with cancer or TSC. **Methods:** 7 randomized, double-blind, phase 3 studies of EVE were included: RECORD-1 (RCC), RADIANT-2 (NET), RADIANT-3 (pNET), BOLERO-2 ($HR^+/HER2^-$ breast cancer), BOLERO-3 ($HER2^+$ breast cancer), and EXIST-1 and -2 (TSC). Only events from the double-blind period were included. Kaplan-Meier (KM) methods were used to analyze times to first stomatitis and recurrence. Stratified Cox regression analysis adjusted for known baseline prognostic factors was used to assess the association between stomatitis occurrence within 8 wk of EVE start and PFS in cancer pts and response rate in TSC pts. **Results:** 1,455 cancer and 157 TSC EVE-treated pts were analyzed. Crude stomatitis incidence was 66.9% in oncology pts (8.6% grade 3/4) and appeared early (median 0.82 mo; 95% CI 0.7-1.0; 2 mo KM estimate 60.8%). Stomatitis led to discontinuation in 1.7% of pts. Reccurence occurred in 40% and appeared less rapidly (2 mo KM estimate 28.0%). Results were similar in TSC pts. An association between stomatitis and PFS was observed in BOLERO-2 (HR 0.771; 95% CI 0.603-0.987) and RADIANT-3 (HR 0.687; 95% CI 0.465-1.014); association was maintained after correcting for exposure. A similar trend was observed in RECORD-1 (HR 0.866) but not BOLERO-3 or RADIANT-2. In all trials, EVE pts had longer PFS compared with placebo regardless of stomatitis incidence. There were too few TSC pts to reach a conclusion on the relationship between stomatitis and response. **Conclusions:** Stomatitis is common in EVE-treated pts and occurs in the initial wks of therapy. Most events are grade 1/2, rarely lead to discontinuation when actively managed according to recommendations, and recur in $<50\%$ of affected pts. Cancer pts treated with EVE who experienced stomatitis derived benefit consistent with that shown in the overall population, suggesting EVE continuation is beneficial. Ongoing prospective studies will determine the value of prophylactic measures to reduce EVE-induced stomatitis incidence and improve its management.

**646 General Poster Session (Board #110), Mon, 8:00 AM-11:45 AM**

**Disparities among older women with de novo stage IV breast cancer treated with trastuzumab from 1999 to 2009.** *Presenting Author: Ines Maria Vaz Duarte Luis, Dana-Farber Cancer Institute, Boston, MA*

**Background:** To characterize trastuzumab utilization and survival by race/ethnicity in older women with *de novo* stage IV breast cancer who were treated with trastuzumab. **Methods:** We used Surveillance, Epidemiology, and End Results (SEER)-Medicare data to identify patients (pts) ≥66 years with *de novo* stage IV BC diagnosed between 1999-2009 who received trastuzumab. We examined treatment patterns, including time to trastuzumab initiation. We then examined survival time by race/ethnicity using Kaplan-Meier methods and Cox proportional hazards models, adjusting for clinical, sociodemographic, and treatment characteristics. **Results:** Among 579 pts, 452 (78.1%) were non-Hispanic white and 76 (13.1%) were non-Hispanic black. Overall, death was recorded among 418 women (72.2%); the median survival time was 2.4 years (95% CI: 2.1-2.7) and there was a 22% survival rate at 5 years. Compared with white women, black women had a significantly increased adjusted hazard of death (hazard ratio=1.4, 95% CI: 1.04-2.0). Survival for all pts improved over time (Table 1). Overall the odds of early (within 6 months from diagnosis) vs. later (after 6 months) trastuzumab initiation did not differ by race/ethnicity (OR=1.0, 95% CI: 0.5-1.7), but when stratified by hormone receptor (HR) receptor status, white (*v*black) pts with HR negative disease were more likely to have initiated trastuzumab within 6 months (OR: 2.8, 95% CI: 1.4-5.6). **Conclusions:** Although survival times among pts receiving trastuzumab for *de novo* metastatic disease improved over time, we identified racial/ethnic disparities in survival and differences in patterns of care. Additional analyses will include examination of trastuzumab duration and associations with survival.

| Characteristic | Hazard of death (95%CI) |
|---|---|
| **Race** | |
| **Non-Hispanic White** | 1.0 |
| **Non-Hispanic Black** | 1.4 ( 1.04- 2.0) |
| **Hispanic-Other/Unknown** | 1.0 (0.7-1.6) |
| **Year of diagnosis** | |
| **1999-2001** | 1.0 |
| **2002-2005** | 0.7 (0.5-0.9) |
| **2006-2009** | 0.6 (0.4-0.8) |
| **HR** | |
| **Positive** | 1.0 |
| **Negative** | 1.3 (1.03-1.6) |
| **Initiation of trastuzumab** | |
| **Within 6 months** | 1.0 |
| **After 6 months** | 1.6 (1.2-2.0) |

* Adjusting for all variables in Table and age, race, SEER region, location of residence, socioeconomic status, marital status, comorbidity score, grade.

**647 General Poster Session (Board #111), Mon, 8:00 AM-11:45 AM**

**Quality of life (QOL) among patients (pts) with HER2+ breast cancer (bc) treated with adjuvant lapatinib and/or trastuzumab in the ALTTO study (BIG 2-06, Alliance N063D).** *Presenting Author: Amylou C. Dueck, Mayo Clinic, Scottsdale, AZ*

**Background:** The Adjuvant Lapatinib and/or Trastuzumab Treatment Optimisation (ALTTO; NCT00490139) study was an international randomized open-label phase III study of 2 targeted therapies for HER2+ bc. Efficacy results will be reported in a separate abstract. **Methods:** Pts were randomized to 1 of 4 arms with sequential or concurrent chemotherapy: (A) trastuzumab (T) for 52 weeks (w); (B) oral lapatinib (L) for 52w; (C) T for 12w followed by 6w washout followed by L for 34w; or (D) T+L for 52w. Functional Assessment of Cancer Therapy-Breast (FACT-B) and Linear Analogue Self-Assessment (LASA) items measuring overall and 5 QOL domains, fatigue, rash, and diarrhea were administered on paper at baseline, w12, w52, year 3, and year 5 in pts enrolled in ALTTO through the US NCI CTSU. Mean scores were compared using analysis of covariance and paired t-tests. **Results:** Among 777 pts, 607, 521, and 492 completed booklets at baseline, w12, and w52. At w12, worsening of LASA domains (overall QOL, mental, physical, social wellbeing), FACT-B Trial Outcome Index (TOI), fatigue, rash and diarrhea reached statistical significance within all arms (all $p<0.05$ except FACT-B TOI for arm C $p=0.21$). Worsening was similar across arms for these LASA domains and fatigue. Diarrhea worsening was more severe in upfront L-containing (B & D) arms compared to upfront T alone (A & C) arms (B vs A, B vs C, D vs A, D vs C $p<0.001$). Rash worsening was most severe in B (vs C $p=0.02$, vs D $p=0.007$, vs A $p=0.10$). At w52, LASA domains, fatigue, and FACT-B TOI returned to baseline levels with changes similar across arms (all $p>0.05$). Rash (C vs A, D vs A $p<0.05$) and diarrhea (B vs A, C vs A, D vs A, C vs B, D vs B $p<0.05$) exhibited statistically significant worsening from baseline in L-containing arms relative to A. **Conclusions:** While L had a larger negative impact than T on diarrhea and rash, QOL did not appear to differ across arms. Patient QOL was negatively impacted similarly across arms at w12 but returned to baseline by the end of the treatment period at w52. These data enhance the understanding of QOL impact of anti-HER2 therapy in pts with early stage bc. Long term QOL collection is ongoing. Clinical trial information: NCT00490139.

**648 General Poster Session (Board #112), Mon, 8:00 AM-11:45 AM**

**Neoadjuvant chemotherapy with nonpegylated liposome-encapsulated doxorubicin (NPLD) plus cyclophosphamide followed by trastuzumab plus nabpaclitaxel for HER2-positive breast cancer (BC).** *Presenting Author: Silvana Saracchini, Pordenone, Italy*

**Background:** Using a liposomal delivery system NPLD has shown similar efficacy and less cardiac toxicity compared to conventional anthracyclines. Similarly albumin-bound paclitaxel (nabpaclitaxel) has demonstrated higher response rates and improved tolerability compared to conventional taxanes. This study aimed to evaluate the activity and safety of neoadjuvant chemotherapy with NPLD, nabpaclitaxel and trastuzumab for early or locally advanced HER2 positive BC. **Methods:** Preoperative treatment included NPLD (60 mg/mq iv) plus cyclophosphamide (600 mg/mq iv) every 3 weeks for 4 cycles followed by nabpaclitaxel (260 mg/mq iv) plus trastuzumab (8 mg/mq loading dose iv, then 6 mg/mq iv) every 3 weeks for 4 cycles. All patients received granulocyte colony-stimulating factor as prophylaxis of febrile neutropenia. Primary objective of the study was pathologic complete response (pCR) defined as the absence of residual invasive cancer both in the breast and regional nodes. Also, breast MRI, Contrast-Enhanced-Spectral-Mammography (CESM) and Ki-67 after 1 cycle of chemotherapy were exploratory investigated to assess the ability to predict pCR. **Results:** 15 pts were treated from September 2011 to November 2013. 14 pts were evaluable for response and completed the planned treatment. Median age was 52 years (range: 28-70), the majority of pts had T2 stage (64%), clinical nodes involvement N+ (71%), ER positive (64%). 6 out of 14 pts had clinical stage III BC. All tumours were grade 3 and 93% had Ki-67 ≥20%. pCR was reported in 64% (9 of 14). The most frequent grade 3 adverse event was myalgia (21%). Breast MRI after 1 cycle showed a significant difference on "signal-intensity/time" (SIT) curve between pCR pts and no-pCR pts, with an increase (type-II to type-III) in 50% of pCR pts and 0% of no-pCR pts. **Conclusions:** The nanoparticle formulations, nabpaclitaxel and NPLD, combined with trastuzumab seem to be an active and manageable regimen. It may represent an attractive and promising option in neoadjuvant treatment for HER2 positive BC. The role of Breast MRI, CESM and Ki-67 needs further exploration to predict pathologic response.

**649 General Poster Session (Board #113), Mon, 8:00 AM-11:45 AM**

**Correlation of high levels of HER2 measured by multiplex mass spectrometry with increased overall survival in patients treated with anti-HER2-based therapy.** *Presenting Author: Paolo Nuciforo, Vall d'Hebron Institute of Oncology, Barcelona, Spain*

**Background:** There is evidence that increased absolute levels of the HER2 receptor in breast cancer positively correlates with a clinical benefit from anti-HER2 therapies. The current method of HER2 evaluation, immunohistochemistry (IHC), does not allow for absolute HER2 quantification and is prone to false-positives. Thus, a significant portion of patients classified as HER2-positive actually express low levels of the receptor. We quantitated absolute levels of HER2 using a mass spectrometry-based assay and correlated expression levels with the anti-HER2 therapy benefit. **Methods:** Formalin-fixed, paraffin-embedded (FFPE) tumor sections were microdissected and proteins were solubilized and digested by trypsin in Liquid Tissue buffer. After digestion, internal standards were added and absolute quantitation for multiple proteins was performed using selected reaction monitoring (SRM) mass spectrometry. **Results:** 26 HER2-positive (IHC 3+) breast cancer samples from patients treated with anti-HER2 therapy were obtained from Vall d´Hebron Hospital. Nineteen patients were treated with trastuzumab-based therapy; six were treated with a combination of anti-Her2 therapies. HER2 quantitation by SRM revealed receptor level ranges from 283 to 12840 amol/$\mu$g. Based on the median HER2 expression of the trastuzumab-only treated patients, the patients were divided into two subgroups. The subgroup with high expression levels of HER2 protein (average of 7461 amol/$\mu$g) had an overall survival time of 82.8 months whereas the subgroup with low levels of HER2 (average of 1823 amol/$\mu$g) had a significantly shorter survival time of 55.3 months. **Conclusions:** We used a non-antibody based assay to quantify absolute levels of HER2 in samples from patients treated with anti-HER2 therapy. We found high variability in HER2 expression within a patient population that had been homogenously classified as 3+ by IHC. High levels of HER2 correlated with increased overall survival following anti-HER2 therapy. This study demonstrates the need for improved quantitation of HER2 protein levels prior to initiating anti-HER2 therapy.

**650 General Poster Session (Board #114), Mon, 8:00 AM-11:45 AM**

**T-DM1 in HER2-positive breast cancer brain metastases (BM).** *Presenting Author: Rupert Bartsch, Department of Medicine I, Clinical Division of Oncology and Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria*

**Background:** Local treatment options such as radiotherapy or neurosurgery are the mainstay of BM management. Whole brain radiotherapy (WBRT), however, is associated with severe late-toxicity. The LANDSCAPE trial established lapatinib plus capecitabine (LapCap) as primary systemic treatment in oligosymptomatic patients (pts) with multiple Her2-positive BM. Limited evidence exists regarding the activity of antibodies in BM. T-DM1 is an antibody-drug conjugate linking trastuzumab (T) to an anti-microtubule agent. T-DM1 provides activity in pts progressing upon T and has lower toxicity as compared to LapCap. Here, we investigated the activity of T-DM1 in newly diagnosed or progressive BM. **Methods:** A total of six consecutive pts (median age 55 years) with Her2-positive breast cancer and BM were treated with T-DM1. In two asymptomatic pts, T-DM1 was administered as primary systemic therapy, while four subjects had already received local therapy and had documented CNS progression. T-DM1 was administered intravenously at a dose of 3.6 mg/kg body weight every three weeks; re-assessment of disease status was performed every three cycles. At baseline and restaging, MRI was performed. CNS response was defined as a reduction of lesion size of $\geq$50%. **Results:** Median follow-up was 6 months (m) and median brain metastases-free survival 11 m, respectively. All pts had received prior T, three (50%) had already received LapCap, and two (33.3%) pertuzumab. Currently, 4/6 pts (1 with primary treatment and 3 receiving T-DM1 upon CNS progression) are assessable for CNS response. 2/4 pts (50%) had partial remission, while one patient progressing upon prior local therapy had stable disease lasting for 15 cycles. One patient had minor response on MRI but no reduction of pre-existing brain oedema and increasing cortisol doses and was therefore deemed PD. A significant LVEF drop was observed in one heavily pretreated patient. **Conclusions:** This prospective case series again indicates that systemic therapy offers activity in Her2-positive BM. Currently, LapCap remains the standard of care. Still, T-DM1 offers relevant clinical activity; therefore, the role of T-DM1 in BM should be investigated in larger studies.

**651 General Poster Session (Board #115), Mon, 8:00 AM-11:45 AM**

**A phase 1 study of MM-111, a bispecific HER2/HER3 antibody fusion protein, combined with multiple treatment regimens in patients with advanced HER2-positive solid tumors.** *Presenting Author: Donald A. Richards, Tyler Cancer Center, US Oncology Research, McKesson Specialty Health, Houston, TX*

**Background:** MM-111 (111) inhibits ligand activated HER3 signaling in HER2+ tumors. This study evaluated the safety of 111 combined with standard of care (SOC) HER2-targeting regimens (Rx): capecitabine (X) + cisplatin (C) + trastuzumab (T) (Arm 1); lapatinib (L) +/- trastuzumab (Arm 2); paclitaxel (P) + trastuzumab (Arm 3); lapatinib + paclitaxel + trastuzumab (Arm 4); docetaxel (D) + trastuzumab (Arm 5). **Methods:** This was a multi-arm Phase 1, dose escalation study of 111 in combination with SOC regimens to evaluate safety, pharmacokinetics (PK), and anti-tumor activity. Patients were required to have documented advanced HER2-positive cancer and adequate organ function. Each arm was designed to run as a separate Phase 1 study to address safety and tolerability and utilized a "3 + 3" design with standard dosing of the SOC regimen. 111 was dosed weekly at 10 mg/kg and escalated up to 20 mg/kg where possible. For Arm 5, 111 was dosed q3w starting at 30mg/kg and escalated up to 40mg/kg. **Results:** A total of 86 patients (11 bladder, 46 breast, 15 gastro-esophageal, 14 other cancers) were enrolled and treated across all five arms. Dose-limiting toxicities (DLTs) included anemia, acute renal failure (assessed as cisplatin-related), chest pain, decreased appetite, diarrhea, febrile neutropenia, hyperuricemia, hypokalemia, hyponatremia, hypophosphatemia, mucosal inflammation, nausea, neutropenia, stomatitis, thrombocytopenia, and vomiting. An MTD was not reached in Arms 2-5; Arm 1 required a capecitabine dose reduction. **Conclusions:** Treatment with 111 and SOC HER2-directed regimens was feasible. The Recommended 111 Phase 2 doses are 20mg/kg QW and 40mg/Q3W. Additional safety, PK and preliminary activity data will be provided. Clinical trial information: NCT01304784.

**Patient outcomes summary.**

**TPS652 General Poster Session (Board #116A), Mon, 8:00 AM-11:45 AM**

**Comparison of weight loss among early-stage breast cancer patients post chemotherapy: Nutrition education in combination with weight loss acupuncture versus nutrition education alone.** *Presenting Author: Jami Fukui, Mount Sinai Medical Center, New York, NY*

**Background:** Obesity and weight gain are significant concerns for breast cancer survivors. Obesity at diagnosis of breast cancer is an established negative prognostic factor and the Nurses' Health Study suggest that post-diagnosis weight gain may increase risk for recurrence. Up to 96 percent of women gain weight during treatment and once a woman has been diagnosed with breast cancer, she is at increased risk for other cancers, diabetes and cardiovascular disease. Several studies report an inverse relationship between weight gain and disease free survival. Continued efforts to identify appropriate weight management interventions aimed at promoting overall health and long term survivorship are needed. In this study, we will examine whether adding weight loss acupuncture to a nutrition education program for weight loss could improve short and long term weight loss among breast cancer survivors post treatment with chemotherapy. Vtrim is an online, evidence based, 12 week behavior modification program for weight management and has been used in breast cancer survivors, with a recent study showing weight change and safety in this population. Meta-analyses have suggested that acupuncture may be helpful for weight loss in obese women not diagnosed with breast cancer and without the common side effects found in alternative medicinal options. **Methods:** We plan to enroll obese women who have been diagnosed and treated for breast cancer in a twelve week weight loss program. The participants will be randomized to two groups: weight loss acupuncture plus nutrition intervention or nutrition intervention alone. Women in the acupuncture group will receive weekly body and/or auricular acupuncture once a week at the Pain Management and Integrative Medicine Clinic at Mount Sinai Medical Center, in addition to attending the online group-based nutritional education sessions in which all study participants will partake. All study participants' weight loss will be assessed at the end of twelve weeks, with follow-up at twenty-four weeks, then every 3 months for the first year, then every 6 months until year two, to evaluate weight loss maintenance.

**TPS653 General Poster Session (Board #116B), Mon, 8:00 AM-11:45 AM**

**A phase II randomized, double-blind, placebo-controlled multicenter trial evaluating the efficacy and safety of enzalutamide in combination with exemestane in estrogen or progesterone receptor-positive and HER2-normal advanced breast cancer.** *Presenting Author: Denise A. Yardley, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** The androgen receptor (AR) is expressed in the majority of patients (pts) with ER/PgR+ breast cancer (BC)(Collins LC et al. *Mod Pathol*. 2011;24:924–931; Loibl S et al. *Breast Cancer Res Treat*. 2011;130:477–487). In ER+ cell lines, AR over-expression can lead to hormone-resistance (De Amicis F et al. *Breast Cancer Res Treat*. 2010;121: 1-11). Androgen stimulated growth of ER+/AR+ cells lines can be blocked by enzalutamide (ENZA), a potent oral inhibitor of AR. Treatment with exemestane (EXE) can increase androgen levels (Takagi K, et al. *Endocr Relat Cancer*. 2010;17:415–430), the addition of ENZA to EXE may inhibit any androgen-mediated breast tumor growth. **Methods:** This randomized placebo (PBO) controlled phase 2 trial will evaluate EXE with or without ENZA (160 mg/day) in 240 patients (pts) with advanced BC (aBC) that is ER/PgR+ and Her2 normal (NCT02007512). Two parallel enrolling cohorts (C) will each evaluate 120 pts who have received either no (C1) or 1 (C2) prior hormone therapy for aBC. Randomization (1:1) is stratified (Y/N) by prior hormone, prior aromatase inhibitor (AI) and hormone resistance. Eligible pts must have $\leq$ 1 non-hormone regimen and ECOG $\leq$1; non-measurable bone or skin disease is allowed. Pts with CNS disease or history of seizure are excluded. Tissue submission for determination of AR expression is mandatory. The co-primary endpoint (EP) is progression-free survival (PFS) in all pts and in those with AR+ disease. Cross-over is allowed following RECIST 1.1 progression. Additional EPs include clinical benefit rate (complete/partial response or stable disease at $\geq$24 weeks); response rate; duration and time to response, safety and tolerability. Efficacy analyses will be conducted on all randomized pts (ITT), a minimum of 90 PFS events/cohort is required to estimate the median PFS and hazard ratio. Approximately 55 PFS events, for a target HR = 0.67, are required in the AR+ subset. The definition of "AR+" will be determined prior to unblinding. Clinical trial information: NCT02007512.

**TPS654 General Poster Session (Board #117A), Mon, 8:00 AM-11:45 AM**

**Adjuvant palbociclib (P) plus endocrine therapy (ET) for hormone receptor positive (HR+) breast cancer: A phase II feasibility study.** *Presenting Author: Erica L. Mayer, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Cell cycle inhibition is a target of interest for novel cancer therapeutics. P is an orally active inhibitor of CDK4/6, causing cell cycle arrest at the G1-S transition. In an interim analysis of a phase II first-line study in HR+ metastatic breast cancer (MBC), patients (pts) randomized to letrozole (L) plus P had prolonged progression-free survival compared with L alone (26.1 vs 7.5 mos, HR 0.37, p<0.001) (Finn et al SABCS 2012). The most common toxicity with P is neutropenia, typically non-cumulative and uncomplicated. Given observed benefits of LP in HR+ MBC, exploring the feasibility of P in the adjuvant setting is warranted. **Methods:** This is a phase II single arm trial evaluating the feasibility of 2 yrs of combination P and adjuvant ET. Eligible pts are postmenopausal, with HR+ stage II (not T2N0)-III invasive breast cancer. Pts must have demonstrated tolerance of adjuvant aromatase inhibitor (AI) by completion of 3-24 mos of AI without significant adverse events (AE), with plan for at least 2 more yrs of AI. Pts will receive P at 125 mg daily, 3 wk on/1 wk off in a 28d cycle, plus continuous physician's choice AI (L, anastrozole, or exemestane), for planned duration 2 yrs. Neutropenia monitoring occurs every 2 wks for the first 3 cycles, then monthly for the duration of treatment. Pts may be removed from study for toxicity, non-adherence, or other events related to tolerability; pts who recur or complete 2 yrs of therapy will be censored for the primary endpoint. The primary objective is to evaluate the treatment discontinuation rate at 2 yrs; if the rate is >50%, the treatment duration will not be considered feasible, whereas a rate <33.3% would be considered feasible and worthy of further study for efficacy. Discontinuation rates at 2 yrs will be estimated by Kaplan Meier with 95% confidence bands. The total sample size is 120 pts, providing 92% power to reject the null hypothesis using a one-sided alpha = 0.025, and accounting for a censoring rate of up to 20% over the 2 yrs. Secondary endpoints include AE graded by CTCAE 4.0 and adherence to oral therapy. Two interim analyses for futility are planned when 66% and 100% of pts have received 6 mos of therapy. Clinical trial information: NCT02040857.

**TPS655^ General Poster Session (Board #117B), Mon, 8:00 AM-11:45 AM**

**Phase II, randomized, placebo-controlled study of BYL719 or buparlisib (BKM120) with letrozole for neoadjuvant treatment of postmenopausal women with HR+/HER2−, *PIK3CA* mutant or wild-type, breast cancer (BC).** *Presenting Author: Ingrid A. Mayer, Vanderbilt-Ingram Cancer Center, Vanderbilt University, School of Medicine, Nashville, TN*

**Background:** The PI3K/AKT/mTOR pathway is frequently activated in BC, with mutations in *PIK3CA* particularly common in hormone receptor-positive (HR+) tumors. In preclinical studies of HR+ BC, BYL719 (an $\alpha$-specific PI3K inhibitor) and buparlisib (a pan-PI3K inhibitor) have shown synergistic effects *in vitro* and near-complete tumor regression *in vivo*, respectively, when used in combination with hormone therapy. **Methods:** This is a Phase II, randomized, double-blind, placebo-controlled trial of BYL719 (300 mg QD) or buparlisib (100 mg QD) combined with letrozole (2.5 mg QD) for the neoadjuvant treatment of postmenopausal women with HR+/HER2– BC (NCT01923168). Key inclusion criteria are stage T1c–T3, any N, M0, operable BC; measurable disease; HR+, HER2– BC; known *PIK3CA* status (mutant or wild type) and Ki-67 level, determined centrally; Eastern Cooperative Oncology Group performance status $\leq$1; and adequate bone marrow and organ function. Key exclusion criteria are locally recurrent/metastatic disease and prior systemic therapy or radiotherapy for current BC. Patients will be assigned to 1 of 2 cohorts (*PIK3CA* mutant or wild type) and randomized to 1 of 3 arms (letrozole + BYL719, buparlisib, or placebo), stratified by Ki-67 level (<14% vs $\geq$14%) and lymph node status (+ve or –ve). Patients will be treated for 24 weeks, until surgery. The primary endpoint is pathologic complete response (pCR; defined as ypT0/Tis, ypN0) after 24 weeks' treatment. The secondary endpoints are objective response rate (complete + partial, per RECIST 1.1), safety, rate of breast-conserving surgery, correlation between pCR and Ki-67 changes from baseline to Day 15 and to surgery, response (defined as central preoperative endocrine prognostic index score of 0), and pharmacokinetic profiles of all drugs used in the combination treatments. For each cohort, pCR rates will be summarized by treatment arm. The activity signal with either combination will be established if pre-defined proof-of-concept criteria are met. Approximately 360 patients will be randomized. Global recruitment is ongoing. Clinical trial information: NCT01923168.

**TPS656 General Poster Session (Board #118A), Mon, 8:00 AM-11:45 AM**

**PERSEPHONE: Duration of trastuzumab with chemotherapy in patients with HER2-positive early breast cancer—Six versus twelve months.** *Presenting Author: Helena Margaret Earl, Department of Oncology, NIHR Cambridge Biomedical Research Centre and Cambridge Breast Cancer Research Unit, University of Cambridge, Cambridge, United Kingdom*

**Background:** PERSEPHONE is a randomised controlled trial comparing six months of trastuzumab to the standard 12 months in patients with HER2 positive early breast cancer. **Methods:** 4,000 patients will be randomised into the two arms (1:1). The power calculations assume that the disease-free survival (DFS) of standard treatment (12 months trastuzumab) is 80% at 4 years. Randomisation of 4,000 pts will allow the trial to prove non-inferiority of six months trastuzumab (5% 1-sided significance & 85% power). Non-inferiority is defined as 'no worse than 3%' below the control arm (12 month) 4 year DFS. Primary outcome is DFS, and secondary outcomes are overall survival (OS) non-inferiority; cost effectiveness; cardiac function & quality of life. Tumour blocks are collected to research molecular predictors of survival with respect to duration of trastuzumab treatment. Blood samples are analysed for single nucleotide polymorphisms (SNPs) as pharmaco-genetic determinants of prognosis, toxicity and treatment outcome. Exciting developments led to a protocol amendment (Dec 2013) which allows sites to administer IV or sub-cutaneous trastuzumab according to their standard practice. Cardiology data on the first 2,500 patients is now being analysed. PERSEPHONE is funded by the NIHR HTA programme in the UK. Results: PERSEPHONE commenced recruitment in October 2007. At abstract submission, 3,166 pts (79%) had been randomised from 154 UK sites. Recruitment is due to complete mid-2015 with the first planned interim analysis of the primary outcome mid-2016. The iDMSC reviewed all data available on HERA and PHARE in 2012 as well as a PERSEPHONE interim analysis. There were no safety findings or signals that would warrant a change of the study plan & the high quality of data was noted. Conclusion:PERSEPHONE continues the active recruitment phase as planned with the sub-cutaneous form of trastuzumab proving popular. Publication of early PHARE results have reinforced interest in the PERSEPHONE trial both nationally and internationally. There has been full support from the Breast International Group (BIG) and the international breast cancer community to answer this important shorter duration question. Clinical trial information: 52968807.

**TPS657 General Poster Session (Board #118B), Mon, 8:00 AM-11:45 AM**

**Bevacizumab plus paclitaxel optimization study with interventional maintenance endocrine therapy in advanced or metastatic ER-positive HER2-negative breast cancer: JBCRG-M04 (BOOSTER) trial.** *Presenting Author: Shigehira Saji, Department of Target Therapy Oncology, Graduate School of Medicine, Kyoto University, Kyoto, Japan*

**Background:** In the standard management of inoperable or recurrent breast cancer (BC), active therapy is continued until disease progression (PD) or unacceptable toxicity. In patients (pts) receiving first-line bevacizumab (BV) plus paclitaxel (PTX), this strategy results in some pts discontinuing treatment because of PTX-related peripheral sensory neuropathy despite sustained tumor response. To overcome this problem, we propose a practical treatment strategy in pts with ER-positive HER2-negative BC, introducing temporary BV + endocrine maintenance therapy in pts responding to BV + PTX followed by BV + PTX reintroduction at first PD. This strategy may reduce the impact of peripheral sensory neuropathy, enable pts to maintain their quality of life (QOL) and prolong disease control. **Methods:** JBCRG-M04 (BOOSTER; UMIN000012179; ClinicalTrials.gov NCT01989780) is a multicenter open-label randomized phase II trial in pts with ER-positive HER2-negative inoperable or recurrent BC. After 16–24 weeks of induction therapy with BV 10 mg/kg q2w + PTX 90 mg/m$^2$ days 1, 8 and 15 q4w, pts achieving a complete or partial response or stable disease (investigator assessed) are randomized to either A: continued BV + PTX; or B: a switch to maintenance BV + endocrine therapy, followed by BV + PTX at the time of either PD or clinical PD on maintenance therapy. Tumor tissue, DNA and sequential plasma samples are collected before and during treatment for biomarker research. The primary endpoint is time to failure of strategy (TFS), defined as the interval between randomization and either PD on study therapy, change to new agent not in study regimen, first PD not followed by BV + PTX in arm B, or death. The planned sample size of 160 pts provides 80% power to detect a 6-month increase in TFS in arm B versus arm A. Secondary endpoints include overall survival, 2-year survival rate, progression-free survival, safety and QOL. Biomarker analyses include correlations between biomarkers and response, changes in angiogenesis regulators and comparison of biomarker levels between initial and reintroduced BV + PTX. Clinical trial information: NCT01989780.

**TPS658 General Poster Session (Board #119A), Mon, 8:00 AM-11:45 AM**

**A single-blind, randomized, placebo-controlled phase II study to evaluate the impact of oral bisphosphonate treatment on bone mineral density in osteopenic women receiving adjuvant aromatase inhibitors: Interim analysis of "BONADIUV" trial.** *Presenting Author: Vieri Scotti, Florence University Hospital, Florence, Italy*

**Background:** Aromatase inhibitors (AIs) are a highly effective well-tolerated treatment for post-menopausal endocrine-responsive breast cancer (BC). However, their use is associated with accelerated bone loss and increased risk of fractures. The ARIBON trial published by Lester et al in 2008 showed that monthly oral ibandronate improves bone density and normalizes bone turnover in patients treated with anastrozole. BONADIUV trial is a single-blind, randomized, placebo-controlled phase II study designed to evaluate the impact of oral ibandronate (150 mg monthly) on bone mineral density (BMD) in osteopenic women on AIs in adjuvant setting. **Methods:** All patients underwent histological proven diagnosis of BC. Patients received breast surgery and adjuvant treatment according to clinical and pathological status at Our Institute. Enrolled patients were candidate to 5 years of adjuvant AIs. Major exclusion criteria were: previous diagnosis of solid tumors, psychiatric disorders, premenopausal status, smokers patients, chronic use of steroids, ipertyroidism, iperparathyroidism, rheumatoid arthritis, severe thinness (body mass index $<16$), age less than 18 years or more than 70. All patients were treated with vitamin D supplementation for an overall treatment of 24 months. The primary endpoint was the change in BMD at lumbar spine or hip after 12 and 24 months of treatment in ibandronate-treated patients (Arm A) compared with those receiving placebo (Arm B). Patients were also stratified by menopausal age, body mass index and age. Secondary end points included adverse events monitoring. Common Terminology Criteria for Adverse Events (CTCAE) 4.0 were utilized to record toxicity related events. Recruiting is ongoing: 105 of planned 196 patients have been enrolled. Fifty-three patients were allocated in arm A and 52 patients were allocated in arm B. At 12 months' follow up visit, complete data were assessable in 86 cases. At 24 months' follow up visit, complete data were assessable in 40 patients.

**TPS659 General Poster Session (Board #119B), Mon, 8:00 AM-11:45 AM**

**A phase III randomized trial of niraparib versus physician's choice in previously treated, HER2-negative, germline-BRCA mutated breast cancer patients: Intergroup study EORTC-1307-BCG and BIG5-13.** *Presenting Author: Konstantinos Tryfonidis, EORTC Headquarters, Brussels, Belgium*

**Background:** Germline mutations of *BRCA1/BRCA2* genes are a cause of hereditary breast or ovarian cancer. Cancers arising in women with germline *BRCA1/BRCA2* mutations are defective in DNA repair, and *BRCA* deficient cancer cells are hypersensitive to PARP inhibitors (Bryant et al., 2005; Farmer et al., 2005). Niraparib is a potent,selective inhibitor of PARP-1 and PARP-2 that demonstrated activity in *BRCA1* or *BRCA2* mutated cancer cell lines. Responses have been reported with Niraparib in women with *BRCA1.2* related breast and ovarian cancer. (Michie et al, 2013). **Methods:** Patients with HER2 negative metastatic breast cancer (306), with centrally confirmed *BRCA1* or *BRCA2*germline mutations, will be randomized 2:1 open-label study, to either niraparib 300mg (3x 100 mg niraparib capsules) administered orally QD continuously or physician's choice of single-agent chemotherapy (eribulin, vinorelbine, capecitabine or gemcitabine) administered in 3 weekly cycles. Patients must have received prior therapy that included a taxane and anthracycline and should be pretreated with up to 2 prior cytotoxic regimens for advanced/metastatic disease. Patients with hormone receptor positive disease can be included if they progressed during one prior hormonal therapy. The primary objective is to compare the progression-free survival (PFS) (RECIST v 1.1) on niraparib versus physician's choice, assessed by blinded, central review. The key secondary objective is to compare overall survival between patients in niraparib versus physician's choice. Sample size is based on Overall Survival (OS). The hypothesis of median PFS improvement is 3 versus 6 months for physician's choice and niraparib respectively, with a hazard ratio of 0.5, and power of 99.6% for the primary PFS analysis. Assuming an increase in OS from 9 to 13 months, the study has 80% power at a 1-sided alpha of 0.025. Secondary endpoints are PFS by investigator-based assessment, safety, time to treatment failure, Response Rate, Duration of response, HRQoL. This trial is enrolling patients from European, North American countries and Israel and is sponsored by TESARO. Clinical trial information: NCT01905592.

**TPS660 General Poster Session (Board #120A), Mon, 8:00 AM-11:45 AM**

**Phase I dose-escalation trial of ONT-380 in combination with trastuzumab in participants with brain metastases from HER2+ breast cancer.** *Presenting Author: Otto Metzger-Filho, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Central nervous system (CNS) metastases remain an important cause of morbidity and death for patients diagnosed with HER2+ breast cancer (BC). ONT-380 is an orally active reversible and selective HER2 inhibitor. In pre-clinical studies ONT-380 showed superior CNS penetration and improved overall survival (OS) when compared with lapatinib. In a previous phase I study, ONT-380 demonstrated an acceptable safety profile, with a low incidence and severity of diarrhea and rash. Dose limiting toxicity was represented by transient and reversible transaminases elevation. Clinical activity was observed. We therefore designed a Phase I clinical trial combining ONT-380 with trastuzumab for patients diagnosed with HER2+ BC and CNS metastases. **Methods:** This is an open-label, dose finding phase I study. The primary objectives are to determine the maximum-tolerated dose and schedule of ONT-380 in combination with trastuzumab in patients with HER2+ BC and CNS metastases. Secondary objectives include CNS objective response rate by RECIST and volumetric criteria, progression-free survival and OS. Correlative science analysis includes collection of circulating tumor cells at baseline and time of progression for molecular characterization, including FISH studies for EGFR, HER2, Met, and Myc. The study has two parallel arms with two dose regimens of ONT-380, either twice-daily or once-daily, in combination with standard dose trastuzumab. The dose level of ARRY-380 in the initial and subsequent dose escalation cohorts will be 450 and 600mg for the BID regimen and 750, 900, 1200mg for the QD regimen. Eligibility criteria include measurable disease in the CNS, ECOG performance status 0 to 2, and no limit on prior therapies. We utilize a 3+3 dose escalation design with an expansion phase of 16 participants per arm, which will provide additional information on the safety and biologic activity of the treatment combination. In addition, 16 participants per arm at the MTD will give an 89% probability of selecting the best regimen under a "pick the winner" selection design if true probabilities of clinical benefit are 10% and 30% respectively. Clinical trial information: NCT01921335.

**TPS661 General Poster Session (Board #120B), Mon, 8:00 AM-11:45 AM**

**Prevention of stomatitis in patients with hormone receptor–positive advanced breast cancer treated with everolimus plus exemestane: A phase II study of a steroid-based mouthwash.** *Presenting Author: Hope S. Rugo, University of California San Francisco Medical Center, San Francisco, CA*

**Background:** Stomatitis is a frequent adverse event associated with the oral mTOR inhibitor everolimus that can impact treatment adherence. Steroid mouthwashes, gels, or pastes used to treat recurrent aphthous stomatitis have been proposed as potential preventive therapies. This phase II, single-arm study will evaluate a steroid-based therapeutic intervention to prevent stomatitis (grade ≥2) in breast cancer patients taking everolimus + exemestane. **Methods:** Eligibility includes patients with HR-positive, HER2-negative advanced breast cancer, no evidence of stomatitis or other oral pathology, and a plan to start therapy with everolimus + exemestane. A baseline oral assessment will be conducted. Treatment consists of a steroid-based mouthwash (alcohol-free 0.5 mg/5 mL dexamethasone solution), swished in the mouth for a minimum of 2 minutes 4 times per day, starting on the first day of everolimus and exemestane administration. Patients will be instructed to abstain from eating or drinking for at least 1 hour after using the mouthwash. Preventive therapy will continue for 56 days, with optional continued use for an additional 56 days. The primary endpoint of this trial is the incidence of stomatitis (grade ≥2) at 56 days, defined as meeting at least 1 of the following criteria: ≤50 on Normalcy of Diet Scale to assess oral intake and a rating of 7 on two consecutive days or a rating of 8, 9, or 10 on any one day using a visual analog scale to assess oral pain. Secondary endpoints include average number of times per day the mouthwash regimen was performed and time to resolution of stomatitis (grade ≥2). Assuming a 13% absolute reduction in the rate of grade ≥2 stomatitis from the historical control rate of 33% and 1-sided type 1 error = 0.05 and power = 80%, 73 evaluable patients are required. To account for an estimated 25% of the total patient population being nonevaluable, 97 patients will be enrolled. Support: Novartis Pharmaceuticals Corporation. Clinical trial information: NCT02069093.

**TPS662 General Poster Session (Board #121A), Mon, 8:00 AM-11:45 AM**

**A phase 1b study of ONT-380, an oral HER2-specific inhibitor, combined with ado-trastuzumab emtansine (T-DM1), in HER2+ metastatic breast cancer (MBC).** *Presenting Author: Virginia F. Borges, University of Colorado Cancer Center, Aurora, CO*

**Background:** ONT-380 is a selective small molecule inhibitor of HER2 kinase with nanomolar potency. Unlike dual HER2/EGFR agents, it does not inhibit EGFR at clinically relevant concentrations, decreasing the potential for EGFR-related toxicities. In preclinical studies, ONT-380 demonstrated greater than additive activity with trastuzumab, and was active in models of CNS metastases. In a single-agent phase 1 study in 50 patients (pts) with metastatic HER2+ cancer, the MTD was 600 mg BID, with DLT consisting of reversible Grade 3 ALT/AST in 2 of 4 pts treated at 800 mg. In 22 HER2+ breast cancer pts treated at doses ≥ 600 mg BID, the clinical benefit rate (partial response [n = 3] plus stable disease for at least 6 months [n = 3]) was 27%. Based on data supporting dual blockade of HER2, ONT-380 is now being evaluated in combination with T-DM1. **Methods:** The study objectives are to determine the safety, MTD/Phase 2 dose, and preliminary anti-tumor activity of ONT-380 given in combination with T-DM1 in pts with or without CNS metastases. Potential biomarkers of response and pharmacokinetics will also be assessed. A 3+3 design will evaluate up to four dose levels of ONT-380 (starting at 300 mg PO BID) given with T-DM1 (3.6 mg/kg IV once every 21 days). The study population includes up to 48 adult pts with HER2+ MBC who have received prior trastuzumab and a taxane, but not T-DM1, for metastatic disease. Pts with either treated CNS metastases or asymptomatic untreated CNS metastases are also eligible. Two expansion cohorts are planned, including an MTD/Phase 2 dose expansion cohort, and a cohort of pts with CNS disease, including either untreated, asymptomatic CNS metastases or CNS metastases that have progressed after local therapy. Systemic disease response will be evaluated using RECIST 1.1. CNS response will be evaluated by RECIST 1.1, modified RECIST 1.1, and volumetric criteria. Potential biomarkers of response include the presence of p95 HER2 and HER2 mutations in archived tumor biopsies. Treatment will continue until unacceptable toxicity, disease progression, or withdrawal of consent. Clinical trial information: NCT01983501.

**TPS663 General Poster Session (Board #121B), Mon, 8:00 AM-11:45 AM**

**A phase 1b study of ONT-380, an oral HER2-specific inhibitor, combined with capecitabine and trastuzumab, in HER2+ metastatic breast cancer (MBC).** *Presenting Author: Erika Paige Hamilton, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

**Background:** ONT-380 is a selective small molecule inhibitor of HER2 kinase with nanomolar potency. Unlike dual HER2/EGFR agents, it does not inhibit EGFR at clinically relevant concentrations, decreasing the potential for EGFR-related toxicities. In preclinical studies, ONT-380 demonstrated greater than additive activity with trastuzumab, and was active in models of CNS metastases. In a single-agent phase 1 study in 50 patients (pts) with metastatic HER2+ cancer, the MTD was 600 mg BID, with DLT consisting of reversible gr 3 ALT/AST in 2/4 pts at 800 mg. In 22 HER2+ breast cancer pts treated at doses ≥ 600 mg BID, the clinical benefit rate (partial response [n = 3] plus stable disease for at least 6 months [n = 3]) was 27%. Based on data supporting dual blockade of HER2, as well as preclinical activity of ONT-380 in the CNS, ONT-380 is now being evaluated in combination with capecitabine and trastuzumab. **Methods:** The study objectives are to determine the MTD/Phase 2 dose and preliminary anti-tumor activity of ONT-380 given with capecitabine alone, trastuzumab alone, and both capecitabine and trastuzumab in pts with and without CNS metastases. The study population includes adult pts with HER2+ MBC who have received trastuzumab and ado-trastuzumab emtansine (T-DM1) but not capecitabine for metastatic disease. A 3+3 design will evaluate up to three dose levels of ONT-380 (starting at 300 mg PO BID) given in combination with either capecitabine (1000 mg/mg$^2$ PO BID for 14 days of a 21-day cycle) or trastuzumab (8 mg/kg IV loading dose; 6 mg/kg IV once every 21 days). If both combinations are tolerable, ONT-380 will be evaluated with both capecitabine and trastuzumab. Expanded cohorts of pts with and without CNS metastases may be enrolled for either doublet or triplet combinations. Tumor response will be evaluated using RECIST 1.1. CNS response will be also evaluated by modified RECIST 1.1 and volumetric criteria. Potential biomarkers of response, including p95 HER2 and HER2 mutations, will be assessed in archived tumor biopsies. Treatment will continue until unacceptable toxicity, disease progression, or withdrawal of consent. Clinical trial information: NCT02025192.

**TPS664 General Poster Session (Board #122A), Mon, 8:00 AM-11:45 AM**

**RTOG 1119: Phase II randomized study of whole brain radiotherapy with concurrent lapatinib in patients with brain metastasis from HER2-positive breast cancer—A collaborative study of RTOG and KROG (NCT01622868).** *Presenting Author: David M. Peereboom, Cleveland Clinic, Cleveland, OH*

**Background:** The addition of trastuzumab to cytotoxic chemotherapy has improved outcomes for patients with HER2 positive breast cancer. Increased survival coupled with limited blood-brain barrier (BBB) penetration of trastuzumab may contribute to the increased incidence of brain metastasis in these patients. Half of these patients die of intracranial disease progression rather than extracranial disease. Therefore, strategies to improve survival must include increased CNS disease control in these patients. Lapatinib crosses the BBB and demonstrates modest activity against intracranial metastases. Based upon preclinical data and results of a phase I study, we hypothesize that lapatinib plus WBRT can improve the intracranial disease control compared to WBRT alone. **Methods:** We initiated a randomized phase II trial of WBRT (37.5 Gy/3 weeks) plus or minus concurrent lapatinib (1000 mg qd x 21 during WBRT and for 21 days after). Non-CNS penetrating HER2 targeted therapy is permitted throughout the study, but patients not on trastuzumab, pertuzumab or any other breast cancer therapy at study entry are not permitted to begin this therapy while on protocol treatment, but may begin it 24 hours after completion of protocol treatment. Eligibility includes HER2+ breast cancer with at least one measurable, unirradiated parenchymal brain metastasis (≥10 mm on enhanced MRI). The two populations targeted for accrual include patients with 1) newly diagnosed, multiple brain metastases or 2) progressive brain metastases after stereotactic radiosurgery (SRS) or surgical resection of 1-3 metastases. Patients are stratified by breast-specific graded prognostic assessment; use of non-CNS penetrating HER2 targeted therapy; and prior SRS or surgical resection. The primary endpoint is complete response rate in the brain 12 weeks after WBRT. Secondary endpoints include objective response rate, lesion-specific response rate, CNS progression free survival, and overall survival. 29 of 143 planned patients have enrolled. Supported by NCI U10 grants CA21661 & CA37422. Clinical trial information: NCT01622868.

**TPS665^ General Poster Session (Board #122B), Mon, 8:00 AM-11:45 AM**

**Targeting HSP90 in breast cancer: Enchant-1 (NCT01677455) phase 2 proof of concept study of ganetespib in first-line treatment of women with metastatic breast cancer.** *Presenting Author: David A. Cameron, University of Edinburgh, Edinburgh, United Kingdom*

**Background:** Hsp90 is a chaperone protein required for the activation of several client proteins critical to breast cancer growth and aggressiveness, including HER2, HIF1-$\alpha$, EGFR, ER, PI3K, AKT, p53 and VEGFR. Ganetespib, a novel Hsp90 inhibitor, has preclinical activity in HER2+, ER+/PR+ and triple negative breast cancer (TNBC) models. Clinical trials showed a favorable safety profile with early signals of activity in patients (pts) with HER2+ disease, as well as TNBC. The ENCHANT-1 trial aims to further evaluate ganetespib single-agent activity in metastatic breast cancer (mBC) and identify biomarkers predictive of outcome. **Methods:** ENCHANT-1 is an international, Phase 2 study in 1st line mBC. Pts are assigned to one of the following 3 cohorts: Cohort A, HER2 amplified (n=35), Cohort B, TNBC (n=35), Cohort D, Hormone receptor (HR) positive (n=35). Pts with previously untreated mBC are eligible for treatment with ganetespib twice weekly on a 3 out of 4 wk schedule, for a total of up to 12 wks. HER2+ and HR+ pts must have received prior anti-HER2 therapy and endocrine therapy, respectively. At disease progression, pts will receive combination therapy of weekly ganetespib (150 mg/m$^2$) and weekly paclitaxel (80 mg/m$^2$) on a 3 out of 4 wk schedule. Primary endpoint: ORR assessed using RECIST1.1 criteria. Key secondary endpoints include metabolic response assessed by PET/CT at wk 3 utilizing modified EORTC criteria. Tumor genetic signature and proteomic profiling are performed on patient's tumors in an effort to develop biomarkers of response. At the time of submission, a total of 46 pts were enrolled; TNBC (n= 38) and HER2+ (n=8). Clinical trial information: NCT01677455.

**TPS666 General Poster Session (Board #123A), Mon, 8:00 AM-11:45 AM**

**Phase I/II trial of ruxolitinib in combination with trastuzumab in metastatic HER2-positive breast cancer.** *Presenting Author: Kevin Kalinsky, Columbia University Medical Center, New York, NY*

**Background:** Integrated analysis of whole genome RNAi screening with computationally reverse engineered interactome models identified IL6/JAK/STAT as a master regulator pathway essential for growth of ErbB2/HER2 positive breast cancer. Ruxolitinib (R), FDA-approved treatment for myelofibrosis, inhibits JAK1 and JAK2. The combination of R plus Trastuzumab (T) is synergistic in tumor growth inhibition in mouse xenografts of HER2 amplified breast cancer cell lines. These data provide a strong rationale for studying the efficacy of combination R and T in a clinical trial. **Methods:** A multi-center, open-label, phase I/II (P1/2) trial of R plus T in HER2+ metastatic breast cancer (MBC) who have progressed on T-based therapy. P1 will be an adaptive design with 10 patients, using the time-to-event continual reassessment method. The recommended P2 dose (RP2D) will be used in a non-randomized, open-label P2 trial with 30 evaluable patients. Given the anticipated limited overlapping toxicities, 33 patients are expected for the P1/2 (range: 33-42 pts). The duration of a treatment cycle will be 21 days. R will be taken orally twice a day continuously. The P1 dosing range will be 10-25 mg BID. T will be administered on Day 1 of each cycle at standard dosing. The primary endpoint is progression-free survival (PFS). Assuming a historical PFS of 8 weeks with single-agent agent HER2-targeted therapy in HER2+ MBC after progressing on T-based therapy, we predict that patients receiving the combination of R plus T will have a PFS of at least 13 weeks. With a 2-sided alpha of 0.05, we have 80% power to detect a difference with 30 pts. Objective Response Rate (ORR) will be assessed by imaging every 9 weeks. Blood samples will be obtained for biomarker analysis pre-treatment, on-treatment on cycle 2 day 1, and then at progression. Pre-treatment biopsies from archival tissue or new biopsy, prior to cycle 2 day 1, and upon progression of disease will be discussed with pts with accessible disease. Predictive markers include tumor pSTAT3 expression(tumor), tumor gene expression, and serum IL-6, IL-8, and C-reactive protein.

**TPS667 General Poster Session (Board #123B), Mon, 8:00 AM-11:45 AM**

**A phase II study with lead-in safety cohort of cabazitaxel (C) plus lapatinib (L) as therapy for HER2+ metastatic breast cancer (MBC) with intracranial metastases (mets).** *Presenting Author: Denise A. Yardley, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** Although HER2-targeted therapy has improved outcomes in HER2+ breast cancer (BC) patients (pts), CNS mets continue to be a significant source of morbidity and mortality. Inability of drugs like trastuzumab to cross the blood-brain barrier (BBB) renders the CNS a sanctuary site for mets. L is a small molecule tyrosine kinase EGFR1/HER2 inhibitor that crosses the BBB and is active against CNS mets. C is a new taxane approved for prostate cancer that is also active in taxane-resistant metastatic breast cancer (MBC) and distinguishes itself by its ability to cross the BBB. The activity shown by C in taxane-resistant MBC as well as the CNS penetrance of both C and L make this an attractive combination for HER2+ MBC pts with CNS mets. **Methods:** This is an open-label, non-randomized, phase II study with a lead-in safety cohort (NCT01934894). Pts $\geq$ 18 yrs with HER2+ (by FISH or IHC 3+) MBC and CNS mets are eligible. Patients must have either at least 1 untreated measurable CNS lesion $\geq$ 5mm in longest dimension on MRI or at least 1 previously treated (by WBRT and or/SRS) CNS lesion with evidence of intra-cranial disease progression following WBRT or SRS. Pts must have had at least 1 prior HER2 therapy; first line MBC pts are eligible only if they progressed during or within 6 mos of adjuvant therapy. Prior treatment (tx) with C is not permitted. During the lead-in, cohorts of 3 pts will be treated with escalating doses of q 3 weeks (wks) C and daily L to determine the tolerability and optimal dose. Subsequent pts will be treated with the identified optimal dose combination. Each tx cycle is 3 wks and systemic and intra-cranial disease restaging will occur every 2 cycles for the first 8 cycles and then every 3 cycles until PD or unacceptable toxicity. The primary study objectives are to determine the safety and CNS ORR (ORR=CR+PR) of the combination of C and L in HER2+ MBC pts. Secondary objectives include evaluation of the clinical benefit rate ([CBR]CR+PR+SD $\geq$ 6 mos), 3- and 6-mo PFS rate for CNS mets, and response rate and CBR for extra-cranial mets. The trial is ongoing. Clinical trial information: NCT01934894.

**TPS668 General Poster Session (Board #124A), Mon, 8:00 AM-11:45 AM**

**A phase II study of eribulin mesylate in combination with trastuzumab and pertuzumab in patients (pts) with metastatic, human epidermal growth factor receptor 2-positive breast cancer.** *Presenting Author: Rachel A. Freedman, Dana-Farber Cancer Institute, Boston, MA*

**Background:** As a single agent, eribulin is associated with prolonged overall survival compared to treatment of physician's choice in pts with heavily pre-treated metastatic breast cancer (MBC). In the first-line setting, pertuzumab improves progression-free and overall survival when added to trastuzumab and chemotherapy; however there are limited data in the second line or beyond. This study will evaluate the efficacy of eribulin in combination with trastuzumab and pertuzumab in pts with HER2+ MBC who have progressed after at least 1 line of trastuzumab-based therapy. **Methods:** This is a single center, single-arm, phase II study. Prior to the start of the phase II study, a safety run-in was conducted and enrolled 6 patients. The established dose of eribulin was 1.4mg/m$^2$ on days 1, 8 of a 21 day cycle. Pts will undergo mandatory metastatic biopsies at baseline and optional biopsies at progression. Circulating tumor cells (CTC) will also be collected. The primary aim is objective response rate, RECIST 1.1. Secondary aims include: (a) Clinical benefit rate, progression free and overall survival (b) safety and tolerability, and (c) mechanisms of response and resistance to HER2-directed therapy, including MET and HER2 co-amplification in CTCs, comparisons of mutational profiles and copy number variation in primary vs. metastatic tumors and in pre-treatment vs. resistant tumors, and exploration of correlations between tumor characteristics and pts outcomes. This is a two-stage Simon Minimax design. In the first stage, 34 pts will be entered. If there are at least 9 responses, the study will continue to the second stage where another 22 pts will be entered. If there are at least 18 responses among the 56 pts, the regimen will be declared worthy of further study. There is a 90% chance of declaring the regimen worthy of further study if the true response rate is 40% and a 10% chance of declaring the regimen worthy of further study if the true response rate is 24% (90% power, 10% Type I error rate). The phase II portion began enrollment in January 2014. The estimated accrual rate is 3-5 patients/month. Clinical trial information: NCT01912963.

**TPS669 General Poster Session (Board #124B), Mon, 8:00 AM-11:45 AM**

**Phase Ib trial of trastuzumab emtansine (TE) in combination with lapatinib (L) plus nab-paclitaxel in metastatic HER2-neu overexpressed breast cancer patients: STELA trial.** *Presenting Author: Tejal Amar Patel, Houston Methodist Cancer Center, Houston, TX*

**Background:** Therapies directed at HER2 establish a successful treatment paradigm, but de novo and acquired resistance exist. Multiple large randomized clinical trials have demonstrated that dual HER2 targeted therapies are synergistic and result in improved efficacy. We hypothesize that dual targeted therapy with trastuzumab-emtansine and lapatinib will affect both PI3K and ERK1,2 MAPK pathways. This trial was designed to determine the maximum tolerated dose (MTD) and dose limiting toxicities (DLTs) of trastuzumab-emtansine (TE) and lapatinib (L), together with Nab paclitaxel (A). **Methods:** Eligible patients have stage IV HER2 positive breast cancer, normal LVEF, and Peripheral neuropathy $<$ grade 2. Phase IB planned for up to 9 patients in a standard 3+3 dose de-escalation design. Starting dose level of TE 3.6mg/kg, Lapatinib 750mg and Abraxane(A) 80 mg/m2. DLTs were defined as $\geq$ grade 3 non hematological toxicity attributed to the study drugs. Currently, our lead cohort has three patients with manageable toxicities and we will start expansion cohort soon. The secondary endpoint includes the description of DLT and other toxicities, document anti-tumor activity as assessed by RECIST 1:1 criteria as well as plasma pharmacokinetics and pharmacodynamics of TE in combination of L and A as well as potential biomarkers of response including HER2 expression levels, PTEN, PI3K and others.

**TPS670^ General Poster Session (Board #125A), Mon, 8:00 AM-11:45 AM**

**Phase 2 feasibility study of dose-dense doxorubicin and cyclophosphamide (AC) followed by eribulin mesylate with or without prophylactic growth factor (GF) for adjuvant treatment of early-stage breast cancer (EBC).** *Presenting Author: Tiffany A. Traina, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** In a previous phase 3 randomized, open-label trial, eribulin mesylate demonstrated antitumor activity and significantly improved overall survival (OS) in patients (pts) with heavily pretreated locally advanced or metastatic breast cancer. This trial will assess feasibility of eribulin as adjuvant therapy following dose-dense AC for pts with HER2-normal EBC. The study required prophylactic pegfilgrastim with each AC cycle; with eribulin, GF was used following a neutropenia episode (Cohort 1). Based on neutropenic events without prophylactic GF in Cohort 1 and to improve feasibility, Cohort 1 was closed and the study was amended to require prophylactic GF with eribulin (Cohort 2). **Methods:** Pts with confirmed HER2-normal, stage I-III invasive EBC and adequate bone marrow, liver, and renal function may enroll. Pts receive dose-dense AC (doxorubicin 60 mg/m$^2$ IV + cyclophosphamide 600 mg/m$^2$ IV) on Day 1 of a 14-day cycle x 4 cycles, followed by 4 cycles of eribulin mesylate (1.4 mg/m$^2$ IV) on Days 1 and 8 every 21 days. A protocol amendment established 2 cohorts. Cohort 1 includes the 55 pts enrolled, who received GF at physician's discretion following a neutropenic event during eribulin treatment (per original protocol). Cohort 2 will include 55 new pts who will receive prophylactic GF on Days 3, 4, 10, and 11 of each eribulin cycle. Feasibility is determined by the ability to complete the eribulin portion of the regimen with no dose delay/reduction due to eribulin-related AE. A feasibility target of 80% was set. Feasibility rates will be calculated separately in the 2 cohorts. Relative dose intensity of eribulin and toxicities will be summarized by cohort. Exploratory objectives include efficacy endpoints of 3-year disease-free survival and OS. Clinical trial information: NCT01328249.

**TPS671^ General Poster Session (Board #125B), Mon, 8:00 AM-11:45 AM**

**A single-arm, open-label, phase 2 study of MGAH22 (margetuximab) [fc-optimized chimeric anti-HER2 monoclonal antibody (mAb)] in patients with relapsed or refractory advanced breast cancer whose tumors express HER2 at the 2+ level by immunohistochemistry and lack evidence of HER2 gene amplification by FISH.** *Presenting Author: Mark D. Pegram, Stanford University, Stanford, CA*

**Background:** Response to trastuzumab (T)-based chemoimmunotherapy in metastatic breast cancer segregates according to expression of the Fcg receptor, CD16A, allotypes with patients homozygous for the 158V variant having superior outcomes to patients expressing the 158F variant (Musso-lino, J Clin Oncol 2008, 26:1789-1796). Margetuximab is a chimeric anti-HER2 mAb with antigen specificity and affinity similar to T's and an Fc domain engineered for increased binding to both allotypes of CD16A. Margetuximab exhibited enhanced ADCC against HER2-positive tumor cells, including T-resistant and HER2-low expressing cells. Margetuximab demonstrated increased activity against HER2-low expressing human tumor xenografts. In toxicology, margetuximab was well tolerated (15-150 mg/kg) (Nordstrom, Breast Cancer Research 2011, 13:R123). In Phase 1 testing involving 34 heavily pre-treated patients with HER2-positive neoplasms, margetuximab was well tolerated - MTD not exceeded at 6 mg/kg qw. The major safety findings were infusion reactions, which responded promptly and were largely ameliorated by pre-medications. Margetuximab produced clinical benefit at doses as low as 0.1 mg/kg qw and best responses of PR were noted in 5 patients [Burris, J Clin Oncol 2013, 31 (suppl; abstr 3004)]. **Methods:** The current study employs a Simon 2-stage design to determine if margetuximab has sufficient activity (>/= 5 responses in 41 evaluable) to justify further development in advanced breast cancer patients whose tumors exhibit 2+ HER2 expression and lack evidence of gene amplification by central testing. Time-delimited endpoints will be captured. Exploratory objectives include: PK/PD, FcgR allotype-response, and cytokine-AE relationships, ability of patient PBMCs to mediate ADCC, lymphocyte subsets and activation markers; circulating tumor cells and circulating nucleic acids. Three evaluable patients have participated thus far in the study. Clinical trial information: NCT01828021.

**TPS672 General Poster Session (Board #126A), Mon, 8:00 AM-11:45 AM**

**Phase I study of BYL719 and trastuzumab-MCC-DM1 (T-DM1) in HER2-positive metastatic breast cancer (MBC) patients with progression on trastuzumab and taxane-based therapy.** *Presenting Author: Sarika Jain, Northwestern University, Robert H. Lurie Comprehensive Cancer Center, Chicago, IL*

**Background:** Despite the considerable efficacy of trastuzumab, eventually all HER2-positive MBC patients develop resistance and disease progression. Upregulation of the PI3K pathway and oncogenic activating mutations of *PIK3CA* mutations have been implicated in trastuzumab resistance. Simultaneously targeting HER2 and PI3K pathways may allow for a more effective treatment option in this population. **Methods:** This investigator-initiated phase I, open-label, single arm study employs a dose-escalating 3+3 design to determine safety and efficacy of T-DM1 (an antibody-drug conjugate that incorporates the HER2-targeted properties of trastuzumab with a microtubule-inhibitory agent) in combination with an oral PI3K inhibitor BYL719 in patients with HER2-positive locally advanced or MBC whose disease has progressed on trastuzumab and taxane-based regimens in the metastatic setting or within 6 months in the adjuvant setting. Three to 6 patients are being enrolled in 3 successive cohorts with dose escalation of daily BYL719 (Cohort 1: 300 mg, Cohort 2: 350 mg, Cohort 3: 400 mg). T-DM1 is given at the FDA approved dose of 3.6 mg/kg every 3 weeks. At the maximum tolerated dose (MTD), an additional 10 patients will be enrolled to gain further knowledge on safety. The primary objectives are to determine safety, tolerability, feasibility, and MTD. The secondary objectives will evaluate pharmacokinetics of BYL719 and efficacy. Exploratory endpoints will examine alterations of the *PIK3CA* gene, decrease of PTEN expression and other Akt/mTOR downstream markers. This will be performed on archival metastatic tumor tissue or an optional baseline tissue biopsy and compared to optional tissue biopsy after 3 cycles of treatment. Clinical trial information: NCT02038010.

**1000^** **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Association of increased tumor-infiltrating lymphocytes (TILs) with immunomodulatory (IM) triple-negative breast cancer (TNBC) subtype and response to neoadjuvant platinum-based therapy in PrECOG0105.** *Presenting Author: Shaveta Vinayak, University Hospitals Case Medical Center/ Case Western Reserve University School of Medicine, Cleveland, OH*

**Background:** Increased TILs are prognostic and predictive of therapy response in TNBC. PrECOG 0105, a neoadjuvant trial of carboplatin, gemcitabine and iniparib, enrolled 80 pts with clinical stage I-IIIA TN or BRCA1/2 mutation-associated BC. This correlative study was designed to assess the association of pre-therapy TILs in PrECOG 0105 with pathologic response, germline BRCA1/2 genotype & gene expression profiles, including TNBC subtypes. **Methods:** Evaluable pts had TNBC and completed at least 4 of 6 planned cycles of therapy. H and E stained tumor sections from pre-therapy biopsies were evaluated by a central pathologist for density of stromal (sTILs) and intratumoral (iTILs) lymphocytes. Pathologic response was assessed by the residual cancer burden (RCB) index. All patients had comprehensive BRCA1/2 genotyping. TNBC subtypes were derived from Affymetrix U133 plus 2.0 arrays. **Results:** 70 pts were included in this analysis. Median age = 47 yrs, median T size = 3.2 cm, 20% BRCA1/2 mutant & 48% node positive. 76% of tumors had at least 10% sTILs (range 10-80%) & 31% at least 10% iTILs (range 10-40%). Lymphocyte-predominant BC (LPBC), defined as ≥50% sTILs, was seen in 13%. pCR rate was highest (56%) in LPBC, though not significantly different from the non-LPBC group (38%, p=0.47). sTILs were significantly associated with TNBC subtype; median sTIL = 40% in the IM subtype, 15% in BL1, 20% in BL2, 10% in LAR, 0% in M, and 10% in MSL (p=0.0005). iTILs were also significantly associated with TNBC subtypes (p=0.0003); iTIL>0 for 10/14 (71%) in IM subtype, 1/7 (14%) in BL1, and 0 in others. Association with BRCA1/2 mutation status was not significant. In a multivariate model, each 10% increase in iTILs (OR 2.62 [95% CI 1.08 – 6.35]; p=0.03), but not sTILs (OR 1.17 [95% CI 0.87 – 1.58];p=0.28) was independently associated with pCR (RCB=0). However, both sTILs (p=0.02) and iTILs (p=0.009) were significantly associated with continuous RCB value. **Conclusions:** Both sTILs and iTILs are predictive of response to platinum-based neoadjuvant therapy and are significantly associated with TNBC subtypes, with the highest frequency in the IM subtype. Clinical trial information: NCT00813956.

**1001** **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Expression of novel immunotherapeutic targets in triple-negative breast cancer.** *Presenting Author: Gargi Dan Basu, Caris Life Sciences, Phoenix, AZ*

**Background:** Triple negative breast cancer (TNBC) is an aggressive form of breast cancer that lacks expression of ER, PR and HER2. Targeted treatment options for TNBC are limited, and novel potential molecular targets need to be evaluated. This study examined biomarkers involved in immune evasion including PD-L1 and its association with other biological pathways as potential treatment options for TNBC patients. **Methods:** We analyzed 511 TNBC samples using a multiplatform approach including whole genome mRNA expression (HumanHT-12 v4 BeadChip Illumina Inc., San Diego, CA), protein expression (immunohistochemistry), gene copy number changes (in situ hybridization) and gene sequencing. PD-L1 IHC was performed on 22 samples. **Results:** Within the TNBC patient cohort, there were subsets with elevated mRNA expression of immune markers including PD-L1, CTLA4, IDO1 and B7-H3. Cancer cell-specific over-expression of PD-L1 protein was present in 50% of TNBC tumors. Androgen receptor (AR) was over-expressed in 17% of the TNBC cohort and AR-negative TNBC patients were more likely to express PD-L1 (p =.05), CTLA-4 (p =.001), and IDO1 (p = 2.8e-05). Spearman correlation test showed a positive correlation of PD-L1 with CTLA-4 (0.52), IDO1 (0.48), PIK3CA (0.39), and PTEN (0.11). Differential expression analysis between high and low PD-L1 expressing tumors identified 144 genes. Pathway analysis of the 144 genes indicated significant enrichment of DNA repair genes. Consistent with these findings, PD-L1 expression was negatively associated with BRCA1 expression (p=0.001) and positively correlated with HUS1 and FANCA expression (p=8e-13). **Conclusions:** The expression of immune regulatory targets in the TNBC population suggests that immune- targeted therapies may be effective in subsets of TNBC. This is particularly true for patients with AR-negative TNBCs who may benefit from PD-L1 and CTLA-4 targeted therapies. The positive correlation of PIK3CA and PD-L1 may indicate that combination therapy targeting both pathways may be beneficial. In addition, the inverse correlation of BRCA1 with PD-L1 suggests a potential role for platinum-based therapy in combination with anti-PD-L1. Further prospective validation of these findings is ongoing.

**1002** **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**RNA-sequencing of residual triple-negative breast cancers after neoadjuvant chemotherapy compared to matched pretreatment biopsies from the Hoosier Oncology Group trial BRE09-146.** *Presenting Author: Milan Radovich, Indiana University School of Medicine, Indianapolis, IN*

**Background:** Residual disease after neoadjuvant chemotherapy in triple-negative breast cancer (TNBC) patients entails a high risk of disease recurrence. We investigated the transcriptomes of residual disease versus matched pre-treatment biopsies from a post-neoadjuvant TNBC trial to understand mechanisms of treatment resistance and to identify potential therapeutic interventions. **Methods:** RNA-sequencing of 44 TNBC tumors with high tumor cellularity (22 matched pre- and post-neoadjuvant specimens) was performed using the Ion Proton Next Generation Sequencer. RNA-seq data was aligned to the genome followed by expression and network analysis. **Results:** Statistical analysis resulted in 1,022 genes differentially expressed between matched pre- and post-neoadjuvant chemotherapy samples (p<0.01). Pathway analysis identified significant down-regulation of immune genes ($P<1x10^{-5}$), which correlated with histologic observation of the depletion of lymphocytic cells in the post-neoadjuvant specimens (p=0.018). To identify novel therapeutic modalities, we employed upstream regulator analysis which predicts transcriptional regulators that are activated based on differentially expressed genes. Our top activated regulator in post-neoadjuvant specimens is MAPK1 ($p=1.13x10^{-4}$), a key component of the MEK/ERK pathway. To further identify novel markers of residual disease, we analyzed for precursor microRNAs. Differential expression identified significant up-regulation of our top hit, miR-663B ($P=2x10^{-4}$, Fold-Change=3.4) in residual disease tumors. **Conclusions:** RNA-seq and histology identified significant depletion of immune cells in residual disease, which has been previously associated with poor prognosis in breast cancer. We further identified a highly activated MAPK1 network, suggesting the potential use of MEK/ERK inhibitors in clinical trials for this population. Lastly, we identified a novel clinical biomarker, miR-663B, which is known to mediate in vitro TNBC resistance to doxorubicin, cyclophosphamide, and docetaxel.

**1005** **Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Pathological complete response (pCR) rates after carboplatin-containing neoadjuvant chemotherapy in patients with germline *BRCA* (g*BRCA*) mutation and triple-negative breast cancer (TNBC): Results from GeparSixto.** *Presenting Author: Gunter Von Minckwitz, German Breast Group/ University Frankfurt, Neu-Isenburg, Frankfurt, Germany*

**Background:** We previously showed in participants with TNBC of the neoadjuvant phase II GeparSixto study (NCT01426880) that the addition of carboplatin can substantially improve the pCR rates from 36.9% with weekly paclitaxel/non-pegylated liposomal doxorubicin (PM) to 53.2% with PM plus weekly carboplatin (AUC2) (PMCb) (von Minckwitz et al, Proc ASCO 2013). We aimed to assess how far this benefit is correlated with g*BRCA* mutation or with a family history for breast or ovarian cancer. **Methods:** Full blood samples with sufficient amount of DNA were available in 295 (94%) out of 315 participants of GeparSixto with TNBC. We searched for gBRCA mutations by MLPA and Fluidigm screening for recurrent pathogenic *BRCA1/2* alterations. In combination, both methods enable us to detect approximately 60% of all expected mutation carriers. Participants with so far undetected mutations are currently under investigation by employing next generation sequencing (NGS) techniques to detect additional pathogenic germline alterations in *BRCA1/2* or other breast cancer predisposing genes. **Results:** At total of 38 mutation carriers (35 BRCA 1, 3 BRCA 2) have so far been identified (31 by central testing and 7 known results from local testing). Additional 78 patients have a known family breast cancer history. 179 patients have so far neither a mutation nor a family history. Overall pCR (ypT0 ypN0) rate increased from 40.2% in patients with no identified risk, to 44.9% in patients with family history only, to 57.9% for patients with g*BRCA* mutation. Adding carboplatin to PM increased the pCR rate by 14% (odds ratio, OR 1.79) in patients without increased risk, by 20% (OR 2.29) in patients with family history only, and by 25% (OR 2.75) for patients with g*BRCA* mutation. **Conclusions:** g*BRCA* mutation and family history are predictors for higher pCR rates after neoadjuvant anthracycline/taxane based chemotherapy in TNBC. Additive effect of carboplatin is most prominent in patients with g*BRCA* mutation. Updated results after complete g*BRCA* mutation analysis will be presented at the meeting. Clinical trial information: NCT 01426880.

**1006 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Adoption of hypofractionated radiotherapy (HyRT) for ductal carcinoma in situ (DCIS): A SEER-Medicare study.** *Presenting Author: Aaron David Falchook, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

**Background**: Multiple randomized trials published in 2008-2010 demonstrated that for women with early-stage invasive breast cancer receiving adjuvant radiotherapy (RT) after a lumpectomy, shorter course (hypofractionated) RT is non-inferior to conventionally fractionated RT (CRT). However, the role of HyRT has not been evaluated prospectively for DCIS. The purpose of this study is to examine adoption of HyRT in DCIS. **Methods**: DCIS patients diagnosed from 2004-9 in the Surveillance Epidemiology and End Results (SEER)-Medicare database were included, with Medicare claims data available through 2010. A total of 4,459 women received lumpectomy followed by external beam RT. The number of RT treatments received by each patient was determined from Medicare claims, and grouped into: accelerated partial breast irradiation (APBI, ≤12 treatments), HyRT (13-24), or CRT (≥25). Proportions of women receiving different fractionation schemes were described per year of RT, and in subgroups based on patient and disease factors. Multivariate logistic regression was used to examine factors associated with receipt of HyRT (vs. CRT). **Results**: Utilization of HyRT increased from ~4% to 8.8% in 2008 and 11.2% in 2009-10, with corresponding decreases in CRT (Table); external beam APBI utilization was low and stable during the study years. HyRT was more common in older women. On multivariate analysis, older age (OR 1.8 for age 80+ vs. age 66-69, p=.002), later RT years (OR 2.8 for 2009-10 vs. 2005, p<.001) and higher regional education were significantly associated with increased utilization of HyRT, while higher grade was associated with less HyRT (OR .8 for Grade 3 vs. Grade 1, p=.06). Race, marital status, comorbidity, and laterality (left vs. right) were not significantly associated with HyRT. **Conclusions**: Utilization of HyRT increased after 2008 coinciding with trial publications for invasive cancer, even though the efficacy of this treatment for DCIS has not been clearly established.

**Trends in treatment patterns and outcomes for DCIS patients: A SEER population-based analysis.** *Presenting Author: Mathias Worni, Department of Surgery, Division of Surgical Oncology, Duke University Medical Center, Durham, NC*

**Background:** Ductal carcinoma in situ (DCIS) is considered a precursor lesion of invasive ductal cancer of the breast, and current therapy aims to prevent progression to invasive disease. However, the impact of contemporary treatment options on breast-cancer survival remains poorly defined. **Methods:** The Surveillance, Epidemiology, and End Results (SEER) registry was queried from 1991-2010 for patients with DCIS. Age-adjusted incidence rates were calculated, and trends in treatment patterns were analysed using the Cochran Armitage trend test. Survival analyses were performed with inverse probability weight (IPW) adjusted competing risk analysis for cancer specific (CSS) and cox proportional hazard regression analysis for overall survival (OS). **Results:** 121,080 DCIS patients were included in the analysis. Age-adjusted incidence rates increased from 23.2/100,000 females in 1992 to 36.4/100,000 in 2010. Highest incidence rate was found among females age 60-79 years in 2010 (83.8/100,000). Most patients were treated with lumpectomy and radiation therapy (breast conservation therapy, BCT) (43.0%), followed by lumpectomy alone (26.5%), unilateral (23.8%) or bilateral mastectomy (4.5%), and no treatment (2.3%). Rates of unilateral mastectomy significantly decreased from 1991 (44.9%) to 2010 (19.3%), as did lumpectomy alone (29.8% to 22.3%), while increased rates of BCT (24.2% to 46.8%) and bilateral mastectomy (0% to 8.5%) were observed (p for trend <0.001 for all comparisons). On IPW adjusted analysis, CSS was superior to BCT compared to mastectomy (hazard ratio HR: 1.16, 95% CI: 1.00-1.33, p=0.048) while no difference was found for lumpectomy alone over mastectomy (HR: 0.90, CI: 0.77-1.05, p=0.17). Compared to mastectomy, patients undergoing BCT demonstrated improved OS (HR: 1.17, CI: 1.12-1.22, p<0.001) while patients undergoing lumpectomy alone demonstrated worse OS (HR: 0.79, CI: 0.76-0.83, p<0.001). **Conclusions:** The incidence of DCIS in females continues to rise, particularly in women 60-79. There has been a significant shift in treatment patterns towards BCT and bilateral mastectomy. Using IPW adjustment, CSS and OS were best for patients undergoing BCT compared to all other treatment groups.

**1008 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Predicting local recurrence using PAM50 in postmenopausal endocrine responsive breast cancer patients.** *Presenting Author: Florian Fitzal, Medical University of Vienna, Vienna, Austria*

**Background:** Breast conservation may lead to increased local recurrence rates compared with mastectomy. We investigated whether genetic expression profiling using PAM50 may predict local recurrence free survival (LRFS) independent of established factors **Methods:** Tumor blocks from patients randomized within the ABCSG 8 trial comparing tamoxifen with tamoxifen followed by anastrozole after surgery were analysed by the PAM50 assay (Prosigna, NanoString Technologies). Postmenopausal patients with endocrine responsive her2neu negative breast cancer were included. The risk of recurrence (ROR) score as well as biological subtypes (Luminal A and B) were correlated with LRFS. **Results:** 1,308 patients were analysed. 59% were <65 years, 79% had breast conservation (BCT) followed by radiotherapy and 32% were nodal positive. 72% had a low ROR score, 68% were luminal A while 28% had a luminal B cancer. After a median follow up of 11 years, 34 locoregional recurrences were observed, defined as ipsilateral in breast or axillary recurrences. Cox regression model showed that the ROR score significantly predicted LRFS independent from nodal status, tumor size and age (p<0.0081). Patients with high risk (ROR ≥ 57) had a LRFS of 94.4% while low risk patients (ROR < 57) showed a 98.4% 10-year LRFS (p=0.0005). Biological subtype analysis did also show a significant difference in LRFS comparing luminal A (98.1% 10-year LRFS) and luminal B cancer (95.9% 10-year LRFS, p=0.022). Multivariate analyses demonstrated that BCT did not significantly influence LRFS and was oncologically "safe" even in high risk patients (p=0.174). **Conclusions:** The PAM50 ROR score and intrinsic subtype are independent predictors for LRFS. Mastectomy seems unlikely to imporve LRFS in high risk patients. Clinical trial information: NCT00291759.

**German Adjuvant Intergroup Node Positive (GAIN) study: A phase III trial to compare IDD-ETC versus EC-TX in patients with node-positive primary breast cancer—Final efficacy analysis.** *Presenting Author: Volker Jochen Moebus, Klinikum Frankfurt Hoechst, Frankfurt, Germany*

**Background:** Intense dose-dense (idd) epirubicin (E), paclitaxel (T), cyclophosphamide (C) (idd-ETC) resulted in a superior disease-free (DFS) and overall survival (OS) compared to conventionally dosed EC-T (q3w) chemotherapy in primary breast cancer patients (pts) with ≥4 involved lymph nodes (LN) (Möbus et al, JCO 2010). The GAIN trial had a 2x2 factorial design for investigating two different dose-dense chemotherapy regimens as well as the use of adjuvant ibandronate treatment. Ibandronate results have been reported previously (von Minckwitz et al, JCO 2013). Here we report the final results of the chemotherapy comparison. **Methods:** Pts were randomized to idd-ETC (E:150 mg/m², T:225 mg/m², C:2500-2000 mg/m², i.v. day 1, q15 for 3 cycles each) or EC followed by T plus capecitabine (X) (EC-TX) (E: 112.5 mg/m² + C: 600 mg/m², i.v. day 1, q 15 for 4 cycles followed by T: 67.5 mg/m² i.v. day 1, q 8 for 10 weeks + X: 2000 mg/m² p.o. day 1-14, q 22 for 4 cycles). After recruitment of 1,500 patients the dose of C was reduced to 2000 mg/m². Pts aged 18-65 years with involved axillary LN were eligible. 3000 pts with 801 events were needed to show an increase of 5-year DFS (primary endpoint) from 75% to 79% for patients receiving EC→TX after 8 years total study duration. **Results:** 3,023 patients were randomized from 06/2004 until 08/2008. Median age was 50 years; pN1 (37.7%), pN2 (35.4%), pN3 (26.9%); 46.6% were grade 3. With a median follow up of 74 months we observed 644 DFS events (327 with idd-ETC; 317 with EC-TX) (HR 0.94; log-rank p=0.47). 5-year DFS was 80% with idd-ETC and 82% with EC-TX. No different treatment effect was observed in predefined subgroups. 383 pts have died (205 with idd-ETC; 178 with EC-TX) (HR 0.85; log-rank p=0.10). Hematological toxicity was higher in the idd-ETC arm, but 3 and 11 treatment related deaths occurred in the idd-ETC and EC-TX arm, respectively. **Conclusions:** Both dose-dense regimens achieved a highly favorable 5-year DFS superior to our assumptions mainly based on the preceeding idd-ETC study. The addition of a fourth cytostatic drug (here capecitabine) did not improve efficacy of dose-dense therapy, but led to higher toxicity. Clinical trial information: NCT 001 968 72.

**1010 Poster Highlights Session (Board #2), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Adjuvant gemcitabine for high-risk breast cancer (BC) patients: Final survival results of the randomized phase III SUCCESS-A study.** *Presenting Author: Wolfgang Janni, Department of Gynecology and Obstetrics, University of Ulm, Ulm, Germany*

**Background:** Gemcitabine (G) has shown to have a relevant single agent efficacy and to improve chemotherapy response to taxanes in advanced BC patients. Aim of this study was to evaluate the effect of G on disease free survival (DFS) in high risk adjuvant BC patients. **Methods:** This is a phase III, randomized, open label trial of FEC-Doc vs. FEC-DocG (3 cycles of FEC (500/100/500 mg/m$^2$) followed by 3 cycles of docetaxel (Doc; 100mg/mg$^2$) every three weeks (q3w) *vs.* 3 cycles of FEC followed by 3 cycles of G (1,000 mg/m$^2$ d1,8) and Doc (75 mg/m$^2$) q3w). Key inclusion criteria: stage N1 or T2–T4 or grade 3 or age ≤ 35 or hormone receptor (ER/PR) negative. Key exclusion criteria: locally recurrent/metastatic disease; prior systemic therapy or radiotherapy for current BC. Strata for randomization: nodal, ER/PR, menopausal and HER2 status and grading. Primary and secondary study aims were DFS and overall survival (OS). Survival rates were estimated by the Kaplan-Meier method. Cox regression models were fitted to estimate unadjusted hazard ratios (HRs). Further exploratory analyses investigated treatment differences within patient subgroups. **Results:** 3,754 patients were randomized to FEC-Doc (n=1898) or FEC-DocG (n=1856). Median observation time was 5.3 ys with 456 (238 vs. 218; FEC-Doc vs. FEC-DocG) events for DFS and 269 (140 vs. 129) events for OS. Mean age was 53.5 ys and 58.7% were ≥ T2, 66.1% were nodal positive, 29.3% ER and PR negative and 23.5% HER2 positive. 5-year DFS rate was 0.87 for both randomization arms and 5-year OS was 0.93 for both arms. HRs for DFS and OS were 0.93 (95%CI: 0.78-1.12; p=0.46) and 0.94 (95%CI: 0.74-1.19; p=0.60). Further analyses, accounting for age, body mass index, tumour stage, grading, lymph node status, tumor type, hormone receptor and HER2neu status, did not generate any hypothesis for subgroup-specific efficacy. **Conclusions:** AdjuvantGemcitabine does not improve the efficacy of FEC-Doc chemotherapy for high risk breast cancer patients. With regard to the risk-benefit ratio, we do not recommend adjuvant Gemcitabine for the adjuvant treatment of high risk breast cancer patients. Future analyses will report on circulating tumor cells, serum markers and pharmacogenomics. Clinical trial information: 2005-000490-21.

**1011 Poster Highlights Session (Board #3), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase III study of vinflunine plus gemcitabine versus paclitaxel plus gemcitabine in the first-line treatment of anthracycline pretreated advanced breast cancer.** *Presenting Author: Antonio Llombart, Arnau de Vilanova Hospital, Valencia, Spain*

**Background:** Paclitaxel (PTX), plus gemcitabine (GEM) showed survival advantage over paclitaxel in advanced breast cancer (ABC) patients who relapsed after adjuvant anthracycline. This was associated with increased toxicity, especially neurotoxicity. Vinflunine (VFL) plus GEM was confronted to PTX- GEM in this clinical setting. **Methods:** This open-label phase 3 study enrolled 1004 Her-2 negative ABC patients who had received neo- or adjuvant anthracycline more than 12 months prior to study entry. Patients were randomised to VFL 320 mg/m$^2$ on day 1 plus GEM 1000 mg/m$^2$ on days 1 and 8 every 3 weeks (N = 503) or PTX 175 mg/m$^2$ on day 1 plus GEM 1250 mg/m$^2$ on days 1 and 8 every 3 weeks (N = 501). Randomisation was stratified by PS, (neo)adjuvant taxane, disease measurability and visceral lesions. The primary objective was to test the non-inferiority of VFL-GEM vs PTX-GEM in terms of PFS assessed by a blinded independent review committee in the intent-to-treat population assuming a median PFS of 5.2 months in the control arm and a 20% margin. **Results:** Patients had a median age of 54 years [range: 22-79]; visceral disease for 84.5% and 33.7% had received adjuvant taxane. The median number of cycles was 6 in both arms. Median PFS was 8 months for VFL plus GEM and 8.4 months for PTX plus GEM (HR 1.05, 95%CI: 0.91-1.20, P = 0.54). The upper limit of HR 95% CI being below 1.25, non-inferiority was demonstrated. Response rates were 11.3% for VFL plus GEM and 14.6% for PTX plus GEM (P = 0.10). Median OS were similar: 18.9 months for VFL plus GEM and 19.1 months for PTX plus GEM. Rate of toxic deaths was 1.6% for VFL plus GEM and 0.4% for PTX plus GEM. Grade 3 - 4 neutropenia was common in both arms (74.3% of patients for VFL plus GEM vs 60% for PTX plus GEM), but rarely complicated (< 5% of febrile neutropenia or neutropenic infection in both arms). Grade 3 - 4 constipation was more frequent for VFL plus GEM (7.3% vs 0.2%) and grade 3 - 4 peripheral sensory neuropathy for PTX plus GEM (6.7% vs 0.8%) as well as alopecia (63.5% vs 40.4%). **Conclusions:** VFL plus GEM can be seen as an alternative option to PTX plus GEM considering its similar efficacy and its reduced neurotoxicity.

**1012 Poster Highlights Session (Board #4), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Randomized phase III study of taxane versus TS-1 as first-line treatment for metastatic breast cancer (SELECT BC).** *Presenting Author: Fumikata Hara, National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan*

**Background:** Taxanes have been standard regimen as the first-line chemotherapy for metastatic breast cancer. However side effects such as neutropenia, peripheral neuropathy, edema or alopecia are important concerns. Phase II clinical trials of TS-1, an oral 5-fluorouracil derivatives (tegafur, 5-chloro-2,4-dihydropyrimidine, and potassium oxonate), have shown good clinical efficacy and tolerability. Therefore, we conducted a phase III open-label randomized controlled trial (SELECT BC) to verify the non-inferiority of TS-1 in overall survival (OS) to taxane as first-line chemotherapy for metastatic breast cancer. **Methods:** Six hundred eighteen patients receiving first-line chemotherapy for metastatic breast cancer were randomly assigned to either taxane group (n=309) or TS-1 group (n=309). In the taxane group, patients received docetaxel 60-75mg/m2 q3w, paclitaxel 80-100mg/m2 q1w or paclitaxel 175 mg/m2 q3w at the discretion of the treating physician. In the TS-1 group, patients received TS-1 40–60 mg twice daily based on the patient's body surface area for 28 days on, 14-day off. The primary endpoint was OS, with a non-inferiority margin of 1.333. Secondary endpoints were time to treatment failure (TTF), progression free survival, adverse events, health-related quality of life and cost-effectiveness. **Results:** After a median follow-up of 34.6 months, median OS was 37.2 months in the taxane group and 35.0 months in the TS-1 group (hazard ratio 1.05, 95% CI 0.86–1.27, p=0.015). Median TTF was 8.9 months in the taxane group and 8.0 months in the TS-1 group (hazard ratio 1.10, 95% CI 0.93–1.30, p=0.022). The incidences of diarrhea, mucositis and nausea were higher with TS-1, whereas the incidences of edema, peripheral neuropathy, arthralgia, allergic reaction, fatigue and alopecia were higher with taxanes. Utilities measured by EQ5D during treatment were similar (repeated measures ANOVA p=0.66) between two groups. **Conclusions:** SELECT BC clearly demonstrated that OS with TS-1 is not inferior to that with taxane in patients receiving first-line chemotherapy for metastatic breast cancer. TS-1 monotherapy would be one of the standard regimens for this patient population. Clinical trial information: C000000416.

**1013^ Poster Highlights Session (Board #5), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Vinflunine plus capecitabine for advanced breast cancer previously treated with or resistant to anthracycline and resistant to taxane: A phase III study versus capecitabine.** *Presenting Author: Matti S. Aapro, Clinique de Genolier, Genolier, Switzerland*

**Background:** Vinflunine (VFL) is a microtubule inhibitor with single-agent activity in advanced breast cancer (ABC) pretreated with anthracycline (A) and resistant to taxane (T). Synergy with capecitabine (CAPE) was demonstrated in this setting. This phase 3 study compared VFL plus CAPE with CAPE alone in A pretreated or resistant and T-resistant ABC. **Methods:** Open-label, multicenter study, in which 770 ABC patients with up to 3 prior chemotherapy (CT) regimens were randomised to VFL 280 mg/m$^2$ on day 1 plus CAPE 1,650 mg/m$^2$ (N = 384) or to CAPE alone at 2,500 mg/m$^2$ (N = 386) on days 1 to 14 every 3 weeks. Randomization was stratified by resistance to anthracycline, performance status, disease measurability and number of prior lines of CT for ABC. Primary endpoint was PFS assessed by a blinded independent review committee (IRC) in the ITT population. **Results:** Patients had a median age of 54 years (range: 27 - 81); metastatic disease for 97%; anthracycline resistance for 63%; received study treatment as first (20%), second (48%) or > third (32%) CT line for ABC. The median number of cycles was 6 for VFL plus CAPE and 5 for CAPE. VFL plus CAPE prolonged PFS compared to CAPE (median 5.6 vs 4.3 months, HR = 0.84, 95% CI 0.71-0.99, P = 0.0426). The response rate assessed by IRC was numerically greater for VFL plus CAPE than for CAPE (22.9% vs 17.9%, P = 0.1030); the disease control rate was statistically superior with the combination (57.3% vs 47.9%, P = 0.0089). Median OS analysed after 643 deaths (83.5%) was 13.9 months for VFL plus CAPE and 11.7 months for CAPE (HR = 0.98, 95% CI = 0.83-1.15, P = 0.7657). The most frequent grade 3-4 drug-related adverse events were neutropenia for VFL plus CAPE (11% of patients vs 3.7% for CAPE) and hand-foot syndrome for CAPE (18% vs 3.7% for VFL plus CAPE). Quality of life global health status score (QLQ-C30) was preserved for VFL plus CAPE while there was a deterioration for CAPE from week 12. **Conclusions:** VFL plus CAPE demonstrates a statistically significant improvement in PFS and a clinically meaningful improvement in OS compared to CAPE alone. VFL plus CAPE is a new well tolerated option for A/T pretreated/resistant patients with ABC. Clinical trial information: NCT01095003.

**1014 Poster Highlights Session (Board #6), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**ARTemis: A randomised trial of bevacizumab with neoadjuvant chemotherapy (NACT) for patients with HER2-negative early breast cancer—Primary endpoint, pathological complete response (pCR).** *Presenting Author: Helena Margaret Earl, Department of Oncology, NIHR Cambridge Biomedical Research Centre and Cambridge Breast Cancer Research Unit, University of Cambridge, Cambridge, United Kingdom*

**Background:** Bevacizumab (bev) has been used with NACT in breast cancer trials. Geparquinto reported benefit for bev in triple negative (neg) patients (pts) (pCR 36.4% v 27.8% p=0.02), as did CALGB 40603 (pCR 52% v 44%, p=0.057), although the NSABP-B40 study showed benefit in ER-positive (pos) pts (pCR 23.3% v 15.2%, p=0.008). **Methods:** ARTemis is a randomised phase 3 trial adding bev to NACT (docetaxel (D)-FEC). Pts with HER2-neg invasive breast cancer were eligible. Stratification was by age, ER status (neg: weak pos: strong pos), tumour size (T2:T3/4), clinical involvement of axillary nodes and inflammatory/locally advanced disease. Pts were randomised (1:1) to bev+D-FEC or D-FEC. The primary endpoint was pCR, defined as no residual invasive cancer in the breast or axillary lymph nodes after NACT. 800 pts were required to detect 10% differences in pCR rates, at the 5% (2-sided) level of significance with 85% power. **Results:** 800 pts were randomised from 66 UK centres (May'09 to Jan'13). 68% were <50 years old, 19% had inflammatory and/or locally advanced disease, 79% of tumours <50mm, 52% clinical node pos and 33% ER-neg. A 2-reader independent review of pathology reports was carried out. Significantly more pts on bev+D-FEC had a pCR (22% (18-27%) vs 17% (13-21%) with D-FEC; p=0.03 [adjusted for stratification factors]). pCR rates differed significantly across ER groups (neg 38%, weak pos 39%, strong pos 7%; p<0.0001). Treatment effect of bev remained significant after adjustment for ER (p=0.03). **Conclusions:** ARTemis showed a significant improvement in pCR with the addition of bev to D-FEC. ER-neg and ER-weak pos / HER2-neg breast cancer pts appeared to benefit most from bev, whilst pCR rates in ER-strong pos pts were lower and did not appear to show improvement from the addition of bev. Our results are similar to those reported in Geparquinto and CALGB 40603. Clinical trial information: 68502941.

| Factor | D-FEC pCR (95% CI) | bev+D-FEC pCR (95% CI) | p* |
|---|---|---|---|
| **ER-neg (Allred 0-2) (n=253)** | 32% (24-41) | 44% (36-54) | 0.03 |
| **ER-weak pos (Allred 3-5) (n=67)** | 26% (13-44) | 52% (34-69) | |
| **ER-strong pos (Allred 6-8) (n=461)** | 7% (4-11) | 6% (3-10) | |

* p-value across treatment groups, after adjusting for ER.

**1015 Poster Highlights Session (Board #7), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Resource utilization in patients with breast cancer treated with generic versus branded docetaxel.** *Presenting Author: Stephen E. Jones, US Oncology Research, LLC, McKesson Specialty Health, The Woodlands, TX*

**Background:** This study was to assess health resource utilization in patients with breast cancer (BC) treated with generic (available in US since 2011) vs branded docetaxel. **Methods:** A retrospective inception cohort was analyzed in Clinformatics DataMart healthcare claims database. Patients (female, aged ≥18 years) were identified between Apr 1, 2011 and Jun 30, 2012 if they had an ICD-9:174 for BC, initiated docetaxel, and had 6-month continuous insurance coverage pre (baseline) and post (follow-up) docetaxel initiation. The 50 most frequent claims for clinical diagnoses, procedures and prescriptions were evaluated between generic and branded docetaxel along with health resource utilization and expenditures, with hierarchical mixed effects model adjustment for potential confounding. **Results:** 1,955 patients diagnosed with BC were identified, of which a total of 98 generic and 262 branded docetaxel users were included in the final analysis. For the majority of patients, the source of docetaxel was not apparent. Patient characteristics were comparable at baseline between study groups. During follow-up, the generic cohort showed a higher rate of claims for neutropenia (67.3% vs 48.9%; p<0.01) and malaise and fatigue (22.4% vs 13.7%; p<0.05) among medical diagnoses. The branded was higher in nausea and vomiting (43.5% vs 29.6%; p=0.02). The rate of neutropenia remained higher in generic vs branded (73.9% vs 52.8%; p<0.01) even after adjusting for history of neutropenia and baseline use of G-CSF and fosaprepitant. The generic cohort had more fosaprepitant use at follow up (54.1% vs 30.2%; p<0.01). The higher odds of neutropenia was observed in generic with (OR=2.49; p= 0.03) or without (OR=1.41; p= 0.31) fosaprepitant use during follow up. Mean outpatient costs excluding docetaxel drug costs were higher in the generic ($59,177 vs $50,243; p<0.01), and remained significantly higher ($54,282 vs $46,698; p=0.03) after adjustment for baseline healthcare costs, inpatient admissions, etc. **Conclusions:** Use of generic vs branded docetaxel in BC was associated with about 40% more medical claims for neutropenia and higher ambulatory care costs at 6 months follow up. Further research is needed to confirm these findings.

**1016 Poster Highlights Session (Board #8), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Outcome of male patients and black patients enrolled in S0221, an intergroup chemotherapy study.** *Presenting Author: G. Thomas Budd, Cleveland Clinic, Cleveland, OH*

**Background:** Assessment of the outcome of minority populations within clinical trials may give insight into important tumor and host factors relevant to those populations. **Methods:** S0221 is a phase III trial of various dose-schedules of doxorubicin, cyclophosphamide and paclitaxel. S0221 allowed enrollment of male patients, and was sufficiently large to enroll significant numbers of minority populations. Here, we report the outcome of male patients and patients of black race. **Results:** Among 3236 total patients entered on S0221, 23 (0.7%) were male and 378 (12%) were of self-reported black race. Non-significant differences in male/female patients were seen in HER2 positivity (9%/19%), hormone receptor (HR) positivity (100%/66%), lymph node negativity (17%/26%), and treatment completion rate (70%/74%), but men were more often ≥60 years old (48%/21%, p=0.006). Males had significantly worse disease-free survival (DFS), with 5-year DFS 49%/82%; HR=3.16, Log-Rank p=0.0003. Male sex remained an adverse factor for DFS in a Cox model adjusted for treatment, HER2 status, HR status, age, and nodal status (HR=3.53, p<0.001). Black/non-black patients did not significantly differ in HER2 positivity (22%/18%). Black patients were less likely to be HR-positive (51%/69%, p<0.001), to have >4 nodes involved (29%/36%, p=0.02), to be age >60 years (15%/22%, p=0.008) and to complete treatment (63%/75%, p<0.001). Black patients had worse DFS, with 5-year DFS of 75%/82%; HR=1.55, Log-Rank p=0.0001. Black race remained an adverse factor for DFS in a Cox model adjusted for treatment, HR status, HER2, age, and nodal status (HR=1.48, p=0.001) or when analysis was limited to those completing therapy, adjusted for treatment (HR=1.48, p=0.01). **Conclusions:** Male patients enrolled in S0221 had a markedly worse DFS, a finding which persisted after adjustment for tumor characteristics. Black patients in S0221 treated with 3rd generation regimens had a worse DFS than non-black patients. These results are similar to those for post-menopausal HR+ black patients treated with a 2nd generation regimen (5FU/doxorubicin/cyclophosphamide) in S8814, suggesting a generalized phenomenon which is not improved with contemporary regimens. Clinical trial information: NCT00070564.

**1017 Poster Highlights Session (Board #9), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Randomized phase II study of weekly paclitaxel with or without carboplatin followed by cyclophosphamide/epirubicin/5-fluorouracil as neoadjuvant chemotherapy for stage II/IIIA HER2-negative breast cancer.** *Presenting Author: Kenji Tamura, Department of Breast and Medical Oncology, National Cancer Center Hospital, Tokyo, Japan*

**Background:** Platinum based neoadjuvant chemotherapy (NAC) in HER2-negative breast cancer (HNBC) has a potential to improve pathological complete response (pCR). We evaluated the efficacy and safety of carboplatin (CBDCA) and weekly paclitaxel (wPTX) followed by cyclophosphamide, epirubicin, and 5-fluorouracil (CEF) as NAC for HNBC. **Methods:** Patients with stage II-IIIA HNBC were randomly assigned to preoperatively CP-CEF arm (4 cycles of CBDCA [area under the curve 5 mg/mL. min, day 1, every 3 weeks] and wPTX [80 mg/m$^2$, day 1, 8, 15, every 3 weeks] followed by 4 cycles of CEF [500/100/500 mg/m$^2$, day 1, every 3 weeks], or P-CEF arm (4 cycles of wPTX followed by 4 cycles of CEF). The primary endpoint was pCR rate. Breast tumor tissues by preoperative biopsy were tested for Ki-67, EGFR, Cytokeratin (CK) 5/6, BRCA1, vimentin, ERCC1 and ZEB1 by immunohistochemistry (IHC). **Results:** Of 181 eligible patients, 89 were randomly assigned to the CP-CEF arm and 92 to the P-CEF arm. Two patients in each arm refused to receive NAC. Overall 88 patients in the CP-CEF arm and 91 patients in the P-CEF arm were assessable for efficacy and safety. The primary endpoint; pCR rate in the CP-CEF arm was significantly higher than that in the P-CEF arm (31.8 vs. 17.6%, p = 0.01). Among patients with triple-negative breast cancer (TNBC), the pCR rate in the CP-CEF arm was significantly higher than that in the P-CEF arm (61.2% vs. 26.3%, p = 0.003). Grade 3-4 neutropenia was observed in the CP-CEF arm more frequently than in the P-CEF arm (65.9% vs. 38.5%). We gained 46 tumor samples from the registered patients (26%). EGFR, CK5/6 and BRCA1 expressions were significantly frequent in TNBC. EGFR expression was significantly associated with pCR rate in the 46 patients (45.0% vs. 11.5%, P=0.010), and in patients in CP-CEF arm (63.8% vs. 18.2%, P=0.040), but not in patients in P-CEF arm. **Conclusions:** Adding CBDCA to neoadjuvant wPTX followed by CEF for HNBC statistical significantly improved pCR rate with a favorable safety profile. EGFR expression by IHC is a potent predictive biomarker of response to the CP-CEF regimen as NAC. Clinical trial information: 000003355.

**1019^ Poster Highlights Session (Board #11), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Cisplatin with or without rucaparib after preoperative chemotherapy in patients with triple-negative breast cancer (TNBC): Hoosier Oncology Group BRE09-146.** *Presenting Author: Sujaata Dwadasi, Indiana University, Indianapolis, IN*

**Background:** Patients (pts) with triple negative breast cancer (TNBC) who have residual disease after preoperative chemotherapy have a high risk of recurrence. No standard systemic therapy has proven benefit. Data suggest that some pts with TNBC and/or BRCA mutations may be sensitive to DNA-damaging chemotherapy and PARP inhibition. **Methods:** Eligible pts with TNBC or known BRCA mutations who had residual lymph node involvement or > 2 cm invasive disease after anthracycline or taxane neoadjuvant therapy were assigned 1:1 to postoperative cisplatin (C: 75 mg/m$^2$D1 q3 wks x 4) +/- rucaparib (R: 24-30 mg IV D1,2,3 q3 wks x 4 followed by rucaparib 30 mg IV or 100 mg orally wkly for 24 wks). BROCA analysis (U. Washington) was used to identify deleterious germline mutations. The primary objective is 2-yr DFS. **Results:** 128 pts were enrolled. Median age was 48; 6 pts were known at study entry to have BRCA1 or BRCA2 mutations. Neoadjuvant therapy included anthracyclines in 57% and taxanes in 91%. Median tumor size at surgery was 1.9 cm (0-11.5) with median LN involvement 1 (0-38); Toxicity required C dose reduction (20% of pts) or delay (~43% of pts) in both arms. R dose reduction was uncommon (6%). Overall 73% of pts completed planned C. With a median follow-up of 9 months, 1-yr DFS was similar (~76%) in both treatment groups. BROCA identified deleterious mutations in 22/101 (22%) pts (8 BRCA 1, 12 BRCA 2, 2 BRIP1). 1-yr DFS in the 22 pts with mutations was ~85% compared to 79% without mutations. Whole transcriptome sequencing of paired pre vs. post preoperative chemotherapysamples will be reported separately (Radovich et al, ASCO 2014). **Conclusions:** The addition of low dose rucaparib (current phase II monotherapy dose 600 mg orally twice daily) did not impact the toxicity of cisplatin or improve 1-yr DFS. Comparison to predicted DFS based on residual cancer burden (RCB) is planned to investigate potential benefit from cisplatin. Genetic testing was underutilized in this high risk population with only 30% of BRCA1 and BRCA2 mutations identified as part of routine clinical care. Clinical trial information: NCT01074970.

**1020 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Identification of biomarkers to predict response to single-agent platinum chemotherapy in metastatic triple-negative breast cancer (mTNBC): Correlative studies from TBCRC009.** *Presenting Author: Steven J. Isakoff, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background**: TNBC has a poor prognosis compared to other BC subtypes and lacks therapeutic targets. We previously reported TBCRC009, a multicenter single-arm phase II study of single-agent platinum in 86 patients (pts) with mTNBC: the objective response rate (ORR) was 25.6% overall and 54.5% vs. 19.7% (p=0.02) in BRCA1/2 carriers (n=11) vs. noncarriers (n=66). Six long-term responders remain disease free at median follow up of ~4 yrs. Here we explored biomarkers of response to platinum in TBCRC009. **Methods**: Participants had measurable disease, available archival tumor, ≤1 prior metastatic therapy, and no prior platinum chemotherapy. By physician choice, pts received cisplatin 75mg/m$^2$or carboplatin AUC=6 every 21 days. Co-primary endpoints were: 1) ORR and 2) p63/p73 expression by RT-PCR as a predictor of response. Tumor-based exploratory studies included: gene expression (GE) profiling, PIK3CA and p53 mutational status, and homologous recombination deficiency (HRD) assays correlating with BRCA1/2 inactivation. **Results**: Among 61 pts evaluable for co-primary endpoint 2, 28 (46%) had the pre-specified p63/p73 ratio ≥2, which did not predict response to platinum (ORR 18% vs. 27% in p63/p73 ≥2 vs. <2, respectively, p=0.54). 36/54 pts (67%) had p53 mutations, and 9/55 pts (16%) had PIK3CA mutations, but neither correlated with ORR. PAM50 analysis from global GE profiling identified 60% (32/53) basal-like tumors, which showed a higher ORR that did not reach significance (28% vs. 10% in basal vs non-basal, p=0.17). All HRD assays, including Loss Of Heterozygosity (LOH), Telomere Allelic Imbalance (TAI), and Large-scale State Transition (LST), scored higher in BRCA1/2 carriers than non-carriers, and in responders than nonresponders among the small group of 22 non-carriers with available tissue (HRD-LST responders vs. nonresponders, p=0.0016). **Conclusions**: Single-agent platinum is effective in both *BRCA1/2*-associated and sporadic mTNBC. Although established biomarkers failed to predict responses, HRD assays may identify sporadic TNBC tumors that are BRCA1/2-like and responsive to platinum chemotherapy. Clinical trial information: NCT00483223.

**1021 Poster Highlights Session (Board #14), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase II trial of single agent PARP inhibitor ABT-888 (veliparib [vel]) followed by postprogression therapy of vel with carboplatin (carb) in patients (pts) with stage BRCA-associated metastatic breast cancer (MBC): California Cancer Consortium trial PHII-96.** *Presenting Author: George Somlo, City of Hope, Duarte, CA*

**Background:** We reported on a phase I trial showing 54% confirmed partial response (PR) with carb + vel. Here we describe single agent vel activity and, upon progression, the feasibility and efficacy of continuing administration of vel + carb. **Methods:** Pts with MBC with BRCA1 or 2 mutations, an ECOG performance status of ≤ 2, and measurable disease were eligible. Prior PARP-inhibitor therapy (Rx) , platinum Rx for MBC, or central nervous system metastasis requiring Rx were exclusions. Vel was administered orally at 400 mg twice daily (BID). Cohorts (BRCA1 and BRCA2) were studied independently: 2 or more PRs to vel out of 10 pts were required to proceed to accrual of 22 pts per cohort. Upon progression, carb (AUC of 5) iv every 21 days, and vel 150 mg orally BID were prescribed. **Results:** Between 10/2012 and 1/2014, 44 pts enrolled (41 treated) carrying BRCA1 (N=21) or BRCA2 (N=20) mutations. The median age was 43-years (range; 28-68); 50% of pts had hormone receptor + BC. Pts received 3 prior chemo-regimens (0-7). The current PR rate in pts with at least 4 cycles of follow-up is 2/12 (17%) for BRCA1 and 3/13 (23%) for BRCA2. Three pts withdrew from treatment during the first cycle of vel due to grade 2 seizure (1), grade 3 thrombocytopenia (PLT [1]), grade 2 PLT and neutropenia (1). Time to failure (TTF) on vel is 2.0 months (0-10.5+), and 5.1 months (0.9-10.3+) for the two cohorts (BRCA1, BRCA2, respectively). Twenty pts are still on vel (8 BRCA1, 12 BRCA2). Of the 10 pts to proceed to vel + carb so far, 1 PR in a BRCA1 pt was observed. **Conclusions:** Vel is active when given at 400 mg BID daily. Further trials are indicated to assess its benefit whether in combination or as a single agent in both BRCA1 and BRCA2-associated BC. Clinical trial information: NCT01149083.

**1022 Poster Highlights Session (Board #15), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Efficacy of neoadjuvant carboplatin/docetaxel chemotherapy in sporadic and *BRCA*-associated triple-negative breast cancer (TNBC).** *Presenting Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS*

**Background:** Recent studies demonstrate that addition of carboplatin to anthracycline/taxane chemotherapy improves pathological complete response (pCR) in TNBC. In vitro data exhibits synergy between platinum compunds and taxanes in TNBC. Efficacy of anthracycline-devoid neoadjuvant platinum/taxane combination in sporadic and *BRCA*-associated TNBC is not well known. Aim: To evaluate the efficacy of neoadjuvant Carboplatin/Docetaxel in sporadic and *BRCA*-associated TNBC utilizing clinical and *BRCA* mutation data from a prospective registry. **Methods:** 205 patients with stage I (T>1cm) II or III TNBC were enrolled in a prospective multisite registry between 2011-2013, out of which 42 patients received neoadjuvant chemotherapy regimen of Carboplatin AUC 6 + Docetaxel 75 mg/m$^2$every 21 D (4-6 cycles). Following neoadjuvant therapy, all patients underwent breast surgery. pCR (no evidence of invasive tumor in the breast and axilla) and Residual Cancer Burden(RCB) was evaluated. RCB of 0 or1 was designated as near pCR (pCRn). All patients underwent comprehensive BRACAnalysis (Myriad). **Results:** For the 42 eligible patients, median age was 51 years (range 27-80), 19%: African-American and 57%: postmenopausal. Median tumor size was 3 cm and 33% LN positive. 90% of patients received 6 and 10% received 4 cycles of chemotherapy. The overall pCR and pCRn rates were 62% and 74%, respectively. 33% (14/42) of patients carried deleterious *BRCA* mutation (11 *BRCA1*, 3 *BRCA2*). For *BRCA*mutation carriers, both pCR and pCRn rates were 86%(12/14). For sporadic TNBC (N=28), pCR and pCRn rates were 50% and 68%, respectively. Tumor size, LN status, age and number of cycles of chemotherapy did not impact pCR rate. pCR was higher in BRCA mutation carriers compared to sporadic TNBC (p=0.04). **Conclusions:** We report very encouraging near pathologic response in both sporadic (68%) and *BRCA*-associated (86%)TNBC with a neoadjuvant platinum/taxane chemotherapy regimen. This Carboplatin/Docetaxel combination yielded pCR rates similar to observed rates with A/C plus Carboplatin however, is devoid of potential cardiac and secondary leukemia side effects and should be explored further in randomized studies.

**1023 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Does pathologic complete response predict for outcome in *BRCA* mutation carriers with triple-negative breast cancer?** *Presenting Author: Shani Paluch-Shimon, The Breast Cancer Unit, Institute of Oncology, Sheba Medical Center, Modiin, Israel*

**Background:** Pathological complete response (pCR) has been demonstrated to serve as a surrogate for outcome in patients receiving neo-adjuvant systemic therapy (NAT) for triple negative (TN) breast cancer (BC). To date no data has been published to establish if this is also true for *BRCA1/BRCA2*mutation carriers with TNBC. **Methods:** From a prospective NAT database of 588 BC cases, 80 TN cases who had undergone BRCA genotyping were identified. All received dose-dense chemotherapy with an anthracycline and a taxane. pCR was defined as absence of invasive disease in breast and lymph nodes. A logistic regression model was fitted to examine association between BRCA1/2 status and pCR. Survival outcomes were evaluated using Kaplan-Meier method, differences between study groups calculated by log-rank test. **Results:** 37 BRCA1/2 carriers and 43 non-carriers were identified. The BRCA1/2 carriers had superior pCR compare with non-carriers (61% vs. 39% , p=0.007). Despite the higher pCR, there was no difference in Relapse Free Survival (RFS) between the BRCA1/2 carriers and non-carriers. Amongst those that achieved pCR there was superior RFS for non-carriers compared with BRCA1/2 carriers (Log-rank p=0.043). Conversely, amongst those that did not achieve a pCR, the RFS was superior amongst BRCA1/2 carriers (Log-rank p=0.024). No difference in RFS were noted amongst BRCA1/2 carriers with or without pCR (Log-rank p=0.712), while in the non-carrier group RFS was superior for those achieving pCR compared with those not displaying a pCR (Log-rank p<0.0001). Preliminary translational data demonstrate ALDH1 over-expression in the BRCA1/2 carriers pre-treatment biopsies but not in the non-carriers. **Conclusions:** BRCA1/2 associated TN BC differs to non-BRCA TN in chemo-sensitivity as demonstrated by superior pCR, We demonstrate here for the first time that pCR in BRCA1/2 carriers, is not a surrogate for RFS as opposed to pCR in non-BRCA TN BC. The chemo-sensitivity in BRCA associated TNBC may increase the mutational spectrum in these tumors due to predisposition to DNA breaks, resulting in selection of more aggressive, metastases prone clones, in addition, BRCA1/2 tumors may be enriched for breast cancer stem cells.

**1024 Poster Highlights Session (Board #17), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Triple-negative breast cancer subtypes and pathologic complete-response rate to neoadjuvant chemotherapy: Results from the GEICAM/2006-2003 study.** *Presenting Author: Angela Santonja, Instituto de Investigacion Biomedica de Malaga, IBIMA, Malaga, Spain*

**Background:** Triple negative breast cancer (TNBC) is a heterogeneous disease with distinct molecular subtypes that differentially respond to chemotherapy (CHT) and targeted agents. In a recent study, Lehmann et al. (JCI 2011) identified six molecular subtypes of TNBC, characterized on the basis of gene ontologies and differential gene expression. However, their clinical utility remains unclear. We aimed to explore the clinical relevance of these molecular subtypes in TNBC determining differences in response to neoadjuvant chemotherapy in a randomized phase II trial, the GEICAM/2006-03. **Methods:** The GEICAM/ 2006-03 study evaluated a regimen of anthracyclines and taxanes +/- carboplatin in the neoadjuvant treatment of patients (pts) with TNBC (Alba, BCRT 2012). We determined TNBC molecular subtypes in FFPE pre-treatment tumor biopsies from pts recruited in this study. Gene expression profile was determined using HTA 2.0 arrays (Illumina). Subtypes were identified with the online tool TNBC type (http://cbc.mc.vanderbilt.edu/tnbc). Finally, we explored the association of the Lehmann subtypes with the pathological complete response (pCR) in breast and axilla (Miller and Payne criteria) using Fisher's exact test. **Results:** From the 94 enrolled pts, we processed 46 pre-treatment tumor samples in a central lab and isolated high-quality RNA for microarray analysis in 39 (42%); 7 samples are still pending to be analyzed. Tumors were classified as follows: 4 BL1, 2 BL2, 8 IM, 5 LAR, 3 M, 3 ML with 7 pts that couldn't be assigned to any subtype and were not included in this analysis. Three (75%) of the BL1 subtype pts achieved a pCR (p-value=0.075). In contrast, IM and LAR achieved the lowest pCR rates (12% and 20%, respectively). In the carboplatin-treated patients, 100% of BL1 patients showed pCR (p-value=0.033) in contrast with none of the IM and LAR pts. **Conclusions:** Our preliminary findings suggest that TNBC subtypes can predict tumor response to neoadjuvant CHT, supporting their potential clinical utility in diagnosis, treatment selection and drug development, bringing TNBC pts a step closer to personalized medicine.

**1025 Poster Highlights Session (Board #18), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**In silico analysis of a multifactorial consensus signature (ConSig) for predicting response to anthracycline (A)-based neoadjuvant chemotherapy (NAC) in triple-negative breast cancer (TNBC) patients (pts).** *Presenting Author: Natalie Heather Turner, Sandro Pitigliani Medical Oncology Department, Hospital of Prato, Istituto Toscano Tumori, Prato, Italy*

**Background**: There are no validated predictive biomarkers for A response. While A is effective therapy in some, many breast cancer pts do not benefit. Due to the complex processes required for A-induced cytotoxicity, a prospectively defined multifactorial consig may improve prediction of A sensitivity in TNBC pts, a group whose only standard systemic treatment option is chemotherapy. **Methods**: ConSigs were constructed using various combinations of components (genes/gene signatures) that were based on five steps required for A function: drug penetration, nuclear topoisomerase IIα (topoIIα) protein location, increased topoIIα mRNA expression, induction of apoptosis, and immune response. The performance of each ConSig to predict pathologic complete response (pCR) in TNBC pts treated with A without taxane (T) NAC was assessed by in silico analyses of publicly available gene expression data. Correlation between ConSig expression and pCR was evaluated using ROC analyses. To assess specificity for A, ConSigs were reassessed in pts receiving A + T NAC. **Results**: 147 TNBC pts treated with A without T and with gene expression data derived using the same platform (Affymetrix HG-U133) were identified, 28 with pCR. Single components significantly correlated with pCR were drug penetration measured by HIF1α signature (AUC 0.64, p=0.005), nuclear topoIIα location measured by LAPT4MB mRNA (AUC 0.61, p=0.03) and immune response measured by STAT1 signature (AUC 0.65, p=0.03). The most powerful combination for prediction of A response was *ConSig1*, which included these three components plus topoIIα mRNA. It performed better than single components, showing higher correlation with pCR (AUC 0.71, $p=5.3x10^{-6}$), high negative value (NPV) value and high odds ratio (OR) for no pCR (see Table). *ConSig1* was A-specific with no correlation with response seen in pts treated with A + T. **Conclusions**: With further validation, *ConSig1* may allow improved selection of TNBC pts for A treatment.

| | Performance of *ConSig1* | | |
|---|---|---|---|
| **Cohort** | **NPV (95% CI)** | **OR** | **P value** |
| **A (n=147)** | 93% (84%-98%) | 5.53 | 0.001 |
| **A + T (n=301)** | 67% (58%-75%) | 1.04 | 0.85 |

**1026 Poster Highlights Session (Board #19), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Biomarker panel (TheraPrint) analyzed as a predictor of response to neoadjuvant chemotherapy in patients with locally advanced breast cancer.** *Presenting Author: Peter D. Beitsch, Dallas Surgical Group, Dallas, TX*

**Background:** TheraPrint for breast cancer patients is a novel genomic assay that provides information on clinically relevant markers for likely sensitivity and resistance to therapies. The aim of the current study was to correlate chemosensitivity in a neo-adjuvant trial to TheraPrint results. **Methods:** The mRNA level of 55 genes was measured in formalin fixed paraffin embedded (FFPE) tumor samples submitted from 42 institutes in the US as part of the NBRST trial and compared to a large reference population (TheraPrint). The prospective Neo-adjuvant Breast Registry Symphony Trial (NBRST) study includes informed consenting women aged 18–90 with histologically proven breast cancer, who are scheduled to start neo-adjuvant chemo- or endocrine therapy. The correlation of chemosensitivity to TheraPrint results is measured by pathologic Complete Response (pCR) defined as the absence of invasive carcinoma in both the breast and axilla at microscopic examination of the resected specimen, regardless of the presence of carcinoma in-situ. Differentially expressed genes were identified by Analysis of Variance (ANOVA) with corrected p-value (FDR) <0.05. **Results:** 204 Patients (T1-4 N0-3) received neo-adjuvant chemotherapy and had definitive surgery. The overall pCR rate was 24%. Listed in the table are those genes that were significantly differentially expressed between patients with a pCR versus those with residual disease (p>0.05, Fold change >1.5). **Conclusions:** This study has identified 13 genes with statistically significant correlation between expression and response to neo-adjuvant chemotherapy indicating that TheraPrint can give indication for response prediction to chemotherapy. Clinical trial information: NCT014799101.

This list of genes is significantly associated with PTEN activation, ER inhibition and estrogen-related signaling pathways (Ingenuity Pathway Analysis).

**1027 Poster Highlights Session (Board #20), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Quantitative assessment of CD3, CD8, and CD20 in tumor-infiltrating lymphocytes and predictive value for response to neoadjuvant chemotherapy in breast cancer.** *Presenting Author: Jason R. Brown, Yale School of Medicine, New Haven, CT*

**Background:** Tumor infiltrating lymphocytes (TILs) have been associated with response to neoadjuvant therapy. However, typical analysis of TILs is subjective, semi-quantitative and does not differentiate between subpopulations. Here we describe a quantitative objective method for measurement of TIL subsets, including CD3, 8, and 20 and assess their predictive value for therapeutic response. **Methods:** We used a quantitative immunofluorescence (QIF) assay to measure stromal expression of CD3 (T cell), CD8 (cytotoxic T cell), and CD20 (B cell) on a single slide using AQUA technology. This method was validated by comparison to flow cytometry on fresh tonsil tissue. To assess the predictive value of TIL markers, we used a cohort of 105 consecutive (2002 - 2010) invasive breast cancer patients that received neoadjuvant therapy and had obtainable pre-surgical biopsy tissue. Percentage TIL infiltrate in the tumor stroma was estimated by two pathologists on H and E stained slides of these biopsies. Images from each specimen were collected in 4 to 118 fields of view, and we obtained summary scores for CD3, 8 and 20. **Results:** In tonsil specimens, lymphocyte percentage and proportions of CD3, CD8, and CD20 positive lymphocytes were similar between flow cytometry and QIF. Pathologist TIL count (H&E TIL) was predictive of pCR ($p = 0.0171$, OR: 6.458) despite fair interobserver reproducibility ($k = 0.390$). AQUA scores for CD3 ($p = 0.0193$, OR: 1.960), CD8 ($p = 0.0225$, OR: 2.021), and CD20 ($p = 0.0033$, OR: 1.868) within the stroma predicted pathologic complete response (pCR) in univariate analysis. CD3 ($p = 0.0369$, OR: 2.504) and CD20 ($p = 0.0062$, OR: 3.371) also predicted pCR in multivariate analysis with age, size, nuclear grade, nodal status, and ER, PR, and HER2 status, but only CD20 was significant with Ki-67 AQUA score added ($p = 0.0341$, OR: 5.532). CD20 was more sensitive and specific than CD3 and CD8 and equivalent to H&E TILs (AUC: 0.690 vs. 0.655 vs. 0.629 vs. 0.692). **Conclusions:** We have developed and validated an objective quantitative assay for measuring TILs. H&E TIL, CD3, CD8, and CD20 all predict therapeutic response, and CD20 is independently predictive including all variables.

**1028 Poster Highlights Session (Board #21), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Next-generation sequencing (NGS) in relapsed/refractory triple-negative breast cancer (TNBC) in Israel.** *Presenting Author: Noa Ben-Baruch, Department of Oncology, Kaplan Medical Center, Rehovot, Israel*

**Background:** Relapsed/metastatic TNBC is an aggressive form of the disease that typically responds initially to chemotherapy, but eventually progresses in the majority of patients (pts). We hypothesized that a comprehensive NGS assay (FoundationOne) could identify novel therapy targets not routinely interrogated in TNBC pts. **Methods:** Hybridization capture of 3,769 exons from 236 cancer-related genes and 47 introns of 19 genes commonly rearranged in cancer was applied to ≥ 50 ng of DNA extracted from 26 TNBC FFPE specimens and sequenced to high, uniform coverage. Genomic alterations (GA) including base substitutions, small indels, copy number alterations, and select gene fusions, were characterized and reported for each pt sample. Actionable GAs were defined as those identifying anti-cancer targeted therapies on the market or in registered clinical trials. **Results:** The 26 TNBC pts had a mean age of 49.6 yrs (range, 28-74). All 26 tumors were ER-/PR-/HER2- on routine slide-based testing. Samples used for NGS originated from breast (42%), lymph nodes and axilla (23%), chest wall and muscle (12%), skin (8%) and serous effusion (4%). All 26 cases harbored ≥1 GA, with a total of 113 GAs and a mean of 4.35 GAs per tumor. The most frequent currently unactionable GAs were *TP53* (21, 81%) and *MYC* (8, 31%). Twenty two cases (85%) harbored ≥1 actionable GA; mean, 2.73 actionable GAs per tumor. The most common actionable GAs were *PIK3CA* (7, 27%), *MCL1* (4,15%), *PTEN* (3,12%), *BRCA1* (3,12%), and *BRCA2* (2,8%). One pt (4%) had *ALK* amplification. Activating *ERBB2* point mutations not detectable by IHC/FISH, potentially targetable with anti-HER2 therapies were identified in 2 pts; *EGFR* amplifications, potentially treatable with anti-EGFR TKI were identified in 2 pts (1 pt had both of these GAs). One pt with *ERBB2*mutation received neratinib monotherapy and one pt with EGFR amplification received capecitabine plus cetuximab; both had partial response lasting 8+ months. **Conclusions:** For TNBC, comprehensive genomic profiling can identify a significant number of actionable GAs not currently tested for in routine practice. Results point to the potential of MTOR, anti-HER2, and anti-EGFR targeted therapies for a significant subset of pts.

**1029 Poster Highlights Session (Board #22), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Genomic and protein alterations in 126 triple-negative (TN) metaplastic breast cancers.** *Presenting Author: Sherri Z. Millis, Caris Life Sciences, Phoenix, AZ*

**Background:** Metaplastic breast cancer (MpBC) is a rare subtype (less than 1% of all breast cancers), is generally ER, PR and HER2-negative (TN), demonstrates a claudin-low gene expression profile, and is poorly responsive to cytotoxic therapy. Little is known about the genomic alterations (GA) in MpBC nor about overexpressed proteins that may be amenable to targeted therapy. **Methods:** Of 2000 TN breast cancers (TNBC) referred to Caris Life Sciences since 2009 from 50 states and 59 countries, 126 cases were TN MpBCs based on local pathology evaluation. Specific testing was performed per physician request and included sequencing (Sanger or next generation sequencing [NGS]), protein expression (immunohistochemistry [IHC]), and/or gene amplification (CISH or FISH). **Results:** The Table shows the percent gene mutations, amplifications, and IHC findings for biomarkers that were different between TNBC and MpBCs, as a percentage of total patients tested. **Conclusions:** Comparison of the genomic and protein expression profiles highlights some differences between the two cancers-.Multiplatform profiling shows that most MpBCs have gene alterations in the PI3K pathway. The low RRM1 expression rate suggests possible gemcitabine effectiveness. Other potential therapeutically targetable gene alterations are present at low incidence in this large series of MpBCs.

**Uncovering the dynamic relationship between Ki-67 and mitotic indices in breast cancer.** *Presenting Author: Guilherme Cantuaria, Northside Hospital Cancer Institute, Atlanta, GA*

**Background:** The generation of intra-tumor genetic diversity and metastatic clones relies on frequent passage of cancer cells through error-prone mitoses. Thus, we postulate that low-grade tumors undergo rapid mitotic turnover to drive clonal heterogeneity, while high-grade tumors focus more on their "metastasis program". Metastasis, a multistep dissemination process, requires a phenotypic switch from cell proliferation to migration, since these are mutually-exclusive cellular states. Currently in breast cancer diagnostic practice, the percentage of Ki67-positive "proliferating" cells (Ki67 Index, KI) and number of mitoses/10 high power fields (mitotic index, MI) are evaluated independently and their relationship remains elusive. Here we propose a "mitotic frequency" index (MFI) that rationally combines KI and MI, and provides better prediction of metastatic risk. **Methods:** The relationship between KI and MI was analyzed retrospectively in pathology reports from 2,500 breast carcinoma cases at Northside Hospital, Atlanta, GA. In addition, for an accurate assessment of mitotic frequencies, we measured MI and KI on the same scale and within the same field by optimizing a four-color immunofluorescence staining protocol to co-immunostain paraffin-embedded breast tumor tissues (n=100) for α-tubulin, Ki67, and phospho-histone H3 (p-H3, to identify all mitotic phases including prophase), and stain DNA with Hoechst. **Results:** Retrospective data analysis of 2500 cases show that although KI and MI increased with tumor grade, the grade-wise increase in MI was much slower; consequently, the Ki67-adjusted mitotic scores decreased across grades. In effect, we found a striking grade-wise decrease in frequency of mitoses amongst Ki67-positive cells. Immunofluorescence data (n=100) found lower mitotic frequencies in grade-matched patients with metastatic disease as compared to those without metastasis. **Conclusions:** The KI-MI relationship varies dynamically during tumor progression, with a lower MFI representing a shift in the tumor's agenda from mitosis to metastasis, which indicates elevated metastatic risk. The integrated MFI may thus reveal a new layer of valuable risk-predictive information.

### 1031 Poster Highlights Session (Board #24), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM

**Evaluation of the adjuvant radiation treatment-effect heterogeneity using genomic signature for locoregional relapse and long-term outcome.** *Presenting Author: Maggie Chon U Cheang, Clinical Trials and Statistics Unit at the The Institute of Cancer Research, Surrey, United Kingdom*

**Background:** In a retrospective analysis of two similar randomized radiation therapy (RT) trials (i.e. British Columbia (BC) and DBCG 82b), we reported significant survival benefits for post-mastectomy RT in Luminal A. Here we examined the predictive value of additional genomic profiles in the BC trial for loco-regional recurrences (LRR) and breast cancer survival (BCSS) in node-positive, pre-menopausal breast cancer patients randomized to adjuvant chemoradiation or chemotherapy. **Methods:** In the BC trial, 318 patients received adjuvant cyclophosphamide, methotrexate, fluorouracil and were randomized to with or without postmastectomy RT. From 145 formalin fixed paraffin embedded tissues available, expression profiles of 66 genes were done with the Nanostring nCounter. Treatment effects on LRR and BCSS events were examined by subpopulation treatment effect pattern plots. The research-based PAM50 proliferation score, Risk of Recurrence score (ROR-T and ROR-PT), and genes related to basal-like (ie. 13-genes VEGF-signature (*VEGF*-s), *RAD17, RAD50* and *RB1)* were calculated. **Results:** Overall, patients in the RT arm (n= 69) were significantly associated with better LRR and BCSS than the non-RT-treated arm (n = 76). No significant treatment-effect heterogeneity was detected for *VEGF*-s, *RAD17* and *RAD50* score. Patients with lower *RB1* mRNA level, and higher proliferation score, had better LRR survival when they received RT (Table). The patterns of treatment efficacy on LRR and BCSS were the most significant for the varying levels of risk score (ROR-T, -PT), particularly for patients with higher scores (Table) who showed the poorest prognosis, but whom may still benefit from adjuvant RT. **Conclusions:** *RB1*, proliferation score and ROR-T predicted LRR and BCSS benefit for adjuvant RT. The clinical utility of these biomarkers as predictor requires confirmation in a second independent trial.

**STEPP analysis of the treatment effect of adjuvant RT at 10-years.**

### 1032 Poster Highlights Session (Board #25), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM

**Patterns of care for omission of radiation therapy for elderly women with early-stage breast cancer receiving hormonal therapy.** *Presenting Author: Peyman Kabolizadeh, Department of Radiation Oncology, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background**: For well-selected elderly women who undergo segmental mastectomy for early-stage, ER+ breast cancer, hormonal therapy alone is emerging as an acceptable adjuvant therapy option since the initial publication of CALGB 9343 study in 2004 and update in 2013. The rate of adoption of adjuvant hormonal therapy alone in lieu of radiation therapy (RT) and its associated patterns of care is the subject of this study. **Methods**: The National Cancer Data Base (NCDB) is a oncology outcomes database, which captures 70% of all newly diagnosed cancer patients in the US. We utilized NCDB to identify women aged ³70 diagnosed with T1N0/T1Nx invasive breast cancer who underwent segmental mastectomy from 1998-2011. Only those who received hormonal therapy were included in this analysis. Univariate and multivariable exploratory analyses were performed. **Results**: Of the 182,115 patients who met inclusion criteria, 97,530 (53.6%) patients underwent hormonal therapy and were included in the analysis. The rate of utilization of RT in this subset decreased with time from 84.9% in 1998 to 75.1% in 2011 ($p<0.001$). Academic sites decreased RT utilization most rapidly over this time period where in 2011 the rate of RT utilization was 70.7% as compared to 75.0% and 77.0% in community and comprehensive community facilities respectively ($p<0.001$). From 2003 to 2005 (prior to and following the initial publication of CALGB 9343), RT utilization rate decreased from 88.2% to 78.4%. Multivariable analysis revealed that the factors associated with decreased use of RT include (in order of association): older age, later year of diagnosis, lack of insurance, low grade histology, treatment at academic site, race, rural location, greater comorbidity score, lower median income, and distance from center. **Conclusions**: This study comprehensively assesses the patterns of care associated with the omission of radiation therapy in elderly women with early-stage breast cancer who only received adjuvant hormonal therapy. Since the publication of major clinical trials, this strategy has been increasingly adopted. The strongest predictors of the use of this strategy included advanced patient age at presentation and low-grade disease.

### 1033 Poster Highlights Session (Board #26), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM

**Late axillary recurrence after negative SLNB.** *Presenting Author: Cindy Brown Matsen, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** SLNB is the standard axillary evaluation method for clinically node-negative patients with invasive breast cancer. While axillary recurrence (AR) in the early years after negative SLNB is <2%, studies with longer (>8 yrs) follow-up on large patient numbers are lacking. With concern that current multimodality therapy may delay time to AR, we reviewed long-term SLNB patient outcomes. **Methods:** We identified patients with invasive cancer from a prospective, single-institution database who had a negative SLNB without additional axillary surgery from 1/97-12/00. Cancer, demographic, and treatment data were obtained for all patients. Primary outcome was AR. Overall survival (OS) and distant disease-free survival (DDFS) after AR were secondary endpoints. **Results:** 1529 eligible patients were identified. See table for patient and tumor characteristics. At 10.8 yrs (0-16) median follow-up, overall incidence of AR as a first event was low, n= 13. Median OS after AR was 4.6 yrs and median DDFS after AR was 3.8 yrs. The cumulative incidence of AR was 1.0% (CI 0.5-1.6) overall; cumulative incidence of 0.6% (CI 0.2-0.9) in the first 5 years, 0.4% years 5-10. Late AR (>5 yrs) occurred in 5 patients: 4 ER+, 1 HER2+. In comparison, in a group of contemporaneous SLNB-positive patients undergoing axillary dissection (n=902), overall cumulative incidence of AR was 0.8% (CI 0.2-1.5) at over 10 yrs follow-up. On univariate analysis of AR in SLNB-negative patients, high nuclear grade was the only significant predictor of AR (p=0.01). **Conclusions:** Late AR was an infrequent event after negative SLNB alone emphasizing its long-term safety as a staging procedure. AR after SLNB, like AR after ALND, portends a poor prognosis.

### 1034 General Poster Session (Board #127), Mon, 8:00 AM-11:45 AM

**Predictors of surgery types after neoadjuvant therapy for advanced stage breast cancer.** *Presenting Author: Jamila Alazhri, University of Miami Hospital, Miami, FL*

**Background:** Despite the established guidelines for breast cancer treatment, there is still variability in surgical treatment after neoadjuvant therapy among women with large breast tumors, leading to variability in the outcome. Our objective was to identify possible predictors of the type of surgical treatment; mastectomy versus breast conserving surgery (BCS) in women with T3/T4 breast cancer who received neoadjuvant therapy. **Methods:** Population-based Florida Cancer Registry and U.S. Census from 1996 to 2009 were linked to select women diagnosed with T3/T4 breast cancer who then received neoadjuvant therapy followed by BCS or mastectomy. A multivariable logistic regression model was used to identify significant predictors of type of surgery by including sociodemographic characteristics (race, ethnicity, socioeconomic status, age, marital status, urban/rural residency), tumor characteristics (ER/PR status, histology, grade, SEER stage, regional nodes positivity), treatment facilities (hospital volume, teaching/non-teaching), comorbidities and type of neoadjuvant therapy. Adjusted odds ratios (OR) and 95% confidence intervals (95%CI) were calculated. Type-I error rate was set to 5%. Statistical analyses were performed with SAS v9.3. **Results:** Out of 1,056 patients treated with neoadjuvant therapy for T3/T4 breast cancer, 107 (10%) had BCS and 949 (90%) had mastectomy. After adjusting for the aforementioned characteristics, Hispanic patients were more likely to have mastectomy (OR=3.50; 95%CI:1.38-8.84; p=0.008) than BCS. Compared to localized SEER stage, regional stage with direct extension (OR=3.24; 95%CI:1.60-6.54; p=0.001), regional direct extension and nodes (OR=4.35; 95%CI:1.72-11.03; p=0.002) and distant stage (OR=4.44; 95%CI:1.81-10.88; p=0.001) were significantly more likely to have mastectomy than BCS. Patients who received hormonal neoadjuvant therapy only (OR=0.29; 95%CI:0.12-0.68; p=0.004) were less likely to undergo mastectomy compared to patients receiving both chemo/hormonal therapy. **Conclusions:** Our study suggests that Hispanic ethnicity, advanced SEER stage, and type of neoadjuvant therapy are significant predictors of mastectomy after neoadjuvant therapy.

**1035 General Poster Session (Board #128), Mon, 8:00 AM-11:45 AM**

**Final results of a phase 2 study of ramucirumab (RAM) plus eribulin (E) versus E in advanced metastatic breast cancer (MBC).** *Presenting Author: Denise A. Yardley, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** RAM, a recombinant human IgG1 monoclonal antibody, targets VEGFR-2 and blocks the interaction of VEGF ligands and VEGFR-2. E is a microtubule inhibitor active in MBC. The primary goal of this multicenter US study was to identify if the addition of RAM to E would increase progression-free survival (PFS) in comparison to E alone as third- to fifth-line therapy in patients (pts) with MBC. **Methods:** Pts with locally recurrent or MBC and 2-4 prior chemotherapy regimens in the advanced setting were randomized 1:1 to receive RAM+E or E (E 1.4 mg/m$^2$ days 1 and 8; RAM 10 mg/kg day 1; q21 days). Stratifications included prior antiangiogenic therapy and triple negative status. Prior anthracycline and taxane treatment, normal LVEF, and ECOG PS 0-1 were required. Treated, stable brain metastases were allowed. **Results:** 141 pts with a median age of 56 yrs were in the ITT population (RAM+E, n=71; E, n=70). Median PFS was 4.4 mo in RAM+E and 4.1 mo in E (HR=0.8: 95% CI 0.6-1.2; p=0.4) with a median overall survival (OS) of 13.5 mo and 11.5 mo in the RAM+E and E arm (HR=0.8: 95%CI 0.5-1.3; p=0.4), respectively. Objective response rate was 20% for RAM+E and 24% for E. Median duration of response in RAM+E was 5.5 mo and 3.0 mo in E. Relative mean dose intensity was 95.3% for RAM and 80.7% for E in RAM+E, and 79.0% in E. All-cause treatment emergent adverse events (TEAEs) ≥20% and grade 3 ≥5% are shown (Table). Any grade TEAEs of special interest in RAM+E vs. E included bleeding (18.8% vs. 4.6%), hypertension (HTN) (13% vs. 1.5%), and congestive heart failure (1.4% vs. 0%). RAM+E bleeding included 7 events of epistaxis and 1 grade 3 GI hemorrhage. 3 RAM+E pts and 1 E pt had grade 3 HTN. **Conclusions:** Addition of RAM to E did not improve PFS. Higher rates of fatigue, headache, hypertension, diarrhea, and bleeding were observed in the RAM+E arm. Clinical trial information: NCT01427933.

| | RAM+E (n=69) | | E (n=65) | |

**1036 General Poster Session (Board #129), Mon, 8:00 AM-11:45 AM**

**Prophylactic ciprofloxacin to prevent febrile neutropenia in adjuvant breast cancer patients receiving docetaxel (nonanthracycline) regimens.** *Presenting Author: Meena Okera, Adelaide Cancer Centre, Adelaide, Australia*

**Background:** Febrile neutropenia (FN) is a serious adverse effect of adjuvant chemotherapy for breast cancer. Primary GCSF prophylaxis is recommended for patients at > 20% risk of FN, but is not funded in Australia with docetaxel (non-anthracycline) regimens in adjuvant breast cancer patients (TC and TCH), despite literature reporting rates of FN of up to 50%. Prophylactic antibiotics can prevent FN, but are not routinely incorporated into chemotherapy guidelines for TC and TCH regimens. This retrospective study evaluates the usage and benefit of primary ciprofloxacin prophylaxis, in patients receiving TC and TCH chemotherapy. **Methods:** Retrospective review of breast cancer patients receiving adjuvant TC or TCH chemotherapy between 1.1.11 and 30.6.13 (single centre). Logistic regression analysis used to model the contribution of regimen, primary GCSF use (pegfilgrastim), and prophylactic antibiotic use on presence of FN. **Results:** 131 eligible patients, mean age 55 years (28-77). 96/131 (73%) received TC chemotherapy, 35/131 (27%) received TCH chemotherapy. 97/131 (74%) received primary ciprofloxacin prophylaxis from cycle 1. Primary ciprofloxacin prophylaxis was more frequently prescribed with TC rather than TCH chemotherapy (93% vs 26%). 26 admissions occurred with FN (24 patients). 21/26 admissions for FN occurred after cycle 1 or 2 of chemotherapy. Primary ciprofloxacin prophylaxis significantly reduced the risk of FN (12% vs 41%) and on logistic regression analysis, was the only predictive factor reducing risk of FN (p=0.019). There was no interaction between use of antibiotics and growth factors. Further evaluation of interactions was limited by small numbers. **Conclusions:** There is a high rate of FN amongst breast cancer patients receiving TC and TCH chemotherapy. Primary ciprofloxacin prophylaxis significantly decreases the risk of FN. Primary ciprofloxacin prophylaxis should be considered for patients receiving TC and TCH chemotherapy, where primary GCSF prophylaxis is unavailable.

**Admissions of FN.**

| | Number (%) patients | Number (%) FN admissions |
|---|---|---|
| Ciprofloxacin prophylaxis | 97/131 (74%) | 12/97 (12%) |
| No ciprofloxacin prophylaxis | 34/131 (26%) | 14/34 (41%) |

**1037 General Poster Session (Board #130), Mon, 8:00 AM-11:45 AM**

**Outcomes of 3-weekly doxorubicin and cyclophosphamide followed by paclitaxel (AC/T) in a randomized trial (RCT) compared to a case-control matched British Columbia (BC) breast cancer population.** *Presenting Author: Sheridan Marie Wilson, BC Cancer Agency, Vancouver, BC, Canada*

**Background:** NCIC CTG MA.21 was a North American RCT of 3 adjuvant chemotherapies (adjCT), of which one was 3-weekly AC/T. We compared Relapse Free Survival (RFS) for this standardised adjCT given in MA.21 to that in a general population from a BC database, using a matched case-control design. **Methods:** Matching was based on age +/- 3 years (y) and MA.21 stratification factors: number of positive nodes [NP], surgery type, and estrogen receptor (ER). Patients (pts) who received > 1 cycle of AC/T were included. RFS was defined as time from randomisation (per protocol, AC/T started within 5 days) to recurrence for MA.21, and from first AC/T to recurrence for BC. A sensitivity analysis using HER2 negative (HER2-) pts was done, as testing and trastuzumab (TZ) use changed over time. RFS was estimated with Cox survivor plots, adjusting for factors significant in multivariate Cox step-wise forward regression. **Results:** 473 of 671 BC pts were matched to 473 of 696 MA.21 pts. Median follow up was 8 y and median time from surgery to AC/T was 48 days for both. After matching 52% were ER +; 37% node negative (NN); 62% of MA.21 and 56% of BC cases were HER2-. 76% of NN BC cases were grade 3; grade was unavailable for MA.21. Unadjusted 5 y RFS was 85% (95% confidence interval [CI] 81, 88) for BC and 82% (CI 78, 85) for MA.21. For HER2-only, 5y RFS was 85% (CI 80, 89) for BC and 79% (74, 83) for MA.21 pts. The Table shows multivariable analysis (ER and age were not significant). The HR in HER2- only cases was 0.68 (CI 0.47, 0.98, p = 0.04) for BC vs MA.21 pts. **Conclusions:** BC pts had superior adjusted RFS compared with matched pts who received AC/T in a RCT. We were unable to compare adherence to ET and ethnic distribution, which may explain some of the disparity. Also, BC has long had a low threshold for offering radiation for NP. It is reassuring that RCTs do not appear to overestimate adjCT RFS benefits in the general breast cancer population.

| Variable | Hazard ratio (Hz) | 95% CI | P |
|---|---|---|---|
| BC vs MA.21 | 0.65 | 0.48, 0.89 | 0.008 |
| Endocrine therapy (ET) | 0.44 | 0.33, 0.60 | <0.001 |
| NP (NN as reference) | | | |
| 1-3 NP | 1.24 | 0.86, 1.78 | 0.252 |
| 4-10 NP | 2.46 | 1.65, 3.66 | <0.001 |
| >10 NP | 7.26 | 4.33, 12.19 | <0.001 |
| TZ use | 0.53 | 0.28, 0.991 | 0.047 |

**1038 General Poster Session (Board #131), Mon, 8:00 AM-11:45 AM**

**ABCB1 polymorphism as a prognostic factor in breast cancer patients with neoadjuvant chemotherapy.** *Presenting Author: Hee Jun Kim, Chung-Ang University Hospital, Seoul, South Korea*

**Background:** Expression of the adenosine triphosphate-binding cassette B1(ABCB1) transporter and P-glycoprotein are associated with resistance to anticancer drugs. The purpose of this thesis was to investigate the role of single nucleotide polymorphism (SNP) in the ABCB1 and CYP3A genes in breast cancer patients who were treated with neoadjuvant docetaxel and doxorubicin chemotherapy. **Methods:** Stage II or III breast cancer patients were treated with 3 cycles of neoadjuvant, after which the patients received curative surgery and adjuvant chemotherapy with the same regimen. The polymorphisms of ABCB1 (C3435T, G2677T/A, and C1236T) and CYP3A were genotyped. The correlation of genetic polymorphisms of ABCB1, CYP3A, and clinical outcomes was analyzed. **Results:** Among the 216 patients, *ABCB1 3435*TT genotype had a longer OS than CT/TT. With univariate analysis, good PS, invasive ductal carcinoma, initial operable stage, ER-positivity, non-triple negative phenotype, breast conserving surgery and the TT genotype of C3435T were associated with a lower risk of death. Multivariate analyses demonstrated that good PS, invasive ductal carcinoma, non-triple negative phenotype and initial operable stage were significantly associated with the OS. *ABCB1 3435*TT genotype had a higher AUC than CC/CT genotype for docetaxel ($p$=0.031). These higher AUCs in the C3435TT genotype was associated with increased toxicities of neutropenia ($p$=0.037) and diarrhea ($p$=0.017). **Conclusions:** This study showed that the genetic polymorphism of ABCB1 C3435T might be associated with a longer OS. Our results also suggest that the prediction of docetaxel toxicity might be possible for C3435T polymorphism. Larger prospective studies as well as functional studies in human subjects are warranted.

**1039 General Poster Session (Board #132), Mon, 8:00 AM-11:45 AM**

**The effects of omega-3 fatty acids on chemotherapy-induced neuropathy and inflammation in patients with breast cancer.** *Presenting Author: Ali Esfahani, Hematology and Oncology Research Center, Tabriz University of Medical Sciences, Tabriz, Iran*

**Background:** Axonal sensoryperipheral neuropathy is the major dose-limiting side effect of paclitaxel. Omega-3 fatty acids have beneficial effects on neurological disorders from their effects on neurons cells and inhibition of the formation of proinflammatory cytokines involved in peripheral neuropathy. **Methods:** This study was a randomized double blind placebo controlled trial to investigate the efficacy of omega-3 fatty acids in reducing the incidence and severity of paclitaxel-induced peripheral neuropathy (PIPN). Fifty seven eligible patients with node positive breast cancer were randomly assigned to take omega-3 fatty acid soft gel capsules, 640 mg t.i.d during chemotherapy with paclitaxel for 12 weeks or sun flower soft gel capsules as placebo. Incidence and severity of PIPN, serum level of inflammatory markers: IL-1 beta, IL- 6, TNF-alpha and HsCRP, as well as concentrations of EPA and DHA in the serum phospholipids of the patients, were assessed before the onset of chemotherapy and after the cessation of therapy. **Results:** Twenty one patients (70%) of the group taking omega-3 fatty acid supplement did not develop PN while it was 40.7 %( 11 patients) in the placebo group. A significant difference was seen in PN incidence (OR=0.3, .95% CI= (0.10-0.88), p=0.029), but there was not a statistically significant difference of PIPN severity between the two study groups. The serum levels of aforementioned inflammatory markers were not statistically different between the active group and the control group but, a considerable difference was observed according to the serum concentrations of EPA and DHA after the end of the supplementation period (P<0.001). **Conclusions:** Omega-3 fatty acids may be an efficient neuroprotective supplement for prophylaxis against PIPN. They were able to reduce the incidence of PIPN in these study patients. Patients with breast cancer have a longer disease free survival rate with the aid of therapeutical agents. Finding a way to solve the disabling effects of PIPN would significantly improve the quality of life of these cancer patients. Clinical trial information: NCT01049295.

**1040 General Poster Session (Board #133), Mon, 8:00 AM-11:45 AM**

**Phase II clinical studies of UTD1, an epothilone analog, in metastatic breast cancer.** *Presenting Author: Binghe Xu, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

**Background:** UTD1, a genetically engineered epothilone analog, is a microtubule stabilizing agent that showed promising activities in phase I trials. In this report, two open-label, multicenter phase II studies of UTD1 alone or UTD1 plus capecitabine (CAP) were carried out to evaluate its efficacy and safety in metastatic breast cancer (MBC) patients (pts). **Methods:** In both studies, MBC patient who was pretreated with taxanes, anthracyclines and/or CAP received UTD1 at a dose of 40mg/m$^2$/d intravenously on day 1 to day 5 or at 30mg/m$^2$/d (d1-d5) in combination with CAP (2000mg/m$^2$/d, orally) on d1-d14, every 21 days until disease progression or unacceptable toxicity occurred for a maximum of 6 cycles. The primary endpoint was objective response rate (ORR) and the secondary endpoints were toxicity and progression-free survival (PFS) for the combination. **Results:** 25 pts received a total of 128 cycles in the combination with a median of 6 cycles (range 1-6 cycles) per patient. Among 24 pts who were evaluable for efficacy, responses included one complete response (CR), 11 partial responses (PR), 9 stable diseases (SD), and a median PFS of 7.5 months. In the UTD1 monotherapy, 34 pts received a median of 4 cycles of UTD1 and 30 pts were evaluable for efficacy. One patient had a confirmed CR, 7 had PR and 13 had SD. Peripheral neuropathy (PN) was the major adverse event associated with UTD1 toxicity in both studies, but was manageable. 40% of pts in the combination had grade 3 PN or/and foot syndrome compared to 11% in the monotherapy. One patient was removed from the monotherapy after the first cycle because of grade 3 neurotoxicity, which was reversed after 3 weeks. There were no drug-related deaths in the two studies. Other grade 3 toxicities included neutropenia (12% *vs* 3%, combination *vs* monotherapy), diarrhea (4% *vs* 3%), myalgia/arthralgia (8% *vs* 0%), dizziness (4% *vs* 0 %). **Conclusions:** UTD1 was well-tolerated in both studies with the primary toxicity being PN, and demonstrated notable antitumor activities in MBC pts. 27% of ORR was seen for the monotherapy or 50% of ORR and a median PFS of 7.5 months for the combination. A multicenter, phase III study of UTD1 plus CAP *vs* CAP alone in MBC is underway. Clinical trial information: TRC-13004205.

**1041 General Poster Session (Board #134), Mon, 8:00 AM-11:45 AM**

**Randomized phase II trial comparing docetaxel with or without low-dose metronomic oral cyclophosphamide in first-line treatment of non-triple-negative advanced breast cancer.** *Presenting Author: Leiping Wang, Fudan University Shanghai Cancer Center, Shanghai, China*

**Background:** Oral metronomic chemotherapy may target tumor cells indirectly via antiangiogenic activity, restoration of anticancer immune response, or induction of tumor dormancy. This phase II study (NCT01526499) aims to evaluate the efficacy of metronomic oral cyclophosphamide in addition to docetaxel as first-line therapy. **Methods:** Eligible patients with ER or PR positive or HER-2-overexpressed ABC who previously untreated were randomly assigned to receive docetaxel 75 mg/m$^2$on day 1 with or without continuous oral cyclophosphamide 50mg daily in a 21-day cycle. Patients with HER-2-overexpressed tumors also receive trastuzumab. All patients received docetaxel until disease progression or unacceptable toxicity or withdrawal of consent. Maintenance endocrine and/or trastuzumab were allowed. The primary endpoint was PFS. **Results:** Between Dec 2011 and Nov 2012, 31 patients were randomized to docetaxel (T) group while 35 to cyclophosphamide plus docetaxel (Metro-TC) group. The majority of the patients (83.3%) were hormonal receptor positive; 31.8% were HER2 over-expressed; 84.8% had visceral metastasis and 48.5% had ≥3 metastatic organ sites. Patients' characteristics were well balanced. Median treatment cycles of docetaxel for both groups were eight cycles. In intention-to-treat population with median follow-up of 18 months, median PFS was statistically longer in the Metro-TC group ( not reached) than it was in the T group (13.6 months, 95%CI, 7.0 to 20.2) (P =.04). Median OS had not been reached. The ORR were 51.6% (16/31) in the T and 71.4% (25/35) in Metro-TC group, respectively (P =.09). There was no significant difference of grade 3/4 toxicities between the two groups. Adverse effects were mainly docetaxel-related, including grade 3/4 neutropenia (100%) and febrile neutropenia (n=19, 29.2%). The only significant difference between the two treatment was mucositis (all grade, 10% versus 43%, P=0.003). **Conclusions:** The addition of metronomic cyclophosphamide to standard chemotherapy as first-line treatment for non-triple-negative ABC shows a benefit in PFS without significant increase in toxicity. Clinical trial information: NCT01526499.

**1042 General Poster Session (Board #135), Mon, 8:00 AM-11:45 AM**

**Comparison of six cycles of epirubicin and paclitaxel (ET) versus four cycles of epirubicin and cyclophosphamide, followed by four cycles of paclitaxel (EC-T) as adjuvant therapy for operable breast cancer in women with positive axillary nodes.** *Presenting Author: Peng Yuan, Department of Medical Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

**Background:** To determine if 6 cycles of ET has similar efficacy to 4 cycles of EC followed by 4 cycles of T, but with shorter treatment time and reduced toxicity. **Methods:** Patients with operable breast cancer and positive lymph nodes were enrolled and randomized to receive ET (75/175 mg/m$^2$ X 6 every 21 days) or EC (90/600 mg/m$^2$ X 4 every 21 days) followed by T (175 mg/m$^2$ X4 every 14 days). The primary end point was DFS. The trial was designed to detect the upper limits of the 95% confidence interval of the hazard ratio of ET versus an EC-T < 1.30. A sample size of 905 patients was required to detect the difference ($a$=0.05, $\beta$=80%). Assuming a drop-out rate of 10%, 996 patients were required. The first analysis of DFS was planned at the time when 50% of patients were enrolled. **Results:** Between August 2009 and October 2013, 496 patients were enrolled in the study and 445 patients completed the study treatment protocol, among which 214 patients were in the EC-T arm and 231 patients were in the ET arm. The patient characteristics were well-matched between the two arms. The median age was 49 years in both groups. Of the patients in the EC-T and ET arms, 87.4% and 92.2% were ER/PR-positive, respectively. After a median follow-up of 35.5 months, 28 events were observed (14 each in both arms). The 4-year DFS was 91.3% in the EC-T arm and 91.4% in the ET arm (log-rank p= 0.719,HR = 0.873, 95%CI = 0.416-1.832). Both regimens were well-tolerated. Of the patients in the EC-T and ET groups, 92.1% and 88.7%, respectively, completed all treatment cycles per protocol. Dose reductions were required in 24.8% and 35.5% of the patients in the EC-T and ET arms, respectively. The most frequent grade 3 / 4 toxicities were neutropenia, nausea, and anemia, with no significant difference between the two regimens. **Conclusions:** The toxicity from six cycles of ET were similar to eight cycles of EC-T in patients with node-positive early breast cancer. The efficacy of the two chemotherapy regimens should await the enrollment of additional patients and a longer follow-up. Clinical trial information: NCT01134523.

**1043 General Poster Session (Board #136), Mon, 8:00 AM-11:45 AM**

**Prognostic effect of eribulin-induced liver dysfunction in metastatic breast cancer.** *Presenting Author: Takayuki Kobayashi, Department of Medical Oncology, the Cancer Institute Hospital of the Japanese Foundation for Cancer Research, Tokyo, Japan*

**Background:** Eribulin is a non-taxane, microtubule dynamics inhibitor with a survival benefit for patients with metastatic breast cancer. Although eribulin is well tolerated in patients with heavily pretreated disease, eribulin-induced liver dysfunction (EILD) occasionally occurs in clinical practice, which may results in treatment discontinuation, with subsequent poor disease control. We conducted a retrospective study to clarify the effect of EILD in patients. **Methods:** The medical records of 157 metastatic breast cancer patients treated with eribulin between Jul 2011 and Nov 2013 at Cancer Institute Hospital were retrospectively analyzed. EILD was defined as 1) an increase in alanine aminotransferase (ALT) or aspartate aminotransferase (AST) levels >3 times the upper limit of normal, and/or 2) starting liver-supporting oral drug therapy such as ursodeoxycholic acid and glycyron. Fatty liver was defined as a decrease in the liver-to-spleen attenuation ratio on computed tomography to <0.9. **Results:** The median age was 56 years, median treatment duration was 4.0 months, and mean body mass index (BMI) was 22.9. EILD occured in 42 (27%) patients, including one patient in whom eribulin treatment was stopped due to EILD. The patients with EILD had significantly higher BMI than the remaining 115 patients (25.4 vs. 22.1, p<0.0001), with no difference in the relative dose intensity of eribulin between the two groups (1.21 vs. 1.15 mg/body/week, p=0.36). Interestingly, the patients with EILD had significantly longer progression-free survival (PFS) than the other patients (p=0.018). Furthermore, among 78 patients without liver metastases, 18 with EILD showed significantly longer PFS than the other 60 patients (p=0.0035). During eribulin treatment, 17 (11%) patients developed fatty liver, and their mean BMI was 27.1. Eleven of 17 patients had EILD. **Conclusions:** Although EILD and fatty liver occurred with relatively higher frequency in clinical practice, most of the patients had no severe side effects. We found the paradoxical results showing positive correlation between EILD and PFS, especially in patients without liver metastases. Further studies are needed to confirm our findings in another cohort of patients.

**1044 General Poster Session (Board #137), Mon, 8:00 AM-11:45 AM**

**Three-arm randomized phase II study evaluating oral vinorelbine plus capecitabine versus paclitaxel plus gemcitabine versus docetaxel plus gemcitabine as first-line chemotherapy in patients with metastatic breast cancer: Final results (NorCap-CA223 trial).** *Presenting Author: Saverio Cinieri, Medical Oncology & Breast Unit, Senatore Antonio Perrino Hospital, Brindisi, Italy*

**Background:** Combination chemotherapy (CT) is among the standard treatment options in metastatic breast cancer (MBC), especially in patients (pts) with visceral metastases or need of rapid symptom or disease control. Full oral combination CT of Oral Vinorelbine (OV) + Capecitabine (C) is a convenient and effective alternative to taxane-based intravenous regimens. Aim of this study was to evaluate the efficacy of a full oral and two full intravenous combinations in MBC. **Methods:** Pts with HER2-negative taxane-naïve MBC, with an age ≥18 years were eligible. Pts were randomised to receive, as first-line CT, 3 weekly-cycles of either: ARM A: full oral combination of OV and C; ARM B: paclitaxel plus gemcitabine (G); ARM C: docetaxel plus G. Primary endpoint was disease control rate (DCR). Pts were stratified according to prior anthracycline CT and age < or ≥65 years. **Results:** 149 pts had been treated (ARM A 49; ARM B 50; ARM C 50). Baseline pt characteristics (Arms A/B/C): median age 58/56/57 years; prior (neo)adjuvant CT 49/46/58%; prior anthracycline 39/42/42%; visceral metastases 80/82/74%. Median number of cycles (range): 6(1-37)/6(1-12)/7(1-25). Safety: G3/4 adverse events per pt: neutropenia 50/46/86%, anemia 2/4/8%, infections 2/2/10%, diarrhoea 6/4/2%, vomiting 10/2/2%, fatigue 10/12/22%, alopecia (G2) 8/72/76%, febrile neutropenia (pts) 4/0/3, toxic deaths (pts) 2/1/0. Efficacy: DCR in the intent-to-treat population was [95%CI] 73.5 [59-85] /78 [64-88] /80 [66-90] %; progression-free survival: 7.6 /9.0/11.4 months; time to treatment failure: 4.6/4.8/5.2 months; overall survival: 30.2/29.6/31 months. **Conclusions:** The DCR as well the OS results reported in this trial confirm that the full oral combination of OV + C is an active combination which can be proposed as an alternative to taxane-based regimens as first-line CT in MBC, allowing to delay the constraints of an intravenous CT. As expected, each regimen presented a specific and particular tolerance profile, with, in particular, a low incidence of alopecia after full oral CT.

**1045 General Poster Session (Board #138), Mon, 8:00 AM-11:45 AM**

**Toxicity and prediction of survival benefit with metronomic chemotherapy in metastatic breast cancer.** *Presenting Author: Rabab Mohamed Gaafar, National Cancer Institute, Cairo University, Cairo, Egypt*

**Background:** Metronomic chemotherapy (MC) has shown efficacy in patients with metastatic breast cancer. We therefore tested the efficacy and toxicity of (MC) in pretreated metastatic breast cancer (MBC). **Methods:** This prospective phase II study was conducted in the period between July 2008 till July 2011. The study included 50 cases of heavily pretreated MBC who received (MC) (oral cyclophosphamide 50 mg/day & methotrexate 2.5 mg twice day1 and 2 every week). The primary end point was time to progression (TTP) while secondary end points were response rate, overall survival (OS), safety and impact of treatment on VEGF. **Results:** Forty eight patients were assessed. One case achieved complete response (CR) and 10 cases had partial response (PR) while 19 patients had stable disease with ORR of 22% while CBR was 45.5%. Median TTP was 5 months while median OS was 7 months with a median follow up period of 7 months (ranging from 1 to 33 months). Patients with negative progesterone receptors, ECOG PSI, achieving CR or PR and suffering from leucopenia, neutropenia and anemia due to treatment had significant prolonged TTP while patients with initial early stage at the time of diagnosis of breast cancer, receiving <5 previous treatment lines, achieving response and experienced anemia with (MC) had significant superior OS. In multivariate analysis, achieving response, PS I, time interval since initial diagnosis till starting (MC) and anemia were independent prognostic factors for longer TTP. Initial stage at presentation, number of previous treatment lines and response were independent prognostic factors for OS. No significant difference between the median level of VEGF at baseline and after 3 months. The median level of VEGF at baseline or after 3 months as well as the median percentage of reduction was not correlated with TTP or OS. **Conclusions:** MC is an attractive way of treatment being effective and less toxic. There is certain groups seem to benefit from this treatment especially those with good PS, achieved response and who experienced toxicity with treatment. Further trials are warranted to assess this approach early in the course of the disease and with other more active agents.

**1046 General Poster Session (Board #139), Mon, 8:00 AM-11:45 AM**

**HIP1 expression and response to chemotherapy in breast cancer.** *Presenting Author: Mireia Margeli, Institut Català d'Oncologia - Hospital Germans Trias i Pujol, Badalona, Spain*

**Background:** Huntingtin Interacting Protein 1 (HIP1) is a binding protein to inositol and clathrina that is related to neurodegeneration. Signaling of growth factors receptors trought clathrina is one of the mechanisms by which cells regulate the intracellular signaling. There have been observed high levels of HIP1 protein in breast, colon, kidney, lung, melanoma, ovarian and prostate cancer. Furthermore, HIP expression was negatively correlated with survival in prostate cancer. HIP1 overexpression has been shown to inhibit the degradation of EGFR and estrogen receptor. EGFR expression has been correlated with response to chemotherapy in triple negative breast cancer. **Methods:** Tumor biopsies were obtained from 83 breast cancer patients (p) treated with neoadjuvant chemotherapy, based on four cycles of fluorouracil, epirubicin and cyclophosphamide. Estrogen receptor, progesterone receptor, HER2, cytokeratin 5/6, vimentin and HIP1 were examined by tissue microarray. HER2 were also assessed by chromogenic in situ hybridization. We evaluated the prognostic and predictive value of HIP1 expression. **Results:** HIP1 was evaluated by immunohistochemistry in 83 p, being considered negative if the result was 0 or 1, and positive if it was 2 or 3. The result was 0 in 11 p (13.3%), 1 in 40 p (48.2%), 2 in 25 p (30.1%), and 3 in 7 p (8.4%). The value of huntingtin did not correlate with any of the clinical characteristics of the series, nor with ER, PR, vimentin, or HER2, nor subgroups. Negative HIP1 was correlated in the limit of significance to positive CK5 /6. Overexpression of HIP1 was correlated to higher pathologic response, as shown in table 1. HIP1 was not statistically correlated to DFS or OS, but p with overexpression of HIP1 had a median survival of 50 months whereas it was 67 months for p without overexpression of HIP1. **Conclusions:** HIP1 could be a prognostic and predictive factor in breast cancer. Showing that HIP1 is necessary for breast cancer progression and modulates key growth factor receptors involved in breast cancer, fuels the idea that HIP1 inhibition has therapeutic potential.

**1048 General Poster Session (Board #141), Mon, 8:00 AM-11:45 AM**

**First safety results of an international phase II study evaluating oral vinorelbine as a single agent as first-line chemotherapy for metastatic breast cancer patients with bone metastases (NorBreast-228 trial).** *Presenting Author: Guenther G. Steger, Department of Medicine I, Clinical Division of Medical Oncology, Medical University of Vienna, Vienna, Austria*

**Background:** Oral chemotherapy (CT) is an attractive treatment option for hormone receptor positive, metastatic breast cancer (MBC) patients (pts) pretreated by a hormone therapy. In our phase II study, we evaluated the role of single-agent Oral Vinorelbine (OV) as first-line CT in pts presenting bone metastases without visceral involvement. In this abstract, first safety results of this trial are presented. **Methods:** Main eligibility criteria included: age ≥18 years, documented bone involvement previously untreated by CT, hormone receptor positive disease previously treated by at least one hormone therapy, HER2-negative disease, Karnofsky PS ≥70 and absence of visceral metastases. Study treatment (until progression): OV 80 mg/m$^2$ weekly (following a first cycle at 60 mg/m$^2$ and dose escalation to 80 in the absence of grade 3 or 4 toxicity). One cycle was defined as four weeks of treatment. **Results:** Main pts characteristics in the full population were (n=70): median age: 60.6 years (34% ≥65 years); median Karnofsky PS 90%. Prior hormone therapy 100% (53% in advanced setting); prior (neo)adjuvant CT 63%; prior anthracyclines/taxanes 59/24%; prior palliative radiotherapy 41%. Bone involvement 100%; other metastatic sites: lymph nodes 14%, soft tissue 3%. Median duration of treatment 5.5 months (range 0.9-18.3), median number of cycles: 6 (range: 1-18);61% of pts received at least 6 cycles, 37% of ptsreceived more than 6 cycles and 29% received at least 9 cycles; median relative dose intensity: 83.5%; dose escalation was performed in 79% ofpts.Grade 3/4 adverse events per pt: neutropenia 37%, anemia 4%, diarrhoea 3%, nausea 3%, asthenia 1%, liver toxicity 1%, neutropenic infection 1%, non-neutropenic infection 1%. Grade 2 alopecia was reported in 6% of pts. **Conclusions:** In this particular population of metastatic pts, with hormone receptor positive disease and bone involvement, OV showed an optimal safety profile. These data shows that OV is a well tolerated first-line CT option in this setting, allowing prolonged active treatment in non-progressing pts.

**1049 General Poster Session (Board #142), Mon, 8:00 AM-11:45 AM**

**Survival with docetaxel plus capecitabine comparing with vinorelbine plus capecitabine followed by capecitabine maintenance treatment as first-line therapy in patients with advanced breast cancer: A phase III randomized clinical trial.** *Presenting Author: Binghe Xu, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

**Background:** Docetaxel/capecitabine (TX) is one of the standard regimens recommended by NCCN for metastatic breast cancer treatment. There are few clinical studies directly comparing TX and navelbine/capecitabine (NX), followed by capecitabine maintenance treatment, especially in advanced breast cancer patients previously treated with taxane in adjuvant setting. This study aimed to compare the efficacy and safety of TX and NX medications followed by capecitabine maintenance for patients with metastatic breast cancer. **Methods:** A total of 206 patients with advanced metastatic breast cancer were randomly assigned into TX (n=104) and NX (n=102) treatment groups, both with capecitabine maintenance medication. The primary endpoint was progression-free survival (PFS) and secondary endpoints included overall survival (OS), response rate (RR), duration of response (DOR) as well as safety. **Results:** The TX group achieved longer median PFS than the NX group (8.4 months vs. 7.1 months; $p = 0.0026$, HR = 1.65) and had better median DOR (7.8 months vs. 6.6 months, $p = 0.0451$). In the TX group 48 (46.2%) and in the NX group 42 (41.2%) patients attained maintenance medication. The OS period of the TX group was longer than in NX patients (35.3 months vs. 19.8 months), but without statistical significance. Patients ≥40 years of age, postmenopausal and with visceral metastases were more likely to benefit from a TX regimen in terms of PFS and OS, whereas hormone and positive HER2 receptor and history of taxane treatments did not affect PFS and OS differences between TX and NX patients. The tumor response rates were 55.3% in the TX vs. 54.9% in the NX group. In the TX group hand-foot syndrome occurred more frequently than in the NX group (47% vs. 16.7%, $p < 0.0001$), but frequencies of other minor adverse effects were similar in both groups. **Conclusions:** A TX regimen for advanced breast cancer followed by capecitabine maintenance medication led to longer PFS and DOR than a NX regimen even for patients who were previously treated with taxane in (neo) adjuvant settings. Clinical trial information: NCT01126138.

**1050 General Poster Session (Board #143), Mon, 8:00 AM-11:45 AM**

**Influence of pluripotent stem cell gene polymorphisms on breast cancer susceptibility and response to chemotherapy in a north Indian cohort.** *Presenting Author: Gaurav Agarwal, Department of Endocrine and Breast Surgery, SGPGIMS, Lucknow, India*

**Background:** OCT4, NANOG, LIN28 and SOX2 are the key transcription factors critical for the pluripotency and self-renewal of embryonic stem cells. Their dys-regulation leads to breast cancer cell growth, differentiation and tumor metastasis. We aimed to explore the role of pluripotent stem cell gene polymorphisms in breast cancer susceptibility and response to chemotherapy (CTx). **Methods:** This case-control study included 297 histologically proven female breast cancer patients and 273 healthy controls. Response to CTx was studied in 128 patients receiving neoadjuvant CTx and evaluated for response as per RECIST criteria. The association of tagger SNPs in *OCT4* (rs3130932), *NANOG* (rs11055786), *LIN28* (rs4274112) and *SOX2* (rs11915160) gene with breast cancer susceptibility and response to CTx were examined using Taqman allelic discrimination assays. Statistical analysis was done using SPSS ver 17. **Results:** Heterozygous genotype (P=0.019) and variant allele (P=0.003) of rs11915160 were found to be significantly associated with breast cancer susceptibility in premenopausal women. Similar association was found in dominant model (P=0.014). On univariate analysis of correlation of genotype with clinico-pathological characters, genotype (AG+GG) of rs4274112 polymorphism was found significantly associated with larger tumor size (P=0.040) and positive lymph node (P=0.002). However in multivariate analysis, larger tumor size was not significantly associated, but lymph node metastases was significantly associated with genotype (AG+GG) of rs4274112 polymorphism (P=0.007). Significant association was seen between hormone receptor positive tumors and rs3130932 polymorphism in multivariate analysis, both at the genotypic (AC+AA) (P=0.033) as well as the allelic (C) (P=0.023) levels. **Conclusions:** The *SOX2* rs11915160 variants may confer breast cancer risk in premenopausal women. *OCT4* rs3130932 and *LIN28* rs4274112 genetic variants may have significant effect in clinico-pathological characteristics of breast cancer patients. However, no association was found between any of the studied polymorphisms with response to CTx.

**1051 General Poster Session (Board #144), Mon, 8:00 AM-11:45 AM**

**Nabrax: Neoadjuvant therapy of breast cancer with weekly single-agent nab-paclitaxel—Final efficacy and biomarkers analysis of GEICAM 2011-02 trial.** *Presenting Author: Miguel Martin, Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain*

**Background:** Nanoparticle albumin bound paclitaxel (nab-P) administered weekly showed superior efficacy compared to every 3-weeks docetaxel in a randomized phase II study in first line metastatic breast cancer (Gradishar JCO 2009). We present a phase II trial designed to evaluate the activity and safety of weekly nab-P as neoadjuvant treatment of early stage breast cancer patients (pts) with positive estrogen receptors (ER) and negative HER2. **Methods**: Stage II-III breast cancer pts were included and treated with nab-P weekly (150 mg/m$^2$) on days 1, 8 and 15 every 4 weeks for 4 cycles. Following chemotherapy, pts underwent surgery and adjuvant therapy under the investigator criteria. The primary objective was to determine the percentage of pts with poor response (Symmans residual cancer burden –RCB– class III centrally determined). The study hypothesis was that the RCB III rate will drop from 33% (historical controls treated with docetaxel in the same population, Martin BCRT 2011) to 16% with nab-P. Secondary objectives included good pathological complete response (Symmans RCB class 0+I), objective response rate (ORR), breast conserving surgery (BCS) rate, safety and molecular subtypes and biomarkers (Ki-67, Cav-1, SPARC analyzed in a central lab) correlation with response. The safety and treatment administration analysis was reported previously (Martin SABCS 2013). We report here the efficacy and correlation between RCB 0+I and subtypes/biomarkers from the pre-treatment tumor samples. **Results**: 83 pts were recruited (81 evaluable). Median age was 47 years, 64.2% were premenopausal; most pts were stage II (35.9% IIa and 33.3% IIb). Central pathological response is currently available for 74 pts (7 pending). RCB III rate was 25.7% and RCB 0+I rate was 27%. The ORR by MRI was 76.5% and the rate of conversion to BCS was 40%. In the univariate analysis we found Ki67>20% and high expression of Cav1 in stroma to be correlated with RCB 0+I. **Conclusions:** Our study was unable to show the pre-specified efficacy hypothesis. However the RCB 0+I rate is encouraging taking into account docetaxel activity (13.3%) in this population; nab-P merits further evaluation in randomized trials. Clinical trial information: NCT01565499.

**1052 General Poster Session (Board #145), Mon, 8:00 AM-11:45 AM**

**Adding VEGFR-TKIs to chemotherapy and/or hormonal therapy in advanced breast cancer patients: Results of a meta-analysis.** *Presenting Author: Yucai Wang, Department of Medicine, Rutgers New Jersey Medical School, Newark, NJ*

**Background:** The addition of vascular endothelial growth factor receptor tyrosine kinase inhibitors (VEGFR-TKIs) to chemotherapy and/or hormonal therapy for advanced breast cancer management remains controversial. We reviewed data from RCTs and conducted a meta-analysis to systematically evaluate the benefits and risks of adding VEGFR-TKIs therapy to standard treatment for advanced breast cancer. **Methods:** PubMed, Web of Science and ASCO and ESMO databases were searched. Eligible studies were RCTs that compared treatment outcomes (OS, PFS and/or TTP) of standard therapy with or without addition of VEGFR-TKIs in advanced breast cancer. Study endpoints included OS, PFS, and grade 3 or above adverse events (AEs). Pooled HRs for survival outcomes and RRs for dichotomous data with 95% CI were calculated using comprehensive meta-analysis (v2). **Results:** Nine eligible trials comprising a total of 2,206 patients were identified. VEGFR-TKIs included sorafenib (3), sunitinib (2), vandetanib (2), axitinib (1), and motesanib (1), and standard therapies included paclitaxel (2), docetaxel (3), gemcitabine (2), capecitabine (2), and fulvestrant (1). The addition of VEGFR-TKIs did not improve OS (HR 1.01; 95% CI 0.88-1.16, $P = 0.889$) or PFS (HR 0.87; 95% CI 0.72-1.03, $P = 0.109$). However, adding VEGFR-TKIs increased the risk of hypertension (RR 3.38; 95% CI 1.37-8.30, $P = 0.008$), rash (RR 2.64; 95% CI 1.14-6.14, $P = 0.024$), hand-foot syndrome (RR 4.73; 95% CI 1.33-16.81, $P = 0.016$), and mucosal inflammation (RR 2.41, 95% CI 1.10-5.28, $P = 0.028$), but not the risk of vomiting, diarrhea or neutropenia. **Conclusions:** Our meta-analysis demonstrates that adding VEGFR-TKIs to standard treatment in advanced breast cancer did not improve treatment outcomes, and increased the risk of certain severe AEs, such as hypertension, rash, and hand-foot syndrome and mucosal inflammation. Because of patient and treatment heterogeneities among the trials, eg., ER/PR/HER2 status, locally advanced vs. metastatic, first vs. any line of therapy, additional studies are needed to further evaluate the efficacy of VEGFR-TKIs in advanced breast cancer.

**1053 General Poster Session (Board #146), Mon, 8:00 AM-11:45 AM**

**Phase II study of *pseudomonas aeruginosa*-mannose-sensitive hemagglutinin in combination with capecitabine for HER2-negative metastatic breast cancer pretreated with anthracycline and taxane.** *Presenting Author: Fangfang Lv, Fudan University Shanghai Cancer Center, Shanghai, China*

**Background:** Metastatic breast cancer (MBC) remains an incurable disease despite major therapeutic advances. *Pseudomonas aeruginosa*–mannose-sensitive hemagglutinin (PA-MSHA) has been established to have anti-proliferative effects against breast cancer cells in preclinical experiments, and is indicated for treatment of cancer in China. We performed a phase II trial combining PA-MSHA with capecitabine in patients with heavily pretreated MBC. **Methods:** Eligibility criteria included human epidermal growth factor receptor 2–negative MBC, prior therapy with anthracyclines and taxanes, at least one prior chemotherapy regimen for metastatic disease or early relapse after a taxane plus anthracycline adjuvant regimen, and adequate organ function and performance status. PA-MSHA 1 mg was administered subcutaneously every other day and capecitabine 2000 mg/m$^2$orally twice a day for 2 weeks on, 1 week off. The primary end point was progression-free survival. The trial was registered at www.ClinicalTrials-.gov (ID NCT01380808). **Results:** A total of 97 patients were enrolled. Median progression-free survival (PFS) was 4.0 months [95 % confidence interval (CI) 3.0–4.9), which was not significantly different from that in historical controls. However, median PFS was significantly longer (8.2 months; 95 % CI 6.7–9.7) in 24 patients with moderate immune-related adverse events (irAEs) such as fever or skin induration at the injection site than in those with no or mild irAEs (3.1 months, 95 % CI 2.5–3.6; $p = 0.003$). Overall survival was also improved in these patients (25.4 vs. 16.4 months; $p = 0.044$). PA-MSHA has a good safety profile, with only 6 patients (6.2 %) discontinuing treatment. PA-MSHA did not increase capecitabine-related toxicities such as hand-foot syndrome, nausea, and vomiting. **Conclusions:** Adding PA-MSHA to capecitabine has a good safety profile in patients with heavily pre-treated MBC, although benefit from this regimen might occur only in patients with moderate PA-MSHA–related adverse events. Clinical trial information: NCT01380808.

**1054 General Poster Session (Board #147), Mon, 8:00 AM-11:45 AM**

**Paclitaxel-induced severe sensory peripheral neuropathy is associated with NDRG-1 genetic variant and negative NDRG-1 expression in nerve tissue.** *Presenting Author: Raghav Sundar, National University Health System, Singapore, Singapore*

**Background:** N-myc downstream regulated gene (NDRG)-1 has been implicated in Charcot Marie Tooth disease, a peripheral nerve hereditary disorder and in the development and maintenance of the myelin sheath. We hypothesize that NDRG-1 may be implicated in paclitaxel-induced peripheral neuropathy. **Methods:** Breast cancer patients who received adjuvant weekly paclitaxel were genotyped for 10 single nucleotide polymorphisms (SNPs) in 9 genes, including rs2233335 in NDRG-1 using MassArray (Sequenom) technology. Immunohistochemical (IHC) staining of NDRG-1 was performed on normal nerve tissue in archival lumpectomy/mastectomy specimens. Clinical data including paclitaxel dose intensity and density, onset and severity of neuropathy was correlated with genetic and IHC data. **Results:** Of the 122 patients that were evaluated, 67% were Chinese, median age was 51 (26 – 79) years and 9% had diabetes. Mean total paclitaxel dose administered was 924 (240 – 960) mg/m$^2$. Median duration of treatment was 12 (3 – 18) weeks, with 36% completing full dose intensity (960mg/m$^2$ in 12 weeks). 57.4% developed all grade neuropathy, with 20.5% having ≥grade 2 severity. Severe neuropathy, defined as those requiring dose delay, dose reduction or early termination of chemotherapy, occurred in 9.8%. Expectedly, presence of diabetes correlated with severe neuropathy (36% vs 7%; p=0.01). Of the 10 SNPs evaluated, NDRG-1 (rs2233335) CC/CA genotype was significantly associated with severe neuropathy compared to the AA genotype (28% vs 7%, p=0.016). Of note, patients with the CC/CA genotype and who were younger than 50 years of age had a higher incidence of ≥grade 2 (80% vs 14%, p=0.005) and severe neuropathy (80% vs 6%, p=0.001) than those with the AA genotype. Patients with severe neuropathy were more likely to stain negative for NDRG-1 in nerve tissues compared to those who had no neuropathy (80% vs 0%, p=0.047). **Conclusions:** Absence of NDRG-1 expression on nerve tissue and NDRG-1 rs2233335 SNP is associated with paclitaxel-induced severe neuropathy, and may guide selection of patients who should avoid paclitaxel. Correlation of NDRG-1 SNP with expression and functionality requires further study.

**1055 General Poster Session (Board #148), Mon, 8:00 AM-11:45 AM**

**Clinical predictive models for chemotherapy-induced febrile neutropenia in breast cancer patients: A validation study.** *Presenting Author: Kai Chen, Breast Tumor Center, Sun Yat-sen Memorial Hospital, Guangzhou, China*

**Background:** This study aims to validate a predictive model (Jenkin's model) for febrile neutropenia (FN) during chemotherapy in early-stage breast cancer patients. **Methods:** A total of 428 breast cancer patients who received neoadjuvant/adjuvant chemotherapy (Anthracycline and/or taxane based) without any prophylactic use of colony-stimulating factor were included. Pretreatment absolute neutrophil counts (ANC) and absolute lymphocyte counts (ALC) were used by the Jenkin's model to assess the risk of FN. In addition, we modified the threshold of Jenkin's model and generated Model-A and B. We also developed Model-C by incorporating the absolute monocyte count (AMC) as a predictor into Model-A. The rates of FN in the 1st chemotherapy cycle were calculated. A valid model should be able to identify high-risk subgroup of patients with FN rate >20%. **Results:** Jenkin's model (Predicted as high-risk when ANC≦3.1*10^9/L; ALC≦1.5*10^9/L) did not identify any patient with a significantly high risk (>20%) of FN in our population, even if we used different thresholds in Model-A(ANC≦4.4*10^9/L;ALC≦2.1*10^9/L) or B(ANC≦3.8*10^9/L; ALC≦1.8*10^9/L) . However, with AMC added as an additional predictor, Model-C(ANC≦4.4*10^9/L;ALC≦2.1*10^9/L; AMC≦0.28*10^9/L) identified a subgroup of patients with a significantly high risk of FN (23.1%). **Conclusions:** In our population, the threshold of Jenkin's model should be changed and the AMC should be incorporated as a predictor, to have improved predictive ability.

| Model | Group | ANC (×10^9/L) | ALC (×10^9/L) | AMC (×10^9/L) | Total N | FN rate N(%) | P |
|---|---|---|---|---|---|---|---|
| Jenkin's | I | ≦5.2 | ≦2.4 | n/a | 155 | 15(9.7) | NS |
| | II | ≦5.2 | ≦2.4 | n/a | 93 | 9(9.7) | |

**Bayesian network meta-analysis, comparison of cardiac events associated with liposomal doxorubicin, epirubicin, and doxorubicin in breast cancer.** *Presenting Author: Norihiro Yamaguchi, Mount Sinai Beth Israel, New York, NY*

**Background:** Anthracyclines have the potential for causing cardiac events (CE). Given minimal evidence based data predicting CE rates, a Bayesian network meta-analysis (NMA), a validated statistical methodology provides direct and indirect comparison among different regimens. **Methods:** We conducted a systematic review of prospective randomized controlled trials through MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials and Google Scholar comparing non-anthracycline based regimen (Non), doxorubicin (Dox), epirubicin (Epi), and liposomal doxorubicin (LD). We included studies published up to January 1, 2014, adjuvant and metastatic regimens, but not HER2/neu inhibitor containing regimens. Studies were included in the NMA with consensus of two authors. Our outcome measure was cardiac events greater than CTCAE grade 3. Bayesian NMA was conducted to estimate pooled Odds Ratio (OR). **Results:** Nineteen randomized controlled trials met criteria. We found a trend showing that LD is less cardiotoxic than Dox with an OR of 0.60 and 95% confidence interval (CI) [0.34-1.07]. There was no difference between Epi and LD with an OR of 0.95 and 95%CI [0.39-2.33]. Dox is more cardiotoxic than Non with an OR of 1.57 and 95%CI [0.90-2.72]. **Conclusions:** Our study showed that LD trended with a lower CE rate compared to Epi and Dox, but the difference did not reach statistical significance. One of the reasons is likely the small number of CE. Based on this analysis and given the low CE rate in the clinical context of the selected trials, the potential for cardiac toxicity need not be a major factor in clinical decision making.

| Comparison | Pooled OR | 95% CI |
|---|---|---|
| **LD vs Dox** | 0.60 | 0.34-1.07 |
| **LD vs Epi** | 0.95 | 0.39-2.33 |
| **Dox vs Non** | 1.57 | 0.90-2.72 |

**1057 General Poster Session (Board #150), Mon, 8:00 AM-11:45 AM**

**Assessing the value of weekly blood analysis in patients with localized breast cancer receiving adjuvant treatment with weekly paclitaxel.** *Presenting Author: Raul Diez-Fernandez, Hospital Universitario de Getafe, Getafe, Spain*

**Background:** Paclitaxel is one of the standard adjuvant treatments in localized breast cancer. Weekly paclitaxel has shown to improve disease-free and overall survival compared to every three weeks paclitaxel (Sparano JA et al, 2008). A retrospective analysis was conducted in our center in order to quantify the incidence of thrombocytopenia, neutropenia and impaired liver blood tests in patients with localized breast cancer receiving adjuvant treatment with weekly paclitaxel (80 mg/m$^2$). **Methods:** 163 patients over six years were identified from the chemotherapy prescription database. According to blood analysis results, patients were considered deemed well to receive treatment when neutrophils were $> 1.5$ x10$^9$/L, platelets were $> 100$ x10$^9$/L, ALT $< 10$xULN and bilirubin $< 1.25$xULN. **Results:** Patients received 1,862 infusions. 86 % of patients completed the 12 courses of chemotherapy previously planned and the mean number of weekly treatments was 11.42 per patient. Most patients had received previous treatment with anthracyclines (87.7%) and 46 patients (28.2%) received concurrent trastuzumab. Neutropenia (all grades CTC) occurred on 71 administrations (3.81 %) but was grade 3 in only 9 courses (0.48%); no grade 4 neutropenia was observed. Thrombocytopenia of any grade was not seen and only in two courses platelets were below 100 x 10$^9$/L. Increased blood bilirubin (any grade CTC) was seen in 25 courses of paclitaxel, but only in 9 of them they were above 1.25xULN (0.48%). No ALT results above 10xULN were observed. In 129 courses of chemotherapy the dose was reduced more than 5% (6.92%) but only in 25 courses this was due to neutropenia (1.34%) and in 3 courses due to increased bilirubin levels (0.16%). Treatment was hold 68 times (3.65%) and only in 16 courses this was because of neutrophil levels (0.86%). **Conclusions:** The incidence of neutropenia, thrombocytopenia and impaired liver blood tests is very low in patients with localized breast cancer receiving weekly paclitaxel as adjuvant treatment. Liver blood tests might be spared after the first course of chemotherapy and full blood count does not need to be checked on every course.

**1058 General Poster Session (Board #151), Mon, 8:00 AM-11:45 AM**

**Phase II randomized clinical trial evaluating neoadjuvant chemotherapy regimens with weekly paclitaxel (WP) or eribulin (E) followed by doxorubicin and cyclophosphamide (AC) in women with locally advanced HER2-negative breast cancer (LABC): NSABP FB-9.** *Presenting Author: Jame Abraham, Cleveland Clinic, Cleveland, OH*

**Background:** Eribulin (E) is a non-taxane, tubulin- and microtubule-targeting agent. In the randomized, phase III EMBRACE trial, disease-free survival and overall survival were prolonged in E versus physician's choice in heavily pretreated patients (pts). In this phase II randomized neo-adjuvant clinical trial, WP or E is followed by AC in patients with HER-2 negative LABC. The primary endpoint was pathologic complete response (pCR) in the breast and nodes. **Methods:** A total of 50 pts with LABC were accrued between January and August 2013. Median age was 50.5 years (range: 29-70 years). Twenty-three pts had stage IIB, 16 had stage IIIA, 9 had stage IIIB, and 2 had stage IIIC. Four pts had inflammatory breast cancer. Thirty-three were hormone-receptor positive and 17 were triple negative. Pts were randomly assigned (2:1) to receive either E (n= 31) (1.4 mg/m2 day 1 and day 8) every 3 weeks for 4 cycles, or WP (n= 19) (80 mg/m2) for 12 treatments. Both groups received AC (60 mg/m2 and 600 mg/m2) every 3 weeks for 4 cycles before surgery. Pts were evaluated by clinical examination and breast MRI at baseline and after completion of E or WP. MRI clinical partial response was defined as ≥30% decrease in tumor diameter. **Results:** Significant grade 3 toxicities included diarrhea (2%), febrile neutropenia (2%), mucositis (2%), and thromboembolic events (2%), 1 pt each. No pt experienced grade 3 or higher neuropathy. Baseline and follow-up MRI results are available on 44 pts. In the WP arm, 15/18 (83%) pts had a response (14 PR and 1 CR) and in the E arm, 15/26 (57%) had response (14 PR and 1 CR), either by investigator and/or central review. By central review WP pts had 50% response and E had 45%. Primary endpoint of pCR results will be reported. **Conclusions:** Both regimens are well tolerated with no unexpected toxicities. Both E and WP had moderate activity as per imaging in this LABC. A full analysis of complete pathological response data is pending. Clinical trial information: NCT01705691.

**1059 General Poster Session (Board #152), Mon, 8:00 AM-11:45 AM**

**Acute toxicity in African American and Caucasian patients with adjuvant/neoadjuvant chemotherapy for breast cancer.** *Presenting Author: Mansoor Ul Haq, University of Tennessee Health Sciences Center, Memphis, TN*

**Background:** The incidence of breast cancer is higher in Caucasian (C) compared to African American (AA) patients (pts), however the mortality is higher in AA. This disparity has been explained by a higher stage at diagnosis, triple negative tumors, high nuclear grade, and decreased access to health care among the AA women pts. This difference still persists when these factors are controlled. We hypothesized that AA pts have reduced dose intensity of chemotherapy due to treatment delays and dose reductions as a result of increased acute toxicity leading to inferior outcomes. **Methods:** Data was collected by retrospective chart review on 100 consecutive C and 100 AA pts with early stage breast cancer who received adjuvant or neoadjuvant chemotherapy during 2009 to 2011 at a community cancer center. Data collected included pt demographics, comorbidities, disease characteristics, treatment received, acute toxicities, and pt reported symptom burden as assessed by a validated electronic survey. **Results:** Mean age of C and AA pts was 56.1 vs. 51.5, respectively ($p = .0049$). All pts had ECOG performance status of 0-1, with no race differences. AA pts had higher rates of diabetes (17.0% vs. 11.9%) and hypertension (49.0% vs. 36.6%). The mean Charlson Comorbidity Index score was 3.1 for C and 3.4 for AA ($p = .064$). 44% of C presented at stage II and III as compared to 61% of AA patients ($p = .028$). AA had higher tumor grade ($p = .005$) . For chemotherapy AA got numerically more dose dense AC-paclitaxel, similar docetaxel-cyclophosphamide and less cyclophosphamide-methotrexate-5FU as compared to C. Most common side effects for C and AA respectively were, anemia: 50.5% vs. 68%, neutropenia: 14.9% vs. 12%, nausea: 27% vs. 15%, diarrhea: 13.9% vs. 11%, infection: 13.9% vs. 14% and neuropathy: 16.8% vs. 13%. Treatment delays and dose reductions did not differ between race groups. Patient reported symptom burden also did not differ among race groups. **Conclusions:** Despite difference in comorbidities and stage at presentation, no significant difference was observed in acute toxicities due to chemotherapy, in pt reported symptoms or the rates of chemotherapy delay and dose reduction between C and AA pts with early stage breast cancer.

**1060 General Poster Session (Board #153), Mon, 8:00 AM-11:45 AM**

**Effect of low-dose, short-course sunitinib (Su) on tumor vasculature and tumor blood flow for enhancement of chemotherapy efficacy in breast cancer.** *Presenting Author: Andrea Li Ann Wong, National University Health System, Singapore, Singapore*

**Background:** Continuous VEGFR-I use may ablate vasculature and impede chemotherapy delivery, failing to improve outcome; in contrast, low-dose, short-course VEGFR-I may normalize vasculature and enhance drug delivery. **Methods:** We conducted a phase Ib followed by phase II randomized study in chemonaive breast cancer patients to evaluate 1 week treatment with low-dose Su before each cycle of neoadjuvant doxorubicin/cyclophosphamide (AC) and measured tumor blood flow, vascular and lymphatic density with serial DCE-MRI and biopsy, at baseline, after 1 week Su, and after cycles 1 and 4 AC. **Results:** Phase Ib enrolled 9 patients: 25mg Su (n=3) reduced tumor blood flow; 12.5mg Su (n=6) increased tumor blood flow reflected by plasma volume (Vp) on DCE-MRI and increased SMA/CD31 staining indicating normal vessels, and was used in phase II. 47 patients were randomized in phase II: 24 AC, 23 Su+AC. 68%, 43%, 68%, 92% had T3-4, N+, ER+, HER2- tumor. No significant change in DCE-MRI parameters, SMA/CD31 and podoplanin staining was seen with AC alone. In contrast, Su+AC increased plasma volume and blood flow on DCE-MRI after 1 cycle (Vp 11.5 vs 8.4, p=0.047; F 104 vs 87, p=0.077), and SMA/CD31 double staining after 1 and 4 cycles (22.2 vs 48.9 vs 63.8, p=0.036) reflecting better tumor perfusion from normalized blood vessels. Su+AC also reduced lymphatic density after 1 and 4 cycles (podoplanin 3.3 vs 1.0 vs 0.7, p=0.039). Of note, SMA/CD31 change occurred in patients with good histological response after 1 AC (p=0.036), while podoplanin change occurred in ypN0-1 patients at surgery (p=0.038), and not those with less favorable response. Su+AC led to better histological response (grade 4-5) after 1 cycle (54% vs 25%) and more breast conservation (24% vs 10%), but pCR & node negativity rates (6 vs 5%; 35 vs 33%) were similar to AC alone, and may be due to more dose delay/reduction/omission from neutropenia (29% vs 5%, p=0.087). **Conclusions:** 1 week of 12.5mg Su prior to AC normalizes tumor vasculature to improve perfusion and reduces lymphatic density, which correlated with early histological response and less nodal involvement after chemotherapy, providing proof of concept of potential efficacy of this strategy. Clinical trial information: NCT01176799.

**1061 General Poster Session (Board #154), Mon, 8:00 AM-11:45 AM**

**Correlation between clinical tumor stiffness by elastography and response to neoadjuvant chemotherapy in patients with breast cancer.** *Presenting Author: Mitsuhiro Hayashi, Department of Breast and Endocrine Surgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto-city, Japan*

**Background:** Preclinical study has revealed that tumor stiffness can force tumor progression. Tumor stiffness appears to be caused by increased matrix cross-linking and changing in a number of stroma-related genes' expression, and seems to contribute to high malignant potential of tumor cells or disturb intestinal transportation of anti-tumor drugs in preclinical study. Now ultrasound elastography, can objectively evaluate tumor stiffness, has been clinically applied for differentiation of breast mass, therefore we explored novel clinical significance of tumor stiffness measured by elastography in breast cancer. **Methods:** We reviewed 432 patients with breast cancer who underwent ultrasound elastography before any treatments, including 79 patients who received neoadjuvant chemotherapy (NAC). We compared pre-NAC tumor stiffness with responses to NAC in patients treated by NAC, and investigated correlations between tumor stiffness and clinicopathological factors in all patients. The tumor stiffness was evaluated by fat lesion ratio (FLR) by strain elastography. **Results:** We categorized patients into two groups according to tumor stiffness with a cutoff value of FLR 10: 185 patients with high FLR (Hard tumor group) and 247 patients with low FLR (Soft tumor group). In patients treated by NAC, the hard tumor group had significantly lower pathological complete response (pCR) rate than the soft tumor group: 18% (8/44) vs. 63% (22/35), P<0.0001). There were also significant differences of pCR rate when we limited the analysis to triple negative cases (Hard 25% vs. Soft 88%, P=0.03) and HER2-positive cases (Hard 55% vs. Soft 93%, P=0.02). Multivariate analysis indicated that tumor stiffness was an independent predictive factor of pCR (hard tumor: odds ratio 0.04, 95%CI 0.004-0.226, P<0.0001) as well as HER2 status. In all patients, tumor stiffness was significantly correlated with tumor size, lymph node metastasis and fibrotic finding by conventional ultrasound. **Conclusions:** Pretreatment tumor stiffness evaluated by ultrasound elastography had a significant relationship with response to NAC in patients with breast cancer.

**1062 General Poster Session (Board #155), Mon, 8:00 AM-11:45 AM**

**A pilot study of dose-dense (biweekly) carboplatin plus paclitaxel with or without trastuzumab as neoadjuvant treatment for breast cancer.** *Presenting Author: Teng Zhu, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China*

**Background:** Dose-dense regimens have been shown to improve outcome when given as adjuvant therapy to patients with breast cancer compared with their three weekly counterparts. We investigated the efficacy and safety of dose-dense (biweekly) carboplatin and paclitaxel ± trastuzumab as neoadjuvant treatment in early breast cancer. **Methods:** Patients with tumor more than 2cm with or without node-positive breast cancer received treatment with 4 cycles of carboplatin area under the curve (AUC) 5 biweekly and paclitaxel 175mg/m$^2$ biweekly, and biweekly trastuzumab 4mg/kg was added for human epidermal growth factor receptor 2 (HER2) positive status. All patients received primary prophylaxis (PP) with recombinant human granulocyte colony-stimulating factors (G-CSF) from day 2 to 3. **Results:** Between 01/2009-12/2013, one hundred and twenty-two patients enrolled. The overall pathologic complete response (pCR) rate was 40.1 %( 49 out of 122). The pCR rate was 4.5%(1 out of 22) in patients of Luminal A Subtype; 13.8% in patients of Luminal B(HER2-) Subtype; 50.0% (9 out of 18)in patents of Triple Negative Subtype; 64.0%(16 out of 25) in patients of Luminal B(HER2+) Subtype; 85.0%(18 out of 21) in patients of HER2+ Subtype. 89 of 122 (73%) completed all chemotherapy as planned; the remaining patients (27%) had treatment modifications for toxicity. The dose limiting toxicities resulting in treatment discontinuation included: grade 3/4 neutropenia, grade 3/4 anemia, grade 3/4 thrombocytopenia, and other grade 3 nonhematologic toxicity including bone pain, neuropathy, mucocitis etc. There were 29(23.8%) episodes of grade 3/4 neutropenia, 4(3.27%) episodes of grade 3/4 anemia, and 2 (1.64%) episodes of grade 3/4 thrombocytopenia and there were 3(2.45%) episodes of grade 3 neuropathy. **Conclusions:** Dose-dense neoadjuvant carboplatin plus paclitaxel±trastuzumab is feasible and the regimen is more effective in Luminal B(HER2+) Subtype, HER2+ Subtype and Triple Negative Subtype. Additional study about the postoperative follow-up of this regimen is warranted.

**1063 General Poster Session (Board #156), Mon, 8:00 AM-11:45 AM**

**Is guideline-adherent adjuvant treatment an equivalent option for elderly patients who cannot participate in adjuvant clinical breast cancer trials? A retrospective multicenter cohort study of 4,142 patients.** *Presenting Author: Lukas Schwentner, Department of Gynecology and Obstetrics University Ulm, Ulm, Germany*

**Background:** It is well accepted that innovation in oncology is transported through randomized clinical trials (CT). However, elderly patients (>65) are usually excluded from CT. Therefore this study tries to answer the following questions: (1) Is there a difference in outcome parameters comparing study participants (PA) and elderly patients who are not able to participate? (2) Is guideline adherent treatment an equivalent option for elderly patients (>65)? **Methods:** This German multi-center [17 participating hospitals all are certified as breast cancer centers] retrospective cohort study called BRENDA included study participants <65 (PA) and elderly breast cancer patients >65 (E) obtained from 1992 until 2008. The definition of guideline adherence was based on internationally validated guidelines. **Results:** After adapting the exclusion criteria we included 960 (23.2%) PA and 3.182 (76.8%) E >65. E >65 demonstrate a significantly inferior RFS [RFS: p<0.001; HR=1.67 (95% CI: 1.32-2.11)] and OS [OS: p<0.001; HR=1.98 (95% CI: 1.50-2.62)] compared to PA <65. Within the E group 1.868 (58.7%) patients received guideline adherent adjuvant treatment. However when comparing PA <65 versus guideline conform E >65 we are not able to demonstrate a significant difference in RFS [RFS: p=0.218; HR=1.17 (95% CI: 0.91-1.50)] and OS [OS: p=0.054; HR=1.34 (95% CI: 1.00-1.81)]. However non-guideline adherent E >65 demonstrated significantly inferior survival parameters [RFS: p<0.001; HR=2.10 (95% CI: 1.61-2.62)] [OS: p<0.001; HR=2.50 (95% CI: 1.87-3.33)] compared to PA. **Conclusions:** Guideline adherent adjuvant treatment is an equivalent option for elderly patients who are excluded from participation in clinical trials. There is a strong association between guideline adherence and improved outcome parameters in elderly breast cancer patients.

**1064 General Poster Session (Board #157), Mon, 8:00 AM-11:45 AM**

**Stemness gene expression profile and correlation with clinicopathologic features (CPfs) in breast cancer (BC) patients (pts).** *Presenting Author: Giovanni Benedetti, Medical Oncology Macerata Hospital, Macerata, Italy*

**Background:** Cancer stem cells (CSC) identify a small pool of cells with self-renewal and pluripotency properties responsible of tumor initiation, maintenance and recurrence. The overexpression of genes maintaining pluripotency properties of CSC was described in poorly differentiated BC subtypes. We analyzed a panel of genes, responsible of CSC reprogramming and behaviour in a heterogenous group of BC tissues and correlated the gene expression profile with CPfs and prognosis. **Methods:** 140 primary invasive BC specimens (luminal A/B/Her2+/TN; n. 21/53/41/25) were collected from operated pts. mRNA expression for SOX2, SOX15, ERAS, SALL4, OCT4, NANOG, UTF1, DPPA2, BMI1, GDF3, ZFP42, KLF4 and TCL1 genes was assessed by RT-PCR. Correlations with molecular subtypes, menopausal status, grading, ER, PR, ki67 ($<$ or $>$ 20%), HER2, T-size and node status (N) were evaluated by Fisher's exact test and $\chi^2$ test. Association of stemness genes, CPfs and DFS was estimated by univariate and multivariate Cox-regression analysis ($p \leq 0.05$) . **Results:** In 117 samples assessable, 9 out of 13 stemness genes resulted variably expressed: GDF3 = 9, Sox2= 11, ERAS= 20, sox15 = 25, TCL1= 29, Nanog = 52, KLF4 = 67, SALL4 = 68, BMI1 = 97, without any correlation with molecular subtypes. NANOG, GDF3 and SOX2 significantly correlated with grade 2, N negative and higher KI67 respectively (p=0.019, p=0.029, p= 0.035). At univariate analysis SOX2 expression (HR= 2,357; p= 0.002), KI67 (HR= 2,187; p=0.028), N (HR=2,205; p=0.014); ER/PR (HR=0,582/HR=0,589; p0.065/0.068, respectively) resulted statistically significant. According to multivariate analysis, SOX2 (HR= 2,99; 95% CI 1,41-6,30; p=0.004), N (HR=2,44; 95%CI 1,25-4,76; p=0.009) and T-size >1 (HR=1,77; 95% CI=0,99-3,13; p=0.051) were independently associated with increased risk of recurrence, PR expression was associated with better prognosis (HR=0,57; 95% CI= 0,53-0,29; p=0.035). **Conclusions:** Our analysis confirm that stemness genes are variably expressed in a heterogenous group of BC pts, albeit only specific genes seem to correlate with any CPfs. Of note, SOX2 appeared to be a prognostic marker of recurrence irrespective of other variables.

**1065 General Poster Session (Board #158), Mon, 8:00 AM-11:45 AM**

**Application of a dynamic retraining for each patient using case-specific training cohorts to predict survival in breast cancer patients.** *Presenting Author: Balazs Gyorffy, Ist Department of Pediatrics, Semmelweis University, Budapest, Hungary*

**Background:** To exceed prediction accuracy of previous multigene prognostic classifiers, we propose a new dynamic predictor. Our classifier does not use a single universal training cohort and an identical list of informative genes to predict the prognosis of new cases but a case-specific predictor is developed for each test case. **Methods:** Gene expression data from 3,534 breast cancers with clinical annotation including survival was analyzed. For each test case we select a case-specific training subset including only molecularly similar cases and a case-specific predictor is generated. This method yields different training sets and different predictors for each new patient but preserves the independence of model building and validation. The model performance was assessed in leave-one-out validation and also in 325 independent cases. **Results:** Prognostic discrimination was high for all cases (n=3,534, HR=3.68, p=1.67E-56). The dynamic predictor showed higher overall accuracy (0.68) than the 21-gene predictor (0.64), the 97-gene genomic grade index (0.55) or the 70-gene prognostic signature (0.41). The dynamic predictor was also effective in triple-negative cancers (n=427, HR=3.08, p=0.0093) where the above classifiers all failed. Validation in independent patients yielded similar classification power (HR=3.57). The dynamic classifier is available online at http://www.recurrenceonline.com/?q=Re_training. **Conclusions:** In summary, we developed a new method to make personalized prognostic prediction using case-specific training cohorts. The dynamic predictors outperform static models developed from single historical training cohorts and they also predict well in triple-negative cancers.

**1066 General Poster Session (Board #159), Mon, 8:00 AM-11:45 AM**

**A phase II neoadjuvant trial of sequential triweekly nanoparticle albumin-bound paclitaxel and cyclophosphamide followed by 5-fluorouracil/ epirubicin/ cyclophosphamide in the treatment of operable breast cancer.** *Presenting Author: Norio Masumoto, Department of Surgical Oncology, Hiroshima University, Hiroshima, Japan*

**Background:** Nanoparticle albumin-bound (nab) Paclitaxel has shown favorable efficacy and toxicity profiles compared to other taxanes in the treatment of metastatic breast cancer. In this phase II trial, we evaluated a nab-paclitaxel-containing neoadjuvant regimen in patients with operable breast cancer. **Methods:** Fifty-five women with operable breast cancer without prior treatment were enrolled. All patients were to receive tri-weekly nab-paclitaxel and cyclophsphamide (TRI-ABC) followed by 5-fluorouracil/ epirubicin/cyclophosphamide (FEC) every 3 weeks for 4 cycles. Tri-weekly trastuzumab was administered concomitant with TRI-ABC in HER2-positive (HER2+ or 3+) patients. Primary endpoint was pathologic complete response (pCR; CR) rate in breast cancer tissue and lymph nodes. Secondary endpoints included clinical response, safety, rate of breast conserving surgery and disease-free survival. **Results:** Fifty-four patients received at least 1 dose of chemotherapy and were included in this analysis. All patients completed 4 cycles of TRI-ABC and 50 completed 4 cycles of FEC. The pCR rate was 36.5% (19/54). More patients with HER2-positive or triple-negative cancer experienced a pCR [59% (10/17) for HER2-positive, 57% (8/14) for triple-negative] compared with those of ER-positive/HER2-negative cancer [4% (1/23)]. The most significant toxicities were grade 2/3 neuropathy (16%) in TRI-ABC and grade 3/4 febrile neutropenia (7%) in FEC. **Conclusions:** TRI-ABC and FEC containing neoadjuvant regimen was well tolerated and showed favorable efficacy, especially in patients with chemo-sensitive breast cancer. These results suggest that albumin-bound paclitaxel based neoadjuvant regimen should be further evaluated in patients with ER-negative or HER2-positive breast cancer. Clinical trial information: 000007180.

**1067 General Poster Session (Board #160), Mon, 8:00 AM-11:45 AM**

**Impact of pharmacogenetics on docetaxel as neoadjuvant treatment of breast cancer.** *Presenting Author: Hanjing Xie, Karolinska Institutet, University Hospital, Stockholm, Sweden*

**Background:** Marked inter-individual variability of docetaxel has been reported previously. The pharmacogenetic contribution to variations of docetaxel-related toxicity and therapeutic response has not yet been thoroughly studied. The polymorphic cytochrome P450 (CYP) 3A4 plays en essential role in the metabolism of docetaxel. A comparatively frequent allele - CYP3A4*22, which was recently identified, has been shown to correlate with reduced enzyme activity. In this study, we aimed to investigate the effect of CYP3A4 as well as CYP3A5 genotype on docetaxel treatment in breast cancer patients. **Methods:** In the PROMIX trial, 151 patients with breast cancer received preoperatively six courses of docetaxel and epirubicin. In case of no change or partial response after the first two courses, bevacizumab was added for the remaining four courses. Grade 3 or 4 adverse events (AEs) and data on clinical/radiological and pathological response were addressed in relation to CYP3A4 genotype. Blood samples were used to extract DNA for genotyping analyses. **Results:** The allelic frequency of CYP3A4*22 and CYP3A5 *3 were 3 % and 8 %, respectively. Seven patients had decreased catabolic activity of docetaxel (PM), 22 patients had increased activity (EM), and 121 patients had normal activity (IM). Regarding the toxicity, a clear genetic influence was seen. The frequency of grade 3/4 AEs was significantly higher in the PM group, compared to that in the EM and IM group (P=0.02). 71.4 % of the patients in the PM group reported grade 3/4 AEs, while the frequency for the EM and IM groups were only 45.5 % and 44.6 %, respectively. One single patient was homozygote for both CYP3A4*22 and CYP3A5 *3, thus lacking enzyme activity, experienced a fatal colon necrosis shortly after the first course of treatment. After a median follow up of 25 months, there were in total 33 relapses, but none of them reported from PM group. **Conclusions:** The allelic variants CYP3A4*22 and CYP3A5 *3 contribute significantly to the inter-patient variations of docetaxel treatment. The impact of pharmacogenetics on a widely used drug as docetaxel must be considered in the era of individualized therapies. Genotyping should be considered as a valuable tool for dose optimization. Clinical trial information: NCT00957125.

**1068 General Poster Session (Board #161), Mon, 8:00 AM-11:45 AM**

**Cardiovascular magnetic resonance imaging compared to echocardiogram for detecting doxorubicin-induced cardiotoxicity.** *Presenting Author: Haleem J. Rasool, Mayo Clinic Health System, La Crosse, WI*

**Background:** Doxorubicin is a standard treatment for breast cancer, lymphoma, and leukemia. The benefits of doxorubicin are limited by its potential for cardiotoxicity. In this study we investigated whether MRI is superior to echocardiogram in detecting a reduction in cardiac systolic function indicative of doxorubicin toxicity. **Methods:** We studied all eligible prospective patients ages 18 years and above who presented to Mayo Clinic Health System, La Crosse WI, for the treatment of breast cancer or lymphoma and who were offered treatment with doxorubicin with curative intent dosing (240 - 300 mg/m2) between March 1, 2009 and October 2013. Patients received baseline cardiac MRI and echocardiogram. Both studies were repeated after 4 cycles of treatment. Ejection fraction calculated by both methods was compared and analyzed using the T-test. **Results:** We enrolled 28 eligible patients between the ages of 39 and 78 years. Twenty six patients received baseline echocardiogram and cardiac MRI. Eighteen patients completed the post treatment studies after 4 cycles of doxorubicin. Seven patients declined to undergo post treatment studies. The average baseline EF by echocardiogram was 61.5% and by MRI was 61.8%. Post treatment EF by echocardiogram was 60.9% and by MRI was 57.1%. There was no statistically significant drop in EF by echocardiogram while there was a statistically significant drop in EF using cardiac MRI ($p$ value $< 0.05$). Cardiac MRI findings alone did not lead to any doxorubicin dose reductions. **Conclusions:** Cardiac MRI is superior to echocardiogram in detecting doxorubicin induced reduction in cardiac systolic function. Echocardiogram is less expensive and more convenient for patients while MRI may be more sensitive in detecting doxorubicin cardiotoxicity. A larger study to confirm these findings is needed.

**1069 General Poster Session (Board #162), Mon, 8:00 AM-11:45 AM**

**The efficacy and safety of paclitaxel injection concentrate for nanodispersion (PICN) at two different doses versus paclitaxel albumin-stabilized nanoparticle formulation in subjects with metastatic breast cancer (MBC).** *Presenting Author: Minish Mahendra Jain, KEM Hospital and Research Center, Pune, India*

**Background:** PICN is a novel, solvent- and protein-free, 100-110 nm particle formulation of paclitaxel stabilized with polymer and lipids using Nanotecton Technology. We compared the safety and efficacy of PICN at two different doses versus paclitaxel albumin-stabilized nanoparticle formulation in a 3-weekly schedule in subjects with MBC. **Methods:** In this randomized, controlled non-inferiority trial,180 subjects aged18-65 years, with MBC, ECOG performance status $\leq 2$, estimated survival $\geq 12$ weeks and adequate organ function, were enrolled and randomly assigned to PICN 260 mg/m$^2$, PICN 295 mg/m$^2$, or paclitaxel albumin-stabilized nanoparticle formulation 260 mg/m$^2$. Both PICN and paclitaxel albumin-stabilized nanoparticle formulation were administered as a 30 min infusion in a 3-weekly dosing schedule. Treatment was continued until disease progression or the occurrence of unacceptable toxicity. Efficacy was evaluated according to RECIST 1.1 and safety was assessed using CTC-AE version 4.0. **Results:** A total of 180 subjects were enrolled in the study; 64 to PICN 260 mg/m$^2$ and 58 each to PICN 295 mg/m$^2$ and paclitaxel albumin-stabilized nanoparticle formulation 260 mg/m$^2$. Baseline demographic, medical and treatment history, and histologic criteria were well balanced. By independent blinded radiological assessment, no statistical difference was observed in ORR (Objective Response Rate) when PICN 260 mg/m$^2$ and paclitaxel albumin-stabilized nanoparticle formulation (35.4% v 42.5%, respectively; P=.76) or when PICN 295 mg/m$^2$ and paclitaxel albumin-stabilized nanoparticle formulation (48.8% v 42.5%, respectively; P=.62) were compared. No hypersensitivity reactions occurred with PICN despite the absence of premedication. The most frequently reported AEs were neutropenia, peripheral neuropathy and pain. The incidence of grade 3/4 neutropenia was 12.5, 24.1, and 20.6% in PICN 260 mg/m$^2$, PICN 295 mg/m$^2$, and paclitaxel albumin-stabilized nanoparticle formulation arm, respectively. Grade 3/4 peripheral neuropathy occurred in 7.8, 19, and 15.5% subjects with PICN 260 mg/m$^2$, PICN 295 mg/m$^2$and paclitaxel albumin-stabilized nanoparticle formulation arm, respectively. **Conclusions:** PICN when administered as 3-weekly dosing schedule demonstrated equal efficacy and a favorable safety profile compared to paclitaxel albumin-stabilized nanoparticle formulation in MBC. Clinical trial information: CTRI/2010/091/001116.

**1070 General Poster Session (Board #163), Mon, 8:00 AM-11:45 AM**

**Additional metabolic effects at the neoadjuvant chemotherapy (NCT) of locally advanced breast cancer (LABC).** *Presenting Author: Natalya A Abramova, Rostov Scientific Research Institute of Oncology, Rostov-on-Don, Russia*

**Background:** Dissociation of cellular respiration and oxidative phosphorylation (OF) in the mitochondria promotes activation of regulatory cascades of apoptosis and necrosis. Probably the local impact of drugs that block the various stages of the Krebs cycle - diphenhydramine (D) (NAD↔NADH transformations) or ATF (aerobic ATF resynthesis inhibition due to feedback)- may result in increased the damaging action of cytostatics. Coordination of key Krebs cycle enzymes activity when peritumoral injected D/ATF with clinical efficacy on LABC NCT was investigated. **Methods:** Elegibility criteria included measurable histologically verified LABC T3-4N0-3M0, ECOG$\leq$1. 2 cycles of NCT (FAC) were combined with injection of D/ATF in peritumoral zone 30 minutes before the start of NCT in the test group. Tumor response was assessed and compared to control group. OF processes activity was evaluated by the method of measuring of succinate dehydrogenase (SDH) and $\alpha$-glycerophosphate ($\alpha$-GPDH) in blood peritumoral lymphocytes before and 30 minutes after D/ATF injection, prior to administration of NCT (test group). **Results:** 60 pts were recruited (30- test and 30- control group). Test group tumor response was: CR 16,7%(5),PR 66,6%(20),SD16,7%(5). Control group tumor response was PR 66,6%(20),SD 30,0%(7),PD 3,4%(1). Differences are valid for CR ($p=0.014$) and SD($p=0.019$). Decrease in the activity of LDH after ATF was observed in 62.5% of the samples ($p=0.021$), after D- in 57.9% of the samples ($p=0.024$), the increase in $\alpha$-GPDH after D/ATF- in 41.6% of samples ($p=0.022$). The data showed a decrease in intensity of the OF in peritumoral area by injection of D/ATF. **Conclusions:** Changes in the activity of key Krebs cycle dehydrogenases in peritumoral lymphocytes with injections of D/ATF corresponds to clinical data on significant improvement in tumor response NCT LABC pts.

**1071 General Poster Session (Board #164), Mon, 8:00 AM-11:45 AM**

**Neoadjuvant chemotherapy for patients with breast cancer during pregnancy (BCP).** *Presenting Author: Sibylle Loibl, German Breast Group/Sana Klinikum Offenbach, Neu-Isenburg, Germany*

**Background:** Neoadjuvant therapy (NAT) is increasingly considered the treatment of choice for patients with HER2+ and triple-negative (TNBC) breast cancer. It is recommended to treat patients with breast cancer during pregnancy as closely as possible according to patients diagnosed outside pregnancy. Data on NAT during pregnancy are scarce. We compared patients with BCP who received NAT with pregnant patients who received NAT after delivery. **Methods:** Patients from the registry of the German Breast Group (GBG 29/BIG 02-03) and the international Cancer in Pregnancy initiative with BCP who received NAT were analyzed. A non-pregnant control cohort was matched using the Propensity Score based on age, cT Stage (cT 1-2 vs 3-4), cN Stage (cN0 vs cN+), grading (1 vs 2 vs 3), ER/PgR, HER2, neoadjuvant trastuzumab therapy. **Results:** 103/130 neoadjuvant treated BCP patients were identified with complete data who received NAT during pregnancy (n=62) or after delivery (n=41). Baseline characteristics were comparable. 42% HER2+ and 34% had TNBC. Median age was 34 years. BC was diagnosed in the first or second trimester in 63% of patients with NAT during pregnancy and in 19% of patients with NAT after delivery ($p<0.001$). Non-taxane containing regimen received 26% of patients with NAT during pregnancy compared to 5% of patients with NAT after delivery ($p<0.001$), taxane sequence received 73% and 69%, taxane combination received 0 vs 27%, and neoadjuvant trastuzumab received 64% vs. 77%, respectively. pCR (ypT0 ypN0) rate was 24% vs 23% ($p=1.0$). There was no difference in DFS and OS for patients with NAT during pregnancy vs thereafter (log rank $p=0.940$ and $p=0.653$). **Conclusions:** Based on this first analysis it seems that NAT during pregnancy is as effective as after delivery in patients with BCP. Results of the comparison with a non-pregnant control-cohort treated with NAT will be presented at the meeting.

**1072 General Poster Session (Board #165), Mon, 8:00 AM-11:45 AM**

**Sorafenib (SOR) plus docetaxel (DOC) as first-line therapy in patients with HER2-negative metastatic breast cancer (MBC): A randomized, placebo-controlled phase II trial.** *Presenting Author: Frederik Marme, National Center for Tumor Diseases, Gynecologic Oncology, Heidelberg, Germany*

**Background**: Anti-angiogenic therapy with the monoclonal anti-VEGF antibody Bevacizumab (Bev) in combination with chemotherapy increases overall response rates (ORR) and progression free survival (PFS) but without impact on overall survival. SOR, an anti-angiogenic multi-tyrosine kinase inhibitor (TKI) also targeting tumor growth directly, is approved for advanced renal cell and hepatocellular carcinoma. Three phase IIb trials (SOLTI-0701, NU07B1, AC01B07) have reported efficacy of SOR in combination with chemotherapy in MBC, even after prior Bev (AC01B07). As TKIs might have superior activity we conducted this trial in first-line MBC. **Methods**: Pts were randomized to DOC (75mg/m$^2$ q3w) + either SOR (400 p.o. twice daily (BID)) or placebo. Following an amendment after the inclusion of 63 pts, the SOR starting dose was reduced to 400 mg/d for cycle 1 and 600 mg/d for cycle 2 with the option to increase the dose to 800 mg/d after the second cycle in the absence of > grade 1 toxicities. The planned sample size was 288, but due to slow accrual the study was closed early after 102 patients. The primary end point was progression free survival (PFS). Important secondary endpoints were overall response rate (ORR), duration of response, time to progression (TTP), overall survival (OS) and safety/tolerability. Here we report the data after 78 PFS events in 95 evaluable patients. **Results**: Median age was 57 years with 71.6% of patients being post-menopausal. 74.5 of patients had a positive estrogen receptor (ER) status and 47.1% and 48.0% of patients had a tumor grading 2 and 3, respectively. Overall, as of December 13$^{th}$2013, the median PFS was 7.4 months with a median TTP of 7.9 months, a median duration of response of 8.9 months and an ORR of 47.1%. The corresponding median OS was 21.2 months. Grade 3 to 4 toxicities (> 5% of pts) included neutropenia (31%), lymphopenia (25%), leukopenia (25%), HFSR (19%), diarrhea (11%), febrile neutropenia (9%), and fatigue (8%). **Conclusions**: Final efficacy data including overall survival and detailed safety data will be presented by treatment arm. Comparative efficacy and safety data will also be presented by SOR dosing schedule. Clinical trial information: EUDRACT-Nr. 2008-001090-15.

**1073 General Poster Session (Board #166), Mon, 8:00 AM-11:45 AM**

**Response rates of taxane rechallenge in metastatic breast cancer patients, previously treated with adjuvant taxanes.** *Presenting Author: Arzu Oguz, Baskent University, Medical Oncology Department, Ankara, Turkey*

**Background:** This study was conducted to determine the efficacy of taxane-based regimens in metastatic breast cancer patients who have already taken taxanes in their adjuvant treatments and also to assess the response rates in each treatment line. **Methods:** The data of 938 metastatic breast cancer patients who had taken adjuvant taxane based chemotherapy, were reviewed retrospectively. Besides demographical variables, the treatments that were given when metastases occured, response rates (RR), clinical benefit rates (CBR: complete response (CR)+ partial response (PR) + stable disease (SD)) and progression free survival values were determined. For patient and tumor characteristics, descriptive statistical methods were used. Chi-Square test was used to compare differences between categorical variables. Kaplan-Meier curves were drawn to obtain survival probabilities and log rank test was used to compare these curves between groups. **Results:** Of 938 cases, metastases were detected in 189 (20.1%) during follow-up. The response rate in 45 patients receiving re-challenge with taxanes as first line treatment was 51.2% consisting of 4 (8.8%) complete and 19 (42.2%) partial remissions. The RR and CBR of taxane re-challenge in first line and later line therapies are summarized in the Table. When RR and progression free survivals were taken into account, there were no significant differences detected between patients receiving re-challenge with taxanes who had less than 2 years DFS until recurrence compared with those having DFS values more than 2 years (p values were 0.3 and 0.65 respectively). **Conclusions:** Re-challenge with taxanes both in the first line and later line trearments appear to be effecive and seems to be a reasonable option in taxane pre-treated patient group, due to the satisfactory response rates in all treatment lines. It was not possible to make a suggestion for those patients who had a DFS less than 1 year because of poor number of patients.

**Response rates of taxane rechallenge in treatment lines.**

**1074 General Poster Session (Board #167), Mon, 8:00 AM-11:45 AM**

**Phase I trial of the PARP inhibitor veliparib (V) in combination with carboplatin (C) in metastatic breast cancer (MBC).** *Presenting Author: Robert Wesolowski, The Ohio State University, Columbus, OH*

**Background:** Poly(ADP-ribose) polymerase (PARPi) inhibitors have shown activity in BRCA mutant and triple negative breast cancers (TNBC). The ideal dose and schedule of C and oral PARPi V is not known. We used sequential fluoro-3'-deoxythymidine (FLT) PET imaging and correlated tumor uptake to C with varying doses/schedules of V. **Methods:** To identify the recommended phase 2 dose (RP2D) of V when combined with C in patients (pts) with MBC with either TNBC or HER2 negative/estrogen receptor positive tumors with defective Fanconi Anemia (FA) pathway (i.e. no FANCD2 foci in nuclei of proliferating tumor cells via FA Triple Stain Immunofluroscence test), we used a standard 3+3 phase I design. Escalating doses of V were evaluated on a 7, 14, or 21-day schedules (table). Response was based on RECIST criteria using FDG PET/CT scans. FLT PET was done at baseline, cycle 1 day 7 and 14 or 21 and after cycle 3. Lesions were track-matched with FDG PET/CT and semi-quantitatively assessed using 2D ROI placement in a matched, blinded fashion. **Results:** 44 pts with a median of 2 prior lines of chemotherapy (range 0-3), received a median of 5 cycles (range 1-36); 39 had TNBC. The table shows observed DLTs. Of 43 evaluable pts, 18.6% had a PR; 48.8% had SD. Of 16 pts with BRCA 1/2 mutation or defect in FA pathway, 25% had a PR and 62.5 % had SD. The change in SUV on FLT PET between baseline and follow up scans did not depend on dose or schedule of V (N=24). Pts with PR had significant drop in max SUV of target lesions between baseline and day 14 or 21 FLT PET compared to non-responders (p=0.046 - Wilcoxon Rank Sum test). **Conclusions:** Combination of V and C is active in MBC. Thrombocytopenia was the major toxicity observed. The RP2D is C: AUC 5 and V: 250 mg bid on days 1-21. We observed that early drop in SUV values on FLT PET was predictive of response. The study is supported by U01 CA076576. Clinical trial information: NCT01251874.

**Safety and efficacy of *nab*-paclitaxel (*nab*-P) in patients (pts) with metastatic breast cancer (MBC): Real-world results from a U.S. health insurance database.** *Presenting Author: Debra A. Patt, McKesson Specialty Health, The Woodlands, TX*

**Background:** *nab*-P is an albumin-bound formulation of paclitaxel approved in 2005 for the treatment of breast cancer after failure of combination chemotherapy for metastatic disease or relapse within 6 months of adjuvant chemotherapy, based on an international phase 3 trial comparing *nab*-P with paclitaxel on an every 3 week (q3w) schedule. The objective of this study was to characterize safety and efficacy outcomes of *nab*-P in MBC in the United States using health insurance claims data. **Methods:** A retrospective claims analysis was conductedusing the Optum Research Database (United Health affiliate). The analysis included women aged ≥ 18 years diagnosed with MBC (≥ 2 claims of BC diagnosis separated by ≥ 30 days and ≥ 2 claims of metastatic spread) prior to *nab*-P initiation. Pts had ≥ 6 months of continuous enrollment in a US health insurance plan from January 2005 through September 2012, complete medical coverage and pharmacy benefits, no other primary malignancy, and no prior *nab*-P. Data were supplemented by Social Security Death Index sources. Cohorts were determined by line of therapy, *nab*-P regimen, and schedule. Descriptive statistics were used to characterize outcomes. Endpoints included treatment patterns, time to treatment discontinuation (TTD), overall survival (OS), and safety. **Results:** Of the 664 eligible pts, most were between 40-69 years of age (88%) and had received *nab*-P as ≥ second-line therapy (74%), monotherapy (61%), and weekly dosing (71%). Agents used in combination with *nab*-P included bevacizumab (22%) and HER2-targeted therapies (9%). Median TTD and OS were 6.1 and 17.4 months, respectively. By line of therapy (first, second, and ≥ third), TTD was 7.1, 6.6, and 5.3 months and OS was 22.7, 17.4, and 15.1 months. In a subgroup of pts with aggressive disease (≤ 50 years of age or having ≥ 3 metastases), median OS was 15.6 months, similar to the overall cohort. No new safety signals were observed. **Conclusions:** Consistent with clinical trial data, outcomes in this real-world population confirm the effectiveness and manageable safety profile of *nab*-P in pts with MBC. This analysis will also help evaluate the benefit of *nab*-P in pts aged ≥ 70 years.

**1076 General Poster Session (Board #169), Mon, 8:00 AM-11:45 AM**

**Does chemotherapy schedule matter when combining with bevacizumab? A stratified meta-analysis of randomized controlled trials.** *Presenting Author: Twan Ying Chang, National Taiwan University Hospital, Taipei, Taiwan*

**Background:** Adding bevacizumab (Bev) to chemotherapy (CT) improved the objective response rate and progression free survival (PFS) in many randomized controlled trials (RCTs), but the magnitude of benefit varied. For example, in advanced breast cancer, the magnitude of prolongation of PFS in weekly chemotherapy study (E2100) was more significant than that in non-weekly chemotherapy studies (AVADO and RIBBON-1). We conducted a meta-analysis to examine the association of chemotherapy schedules with Bev benefit in advanced cancers. **Methods:** Through literature search, we identified 26 RCTs which compared combination of Bev plus CT with CT alone for advanced cancers. Among them, 21 RCTs which contained different CT schedules within certain cancer type were enrolled. These included 5, 4, 5 and 7 RCTs for breast, ovary, lung and colorectal cancers. A meta-analysis with random effects model was conducted to generate summary estimates of Bev benefit in terms of the improvement of PFS. CT schedules were classified into weekly (w), non-weekly (non-w), and weekly + non-weekly (w/non-w). We performed the stratified analysis of CT schedules, CT drugs, and CT lines, cancer types, and Bev dosage/schedule. The Bucher's method was used to indirectly compare the PFS improvement from Bev. **Results:** Among the 21 RCTs, 7, 12, and 2 studies were with w, non-w, and w/non-w CT schedules, respectively. Overall, Bev in combination with CT was associated with a significant benefit of PFS (hazard ratio [HR], 0.66; 95% CI, 0.60-0.73). The HRs for w, non-w, and w/non-w CT schedules were 0.53 (95% CI: 0.45-0.63), 0.74 (95%CI: 0.68-0.81), and 0.61 (95% CI: 0.40-0.93), respectively. Using Bucher's method, the benefit of adding Bev was significantly greater in w CT schedule than that in the non-w CT schedule (HR: 0.71; 95% CI: 0.59-0.87). In contrast, the benefit of adding Bev did not statistically differ among various CT drugs, CT lines, cancer types, or Bev dosage/schedule. The overall heterogeneity ($I^2$=76.1% for 21 RCTs) was reduced after CT schedule stratification ($I^2$=36.7% for w and $I^2$=52.1% for non-w CT schedule). **Conclusions:** When combining Bev with CT, weekly CT schedule was associated with greater improvement of PFS.

**1077 General Poster Session (Board #170), Mon, 8:00 AM-11:45 AM**

**Comparison of the clinical treatment score with the adjuvant online score and the risk for recurrence score for estimating prognosis in early-stage high-risk breast cancer patients: A Hellenic Cooperative Oncology Group study.** *Presenting Author: Kyriaki Pliarchopoulou, Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece*

**Background:** Early breast cancer is a heterogeneous disease, and, therefore, prognostic tools have been developed to evaluate the risk for distant recurrence. We compared the Clinical Treatment Score (CTS) with the Adjuvant Online Score (AOS) and the Risk for Recurrence Score (RRS) based on the expression of three proliferation markers (RACGAP1, Ki67 and TOP2A) in high-risk early breast cancer patients. **Methods:** A total of 1,681 patients, enrolled in two prospective phase III trials, were treated with anthracycline-based adjuvant chemotherapy. Formalin-fixed paraffin-embedded primary tumor tissue samples with adequate material were obtained from 898 patients. Sufficient RNA was extracted from 875 samples (52.1% of the randomized patients) followed by multiplex RT-PCR for assessing RACGAP1, Ki67, TOP2A and CALM2 mRNA expression. The CTS integrated the prognostic information from nodal status, tumor size, histological grade and age. **Results:** CTS was prognostic for disease-free survival (DFS, $p<0.0001$), while CTS, AOS and RRS were all prognostic for overall survival (OS, $p<0.0001$, $p<0.0001$, $p=0.036$, respectively). The use of AOS in addition to CTS added prognostic information regarding DFS (LR-$\Delta\chi^2$ 11.9592, $p<0.0001$). However, the use of RRS in addition to CTS was not proven to be a better prognostic tool in terms of DFS (LR-$\Delta\chi^2$ 0.8495; $p=0.357$). For estimating OS, the use of either AOS or RRS in addition to CTS added significant prognostic information. Specifically, the use of both CTS and AOS had significantly better prognostic value vs CTS alone (LR-$\Delta\chi^2$ 28.2266, $p<0.0001$), as well as the use of CTS and RRS vs CTS alone (LR-$\Delta\chi^2$4.2057; $p=0.040$). Additionally, more patients were scored as high-risk by AOS than CTS. **Conclusions:** Using CTS, AOS or RRS provides prognostic information in high-risk early breast cancer patients, with more patients determined as high-risk by AOS. The combination of CTS and AOS adds significant prognostic information compared to CTS alone for DFS, while the combination of CTS with either AOS or RRS are better prognostic tools than CTS alone for OS.

**1078 General Poster Session (Board #171), Mon, 8:00 AM-11:45 AM**

**Chemosensitivity and endocrine sensitivity predicted by mammaprint and blueprint in the Neoadjuvant Breast Registry Symphony Trial (NBRST).** *Presenting Author: Pat W. Whitworth, Nashville Breast Center, Nashville, TN*

**Background:** Classification into molecular subtypes is important for the selection of therapy for patients with breast cancer. Previous analyses demonstrated that breast cancer subtypes have distinct clinical outcome (Gluck, BCRT 2013). The aim of the prospective NBRST study is to measure chemosensitivity as defined by pathological Complete Response (pCR), or endocrine sensitivity as defined by partial response (PR) and metastasis-free survival in molecular subgroups. **Methods:** The study includes women aged 18-90 with histologically proven breast cancer, who are scheduled to start neo-adjuvant chemotherapy (NCT) or neo-adjuvant endocrine therapy (NET), and who provide written informed consent. Additional inclusion criteria include no excision biopsy or axillary dissection, no confirmed distant metastatic disease, and no prior therapy for breast cancer. Treatment is at the discretion of the physician adhering to NCCN approved regimens. **Results:** 336 Patients, T1-4 N0-3, had definitive surgery and the overall pCR rate was 24%. 32/167 (19%) IHC/FISH ERPR+/HER2- patients were re-classified by BluePrint (31 Basal). 43/95 (45%) IHC/FISH HER2+ patients were re-classified by BluePrint (25 Luminal and 18 Basal). 3/74 (3%) IHC/FISH triple negative patients were not Basal by BluePrint. Of 45 (13%) patients classified as Luminal A 32 received NCT; 1 patient (3%) had a pCR; 13 patients received NET and 9 (70%) had a PR. Of 116 (35%) patients classified as Luminal B 111 received NCT and 7 (6%) had a pCR. The pCR rate (17/149 (11%)) in IHC/FISH ERPR+/HER2- patients was higher. 55 (16%) are BluePrint HER2 and received NCT (51 plus trastuzumab); 27 (49%) had a pCR compared to 35/95 (37%) in IHC/FISH HER2+ patients. 120 (36%) are BluePrint Basal and received NCT; 46 (38%) had a pCR, similar to the pCR percentage seen in the 74 patients designated triple-negative by IHC/FISH. **Conclusions:** Molecular subtyping using MammaPrint and BluePrint leads to a reclassification of 23% (78/336) of tumors. BluePrint reclassification resulted in better grouping of patients into expected response groups compared to local surrogate subtyping with immunostains. Clinical trial information: NCT014799101.

**1079 General Poster Session (Board #172), Mon, 8:00 AM-11:45 AM**

**High-dose methotrexate for metastatic breast cancer to the central nervous system: A single-institution review of 46 patients.** *Presenting Author: Margaret A. Schwartz, Northwestern University, Chicago, IL*

**Background:** The prognosis for patients with metastatic breast cancer to the central nervous system (CNS) is poor. Methotrexate (MTX) is an active agent in the treatment of breast cancer and penetrates the CNS at high doses and rapid rate of infusion. **Methods:** We performed an IRB approved retrospective review of patients treated at Northwestern from 8/1/2003 to 12/31/2013. Demographic data collected included date of diagnosis, time to CNS metastases, Karnofsky Performance Status, HER-2 and hormone status, radiographic and/or cytologic response to MTX, progression-free survival (PFS) and overall survival (OS). **Results:** Forty-six patients met criteria for inclusion. All patients were women with a median age of 49 (range 28-80) and average KPS of 70 (range: 20-100). Median number of doses was 4 (range 1-22), dosed at 3.5 gm/m2. The median PFS and OS were 3.4 and 4.1 months (m). Patients with ER/PR- disease had median PFS/OS of 5.2m/8.7m (HER2-) and 1.2m/3.0m (HER2 +). Patients with ER/PR+ disease had median PFS/OS of 3.4m/4.1m (HER2 -) and 3.4m/3.8m (HER2 +). When response was evaluated based on KPS, PFS/OS rates are 6.8m/15.2m for patients with KPS≥70. Patients with KPS<70 had PFS/OS rates of 3.2m/4.0m. Six patients are alive after completing MTX treatment and continue systemic therapies. There were 34 patients with scans for treatment evaluation: 1 complete response, 3 partial responses, and 16 patients had stable disease. Most common toxicities were anemia, hypokalemia, mucositis, transient elevations in liver enzymes, and thrombocytopenia. **Conclusions:** High-dose intravenous methotrexate remains a treatment option for patients with CNS metastases of breast cancer. Patients with ER/PR negative disease trended toward better PFS and OS. Patients with KPS less than 70 may not warrant treatment given shorter survival.

**1080 General Poster Session (Board #173), Mon, 8:00 AM-11:45 AM**

**Effect of overexpression of human kinesin-14 family motor HSET on tumor progression and clinical outcomes in breast cancer patients.** *Presenting Author: Vaishali Pannu, Georgia State University, Atlanta, GA*

**Background:** Centrosomes are frequently amplified in human cancers. Breast cancers, in particular, display extra centrosomes in about 80% of tumor cells. Although amplified centrosomes could potentially compel cells to form multipolar spindles resulting in death-inducing aneuploidy, cancer cells cleverly turn things in their favor by suppressing multipolarity via centrosome clustering during mitosis. Thus cancer cells display bipolar spindles and derive the collateral benefit of maintaining low-level aneuploidy, an edge to their survival. HSET/KifC1, a kinesin-like minus-end directed microtubule motor, has recently found fame as a crucial centrosome clustering molecule. **Methods:** Samples from 193 breast carcinoma patients were immunohistochemically-stained for HSET, and its overexpression was correlated with progression-free survival (PFS) and overall survival (OS). FISH was performed on a subset of 30 samples using BAC probes from HSET locus on Chr. 6 and its centromere. Cell cycle profiling and immunoblot analysis of cell proliferation markers was done in HeLa and stably transfected HeLa-HSET-GFP cells; and in MDA-MB-231 breast cancer cells with or without transient HSET-GFP overexpression. **Results:** HSET was overexpressed in breast cancers and its nuclear accumulation correlates with histological grade. High HSET expression predicted poor PFS and OS. Further, deregulated HSET protein expression in breast cancers was associated with gene amplification and/or translocation. HSET overexpression promotes clonogenic survival and enhances kinetics of progression through G2 and M-phases of cell cycle at least in part, by disrupting spindle assembly checkpoint control. Importantly, HSET overexpression leads to upregulation of survivin, Aurora B, HIF1$\alpha$ and Bcl-2, thus delineating HSET-HIF1$\alpha$-Aurora B as a novel oncoprotein axis that spurs tumor progression. **Conclusions:** We offer first evidence of centrosome-clustering independent roles of HSET that fuel tumor progression and firmly establish HSET overexpression as a driver of tumor evolution. HSET may serve both as a potential prognostic biomarker and as a cancer-selective therapeutic target.

**1081 General Poster Session (Board #174), Mon, 8:00 AM-11:45 AM**

**Adjuvant taxane therapy for early-stage breast cancer: A real-world comparison of chemotherapy regimens in Ontario.** *Presenting Author: Sofia Torres, Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

**Background:** FEC-D (5-FU, epirubicin, cyclophosphamide - docetaxel) and dd (dose-dense) AC-P (doxorubicin-cyclophosphamide - paclitaxel) are considered equally effective regimens in the adjuvant treatment of breast cancer (BC), although never compared directly in a clinical trial. We compared the outcome of BC patients (pts) treated with FEC-D, dd AC-P and AC-P (q3 weekly). **Methods:** Retrospective study including all female BC pts diagnosed in 2003-2009 in Ontario, who received 1 of those regimens (ascertained from New Drug Funding Program and physician claims databases). Primary endpoint: overall survival (OS). Secondary endpoints: emergency room (ER) visits/admissions, risk of heart failure (HF). Analysis were conducted for OS and HF using Kaplan-Meier method and adjusted for confounders using proportional hazard models. Multivariable logistic regressions were performed for ER visits/admissions adjusting for confounders. FEC-D and ddAC-P were compared using propensity score (PS) matching. **Results:** 8,462 pts were identified, 4,710 (55.7%) received FEC-D, 2,065 (24.4%) AC-P and 1,687 (19.9%) dd AC-P. Patient characteristics were imbalanced between the arms. In unadjusted analyses, 5-year OS was 91.7% for FEC-D, 89.0% for dd AC-P and 87.4% for AC-P; after PS matching, it was 92% for FEC-D and 89% for ddAC-P. After adjusting for confounders, risk of death was lower for dd AC-P than AC-P (HR=0.76; 95% CI 0.61-0.96), and higher for dd AC-P than FEC-D (HR=1.24; 0.99-1.54) and for AC-P than FEC-D (HR=1.61; 1.26-2.06). ER visits / admissions during treatment, were higher for FEC-D (respectively, 50.5% and 23.7%), than AC-P (35.2% and 11.6%) and dd AC-P (30.5% and 8.4%); the differences persisted after PS matching (respectively, 48.2% and 23.5% for FEC-D, 31.1% and 8.7% for dd AC-P; p<0.0001). Risk of HF at 5 years for the PS matched groups was 1.37% for FEC-D and 1.49% for dd AC-P (p=0.71). **Conclusions:** OS was better for FEC-D and dd AC-P when compared with AC-P. This may be attributable to imbalances in patient characteristics. Propensity score matching for dd AC-P and FEC-D showed no difference in survival or HF risk between the arms but pts treated with FEC-D continued to have more ER visits/admissions.

**1082 General Poster Session (Board #175), Mon, 8:00 AM-11:45 AM**

**Nonmetastatic inflammatory breast cancer: Evolution of invasive disease-free (IDFS) and overall survival (OS) over a 21-year period.** *Presenting Author: Mahmoud Fekih, Department of Medical Oncology, Gustave Roussy, Villejuif, France*

**Background:** Inflammatory breast cancer (IBC) is a very aggressive type of locally advanced BC with a poor prognosis. Its management incorporating preoperative chemotherapy (CT), surgery, radiotherapy (RT), and hormone therapy (HT), when indicated, has become standard in the late 80s. Little is known regarding the evolution of its prognosis throughout the past 20 yrs. The objective of this single center study was to evaluate the evolution of IDFS and OS among patients (pts) with newly diagnosed, localized IBC. **Methods:** We retrospectively reviewed the records of all pts treated at Gustave Roussy for localized IBC between 01/01/1988 and 31/12/2008. 280 pts were eligible for the study. Pts were subdivided in 4 time groups: 1988 to 1992, 1993 to 1997, 1998 to 2002 and 2003 to 2008. We estimated IDFS and OS from the time of diagnosis using the Kaplan-Meier method. Log-rank tests were used to compare survival curves. **Results:** Median age was 51 yrs (22-91). 52 % of 231 cases tested for ER were positive and 33% of 78 cases tested for Her2 were positive. Pts received CT (98 %), surgery (55 %), RT (96 %) and HT (61%). Pts characteristics, median IDFS and OS across to 4 periods are all reported in Table 1. While IDFS and OS were mostly stable between 1988 and 2002, a significant improvement was noted thereafter (logrank p-value comparing 4$^{th}$period with the 3 other is 0.046 for IDFS and 0.056 for OS). During the 2 last time periods, median IDFS was 38 mo in Her2+ pts vs 46 mo in Her2- pts (p=0.27), while median OS was 96 mo in Her2+ vs 74 mo in Her2- pts (p=0.33). **Conclusions:** This study demonstrated a significant improvement in DFS and OS of IBC over the past two decades, especially since 2003.

**1083 General Poster Session (Board #176), Mon, 8:00 AM-11:45 AM**

**Developing and evaluation of a new clinicopathologic response index after neoadjuvant chemotherapy as a predictor of clinical outcomes in locally advanced breast cancers.** *Presenting Author: Tarek M. A. Abdel-Fatah, Nottingham University City Hospital NHS Trust, Nottingham, United Kingdom*

**Background:** There is an urgent need to identify a set of clinico-pathological criteria which is more sensitive than pathological complete response (pCR) to assess the response to neo-adjuvant chemotherapy (Neo-ACT) and to guide the subsequent adjuvant therapy (AT). **Methods:** We performed a clinico-pathological assessment of 427 patients who had completed Neo-ACT with a median follow-up of 5-years. The patients were divided into: 1) Training set (n=172) treated with anthracycline combination (AC); 2) Internal validation set (n=130) treated with AC+Taxane; and 3) external validation set (n=125) treated with AC-/+Taxane. **Results:** Among the clinico-pathological factors associated with higher risk of relapse and death after Neo-ACT in univariate analysis: absence of fibrosis in both primary tumour site and lymph node (LN), presence of lymphovascular invasion, and increasing number of LN metastases, maintained significance as independent predictors for both disease free survival (DFS) and breast cancer specific survival (BCSS) after controlling for AT and other covariates by using multivariate Cox proportional hazards models with backward stepwise exclusion (p<0.01); whilst the percentage of reduction in primary tumour size was associated with DFS only (p=0.022). New pathological response indecies (NPRIs) for DFS and BCSS were calculated and four prognostic-groups (NPRI-PGs) were identified. Patients with NPRI-PG2 for DFS (n=63/172; 36.6%) and BCSS (66/172; 38.4%) has the same prognosis as those who achieved pCR (NPRI-PG1; 15%). The receiver operating characteristic (ROC) curves indicated that the NPRI outperformed the currently used prognostic factors [area under the curve (AUC) >0.85] and adding NPRI has improved their performance as a predictor for DSF (AUC>0.87) and BCSS (AUC> 0.88). **Conclusions:** The NPRI accurately predicts DFS and BCSS, with a higher sensitivity than pCR . The NPRI can improve the sensitivity and specificity of clinico-pathological response as a study end-point, for assessing response to a Neo-ACT regimen, and can serve as a valuable tool for the discovery of future predictive molecular markers.

**1084 General Poster Session (Board #177), Mon, 8:00 AM-11:45 AM**

**Predicting chemotherapy response in invasive breast cancer.** *Presenting Author: David Harrison, School of Medicine, University of St Andrews, Fife, United Kingdom*

**Background:** The care of patients with estrogen receptor positive (ER+), node negative early breast cancer has been revolutionized by first generation mRNA signatures that have improved the identification of patients with low risk of recurrence following adjuvant hormone therapy who may be spared chemotherapy. Additionally, a signature may be of value in predicting response to chemotherapy in high-risk individuals. We developed a second generation prognostic signature in ER+ breast cancer consisting of a weighted combination of cell division (CCP), immune and receptor genes (molecular score) and clinical parameters (combined score). Here, we aimed to understand the capacity our signature to predict chemotherapy effectiveness regardless of ER status. **Methods:** The first cohort consisted of 247 ER+ patients treated pre-operatively with TFEC or TFAC. Association of the signature with complete pathological response (pCR) was evaluated by logistic regression. The second data set was a population cohort of 431 adjuvant chemotherapy treated and 599 untreated invasive breast cancer patients. The interaction between chemotherapy treatment and CCP, molecular and combined scores was individually tested in a Cox proportional hazards model with distant metastasis free survival as outcome. **Results:** CCP and molecular scores were predictive of pCR in the pre-operatively treated cohort (CCP score p=0.015; molecular score p=0.029). In the population cohort, the test for interaction with adjuvant treatment was highly significant with p-values of 0.000016, 0.000020 and 0.00012 for CCP, molecular score, and combined score, respectively. In all cases higher scores were associated with response or improved outcome. **Conclusions:** A second generation prognostic tool for ER+ invasive breast cancer predicts pre-operative chemotherapy response in an ER+ breast cancer cohort. Molecular and clinical combined components predict outcome in adjuvant chemotherapy treated cohort regardless of ER status. After further studies to validate prognostic and predictive efficacy, the second generation prognostic signature may offer enhanced discrimination for the care of breast cancer patients.

**1085 General Poster Session (Board #178), Mon, 8:00 AM-11:45 AM**

**Amilorides: Familiar antihypertensive medications with a novel potential against breast cancer.** *Presenting Author: Jean Paul Atallah, Staten Island University Hospital-North Shore LIJ Health System, Sanford R. Nalitt Institute for Cancer & Blood-Related Diseases, Staten Island, NY*

**Background:** When compared to normal breast epithelial cells, breast cancer cells exhibit increased metabolic activity, which produces excessive intracellular hydrogen ions (H+). This increase in intracellular acidity (decrease in pH) is ameliorated by increasing the activity of the hydrogen pump, NHE1, which exchanges one intracellular H+ with an extracellular Na+. Therefore, breast cancer cells require the constant activity of NHE1, whereas normal cells do not. **Methods:** The objective of this project is to:1) Test the anti-cancer effects of two different NHE1 inhibitors (5-methyl-N-isobutyl Amiloride (MIA) and the well know antihypertensive Amiloride Hydrochloric Acid (A-HCl) ) on three human breast cancer cell lines (MCF-7, SKBR3, and MDAMB468); 2) Determine whether MIA can potentiate the effects of Cyclophosphamide (CPA) or Doxorubicin (Dox); 3) Assess the relationship between MIA treatment and the pro-survival transcription factor NF-kappa-B. **Results:** Treatment of all of three breast cancer cell lines with either MIA or A-HCl induced a dose-dependent cytotoxic response, with MIA being ~10-times more effective than A-HCl. The cancer cells MDAMB468, which models triple negative breast cancer, were the most sensitive to amiloride treatment. MIA when delivered in combination with CPA, increased the latter's cytotoxic effect, however, this was not seen when breast cancer cells were exposed to a combination of MIA and DOX. In response to MIA treatment alone, breast cancer cells exhibit an immediate increase in nuclear localization of NF-kappaB. **Conclusions:** Our results suggest that amilorides can be used alone or in combination with existing chemotherapies to effectively kill breast cancer cells. Cyclophosphamide with MIA combination demonstrated enhanced antitumor activity. The molecular response of amiloride treatment, involves at least in part, nuclear localization of the transcription factor NF-kappaB. Amilorides as antihypertensives have a very good safety profile. We show that inhibiting NHE1 activity with amilorides offers a novel approach to treating breast cancer.

**1086 General Poster Session (Board #179), Mon, 8:00 AM-11:45 AM**

**Centrosome declustering agents: Potential interphase-targeting antimetastatic chemotherapeutics.** *Presenting Author: Vaishali Pannu, Georgia State University, Atlanta, GA*

**Background:** The recent clinical failure of mitosis-targeted drugs has proven that cells in patient tumors divide infrequently, unlike cancer cells in cultures and xenograft models. Given the preponderance of interphase cells in clinical tumors, we asked whether targeting amplified centrosomes, held in tight clusters throughout interphase, presents a superior chemotherapeutic strategy that sabotages interphase-specific cellular activities such as directional migration. We utilized supercentrosomal N1E-115 murine neuroblastoma cells as a test-bed to study interphase centrosome declustering. **Methods:** We immunostained centrosomes and mitotic spindles in (i) paraffin-embedded clinical tumor samples of high-grade carcinomas of breast, prostate, bladder, head and neck, pancreas and colon, and (ii) cancer cell lines derived from a variety of tumor types, to determine the percentage of cells with amplified centrosomes and mitotic spindles. We analyzed how putative centrosome declustering agents [CDAs, *viz.*, reduced 9-Bromonoscapine (RBN), Griseofulvin (GF) and PJ-34] disperse interphase centrosome clusters and compared them with Paclitaxel, a tubulin polymerizing drug currently in clinical use. Declustering potency of these drugs was ranked using a quantifiable declustering index (DI). **Results:** About 80% of patient tumor cells bear "supercentrosomal" clusters in interphase and mitosis; by contrast, cancer cells in culture exhibit a higher proportion of mitotic cells and lower levels of centrosome amplification. In cultured N1E-115 cells, RBN was the strongest declustering agent (DI=0.36), followed by GF (DI=0.28) and PJ-34 (DI=0.14). Dispersal of interphase centrosome clusters caused Golgi scattering, disrupted focal adhesion contacts, inhibited neurite formation by 70-80% and caused spindle multipolarity. **Conclusions:** CDAs (i) inhibit cell-substrate adhesion and polarized protrusion development, which are essential for directional migration in interphase cells, and (ii) induce catastrophic mitoses, suggesting that (a) disbanding the centrosome-Golgi axis is a potential anti-metastasis strategy and (b) interphase is a clinically important chemotherapeutic target.

**1087 General Poster Session (Board #180), Mon, 8:00 AM-11:45 AM**

**Treatment and prognosis of breast cancer patients with brain metastases according to intrinsic subtype.** *Presenting Author: Sayaka Kuba, Department of Surgery, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

**Background:** It is still unclear how breast cancer (BC) subtype should affect treatment decisions for BC patients with brain metastases (BRM). This study analyzed extent and type of local BRM treatments and their outcomes according to BC subtype in patients with BC and BRM. **Methods:** We reviewed records and database information for women who were treated at the National Kyushu Cancer Center between 2001 and 2010. Patients' BC was divided into three subtypes: luminal (ER+ and/or PgR+, but HER2−); HER2 (HER2+) and TNBC (ER−, PgR− and HER2−). **Results:** Of 524 patients with advanced BC, we reviewed the 65 patients who had BRM and whose records showed ER, PgR and HER2 status, and outcome dates. Of these 65 patients, there were 26 (40%) with luminal BC, 26 (40%) with HER2 BC, and 13 (20%) with TNBC. Symptomatic BRM rates were similar across subtypes (HER2: 81%; luminal: 85%; TNBC: 77%). Percentages of patients with ≤ 4 BRMs did not significantly differ by subtype (HER2: 73%; luminal: 54%; TNBC: 46%; *P*=0.22). For local BRM treatments, 40 underwent stereotactic radiosurgery (SRS) or surgery, 21 received whole brain radiation therapy, and 4 had no local brain treatment. Rates of SRS or surgery for BRMs significantly differed among BC subtypes (HER2: 81%; luminal: 42%; TNBC: 47%; *P*=0.03). Median survival after BRMs also varied significantly by subtype (HER2: 22 months; luminal: 10 months; TNBC: 6 months; *P*=0.02). Having the HER2 subtype, performance status ≤ 1, ≤ 4 BRMs, undergoing systemic therapy after brain metastasis and undergoing SRS or surgery predicted longer overall survival after BRMs appeared. Multivariate analysis demonstrated that without systemic therapy and without having the HER2 subtype were independent factors associated with increased risk of death (HR 2.4, 95 % CI 1.01-5.6; p = 0.05 and HR 2.9, 95 % CI 1.5-5.8; p = 0.003 and respectively). **Discussion:** The number of BRMs is an important prognostic factor, as local brain treatment can be given for patients with BRMs. Patients with HER2 BC had more chance to receive SRS or surgery and better prognosis, as anti-HER2 treatment might be able to control systemic disease. **Conclusions:** Local brain treatments and prognosis differed with subtype in patients with BRM.

**1088 General Poster Session (Board #181), Mon, 8:00 AM-11:45 AM**

**Cosmetic outcome within one year of breast-conserving surgery, after external beam or intraoperative radiotherapy for early breast cancer: Objective assessment of patients from a randomized controlled trial.** *Presenting Author: Norman R. Williams, Clinical Trials Group, Division of Surgery and Interventional Science, University College London, London, United Kingdom*

**Background:** The international randomised controlled TARGeted Intraoperative radioTherapy (TARGIT) trial demonstrated non-inferiority between the technique of TARGIT (Intra-Operative RadioTherapy (IORT) with Intrabeam) and whole-breast external beam radiotherapy (EBRT) in women with early breast cancer. We have shown in a sub study of 342 patients that cosmesis at one year or later is better after TARGIT than EBRT; a significant component was cX2b ("redness", a surrogate for radiation induced erythema grade I or II). The aim of this study was to determine if the single high dose of TARGIT leads to impaired cosmesis within the first year after surgery. **Methods:** Frontal digital photographs were taken of women participating in the TARGIT Trial at a single centre and analysed, blinded to treatment received, by BCCT.core software which produced Harris scores for symmetry, colour and scar; scores for cX2b were also recorded, a high score indicating "redness." **Results:** 17 women (9 EBRT, 8 IORT), median age 65 years (range 50 to 79) had photographs taken at baseline (up to 5 days prior to surgery), then at one month (median 31d), at 6m if given EBRT (median 87d from first fraction), and at 12m (median 332d). All images scored Excellent, Good or Fair with no differences apparent over time or between treatment groups. At 6m there was a significant change from baseline in cX2b in the women given EBRT (see Table); this change persisted to 12m. No change was seen after IORT. **Conclusions:** This objective assessment of aesthetic outcome in patients from a randomised trial demonstrates that "redness" associated with EBRT is significantly worse within 90d of commencement; this change was not seen in women treated with IORT. This study provides further evidence that the objective scoring of cosmesis using BCCT.core is feasible and may be an approach for standardisation, and shows an early beneficial effect of TARGIT on cosmesis.

**Increase in cX2b from baseline mean (SEM).**

| | 1 month | 6 months | 12 months |
|---|---|---|---|
| **EBRT** | -0.04(0.09) | +0.18(0.06)* | +0.18(0.17) |
| **IORT** | +0.02(0.03) | | +0.04(0.10) |

* Significant increase from baseline P = 0.0247, paired t-test.

**1089 General Poster Session (Board #182), Mon, 8:00 AM-11:45 AM**

**Accuracy of ultrasound during neoadjuvant therapy for breast cancer to predict pathologic response.** *Presenting Author: Michael Luke Marinovich, Screening and Test Evaluation Program (STEP), The University of Sydney, Australia*

**Background:** Early assessment of response to neoadjuvant chemotherapy (NAC) for breast cancer may allow therapy to be tailored; however the optimal method for response assessment has not been established. We estimated the accuracy of ultrasound (US) to predict pathologic response (pCR) after NAC using common response criteria and pCR definitions, and estimated incremental accuracy of US over known prognostic variables. **Methods:** Participants in the GeparTrio trial with US tumor measurements at baseline and after two (of six) NAC cycles, and randomised to no change in NAC, were eligible. US partial response in two dimensions was assessed by World Health Organisation (WHO 2D) criteria; Response Evaluation Criteria In Solid Tumors (RECIST) and WHO criteria were also applied to the longest diameter (1D). Four pCR definitions were applied. Sensitivity (correct prediction of pCR), specificity (correct prediction of no-pCR), and diagnostic odds ratios (DORs) were calculated. Areas under the curve (AUCs) were derived from logistic regression models of the probability of pCR, including patient variables with and without US. **Results:** In 832 patients, there was a significant trend for decreasing DORs as the pCR definition became less stringent (p=0.01). For WHO 2D, DORs for the pCR definitions were 4.07 (ypT0 ypN0), 3.75 (ypT0/is ypN0), 3.14 (ypT0/is ypN+/-), and 2.65 (ypT0/is/1a ypN+/-). DORs did not differ between US criteria (p=0.60). Comparable high sensitivity and lower specificity within pCR definitions were found for WHO 2D and RECIST; WHO 1D was highly specific with low sensitivity. Sensitivity was highest for prediction of ypT0 ypN0 by WHO 2D (sensitivity=81.7% specificity=47.6% vs. 42.3% and 80.4% for WHO 1D). Adding US to models including patient variables (age, T stage, histology, subtype) improved the AUC for predicting pCR by 2-3%, regardless of US criterion or pCR definition. **Conclusions:** US accuracy is highest for the prediction of pCR defined as ypT0 ypN0, shown by previous studies to be most predictive of long term survival. WHO 2D and RECIST criteria maximise sensitivity, while specificity is maximised by WHO 1D. Knowledge of the US result modestly improves the prediction of pCR by patient characteristics.

**1090 General Poster Session (Board #183), Mon, 8:00 AM-11:45 AM**

**Local therapy and overall survival for stage IV breast cancer: SEER 1988-2010.** *Presenting Author: Alexandra Thomas, University of Iowa Carver College of Medicine, Iowa City, IA*

**Background:** There is still discussion regarding the role of surgery and radiation therapy (RT), for women who present with metastatic breast cancer. **Methods:** We included women who presented with Stage IV breast cancer from 1988-2010, reported to the Surveillance, Epidemiology, and End Results (SEER) program. Microscopically confirmed, first malignant cancers were included. Treatments were categorized: surgery only, RT only, surgery and RT, and no surgery or RT. Kaplan-Meier survival curves were created. Cox models controlled for age, treatment, hormone receptor (HR) status, marital status, year of diagnosis, and tumor size. Surgery and RT were part of the initial therapy. Surgery was to the primary tumor. RT site was not specified. **Results:** This series included 31,044 women with Stage IV breast cancer. Of these 25% received surgery, 19% received RT, 19% received both surgery and RT and 37% received no surgery or RT. The mean age of women who received surgery and RT was younger than those who received no surgery or RT (59 vs 64, p<0.001). Those who received surgery and/or RT were more likely to be married than those did not (p<0.001). Kaplan-Meier curves revealed that those who received surgery or surgery with RT had better overall survival than those who did not receive either or had RT alone (p<0.001). Age < 45 (HR=0.85), being diagnosed 2006-2010 (HR=0.72), surgery alone (HR=0.70), surgery with RT (HR=0.61), HR positive (HR=0.51), and being married (HR=0.79), conferred survival advantage in our Cox model (all p<0.001). Breast Tumor size ≥ 5 cm increased risk of death (HR 1.35, p<0.001). RT only women tended to have larger breast tumors (p<0.001). Median survival increased overtime, for all treatment groups. **Conclusions:** In this population-based series, local treatment was associated with longer survival. Median survival, by year of diagnosis, has improved markedly.

**1091 General Poster Session (Board #184), Mon, 8:00 AM-11:45 AM**

**Indocyanine green fluorescence imaging system as an alternative to the conventional sentinel lymph node mapping using a radiotracer in breast cancer.** *Presenting Author: Tomoharu Sugie, Kansai Medical University, Hirakata, Japan*

**Background**: Near-infrared fluorescence signal of indocyanien green (ICG) can visualize subcutaneous lymphatic flows and draining (sentinel) lymph nodes (SLNs). In fluorescence ICG Breast Study Group 01 study (fICG BR01), this ICG fluorescence mapping was superior to the dye method in early stage breast cancer (Sugie T, et al. Ann Surg Oncol 2013). The following fICG BR02 study evaluates clinical usefulness of this ICG fluorescence method in comparison to the conventional radioisotope (RI) method. **Methods:** On the day before or on the day of SLN biopsy, $^{99m}$Tc-labelled colloid was injected into the subareolar region of each patient. Before the start of operation, ICG was injected into the subareolar region and lymphatic flows bound for the axilla were traced with PDE camera (Hamamatsu Photonics Co, Japan). A real-time navigation surgery by ICG florescence imaging enabled to identify SLNs to be excised. A gamma probe was used to verify no residual radioactivity in the axilla after SLN removal. **Results:** A total of 847 women with T1-2 breast cancer were enrolled and 821 pts. were included in the per-protocol final analysis. The median pts. age was 55 (range, 22-80) years and the median BMI was 22.1 (range, 14.9-38.8) kg/m$^2$. There was no significant difference in the detection rate between the ICG and RI method (97.2% vs 97.0%). However, a combination of ICG and RI achieved a significant higher detection rate than RI alone (99.8% vs 97%, p<0.001). The involvement of SLNs was found in 180 pts. and a detection rate of positive SLN using ICG fluorescence and RI was 93.3% and 90%, respectively. The detection rate of SLNs with a combination of ICG and RI was improved significantly compared with RI alone (97% vs 90%, p<0.001). There is no serious adverse event due to hypersensitivity to ICG. **Conclusions:** The ICG fluorescence method has a high detection rate of SLN comparable with that of the RI method. A combination of these two methods yield a significant improvement of SLN detection compared with RI alone. The results of this study confirm that ICG fluorescence imaging system is an alternative and/or additive to the conventional SLN mapping using a radioactive tracer in breast cancer. Clinical trial information: UMIN000005167.

**1092 General Poster Session (Board #185), Mon, 8:00 AM-11:45 AM**

**The influence of radiotherapy on sleep disturbances in breast cancer patients.** *Presenting Author: Sheela Hanasoge, Department of Radiation Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Sleep disturbances are distressing and common among breast cancer patients during treatment. However, few studies have examined the impact of radiotherapy (RT) on sleep quality. The goal of this study was to prospectively assess breast cancer patients before, during, and after RT to determine the impact of RT on sleep. **Methods:** Following breast conserving surgery, 80 breast cancer patients were enrolled on a prospective, longitudinal study of sleep before, during, and after whole breast RT. All patients received a dose of 50 Gy followed by a 10 Gy boost. Subjects completed the Pittsburgh Sleep Quality Index (PSQI) before (i.e., baseline), at week 6 of RT, and 6 weeks after RT completion. Demographic, patient- and treatment-related factors were also recorded. Paired t tests were used to test longitudinal differences in PSQI between time points. Linear mixed models were used to identify predictors of higher PSQI scores and poor sleep (i.e., PSQI score >5). **Results:** Before, during, and after RT, 61%, 56%, and 59% of subjects were poor sleepers, respectively. PSQI scores did not significantly change during or after RT compared with baseline measures. On univariate analysis, significant predictors of higher PSQI scores were prior chemotherapy treatment, African American race, and having less than a college education (all $p<0.01$). Tumor stage, axillary lymph node dissection (vs. sentinel lymph node biopsy only), patient age, marital status, and income were not significant predictors of poor sleep. On multivariate analysis, African American race ($p<0.006$) and having less than a college education ($p<0.004$) remained significant predictors of higher PSQI scores at each time point. **Conclusions:** Our findings indicate that sleep disturbances are prevalent during breast cancer treatment. Nevertheless, it appears that RT does not contribute to poor sleep while patient baseline characteristics including African American race and low educational level are associated with higher PSQI scores throughout and after RT. Studies aimed at developing interventions for these patients at risk for sleep disturbances during breast cancer treatment are warranted.

**1093 General Poster Session (Board #186), Mon, 8:00 AM-11:45 AM**

**Do hospitals in a large metropolitan area utilize published breast cancer care practices and guidelines?** *Presenting Author: Christine B. Weldon, Center for Business Models in Healthcare, Chicago, IL*

**Background:** Insufficient utilization of guideline and evidence based care practices contribute to the cancer crisis (IOM 2013). We examined utilization of published breast cancer (BC) care practices and guidelines at hospitals in a large metropolitan area. **Methods:** IRB approved web survey of all 35 hospitals in a large metro area that provide BC treatment. Using guidelines/recommendations (NCCN, NAPBC, ADA, IOM) and peer-reviewed literature (62 studies) we developed a survey on BC care practices. Results analyzed by simple frequencies and Fisher's exact test. **Results:** Response rate: 91% (32/35 sites). Care practices, included in the table, are utilized by < 50% of sites. Radiation oncologist preoperative consults (53%, 8/15) and offering indicated pre-operative chemo* (67%, 10/15) are associated with 15 sites that have high volume (67+/year, Chen CS 2008) BC surgeons, compared to 17 sites without high volume BC surgeons (12%, 2/17) and (24%, 4/17) respectively, $p=0.02$, $p=0.03$. Indicated supportive services, such as a dental checkups (ADA 2008), are more likely at sites with patient-centered written treatment plans (IOM 2011) (58%, 7/12) than at sites without written treatment plans (10%, 2/20), $p=0.006$. **Conclusions:** Low utilization of published care practices and guidelines is concerning and requires attention. Other metro areas and regions should be examined as our findings indicate that patients may have limited local choices of care that is up-to-date on published guidelines and practices.

| Practices | Site utilization n=32 |
|---|---|
| Radiation oncologist consult prior to BC conserving surgery BCS (Jagsi R 2012) | 33% |
| *Offer pre-operative chemotherapy to patients with large tumors-IIA, IIB and T3N1MO considering BCS (NCCN BINV 10) | 48% |
| Reconstructive surgeon consult prior to mastectomy decision (NAPBC 2.18) | 33% |
| Fertility/reproductive health assessment (NCCN BINVC AYAO 6) | 32% |
| Indicated patients referred for dental checkup (ADA 2008) | 28% |
| Patients screened for distress at initial visit, at intervals and at changes in disease status (NCCN DIS A for tool) | 29% |
| Patients are screened for pain at each contact (NCCN PAIN A,C) | 45% |
| Palliative care screening at care initiation and/or regularly during care (NCCN PAL 1 2) | 25% |

**1094 General Poster Session (Board #187), Mon, 8:00 AM-11:45 AM**

**Why women are choosing mastectomy: Influences beyond the surgeon.** *Presenting Author: Andrea Marie Covelli, University of Toronto, Toronto, ON, Canada*

**Background:** Rates of unilateral (UM) and contralateral prophylactic mastectomy (CPM) for early stage breast cancer (ESBC) have been increasing. Surgical decision making is comprised of the surgeon, the patient and the external environment. We sought the perspectives of patients who chose UM +/- CPM and treating surgeons to understand why mastectomy rates have been increasing. **Methods:** We completed a grounded theory qualitative study to examine the surgeon's practice and the patient's decision making that resulted in the choice for UM +/- CPM. Purposive sampling identified women across Toronto, Canada who were suitable candidates for breast conserving therapy (BCT) but underwent UM +/- CPM. Academic and community breast surgeons from across Ontario, Canada and the United States were also recruited. Data were collected through semi-structured interviews, this continued until data saturation was reached. Constant comparative analysis identified key ideas. **Results:** 29 patients and 45 surgeons completed interviews. The dominant theme was 'Desire for control', women strived to improve their cancer outcomes by undergoing more extensive surgery. Surgeons described BCT and UM as equivalent treatment options for ESBC and frequently recommended BCT. Despite this, surgeons described women initiating the request for UM+CPM. In this average risk population CPM was discouraged by the surgeons, describing no survival advantage. The most influential factor in a woman's request for CPM was their personal cancer experiences with family and friends and not the surgical consultation. A previous negative experience with breast cancer translated into an overestimated risk of recurrence, contralateral cancerand subsequent mortality. Women chose UM+CPM to ensure they would 'never go through this again.' Despite feeling confident in their choice most women had ongoing issues with disturbed skin sensation, cosmesis and body image. **Conclusions:** Factors, especially a previous cancer experience, are extremely influential when women choose UM+/- CPM. As many women had long term pain and issues with cosmesis after UM +/- CPM, we suggest women may benefit from education including exposure to other patients' post-operative concerns to aid in their decision making.

**1095 General Poster Session (Board #188), Mon, 8:00 AM-11:45 AM**

**Postoperative complications in nipple-sparing mastectomy.** *Presenting Author: Erin M Garvey, Mayo Clinic Arizona, Phoenix, AZ*

**Background:** Nipple-sparing mastectomy (NSM) has been accepted as a risk reducing procedure and for treatment of select breast cancers. The purpose of this study was to detail the types of postoperative complications experienced at a single center. **Methods:** A prospective breast cancer database was reviewed from June 2006 to November 2013. Patients who underwent NSM were identified and analyzed for postoperative complications. **Results:** Over the 7.5 year study period, a total of 1,630 breast cancer procedures were performed for 1,540 patients. 701 procedures were mastectomies, 392 of which included reconstruction. 160/392 procedures (41%) were attempted NSM and 147/160 (92%) were successful NSM. Most NSMs (87.8%) were followed by implant based reconstruction. The majority of patients were Caucasian (83.7%), average age was 51 years, average BMI was 25.5 and 50.3% were pre-menopausal. 5.4% were current and 30.6% were former smokers. 2.7% were prediabetic and 3.4% were diabetic. The average tumor size was 2 cm and the majority of patients either had DCIS (23.8%) or stage I cancer (40.8%). 29.9% underwent hormonal treatment, 17.7% cytotoxic treatment, 6.8% neoadjuvant treatment and 4.8% radiation treatment. 58.5% of procedures were associated with postoperative complications including a 1.4% rate of autogenous flap loss, 6.1% wound breakdown, 6.8% hematoma, 6.8% flap ischemia, 11.6% infection rate resulting in 12.4% expander/implant loss, 21.8% seroma and 33.3% nipple related complications. Repeat operative intervention was required for 7/9 wound breakdowns, 9/10 flap ischemia cases and 13/49 nipple related complications. No patient, disease or treatment characteristics were statistically associated with an increased risk of postoperative complications on univariate analysis; however, older age ($p=0.09$) and current or former tobacco use ($p=0.08$) trended toward an increase in postoperative complications. **Conclusions:** Nipple-related complications were the most common postoperative complications seen in NSM. Increased age and current or former tobacco use trended toward an increase in postoperative complications.

**1096 General Poster Session (Board #189), Mon, 8:00 AM-11:45 AM**

**Evaluation of cardiac dose reduction with deep inspiration breath hold in patients with left-sided breast cancer receiving adjuvant radiotherapy.** *Presenting Author: Rosanna Yeung, Department of Radiation Oncology, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

**Background:** Studies have suggested increased cardiac morbidity from radiation exposure to the heart and left anterior descending artery (LAD) in breast cancer patients receiving adjuvant radiotherapy (RT). Deep inspiration breath hold (DIBH) techniques have demonstrated reduction to heart, LAD and lung dose in left-sided breast cancers. There is, however, limited data on which patients derive most benefit from DIBH technique. **Objective:** To compare reduction in cardiac and LAD doses using a DIBH technique in left-sided breast cancer patients treated with adjuvant RT to the breast alone versus those also receiving regional nodal RT **Methods:** Twenty consecutive patients with left-sided breast cancer underwent CT simulation in free breathing (FB) and DIBH. Patients were grouped into two cohorts: those receiving whole breast RT alone +/- boost (WBRT) versus whole breast/chest wall RT with regional nodal irradiation (WBRT + RNI). 3D conformal plans were devised, and dosimetric comparisons were made between the two techniques for each cohort. **Results:** Eleven patients received WBRT while nine patients received WBRT + RNI. All patients had comparable CTV coverage on both DIBH and FB treatment plans. Mean heart and LAD doses were lower in all DIBH versus FB plans in both groups, but the benefit was larger in the group receiving RNI compared to those receiving WBRT alone (average relative reduction in mean heart and LAD dose: 55.9% and 71.9% vs 34.2% and 45.1%, respectively). All patients met a mean heart dose of $<$4Gy on DIBH. On FB, only one patient in the WBRT group did not meet this constraint, compared to five patients in the WBRT +RNI group. **Conclusions:** Patients receiving WBRT+RNI had a greater reduction in heart and LAD dose from DIBH than patients receiving WBRT alone. The majority of patients receiving WBRT met a mean heart dose of $<$4Gy on FB planning, while less than half of patients receiving WBRT + RNI were able to meet this constraint. These findings suggest a greater benefit from DIBH treatment in patients receiving RNI, while patients receiving WBRT alone may be safely treated with a FB technique. Ongoing prospective cohorts are being evaluated to ensure validity of these findings.

**1097 General Poster Session (Board #190), Mon, 8:00 AM-11:45 AM**

**The role of surgery in patients with primary metastatic breast cancer (PMBC) receiving monoclonal antibody treatment.** *Presenting Author: Jana Barinoff, Clinic of Gynecology and Obstetrics, Agaplesion Markus Hospital, Frankfurt, Germany*

**Background:** Apart from the individual palliative need, the beneficial effect of surgically removing the primary tumor in PMBC on long-term outcomes, as suggested by retrospective series and meta-analyses, remains controversial. A cohort of 2,401 patients (pts) with metastatic breast cancer from two prospective non-interventional studies (NIS), enrolled between 2000 and 2011, was screened with respect to this question. **Methods:** One study investigated trastuzumab therapy for HER2+ metastatic breast cancer in addition to mainly 1st line chemotherapy. The second NIS observed bevacizumab therapy for mostly HER2– disease additional to chemotherapy as 1st line treatment. Progression-free survival (PFS) was defined as the time from start of antibody therapy to disease progression or death; overall survival (OS) was defined as the time from start of targeted therapy to death of any cause. **Results:** 570 (24%) pts had PMBC, and valid information on primary tumor surgery was available for 568. Out of these, 426 (75%) underwent local surgery (LS). The LS group was characterized by less overall metastatic burden (20% vs. 39% with $\geq$3 sites involved) and a lower proportion of T4 tumors (26% vs. 52%). No major differences were observed with respect to age, hormone receptor and HER2 status, visceral disease, prior palliative treatment and performance status. Numerically, the LS group showed a slightly favorable PFS (medians: 13.6 vs. 11.8 months; p=0.18) and OS (34.1 vs. 31.7; p=0.23). However, in multivariate analysis including all other univariately significant parameters (age, hormone receptor status, visceral disease, number of involved sites, performance status), no trend for better outcome after surgery remained observable, neither for PFS (hazard ratio 0.99; p=0.92) nor OS (0.95; p=0.71). **Conclusions:** In PMBC pts treated with modern targeted therapies, our findings confirm the recent preliminary results from two randomized studies with no survival advantage for LS shown in the overall pt population. However, further analyses are warranted to define specific risk groups, which may benefit from surgical removal of the primaries.

**1098 Poster Highlights Session (Board #12), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A pilot study of preoperative (Pre-op), single-dose ipilimumab (Ipi) and/or cryoablation (Cryo) in women (pts) with early-stage/resectable breast cancer (ESBC).** *Presenting Author: Adi Diab, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Because intratumoral cryo with immune modulation generates a potent systemic anti-tumor immune response in murine models, this strategy may improve outcomes for women with ESBC. In this study, we evaluated the safety of pre-op cryo and/or ipi (10mg/kg) in ESBC pts and explored immune correlates including tumor infiltrating lymphocytes (TILs). **Methods:** Eligibility: age $\geq$18y with operable $\geq$1.5 cm invasive ESBC planning mastectomy (TM). Pts were sequentially assigned to receive pre-op: cryo alone (group A), ipi alone (B), or ipi and cryo (C). Tissue biopsies and/or cryo were performed 7-10d prior to TM. Ipi was administered 8-15d prior to TM (1-5d prior to cryo). The regimen was to be considered safe/tolerable if at least 5/6 pts in each group proceed to TM without delay. Toxicity evaluation continued for 30d after TM for group A and 12wks after ipi administration for groups B&C. Research peripheral bloods for immune correlates were obtained at baseline, biopsy, TM and 2-3 wks thereafter. Blood, biopsy and TM samples were evaluated by flow-cytometry. **Results:** The study is complete. Pre-op cryo-alone, ipi-alone and the combination were well tolerated and the primary safety endpoint was achieved with all 19 enrolled pts undergoing TM without delay. Group A was expanded to 7 pts after a possible technical failure in 1 pt, 6 pts enrolled to group B and 6 pts enrolled to group C. Median age was 48y (range 34-72y). Tumor necrosis/infarction was observed in 9/12 pts who underwent cryo. A trend toward an increased frequency of blood CD4+ICOS+, CD8+ICOS+, CD4+Ki67+ and CD8+Ki67+ T-cells was observed at TM compared with baseline in the ipi treated groups only. Analysis of TILs in the TM specimens suggested a higher ratio of CD8+Ki67+ T-cells to CD4+CD25+FOXP3+ (T-regulatory) cells in group C when compared with A&B. **Conclusions:** Pre-op cryo and ipi, alone or in combination, are safe/tolerable in pts with ESBC. Immune correlates revealed activation of T-cells in the blood in single-dose ipi treated pts and a modest increase in the ratio of tumor CD8+Ki67+ T-cells to T-regulatory cells after combination therapy only. A Phase II study of pre-op ipi and cryo in ESBC is planned. Clinical trial information: NCT01502592.

**1099 General Poster Session (Board #192), Mon, 8:00 AM-11:45 AM**

**A multicenter prospective study of image-guided radiofrequency ablation for small breast carcinomas.** *Presenting Author: Takayuki Kinoshita, National Cancer Center Hospital, Tokyo, Japan*

**Background:** As the management of breast carcinoma evolves toward less invasive treatments, the next step is the possibility of removing the primary tumor without surgery. The most promising noninvasive ablation technique is radiofrequency ablation (RFA), which can effectively kill tumor cells with a low complication rate. **Methods:** To determine if RFA is oncologically and cosmetically appropriate for the local treatment of primary breast carcinoma, this multicenter prospective study used RFA as the sole local treatment of breast tumors $\leq$ 1.5cm in size on ultrasound and MRI. After confirmation that the standard baseline core biopsy for diagnosis and measurement of tumors markers (ER, PgR, HER-2/neu expression and the presence of the Ki-67 proliferative marker) have been obtained, consent will be obtained and the patient scheduled RFA. All patients received adjuvant radiation therapy. The first primary endpoints of this study is successful tumor ablation, as evidenced by negative findings on vacuum-assisted or core biopsies and imaging studies after RFA. The second primary endpoints is the incidence of procedure related adverse events. The response to ablation was evaluated with both vacuum-assisted or core biopsies and imaging studies every 3 months during the first year. The long-term outcomes were assessed using quality of life measurement scales and imaging studies every 6 months thereafter through year 5. **Results:** Of the 58 patients who participated in this study, 55 completed the protocol. In 50 of the 55 (91%) treated patients, successful tumor ablation, as determined by negative findings on vacuum-assisted or core biopsies and imaging studies, was confirmed. In these 50 patients, there were no local or distant recurrences after 1 year. The remaining 5 patients with biopsies positive for residual tumor underwent surgical resection. In 46 of the 50 patients with successful ablation, cosmetic outcomes were excellent after 1 year and only 2 patients experienced minor skin burns during the tumor ablation. **Conclusions:** RFA in patients with early breast carcinoma can achieve local control rates similar to those with wide local excision, but with improved cosmetic results. Clinical trial information: 000008675.

**1100 General Poster Session (Board #193), Mon, 8:00 AM-11:45 AM**

**Development of a novel nomogram predicting nonsentinel lymph node metastases among patients with breast cancer after neoadjuvant chemotherapy (NACT): A transSENTINA substudy.** *Presenting Author: Cornelia Liedtke, University of Schleswig-Holstein, Campus Luebeck, Luebeck, Germany*

**Background:** The optimal timing for sentinel lymph node biopsy (SLNB) in the setting of NACT is still unclear. Recent studies such as SENTINA suggest that performing SLNB in patients with a cN+ status before, converting to cN0 after NACT (arm C) results in a non-acceptable false-negative rate. Therefore, there is a need to predict non-SLN status and tailor axillary surgery after NACT. The goal of this study was to develop an optimized nomogram based on data from SENTINA trial patients. **Methods:** The SENTINA trial with 1,737 patients from 104 institutions was previously described in detail. 181 patients in arm C were analyzed as a development set. Risk factors for non-sentinel node involvement have been selected based on prior univariate logistic regression analysis using a threshold of p<=0.2 and subsequent multivariable logistic regression using a backward selection procedure applying the likelihood ratio test. Validation of the model was carried out using a leave-one-out-validation (LOOV). The performance of the nomograms was evaluated by the area under the receiver operator curve (AUC). **Results:** Selected variables of the final prediction model comprised number of positive resected lymph nodes (OR=1.656, CI: 1.025-2.677, p=0.039), sonographic diameter of largest lymph node (OR=1.126, CI: 1.037-1.223, p=0.005) and tumor diameter after NACT (OR=1.180, CI: 0.962-1.447, p=0.112). A preliminary nomogram was built and yielded a mean AUC of 0.75252 (SD=0.004576, min=0.748, max=0.766) in LOO-validation. Selecting a cutpont of 36%, a sensitivity of 82% and a specificity of 49% may be reached. Additional analyses are ongoing and results will be presented. **Conclusions:** We developed a nomogram for prediction of non-sentinel lymph node metastases following NACT using the SENTINA patient database. The nomogram yielded AUC values comparable to previously presented nomograms. A provisional cutpoint for clinical decision making is described. External validation is planned.

**1102 General Poster Session (Board #195), Mon, 8:00 AM-11:45 AM**

**Mapping of the axilla: Lymph node involvement in level 1, 2, and 3 of the axilla and in the interpectoral region in early breast cancer.** *Presenting Author: Andreas Jakob, Ortenau Klinikum Offenburg, Offenburg, Germany*

**Background**: Axillary clearance provides important information for prognosis and staging. The aim of this study was to determine the involvement of the different regions of the axilla in node positve primary breast cancer (PBC). **Methods**: We conducted a retrospective analysis of data from a single-center, unselected cohort of women with PBC. Between 1997 and 2001 axillary lymph node (LN) dissection comprised of clearance of level 1, 2, and 3 and since 2002 the interpectoral region was also routinely dissected. In all patients level 1 was dissected, level 2 in 98,8%, level 3 in 94,9% and the interpectoral (ip) region in 63,9% of the women. **Results**: We analysed data of 1,868 women with PBC treated at our institution between 1997 and 2009. 740 (39,6%) of the patients had node pos. disease. Out of these patients 267 (36,1%) had only one LN involved. The other patients (63,9%) had more than one pos. LN. The involvement of the different axilla regions dependent on the number of positive LN referring to the dissection frequency was: 1 pos LN: level 1 96,6%; level 2 0,8%; level 3 1,6% ip 1,7%. 3 pos LN: level 1 100%; level 2 8,9%; level 3 7,9%; ip 7,4%; ≥ 1 pos LN: level 198,8%; level 2 29,4%; level 3 18,9%; ip 9,2%. The involvement of level 2,3 and ip region in relation to the number of pos. LN in level 1:1 pos LN: level2 6,4%; level 3 3,3%; ip 2,6%. 3 pos LN: level 2 19,5%; level 3 10,3%; ip 8,9%. 4-9 pos LN: level 2 52%, level 3 27,8%; ip 12,9%. The frequency of stage pN0 was dependent on the number of removed lymph nodes: in patients with less than 10 LN removed, stage pN0 was diagnosed in 77,5% and in patients with more than 23 resected LNs in only 56% **Conclusions**: In 64% of patients with node positive PBC, there are more than one LNs involved. Patients with one positive LN in level 1 will have positive nodes in the other regions in over 10%; with two positive nodes in level 1 in 20%; and with three positive nodes in level 1 in 40%, respectively. In patients with 4-9 positive LNs in level 1, level 3 will be involved in 28%. There is an increased risk of metstatic spread to regions, which are not routinely dissected, dependent on the number of positive LNs in level 1. This could have implications on accurate staging and surgical procedures.

**1103 General Poster Session (Board #196), Mon, 8:00 AM-11:45 AM**

**The prognostic B2-Score for metastatic breast cancer: An external evaluation of 852 patients.** *Presenting Author: Achim Wöckel, Department of Gynecology and Obstetrics University Ulm, Ulm, Germany*

**Background:** The B2-Score is an individual, quantitative assessment of the likelihood of overall survival for advanced breast cancer patients based on routine parameters easily accessible in daily clinical care. Although major progress has been made, the optimal therapeutic management of the individual patient is still unknown. Besides elaborative molecular classification of tumors simple clinical measures such a prognostic score may be helpful to further individualize optimal breast cancer care. This study is a further external evaluation of this score. **Methods:** This German multicenter [17 certified breast cancer centers] retrospective cohort study called BRENDA (Quality of breast cancer care under evidence-based guidelines) included 10.119 advanced breast cancer patients. In the Cox regression model, hormone receptor (HR) status, the specific site of metastasis, and metastatic-free interval (MFI) were associated with survival from first relapse. **Results:** Medianage at primary diagnosis was 63 yrs (range 22-96), median MFI was 17 mths (range 0-200). 78.2% were HR-positive. 88.8% were M0 at primary diagnosis. 73.6% of the M0- patients were treated non-guideline adherent with respect to primary adjuvant therapy. 18% had 2 or more guideline violations. Median [mean] of $B^2$Score was 11 (range 3-38) [12.1; STD 6.4]. 40.0% were low risk, 27.3% intermediate risk and 32.7% high risk. 5 years cumulative survival was 37% (95% CI 31%-44%) for low risk, 25% (95% CI 18%-31%) for intermediate risk and 11% (95% CI 7%-16%) for high risk. Cox-Mantel Hazard Ratio for intermediate risk was 1.34 (p=0.007; 95% CI 1.08-1.66) and for high risk 2.30 (p=<0.001; 95% CI 1.89-2.81) compared to low risk. **Conclusions:** The B2-Score classified these patients into 3 risk groups with highly significant different overall survival, confirming the prognostic value of this score. More than 70% of the advanced breast patients in this study—originally M0—were treated nonguideline adherent with respect to adjuvant therapy.

**1104 General Poster Session (Board #197), Mon, 8:00 AM-11:45 AM**

**Investigating the regulation of e-cadherin mRNA and protein expression by integrin $\alpha 3\beta 1$ in breast cancer cells.** *Presenting Author: Anupam Batra, Albany Medical College, Albany, NY*

**Background:** E-cadherin is an adhesion glycoprotein in epithelial tissues and reduced expression is associated breast cancer metastasis. The cell surface integrin $\alpha 3\beta 1$ is also associated with malignant progression of breast tumors. Our genome-wide microarrays identified that E-cadherin mRNA levels are modulated by $\alpha 3\beta 1$ in MDA-MB-231 breast cancer cells. The current study investigates the association between these two important structural genes in breast cancer progression. **Methods:** MDA-MB-231 cells were stably transduced with lentivirus expressing short hairpin RNA (shRNA) targeting the $\alpha 3$ integrin subunit or with control shRNA. Total RNA was isolated for qPCR with primers specific for integrin $\alpha 3$, E-cadherin, and GAPDH. Immunoblot was performed using mouse anti-serum against E-cadherin or rabbit anti-serum against ERK, followed by secondary horse-radish peroxidase-congugated antibody. Immunohistochemistry (IHC) was then performed using rabbit anti-serum against either $\alpha 3$ or E-cadherin. **Results:** Our experimental model consisted of human breast cancer MDA-MB-231 cells with $\alpha 3\beta 1$-expressing or $\alpha 3\beta 1$-deficient populations. qPCR revealed a 24-fold ($p < 0.05$) increase in E-cadherin mRNA in $\alpha 3\beta 1$-deficient cells relative to controls. These findings confirmed our earlier microarray data, which indicated that $\alpha 3\beta 1$ suppresses the expression of E-cadherin mRNA. However, immunoblot of lysates from the same cells showed increased levels of E-cadherin protein in $\alpha 3\beta 1$-expressing controls relative to $\alpha 3\beta 1$-deficient cells. IHC showed increased staining in $\alpha 3$-expressing cells corroborating immunoblot results. **Conclusions:** E-cadherin mRNA levels were found to be increased in $\alpha 3$-deficient breast cancer cells whereas E-cadherin protein expression was down-regulated in the same cells as detected by immunoblot and IHC. We suggest that E-cadherin may be part of a group of genes up-regulated in the absence of $\alpha 3\beta 1$, but that this regulation is counter-balanced by translational or post-translational down-regulation of E-cadherin protein. Further studies are needed to understand the complex regulatory networks that control E-cadherin expression in response to $\alpha 3\beta 1$ in breast cancer progression.

**1105 General Poster Session (Board #198), Mon, 8:00 AM-11:45 AM**

**Differential response of neoadjuvant chemotherapy with taxane-carboplatin versus taxane-epirubicin in patients with locally advanced triple-negative breast cancer.** *Presenting Author: Jiayu Wang, Department of Medical Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

**Background:** Triple-negative breast cancer (TNBC) may be more sensitive to platinum. The aim of this study was to compare the different pathologic complete response (pCR) in patients with locally advanced TNBC treated with platinum-based neoadjuvant chemotherapy with nonplatinum regimen. **Methods:** Eligible locally advanced TNBC women received either paclitaxel (or docetaxel)- carboplatin (TC) or paclitaxel (or docetaxel)-epirubicin (TE) q3w for up to 4-6 cycles. The primary end point was the rate of pathological complete response (pCR), defined as the absence of invasive cancer in the breast and axilla at the time of surgery. The second end point was the clinical response rate and recurrence free survival (RFS). **Results:** In total, 92 patients were enrolled between January 2009 and December 2012. Of these, 43 patients were assigned to TC group, and 49 to TE group. The pCR rate was higher in TC group than in TE group (37.2% versus 16.1%, p=0.032). The clinical response rates were similar in TC and TE group (83.7% versus 87.8%, p=0.500). The incidence of grade 3–4 neutropenia (TC: 39.5% versus TE: 46.9%, p=0.399) and febrile neutropenia, were not significantly different between two groups. Peripheral neuropathy was frequent but never severe. G3 alopecia was more frequent in TE group than in TC group. RFS has not been evaluated yet because of limited follow-up time. **Conclusions:** This study suggested that platinum-based chemotherapy was superior to nonplatinum regimen in the neoadjuvant treatment of locally advanced TNBC, as measured by pCR. Further large-scale prospective randomized trials are warranted.

**1106 General Poster Session (Board #199), Mon, 8:00 AM-11:45 AM**

**A phase II study of tivantinib (ARQ-197) for metastatic triple-negative breast cancer.** *Presenting Author: Sara M. Tolaney, Dana-Farber Cancer Institute, Boston, MA*

**Background**: Data suggests that MET expression and activation is important for initiation and progression of triple-negative breast cancer. Tivantinib (ARQ 197) is an orally administered agent that was originally presumed to target MET, though recent preclinical data suggests it may inhibit microtubule polymerization. **Methods**: We conducted a two-stage, single arm study of tivantinib in patients (pts) with metastatic triple-negative breast cancer. Pts could receive 1 to 3 prior lines of chemotherapy in the metastatic setting and were required to have measurable disease. Treatment consisted of twice daily oral dosing of tivantinib (360 mg po bid), on a 21 day cycle. Pts underwent restaging scans at 6 weeks, and then every 9 weeks. Response was evaluated using RECIST 1.1, and the primary endpoint was progression-free interval of 6 months (PFS≥6). The target samples size was 26 pts, and if ≥5 pts had PFS≥6 the null rate (10%) would be rejected in favor of a 31% rate of activity. Tumor biomarkers that may predict response to tivantinib were explored. **Results**: The study closed for futility after 22 pts were enrolled; pts had received a median of 2 prior lines of chemotherapy for metastatic disease. Only 1 pt had PFS≥6 (4.5%, 95% CI 0.2%-24.7%). One pt achieved a partial response (PR) for a 4.5% overall response rate, and 6 pts (27%) had stable disease as the best response. The median PFS was 1.2 month (95% CI 1.0-1.4). There were few grade 3+ adverse events (1 grade 3 anemia, 1 grade 3 fatigue, and 3 pts with grade 3/4 neutropenia). Whole exome sequencing of archival tumor tissue and tissue from time of progression in the pt who experienced a PR was also performed. Somatic alterations identified in the post-progression biopsy include mutations in known breast cancer genes MAP2K4 and TP53, as well as a mutation of unknown significance in the kinase domain of JAK2. Biomarker studies of MET expression and amplification in archival tumor tissue are ongoing. **Conclusions**: This represents the first study of tivantinib for the treatment of metastatic triple-negative breast cancer. These results suggest that tivantinib is well tolerated, but is largely inactive when used as monotherapy to treat metastatic triple-negative breast cancer. Clinical trial information: NCT01542996.

**1107 General Poster Session (Board #200), Mon, 8:00 AM-11:45 AM**

**Frequent *BRCA1/2* and *BARD1* germline mutations in triple-negative breast cancer patients.** *Presenting Author: Jacques De Greve, Familial Cancer Clinic and Medical Oncology, University Hospital Brussels, UZ Brussel, Brussels, Belgium*

**Background:** Triple negative breast cancer (TNBC) accounts for 10-20% of all breast cancers and conventional chemotherapy is the only effective systemic treatment. Germline *BRCA1/2* mutations are found in approximately 15% of TNBC patients. PARP inhibitors are being investigated in this subset of patients. In the past we have documented pathogenic mutations in BARD1, a BRCA1 interacting protein, in families at high risk for breast cancer. In the current study we have analyzed the germline DNA from 61 estrogen receptor negative patients included in the TOP trial for the presence of mutations in the *BRCA1, BRCA2* and *BARD1* gene. **Methods:** Patients signed a separate informed consent for the current retrospective genetic analysis and were offered oncogenetic counseling. Genetic variants were detected by High Resolution Melting curve Analysis (HRMA) and confirmed by Sanger sequencing. In Silico tools were used to further characterize these variants. **Results:** Of the 61 ER- patients 42 were TNBC and 19 were HER2-positive. *BRCA1/2* mutations were found in 8/42 (19%) TNBC, but none in the ER-/HER2 cohort. We also found four (10%) strong candidate pathogenic mutations in the *BARD1* gene, including two protein truncating mutations (p.Gln564X and p.Arg641X), while no such mutations were found in 245 control samples. Only two *BARD1* truncating mutations have been reported worldwide earlier in germline DNA from breast cancer patients, including a case we identified in one out of 196 high risk breast cancer families. Our data suggest that TNBC patients are enriched for pathogenic *BARD1* mutations as compared to the incidence in control samples and in high breast cancer risk families. Additional clinical-genomic correlations are being investigated. **Conclusions:** Almost one third of TNBC (29%) have a BRCA pathway mutation. These patients should become eligible for exploring the efficacy of PARP inhibitors.

**1108 General Poster Session (Board #201), Mon, 8:00 AM-11:45 AM**

**The relationship between body mass index, diabetes, and triple-negative breast cancer prognosis.** *Presenting Author: Jose M Pacheco, John Cochran Veterans Affairs Medical Center, Washington University School of Medicine, Saint Louis, MO*

**Background:** Higher body mass index (BMI) and diabetes are associated with worse breast cancer prognosis. However, information on how these variables relate to survival in triple-negative breast cancer (TNBC) is limited. **Methods:** We retrospectively reviewed 501 patients with TNBC first seen at the Washington University Breast Oncology Clinic between January 2006 and December 2010. Cox proportional hazards models were used to determine the relationship between BMI at diagnosis and diabetes with overall survival (OS) and disease free survival (DFS). **Results:** 448 patients had BMI recorded and 71 had diabetes. Of these, 4.50% with BMI available and 2.82% with diabetes presented with stage IV disease. The median age at diagnosis was 53 (23-98) years and follow-up was 40.1 months. There was no significant difference between groups in time from imaging to biopsy, time from biopsy to surgery, receipt of neoadjuvant or adjuvant chemotherapy, pathologic complete response to neoadjuvant chemotherapy, grade, pathological stage or duration of follow-up. Additionally, for BMI groups, there were also no differences in age or menopausal status. Interestingly, baseline BMI and diabetes were not associated with OS or DFS. OS hazard ratios (HRs) for overweight patients (BMI 25.1 to 29.99), those with class I obesity (BMI 30 to 34.99) or BMI ≥ 35 were 0.82 (CI 0.53 – 1.25, p = 0.35), 0.86 (CI 0.56 – 1.33, p = 0.50) and 0.87 (CI 0.54 – 1.40, p = 0.57), respectively. While the HRs for DFS in overweight patients, those with class I obesity or BMI ≥ 35 were 0.83 (CI 0.54 – 1.27, p = 0.39), 0.93 (CI 0.60 – 1.44, p = 0.74) and 0.96 (CI 0.61 – 1.52, p = 0.87), respectively. Similarly, the HRs for diabetics were 1.14 (CI 0.75 – 1.75, p = 0.55) for OS and 0.90 (CI 0.59 – 1.39, p = 0.63) for DFS. **Conclusions:** We conclude that obesity and diabetes did not significantly affect survival for TNBC patients in this single center cohort study.

**1109 General Poster Session (Board #202), Mon, 8:00 AM-11:45 AM**

**Histopathologic and immunohistochemical findings in triple-negative breast cancers showing clinical progressive disease during neoadjuvant chemotherapy.** *Presenting Author: Yuko Tanabe, Department of Breast and Medical Oncology, National Cancer Center Hospital, Tokyo, Japan*

**Background:** Clinical progressive disease (cPD) occurs during neoadjuvant therapy (NAC)in 3–5% of triple negative breast cancer (TNBC) patients. Predictive biomarkers are required for subtype specific characterization given the heterogeneous response to NAC in TNBC. This case-control study retrospectively analyzed histopathological and immunohistochemical data with the aim of detecting potential predictors of cPD. **Methods:** Using a pathology database of patients who had undergone surgical resection, 102 patients with TNBC were identified: 22 with cPD during NAC (PD group) and 80 controls (C group). Formalin-fixed paraffin-embedded tumor tissue sections were immunohistochemically examined for expression of 14 molecules, including ABCB1, which is a member of the ABC transporter family, and the following epithelial-to-mesenchymal transition (EMT) markers: vimentin, Twist NB, E-cadherin, ZEB1, and Snail2. Chi-square tests were conducted to compare differences between the groups. **Results:** Histologically, the PD group included 14 (64%) invasive ductal carcinomas (IDCs) and 8 (36%) metaplastic carcinomas (MPCs). In the C group, 59 (74%) were IDCs, 20 (25%) were types other than IDC or MPC, and only 1 was an MPC (1%) ($p<0.001$). The positive expressions of cytoplasmic vimentin (77%), nuclear Twist NB (27%), nuclear ZEB1 (36%), and nuclear Snail2 (59%) in the PD group were higher than those in the C group (54%, $p=0.049$; 3%, $p=0.0011$; 13%, $p=0.0093$; 48%, $p=0.049$, respectively). Nuclear ABCB1 expression was higher in the PD group (64%) than in the C group (6%) ($p<0.001$); conversely, cytoplasmic ABCB1 was present more frequently in the C group (96%) than in the PD group (77%) ($p=0.011$). The positive expression of nuclear ABCB1, nuclear ZEB1, or cytoplasmic vimentin occurred in 95% of the PD group compared to 61% in the C group ($p= 0.002$). **Conclusions:** A metaplastic phenotype, cytoplasmic vimentin or nuclear ZEB1 expression, and increased nuclear localization of ABCB1 could be predictors for cPD during NAC in TNBC patients.

**1110 General Poster Session (Board #203), Mon, 8:00 AM-11:45 AM**

**Expression of PD-L1 and NY-ESO-1 in early and advanced triple-negative breast cancer.** *Presenting Author: Anna Tessari, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy*

**Background:** Advanced triple negative breast cancer (TNBC) is a poor prognosis disease to which no targeted therapies are available. PD-L1 is a key player in tumor immune escape, and significant responses have been obtained inhibiting this pathway in various malignancies. NY-ESO-1 is a tumor-specific antigen and represents a possible target for vaccine therapy. Here we evaluate PD-L1 and NY-ESO-1 expression in early and advanced TNBC patients. **Methods:** 26 metastatic TNBC patients who underwent both primary surgery and distant lesion biopsy were selected. From representative paraffin-embedded block, we obtained 3 tissue-cores of 1.5 mm diameter for the construction of a tissue microarray, which was evaluated by immunohistochemistry. **Results:** In primary and metastatic lesions NY-ESO-1 was expressed in 12% and 24% of the samples respectively (30.8% overall positivity). PD-L1 was expressed in 100% of early TNBC and in 92% of corresponding metastatic lesions. Two patients lost PD-L1 expression in the distant lesion: one patient received anthracyclines, taxanes and CMF as adjuvant treatment and one received also paclitaxel and carboplatin as first line therapy before the distant lesion biopsy. All but one patient maintaining the PD-L1 expression in the advanced disease received anthracycline for early breast cancer, 52% and 91% adjuvant taxanes and CMF respectively, 26% various first line treatments before the biopsy. This observation is apparently in conflict with the hypothesis that doxorubicin inhibits PD-L1 expression. No correlation between NY-ESO-1 expression and age, time to relapse, presence of metastasis and cytotoxic treatments were observed. **Conclusions:** This study first investigates PD-L1 expression in TNBC patients and reports 100% positivity in the early stage, mostly maintained in the advanced disease. No clear correlation with PD-L1 loss and chemotherapy could be identified. This study reports that NY-ESO-1 is expressed in a subpopulation of TNBC, also in the metastatic setting, that could benefit from an anti-NY-ESO-1 vaccine, and indicates that TNBC is an ideal subgroup for anti-PD-L1 therapies. Patients positive on the early breast cancer specimen could then avoid a further biopsy of the metastatic site.

**1111 General Poster Session (Board #204), Mon, 8:00 AM-11:45 AM**

**Pretreatment neutrophil to lymphocyte ratio may be an useful tool in predicting survival in early triple-negative breast cancer patients.** *Presenting Author: Mirco Pistelli, Department of Medical Oncology, AOU Ospedali Riuniti, Ancona, Italy*

**Background:** There is a growing body of evidence that immune response plays a large role in cancer outcome. The neutrophil to lymphocyte ratio has been used as a simple parameter of systemic inflammation in several tumors. The purpose was to investigate the association between pre-treatment NLR, disease-free survival and overall survival in patients with early triple negative breast cancer (TNBC). **Methods:** We reviewed the records of patients with stage I-III TNBC at our Institution from 2006 to 2011. Patients were divided into two groups, according to a pre-treatment NLR cut off value was 3. The difference among variables was calculated by chi-square test. DFS and OS were estimated using Kaplan-Meier method. Cox analysis was performed to analyze clinical parameters for their prognostic relevance. **Results:** A total of 90 patients were eligible for analysis: 18,7% of patients showed higher pre-treatment NLR (group B). Median age at diagnosis was 53 years (range 28-79). The median follow-up time was 53.8 months (13.1-195.2). There was no significant correlation among pre-treatment NLR and various clinical pathological factors, including age, menopausal status, tumor size, lymph nodes status, grading, Ki-67, necrosis, lympho-vascular invasion. At univariate analysis patients with higher pre-treatment NLR (group B) showed significantly lower DFS ($p<0.01$; HR=0.21, 95% CI 0.01-0.39) and OS ($p<0.01$; HR=0.16, 95% CI 0.007-0.37). Multivariate analysis revealed that pre-treatment NLR was an independent prognostic factors influencing DFS ($p=0.006$; HR=5.12, 95% CI 1.6-16.38) and OS ($p=0.008$; HR=6.84, CI 1.6-28.5). **Conclusions:** Our study suggests that pre-treatment NLR may be associated with DFS and OS of patients with early TNBC and can be easily introduced in clinical practice in order to identify TNBC patients with poor prognosis. Prospective studies are needed to assess the potential role of NLR in guiding treatment decisions, patient selection, and clinical trials design.

**1112 General Poster Session (Board #205), Mon, 8:00 AM-11:45 AM**

**The role of CHFR as a predictive marker of response to taxane-based preoperative chemotherapy in triple-negative breast cancer.** *Presenting Author: Elisavet Paplomata, Department of Hematology and Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Taxanes are frequently used in the treatment of breast cancer. CHFR (checkpoint with forkhead and ringfinger domains) is a novel biomarker of resistance to microtubule targeting agents that can help individualize care and identify targets for overcoming this resistance. Our institution showed that high CHFR is associated with decreased response to taxanes and worse overall survival in patients with lung cancer. The current work evaluated the translational significance of CHFR in breast cancer. **Methods:** We studied a cohort of patients with triple negative breast cancer (TNBC), who were treated with pre-operative taxane-based chemotherapy followed by surgery. Archived paraffin-embedded tissue was stained for CHFR using immunohistochemistry. The level of protein expression was assessed by light microscopy and scored for intensity of staining and percentage of staining cells. CHFR expression was associated with pathologic complete response (pCR) and progression free survival (PFS). Covariates included age, race, stage, grade, tumor size, lymph node involvement, and type of chemotherapy. The univariate association with pCR was assessed using the chi-square test or Fisher's exact test, where appropriate for categorical covariates; and ANOVA for numerical covariates. The univariate and multivariate association with PFS was assessed using the Cox proportional hazard model. **Results:** We analyzed tumor samples from 43 eligible patients, with median age of 57 years. 27.9% of patients achieved a pCR. 88.4% of patients had high CHFR expression. The expression of CHFR was not associated with clinical outcomes: pCR rate or PFS. All analyses were repeated on 30 patients treated with doxorubicin/cyclophosphamide and paclitaxel; the high expression of CHFR still did not have a statistically significant association with pCR or PFS though there was a marginal trend towards better PFS. **Conclusions:** In this cohort of TNBC patients, the majority of tumors had high CHFR expression. This did not associate with clinical outcomes: pCR and PFS. We hypothesize that TNBC may be characterized by high CHFR; evaluation of hormone receptor positive and HER2 positive tumors may be worth exploring.

**1113 General Poster Session (Board #206), Mon, 8:00 AM-11:45 AM**

**Survival outcomes across ethnicities in triple-negative breast cancer.** *Presenting Author: Moira Katherine Rushton, University of Ottawa, Ottawa, ON, Canada*

**Background:** Triple negative breast cancer (TNBC) is a heterogeneous disease characterized by the lack of receptor expression (ER, PR, and HER2/neu negative). Amongst breast cancer types TNBC has a less favourable prognosis. There is a higher incidence of TNBC in African-American women than Caucasian women. What has not been clearly elucidated is whether survival outcomes are different among women with TNBC from different ethnic background. **Methods:** The objective of our study was to determine if significant differences exist in overall survival (OS) of TNBC patients across various ethnicities, including but not limited to Caucasian, African-American, and Asian. Using population data a multivariate analysis was done to take into account age, stage, and treatments received. **Results:** Using data from SEER database 6,227 cases of TNBC across all ethnicities were reported in 2010. At year one of follow-up, mortality rate was 2.6% (n=162) Race was found to be a potential predictor of breast cancer mortality with a mortality rate of 3.13% in American Indian/Alaskan Native and Pacific Islander patients; 2.75% in black patients; 2.6% in white patients. When adjusted for age and stage at time of diagnosis in multivariate analysis, there was no significant difference in OS for any ethnicity when compared to Caucasian patients. Specifically black TNBC patients had an OR 1.089 (p=0.69) and Asian patients OR 1.084 (p=0.87). **Conclusions:** While there was some suggestion that there was a higher one year breast cancer mortality rate in some populations, in multivariate analysis this was not a significant finding. Longer follow-up is needed before conclusions can be made about differences between ethnic groups. We are planning to review other large population databases to gather a greater pool of data to answer this question. Determining if there are certain populations do worse will inform the medical oncology community of an area to focus greater study to determine how to optimize therapies for that patient group.

**1114 General Poster Session (Board #207), Mon, 8:00 AM-11:45 AM**

**The impact of TSG101 in triple-negative breast cancers.** *Presenting Author: Shiva D.J. Sharma, University College Dublin, Belfield, Ireland*

**Background:** TSG101 is an essential protein and constituent of cellular function involved in the sorting and trafficking of cell components destined for processing or degradation and is also integral to exosome production and release. Limited information is known about TSG101 and exosomes in the field of breast cancer and even less in the difficult to treat subset of triple-negative breast cancer (TNBC). We propose that TNBC tumours demonstrating high levels of TSG101 are more likely to recur locally and at distant sites due to enhanced exosome mediated communication in the tumour microenvironment through the propagation of chemoresistance. **Methods:** Cellular viability of our TNBC cell lines (BT-549 and MDA-MB-231) after incremental Paclitaxel treatments were assessed by MTT viability assay. Using an siRNA knockdown we were able to selectively target and reduce the intracellular levels of TSG101 protein. TNBC cell lines were treated with Paclitaxel at 24 and 48 hours. Immunohistochemical staining for TSG101 was performed to evaluate the expression of TSG101 in breast cancer clinical cases. **Results:** Using an MTT viability assay, BT-549 TNBC cells were found to be more sensitive to the chemotherapeutic drug Paclitaxel compared to the MDA-MB-231 TNBC cells which were shown to be more chemoresistant. Following 24 and 48hours of treatment with Paclitaxel the levels of TSG101 in the MDA-MB-231 cells remained level, while the levels of TSG101 were lower in the more Paclitaxel sensitive BT-549 cells. Subsequent exosome profiling of media collected from TSG101 protein knockdown cells showed differential size and number of exosomes released from BT-549 and MDA-MB-231 cells after Paclitaxel treatment. Immunohistochemical analysis of 85 breast cancer cases on TissueMicroArray established strong cytoplasmic staining of TSG101 in 20% of cases, while 53% of tumours demonstrated none/weak staining of TSG101. **Conclusions:** We conclude that TSG101 is differentially expressed in the TNBC in vitro and that expression levels are influenced by Paclitaxel treatment. We also conclude that siRNA knockdown of TSG101 impedes the release of exosomes. We suggest that TNBC tumours that clinically express high levels of TSG101 may express a more aggressive phenotype.

**1115 General Poster Session (Board #208), Mon, 8:00 AM-11:45 AM**

**Pretreatment platelets count levels as a prognostic factor in triple-negative breast cancer in a Hispanic cohort.** *Presenting Author: Saul Campos Gomez, Centro Oncológico Estatal ISSEMYM, Toluca, Mexico*

**Background:** Platelet count has been reported to have predictive value in various cancer entities. Several studies suggest a negative impact of thrombocytosis for patient's survival in different types of cancer. In the case of breast cancer, evidence about involvement of platelets is still inconclusive. Therefore, the aim of our study was to assess the influence of pretreatment platelet count levels on survival and establish its prognostic relevance for breast cancer patients in a large cohort of triple negative breast cancer patients. **Methods:** We retrospectively studied patients diagnosed with primary triple negative breast cancer that had completed all phases of primary treatment from 2005 to 2012, finding 118 patients with platelet counts prior to therapy and clinical follow-up. Baseline platelet numbers were evaluated at diagnosis (before the start of any therapy for disease). Platelet levels were categorized into the following three groups: normal low (< 200 g/L), normal high (200-400 g/L) and thrombocytosis (> 400 g/L). Overall survival (OS) was assessed using the Kaplan-Meier method and were compared using the LogRank test. To evaluate the independent prognostic significance of NLR, multivariate Cox regression models were used. **Results:** Patients with lower platelets count (< 200 g/L) showed significantly lower median overall survival than those with normal high (200-300 g/L) and thrombocytosis (> 400 g/L) (33 months vs. 71 months, log Rank p=0.024). Pretreatment thrombocytosis was observed only in 9 patients (7.6%). Low platelets counts along with advanced stage were independently correlated with poor prognosis, with hazard ratio 1.2 (p 0.02), and 2.1 (p 0.001), respectively. Estimated media OS, for patients with low platelets count, normal high count and thrombocytosis were 56, 38 and 36 months respectively. **Conclusions:** In our retrospective study, normal low platelet counts at time of diagnosis were associated with poor prognosis in triple negative breast cancer. We hypothesize that platelets in normal high levels as scavenger of VEGF and therefore as a potent antiangiogenic cellular component of the tumor microvasculature in triple negative breast cancer can also be considered.

**1116 General Poster Session (Board #209), Mon, 8:00 AM-11:45 AM**

**Antitumoral activity of EC70124, a novel multitarget kinase inhibitor, in triple-negative breast cancer.** *Presenting Author: Maria D. Cuenca-Lopez, Translational Research Unit, Albacete University Hospital, Albacete, Spain, Albacete, Spain*

**Background:** Receptor tyrosine kinases (RTK) and downstream signaling routes play a central role in the genesis and/or promotion of different breast cancer tumors including the triple negative subtype. Kinase inhibitors designed to neutralize their function are in clinical development. We describe the preclinical evaluation of EC-70124, a novel, unique profile, multi-target kinase inhibitor, in triple negative breast cancer. **Methods:** Cell proliferation and growth was measured by MTT uptake and matrigel in a representative panel of triple negative cell lines. Evaluation of apoptosis and cell cycle was performed by flow cytometry. Western-blot and phospho-array kits were used for evaluation of signaling intermediates. To evaluate if EC-70124 combined with other chemotherapy drugs was synergistic we used the CalcuSyn v2.0 software. Gene-set enrichment analyses were performed to identify relevant functions affected by the drug and the identified genes were confirmed by RT-PCR. In vivo anti-tumor effect was evaluated using xenografted animals. **Results:** EC-70124 is a hybrid indolocarbazole analog obtained by combinatorial biosynthesis of Rebeccamycin and Staurosporine pathways and produced by fermentation. Doses of EC-70124 in the nanomolar ranged reduced proliferation in a panel of triple negative cell lines including HS578T, BT549, MDA-MB231 and HCC3153. Treatment with EC-70124 at 500 nM led to an induction of DNA damage measured by γH2AX. Cell cycle analyses showed an arrest at the G2/M phase in HS578T and BT549; that was confirmed by the biochemical evaluation of cell cycle mediators. Gene expression analyses showed different cellular functions induced by EC70124 being up regulation of DNA repair genes one of them. The up-regulation of these genes was confirmed by RT-PCR. EC70124 produced tumor regression of MDA-MD231 tumors in xenografted animals. No major toxicities were observed. Studies in combination with standard of care chemotherapy showed enhanced activity. **Conclusions:** EC-70124 is a novel multi-target kinase inhibitor with anti-tumoral activity in triple negative breast cancer. Its mechanism of action is mediated through an induction of DNA damage and cell cycle arrest at G2/M.

**1117 General Poster Session (Board #210), Mon, 8:00 AM-11:45 AM**

**Similarities between the biology of breast cancer in Kenya among blacks and that seen among whites elsewhere.** *Presenting Author: Nicolas Anthony Othieno-Abinya, University of Nairobi, Nairobi, Kenya*

**Background:** Breast cancer is the commonest type of cancer among women worldwide, and the number one cause of cancer deaths among women. Its incidence increases with age, and the commonest pathological subtype is invasive ductal carcinoma. Hormone receptors (ER/PR) are expressed in about 70% of the cases and are associated with favourable outcome. HERr2/Neu is overexpressed in 20-30% of breast cancers and is associated with aggressive disease with poor outcomes. Tumours not expressing any of these biological features (triple negative) are commonly associated with dire outcome. Reports so far indicate racial differences with triple negative disease being more common among Blacks than other races. **Methods:** A prospective breast cancer care (BRECC) registry at the Kenyatta National Hospital, Nairobi. Details taken included biodata, symptoms, pathology, hormone receptors, HER2 overexpression, mode of diagnosis, stage at diagnosis, intervention and outcome. **Results:** A total of 269 patients - 268 were females, 1 male, all black. Median age was 48 years. Of 260 cases evaluable, 148 (56.9%) were aged $<$ 50 years and 112 (43.1%) $\geq$ 50. The commonest modes of presentation were breast lump in 149 out of 228 cases evaluable (65.4%), breast pain in 70 (30.7%) and nipple changes in 65 (28.5%). Of 181 cases evaluable, 146 (80.7%) were invasive ductal carcinoma. Two out of 113 were grade 1, 48 (42.5%) grade 2, 63 (55.8%) grade 3. Of 62 cases evaluable, 38 (61.3%) were oestrogen receptor positive, 40 (64.5%) progesterone receptor positive and 11 (17.7%) Her2 positive. Hormone receptor positive, HER2 negative cases were 40 (64.5%); hormone receptor negative, HER2 positive were 6 (9.7%); hormone receptor negative, HER2-negative (triple negative) were 10 (16.1%); hormone receptor positive, HER2-positive were 6 (9.7%). **Conclusions:** The median age for breast cancer in Kenya is young, though increasingly approaching that seen in whites. Hormone receptor and HER2 expression levels don't differ significantly from what is reported among whites.

**1118 General Poster Session (Board #211), Mon, 8:00 AM-11:45 AM**

**Mutant p53: A therapeutic target for the treatment of triple-negative breast cancer?** *Presenting Author: Naoise C. Synnott, Education and Research Centre, St.Vincent's University Hospital and School of Medicine and Medical Science, University College Dublin, Dublin, Ireland*

**Background:** Despite intensive efforts, a validated targeted therapy for triple-negative breast cancer (TNBC) remains elusive. One of the most frequent genetic alterations identified to date in TNBC is mutation in the p53 gene, which has been found in $>$ 80% of these samples. The aim of this study was therefore to investigate mutant p53 as a potential target for the treatment of TNBC. **Methods:** Two compounds, PRIMA-1 and PRIMA-$1^{MET}$which have previously been shown to reactivate mutant p53 and convert it to a form with wild-type properties were investigated in a panel of 18 p53 mutant breast cancer cell lines (TNBC = 12; non-TNBC = 6). Cytoxicity was determined using the MTT assay, while induction of apoptosis was measured using both the Cell Death ELISA kit and flow cytometry. **Results:** Using the MTT assay, $IC_{50}$ concentrations across 12 p53 mutant TNBC cell lines ranged from 1.4 to 15.1$\mu$M for PRIMA-1 and from 0.9 to 11.9 $\mu$M for PRIMA-$1^{MET}$. Response to PRIMA-1 correlated significantly with that to PRIMA-$1^{MET}$ ($p<0.0001$). Inhibition of cell growth varied from 4.1 to 90.8% for PRIMA-1 and from 3.1 to 96.6% for PRIMA-$1_{MET}$ using concentration of inhibitor at 6.25 $\mu$M. PRIMA-1 and PRIMA-$1^{MET}$ also reduced the ability of the mutant p53 cells to form colonies with $IC_{50}$ values ranging from 0.16 to 10.7 $\mu$M for PRIMA-1 and from 0.02 to 9.6 $\mu$M for PRIMA-$1^{MET}$. No significant difference in sensitivity for either inhibitor was observed between ER-positive and ER-negative cell lines, HER2-positive and HER2-negative cell lines or between TN and non-TN cell lines. In addition to inhibiting cell proliferation, both PRIMA-1 and PRIMA-$1^{MET}$also induced apoptosis in MDA-MB-453 cells. **Conclusions:** Our preclinical results suggest that targeting mutant p53 with either PRIMA-1 or PRIMA-$1^{MET}$is a potential new approach for treating p53-mutated breast cancer including the subgroup with triple-negative disease.

**1119 General Poster Session (Board #212), Mon, 8:00 AM-11:45 AM**

**Evaluation of *BRCA1*/2 mutation status among women with triple-negative breast cancer.** *Presenting Author: Axel Muendlein, Vorarlberg Institute for Vascular Investigation and Treatment, Feldkirch, Austria*

**Background:** Testing for BRCA1 and BRCA2 mutations in breast cancer patients is used to identify risk of second primary cancers and risk of cancer in the patients' family. A high proportion of BRCA1 mutation positive patients have triple-negative breast cancer (TNBC). TNBC shows a poor prognosis and no effective treatment strategies against TNBC are available to date. However, BRCA-related cancers are sensitive to platinum chemotherapy as well as to drugs targeting poly (ADP-ribose) polymerase enzymes, which are under development so far. Women with TNBC are thought to be more likely to be BRCA mutation carriers, but there have only been limited numbers of studies investigating BRCA1- and BRCA2-mutation status among Caucasian patients with TNBC. **Methods:** We determined the prevalence of BRCA1 and BRCA2 mutations within a cohort of 88 unselected TNBC cases including patients from Germany and Austria. Double-stranded Sanger sequencing of all exons of BRCA1 and BRCA2, respectively, was performed. **Results:** We identified a total of 14 deleterious mutations in BRCA1 and of 4 deleterious mutations in BRCA2, including 10 frame shift, five missense and two nonsense mutations as well as one splice mutation. One of our patients carried two deleterious BRCA1 mutations. The total rate of deleterious BRCA1/2 mutation carriers was 19.3% in our cohort. Furthermore, six mutations with biological significance, but unclear clinical impact, have been found. In total, 15 novel mutations have been identified, which have not been described in public BRCA mutation databases (NCBI, BIC, LOVD, and UMD, respectively) so far. **Conclusions:** We conclude that women with TNBC frequently show BRCA1 as well as BRCA2 mutations. TNBC patients may therefore benefit from BRCA genetic testing to identify those with a masked family history of breast cancer or to indentify candidates who may profit from BRCA-related therapies.

**1121 General Poster Session (Board #214), Mon, 8:00 AM-11:45 AM**

**Classification of molecular subtypes of triple-negative breast cancer using reverse phase protein arrays (RPPAs).** *Presenting Author: Hiroko Masuda, Morgan Welch Inflammatory Breast Cancer Program and Clinic, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Gene expression analyses have identified molecular subtypes of triple-negative breast cancer (TNBC), such as the basal-like subtype and the 7 molecular subtypes that are refining our understanding of breast cancer biology. However, these subtypes are not well defined enough to enable development of targeted therapy or prediction of prognosis in a clinical setting. Reverse phase protein array (RPPA) analysis could be easily adapted to a clinical setting for this purpose because it allows investigation of potential targets at the protein level and can lead to the development of immunohistochemical assays. **Methods:** We used 80 TNBC RPPAs obtained from patients at The MD Anderson Cancer Center between 03/87 and 04/06. RPPA analysis showed 154 breast cancer related proteins, including both total and phosphorylated proteins. We classified the TNBC samples using 2 types of clustering analysis, k-means and hierarchical, and silhouette width analysis. To assess the biological features of each TNBC subtype, we mapped antibody names from the RPPA dataset to HGNC gene symbols and fit a Gene Set Enrichment Analysis. We also performed correlation analysis between each TNBC subtype and recurrence-free survival (RFS) and overall survival (OS). **Results:** Results of both clustering showed that the optimal number of subtypes in the TNBC RPPA dataset was 2-3. Clusters of $k = 2$ from the k-means and hierarchical clustering methods showed the same, indicating that these 2 clusters were stable and sufficiently different and therefore could be reproduced using different methods. The top canonical pathways, which were associated with 2 clusters, were the DNA repair and replication pathway (cluster 1) and the immune response and adipocytokine signaling pathways (cluster 2). OS and DFS rates were different between the 2 clusters, but the differences were not significant (DFS: $p = 0.3$; OS: $p = 0.1$), probably owing to small sample size. **Conclusions:** Two types of clustering analysis showed that we identified 2 stable TNBC subtypes at the protein level. These results indicate that distinguishing between basal and stromal subtypes is a useful first step in identifying TNBC heterogeneity in the clinical setting.

**1122 General Poster Session (Board #215), Mon, 8:00 AM-11:45 AM**

**The outcome of special histologic types of triple-negative breast cancer (TNBC).** *Presenting Author: Katarzyna Pogoda, Department of Breast Cancer and Reconstructive Surgery, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland*

**Background:** Triple-negative breast cancer (TNBC) is a heterogeneous disease. Knowledge of the outcome of special histological subtypesof TNBC can facilitate tailored adjuvant treatment. The aim of the study was to determine recurrence rate and overall survival of special histological subtypes of TNBC in order to select those with excellent and the worst prognosis. **Methods:** Of 4,563 consecutive breast cancer patients diagnosed in Cancer Center and Institute of Oncology in Warsaw, Poland, between the years 2005 and 2008, 502 patients (9%) were TNBC (ER-/PR-/HER2-negative). Median follow-up was 7 years (range 5–9 years). 426 cases with known histological types were selected and analyzed in terms of the disease free and overall survival using the Kaplan-Meier method. Competing risk analysis was performed in order to assess the risk of recurrence and the comparison between types. **Results:** From 426 TNBC subtypes, 352 (82%) cases were classified as ductal not otherwise specified (NOS), 21 (5%) were classified as lobular, 17 (4%) were classified as metaplastic, 10 (2.3%) were classified as medullary, 7 (1.6%) as apocrine, 6 (1.4%) as papillary, 4 (0.9%) as neuroendocrine, 2 (0.5%) as cribriform and 2 (0.5%) were classified as mucinous. 5-year DFS and OS of ductal NOS type was 73% and 62%, respectively. 5-year DFS was the best for patients with apocrine (100%), medullary (100%) and neuroendocrine (100%) types while it was the worst in papillary (50%) and lobular (68%) TNBC. 5-year OS was the best in apocrine (90%) and medullar (100%) types and was the worst in papillary (17%) and lobular (61%) types. In metaplastic TNBC 5-year DFS and OS was 79% and 65%, respectively. Taking into account competing risk of death and different clinical stages of the disease, the risk of recurrence was the highest in patients with lobular TNBC (HR=2.83, p=0.04). **Conclusions:** The diagnosis of special types of TNBC is associated with different outcome if compared with ductal NOS type. Medullary and apocrine types had excellent prognosis while lobular TNBC seems to be the most aggressive and requires intensive treatment. Histological special type of TNBC should be taking into consideration when choosing adjuvant treatment, apart from specified other prognostic factors.

**1123 General Poster Session (Board #216), Mon, 8:00 AM-11:45 AM**

**Outcomes of patients with triple-negative breast cancer compared to non-triple negative breast cancer: A single-center study.** *Presenting Author: Caroline M. Hamm, Windsor Regional Caner Centre, Windsor, ON, Canada*

**Background:** Triple negative breast cancer is defined as estrogen receptor negative, progesterone receptor negative, Her-2-neu negative breast cancer. The lack of targeted therapies for this patient group has been considered to be a negative prognostic factor. **Methods:** Twelve hundred thirty four non-triple negative (n-TNBC) breast cancer patients and 167 triple negative (TNBC) patients were reviewed retrospectively. All patients were treated in a single centre in Ontario, and all received standard of care in Ontario, Canada. Hormone receptor positive patients received anti-estrogen therapy, and Her-2 positive patients received chemotherapy and trastuzumab. **Results:** Although overall progression free survival was statistically inferior for the TNBC group ( $p < 0.001$), important information is found when analyzed by stage at presentation. Median progression free survival (PFS) was not reached for any stage I, nor stage II patient group. There was no difference in overall survival for stage one between the n-TNBC and the TNBC groups, but was inferior for the TNBC group for Stage II and III. Few relapses were seen in the stage 1 TNBC group, and none were identified after 40 months (median follow-up 40 months). All analyses are as of yet unadjusted. **Conclusions:** Although the overall outcome of TNBC patients is inferior to their n-TNBC counterparts, their presenting stage is still vitally important in predicting outcome. Stage 1 TNBC carries a good prognosis, possibly better than the NTN counterpart. Ongoing research to identify these TNBC patients at an earlier stage is vital to improving outcomes in this patient population.

**1124 General Poster Session (Board #217), Mon, 8:00 AM-11:45 AM**

**Surgical removal of primary tumor in metastatic breast cancer: Impact on health-related quality of life (HR-QOL) in a randomized controlled trial (RCT).** *Presenting Author: Rajendra A. Badwe, Tata Memorial Center, Mumbai, India*

**Background:** We have previously reported in a RCT that surgical removal of the primary tumor (versus not) did not significantly improve median overall survival (18.8 Vs 20.5 months) in women with MBC[1]. This procedure would still be worthwhile if it improved the quality of life in these women. We report here HR-QOL analysis of this RCT. [NCT: 00193778]. **Methods:** HR-QOL was assessed in these women using the EORTC QLQC30 and BR23 (English or validated local language versions). The questionnaires were completed by these women at baseline (at randomization) and at protocol defined follow-up time points thereafter. **Results:** Of the 350 women randomized to surgical removal of the primary Vs not, HR-QOL assessment was available at baseline for 178 (surgery=84, no surgery=94), 3-6 months for 139(surgery=74, no surgery=65), 6-9 months for 122 (surgery=65, no surgery=57) and 18-24 months for 94(surgery=45, no surgery=49). The groups were balanced and representative of patients in the main study (N=350) with respect to age, hormone receptor status, site of metastasis, no of metastatic lesions. The mean BR23 arm score was worse in the surgical arm at 3-6 month evaluation (18.9 Vs 10.4, p=0.003) but not at subsequent evaluations whereas mean BR23 breast symptom score was worse in no-surgery arm at 18-24 month evaluation (18.7 Vs 10.0, p=0.009), which corresponds to median OS in these women. There was no significant difference in mean global QOL score between the 2 arms at baseline (64.2 Vs 65.8, p=0.5), 6-9 months (69.9 Vs 67.7, p=0.5), 18-24 months (64.7 Vs 60.0, p=0.3) and all other time points. There was no significant difference between the 2 arms in all other domains of HR-QOL at any time point. **Conclusions:** Surgical removal of the primary tumor did not significantly improve the HR-QOL in women with MBC. Taken together with survival results our data provides strong evidence that surgery for primary should not be routinely performed in women with metastatic breast cancer. Clinical trial information: 00193778.

**1125 General Poster Session (Board #218), Mon, 8:00 AM-11:45 AM**

**Prognostic value of routinely determined tumor infiltrating lymphocytes in triple-negative breast cancer.** *Presenting Author: Jana Pahole Golicnik, Institute of Oncology, Ljubljana, Slovenia*

**Background:** Tumor infiltrating lymphocytes (TIL) was suggested to influence disease outcome in triple negative breast cancer (TNBC). Our hypothesis was that TIL determined by routine histopathological examination (RHE) is a prognostic and predictive factor in TNBC. **Methods:** Clinical and pathological data from 267 consecutively diagnosed and treated patients (pts) with TNBC from the year 2000 to 2006 was retrospectively collected. On RHE, lymphocytic infiltration was evaluated morphologically on H and E slides. Lymphocytic infiltration of the stroma surrounding the tumor or the tumor nests inside the tumor mass was scored as mild, moderate or intensive. The prognostic and predictive impact of TIL was calculated using Cox model. **Results:** The median age of pts was 56 years, 38.6% being premenopausal, 57.3% had tumors >2cm, 80.5% grade 3, 46.1% nodal involvement, and in 23.2% of pts lymphovascular invasion (LVI) was present. TIL was determined in 240 tumors; in 187 (78%) mild or moderate and in 53 (22%) intensive TIL was described. In the whole group of pts 79.8% received chemotherapy, among them 56.5% anthracycline based (A) only, 14.5% A and taxane (AT), 23.8% cyclophosphamide-methotrexate-fluorouracil (CMF) and 5.1 % other schemes. At a median follow-up of 10 years 93 pts progressed. Ten-year disease free survival (DFS) of pts with intensive TIL was 80.8 %, comparing with 60.5% in other pts (p=0.02). The differences in 10-year DFS for pts with intensive TIL was almost significantly better when treated with A (intensive TIL vs other 82.4% vs 62.7%, p=0.06), however this difference was not significant in the CMF group (85.7% vs 66.5%, p=0.16) while the opposite was noted in the AT group (62.5% and 68.8%, p= 0.69). **Conclusions:** In pts with TNBC intensive TIL determined on RHE predicts better disease outcome. In addition, pts with intensive TIL may benefit more from adjuvant A compared with AT.

**Estimated DFS hazard ratios, 95% CI and p-values for the Cox multivariate model.**

| **Variable** | **HR (95%CI)** | **p** |
|---|---|---|
| **TIL (intensive vs other)** | 0.45 (0.22-0.93) | 0.03 |
| **Grade (1+2 vs 3)** | 0.88 (0.67-1.15) | 0.34 |
| **Size (>20 mm vs <20 mm)** | 1.63 (0.98-2.72) | 0.06 |
| **Lymph nodes (positive vs negative)** | 2.39 (1.45-3.92) | <0.01 |
| **LVI (yes vs no)** | 1.17 (0.70-1.96) | 0.54 |

**1126 General Poster Session (Board #219), Mon, 8:00 AM-11:45 AM**

**CK14, FOXA1, and androgen receptor (AR) expression in patients (pts) with triple-negative breast cancer (TNBC).** *Presenting Author: Ayca Gucalp, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** TNBC is recognized to be heterogeneous based on gene expression profiling. An AR+, androgen-dependent subset of TNBC benefits from antiAR drugs. FOXA1, a nuclear mediator of steroid receptor signaling is involved in the regulation of ER and AR. FOXA1 expression in ER+ BC correlates with better prognosis; the significance of FOXA1 in TNBC is not established. We report the rates of FOXA1 expression in relationship to AR, basal markers and outcome in a retrospective cohort of pts with TNBC. **Methods:** We identified 1,032 pts with resectable, TNBC (ER/PR<1%; HER2 0-2+/FISH <2) who had surgery at MSK (1998-2006). Exclusion criteria: neoadjuvant chemotherapy, radiation, inflammatory/metastatic BC. We constructed tissue microarrays from 311 primary tumors (>1cm, post 2002) with three 0.6mm cores per tumor. Standard IHC methods were used. Scored positive: FOXA1 >3 per Badve CCR 2007; AR and EGFR paralleled the ASCO/CAP criteria for ER and HER2 respectively; CK5/6 and CK14 any cytoplasmic stain. Associations were analyzed with Fischer Exact/Spearman correlation tests. Log Rank test was used for survival analysis. **Results:** 303 pts met eligibility criteria. # of positive/evaluable cases: AR 16/283 (6%), FOXA1 79/273 (29%), CK5/6 185/290 (64%), CK14 128/278 (46%) and EGFR 234/289 (81%). There was a significant correlation between FOXA1 and AR (p=1.19E-10). There were inverse correlations between FOXA1 and CK14 (p=0.003), AR and CK14 (p=0.004) and AR and EGFR (p=0.018). 264/291 (91%) pts met Nielsen criteria (NC) for basal-like BC (BLBC). 94% (15/16) of AR+ tumors and 98% (121/124) of CK14+ tumors co-expressed NC. 46% of BLBC by NC expressed CK14. CK14 expression was associated with worse DFS (p=0.003, 5-year DFS 69% vs. 83%) and OS (p=0.01, 5-year OS 71% vs. 85%). FOXA1 expression was not associated with a significant difference in DFS (HR 0.98, p=0.26) or OS (HR 0.99, p=0.52). **Conclusions:** CK14 expression was the only prognostic marker for survival in our cohort. A high proportion of the AR+ tumors are BL according to NC, which is contradictory to gene expression data. There may be differences between these subsets or discordance between protein expression of AR and molecular subtype of TNBC (luminal AR vs. BL).

**1127 General Poster Session (Board #220), Mon, 8:00 AM-11:45 AM**

**The yield of staging investigations in triple-negative breast cancer patients.** *Presenting Author: Renee Elizabeth Lester, Tom Baker Cancer Centre, Calgary, AB, Canada*

**Background:** Current guidelines suggest that asymptomatic Stage I and II node negative patients do not require staging investigations to rule out metastatic disease. Our provincial cancer centre's guidelines released last year recommends blood work (CBC, kidney and liver function), CT scan of chest and abdomen, and bone scan for node positive breast cancer patients. **Methods:** We conducted a retrospective chart review of all triple-negative breast cancer patients diagnosed from January 2008 to December 2010. Triple negative is defined as <1% staining on immunohistochemistry (IHC) for both estrogen receptor (ER) and progestin receptor (PR) as well as the absence of HER2 overexpression on IHC or negative for gene amplification by FISH. The collected data included patients age, date of diagnosis, tumor size, grade, number of lymph nodes, presence/absence of lymphovascular invasion, and whether or not staging investigations were performed and their results. **Results:** One hundred and twelve patients were diagnosed with triple negative breast cancer in our centre between January 2008 and December 2010. Ninety five (86%) underwent staging investigations, 43 (45%) ordered by the medical oncologist and the remainder arranged by the referring physician. Twenty out of thirty stage I patients had some form of imaging (either bone scan, liver ultrasound, or CT). This did not yield any positive studies for metastatic disease. Similarly 25 out of 29 stage IIA patients were staged. Of those 25 patients, 12% had evidence of metastatic spread diagnosed on imaging. All 19 stage IIB patients were staged; of which 10.5% were also found to have metastatic disease. **Conclusions:** Stage I asymptomatic TNBC patients do not require routine staging investigations as the yield is quite low. However this study suggests that newly diagnosed triple negative patients that are stage II (either node negative or node positive) should undergo routine imaging to rule out any metastatic spread as this changes the intent of therapy. Further data collection is warranted.

| Stage | # of pts | # staged | # by MO | # positive | Yield |
|---|---|---|---|---|---|
| 1 | 30 | 20 | 6 | 0 | 0% |
| 2A | 29 | 25 | 14 | 3 | 12% |

**1128 General Poster Session (Board #221), Mon, 8:00 AM-11:45 AM**

**Effect of afatinib alone and in combination with dasatinib in triple-negative breast cancer cell lines.** *Presenting Author: Mohamed F.K. Ibrahim, Molecular Therapeutics for Cancer Ireland, National Institute for Cellular Biotechnology, Dublin, Ireland*

**Background:** TNBC is a subtype of breast cancer negative for expression of estrogen and progesterone receptors and lack of HER2 gene amplification. It is associated with poor prognosis and lack of targeted therapies. Therefore, there is a need for identification of new therapies. EGFR, a member of the ErbB family, is frequently overexpressed in TNBC. Furthermore, crosstalk between EGFR and Src kinase signaling has been observed in breast cancer. The aim of this study is to assess the activity of afatinib, an irreversible pan-HER tyrosine kinase inhibitor alone and in combination with dasatinib, a Src inhibitor, in TNBC. **Methods:** Using proliferation assays, the effect of afatinib was assessed alone and in combination with dasatinib in TNBC cell lines. Combination indexes (CI) at $ED_{50}$, effective dose of combination that inhibits 50% of growth, were determined using the Chou and Talalay equation. CI < 1 implies synergy and CI > 1 implies antagonism. **Results:** The 6 TNBC cell lines tested responded to afatinib with $IC_{50}$ values ranging from 0.02 to 2.44 $\mu$M. As previously shown, the TNBC cell lines showed sensitivity to dasatinib with $IC_{50}$ values ranging from 9.6 nM to 3.1 $\mu$M. The HDQ-P1 cell line, classified as belonging to the basal-like 2 subtype of TNBC, showed significant sensitivity to both afatinib ($IC_{50}$ = 17.5 ± 2.1 nM) and dasatinib ($IC_{50}$= 16.6 ± 5.3 nM). The combination of afatinib and dasatinib was synergistic in 5 of the 6 TNBC cell lines tested (Table). **Conclusions:** Our results suggest that afatinib may have activity in TNBC. We also demonstrate that afatinib in combination with dasatinib may be more effective than either agent alone.

**Effect of afatinib in combination with dasatinib in TNBC cell lines.**

| | | % growth inhibition | | | |
|---|---|---|---|---|---|
| Cell lines | Subtype | Afatinib | Dasatinib | Afatinib + Dasatinib | CI ($ED_{50}$) |
| HCC1143 | Basal-Like 1 | 1 $\mu$M - 30.9 ± 5.6 | 200 nM - 52.6 ± 3.2 | 61.9 ± 3.7 | N/A |
| HCC1937 | Basal-Like 1 | 1 $\mu$M - 53.8 ± 3.1 | 50 nM - 43.1 ± 1.5 | 70.0 ± 2.2 | 0.39 ± 0.09 |
| HDQP1 | Basal-Like 2 | 100 nM - 66.5 ± 2.4 | 200 nM - 87.1 ± 2.5 | 91 ± 0.8 | 0.26 ± 0.05 |

**1129 General Poster Session (Board #222), Mon, 8:00 AM-11:45 AM**

**Correlation of Notch1 expression with clinical characteristics, signaling biomarkers, and survival in breast cancer patients.** *Presenting Author: Aleksandra Filipovic, Imperial College London, London, United Kingdom*

**Background:** Notch1 signalling plays an important oncogenic role in breast cancer and represents a therapeutic target amenable to targeting with small-molecule gamma secretase inhibitors and specific anti-Notch1 monoclonal antibodies. Canonical Notch1 signaling is mediated by nuclear Notch1 cleaved fragment. Some evidence suggests non-nuclear, non-canonical signalling from cytoplasmic or membrane Notch1. Current study aims to investigate the clinical relevance of Notch1 expression in invasive breast cancer. **Methods:** A well-characterised Nottingham Tenovus cohort of invasive breast cancers (n = 1078), with long-term follow up data, was analysed using immunohistochemistry for Notch1 (Santa Cruz, C-20). X-tile software was used to generate cut-off values for further correlation of the Notch1: nuclear (≥ 20% positive cells) and membrane/juxtamembrane staining (≥ 50% cells). **Results:** High Notch1 membrane staining was correlated with high grade (p = 0.001), size > 2cm (p = 0.001), ductal histotype, advanced disease stage (p = 0.044), triple negative phenotype (p = 0.001), HER2 positive status (p = 0.02), HER3 positivity (p = 0.019), basal cytokeratin CK5 expression (p = 0.001) and PI3K activity (p = 0.008). High membrane Notch1 predicted worse breast cancer specific overall survival at 25 years of follow up (p = 0.017). Conversely, nuclear Notch1 was predominantly present in lobular carcinomas and correlated inversely with the triple negative subtype ( p = 0.019) as well as PI3K (p = 0.014), thereby its higher expression was predictive of favourable survival outcome (p = 0.008). **Conclusions:** Different subtypes of breast cancer may rely on different Notch1 signaling pathways, including nuclear and non-nuclear signalling. For the first time, we emphasize the clinical relevance of Notch membrane expression in highly aggressive disease. Therefore, our findings bear significant translational relevance, as we propose that Notch1 membrane expression assessment may be used for stratification of patients who may derive particular benefit from anti-Notch1 monoclonal antibody therapy or other Notch inhibitors in the clinic.

**1130 General Poster Session (Board #223), Mon, 8:00 AM-11:45 AM**

**Association of *TP53* codon 72 polymorphism with *TP53* mutation in triple-negative breast cancer (TNBC) patients.** *Presenting Author: Mathilde Födermayr, Hospital Elisabethinen Linz, Linz, Austria*

**Background:** A high rate of *TP53* mutations was observed in TNBC, suggesting a role in TNBC carcinogenesis. Missense mutations cause single amino acid substitutions with altered protein function. Non-missense (nonsense, frameshift, splice site) mutations lead to functional loss or complete deletion of protein p53. Other reports have focused on *TP53* polymorphisms. Codon 72 polymorphism (SNP rs1042522) is found in a proline-rich region of exon 4, encoding alleles Pro72 (ancestral form; CCC) or Arg72 (CGC) and varies with geographical latitude, accumulating towards the south; it is also common in African-Americans, where a high incidence of TNBC is evident. Effect of anticancer therapy may be influenced, as Pro72 is apparently less effective in apoptosis induction. Here, we investigated the incidence of Arg72 and Pro72 and the association of this polymorphism with *TP53* mutations in a Caucasian population of TNBC patients (pts). **Methods:** DNA was extracted from formalin-fixed paraffin-embedded tissue of operation specimen. For investigating *TP53* mutation status (exons 4-9) DNA was PCR amplified and sequenced. For correlation of two parameters, the Fisher's exact test was used. **Results:** In a cohort of 35 consecutive TNBC pts, 25 *TP53* mutations in 23 pts (65.7%) were observed: 13 missense (52%), 5 nonsense (20%), 4 frame shift (16%), 2 splice site (8%), 1 silent mutation (4%). Distribution of codon 72 polymorphism was 60% Arg/Arg, 11.4% Pro/Pro ($p<0.001$), 28.6% Pro/Arg ($p=0.016$). Non-missense mutations occurred mostly in pts carrying the hetero- or homozygous allele Pro72: Nonsense mutations showed a significant association with Pro/Arg (4/5; $p=0.03$), frameshift mutations with Pro/Pro (2/4; $p=0.02$) compared to Arg/Arg carriers. No correlation of *TP53* mutation status or codon 72 polymorphism with clinical outcome was observed. **Conclusions:** Non-missense *TP53* mutations leading to functional loss or deletion of protein p53 were significantly associated with homo- or heterozygous Pro72 carriers, despite the high rate of homozygous Arg72 carriers in our Caucasian TNBC pts cohort. Further studies elucidating a potential association of Pro72 with TNBC carcinogenesis and treatment response are warranted.

**1131 General Poster Session (Board #224), Mon, 8:00 AM-11:45 AM**

**Evaluation of lymphocyte infiltrate composition in triple-negative mammary carcinomas and its association with clinical-pathologic and demographic data.** *Presenting Author: Geraldine Eltz Lima, Hospital A.C. Camargo, São Paulo, Brazil*

**Background:** Triple-negative breast cancer corresponds to 15-20% of cases. Despite the advances in development of therapies for breast cancer treatment, this subtype still have a dismal prognosis. Chronic inflammation is involved in cancer development. However, the regulatory mechanisms underlying the recruitment and functioning of inflammatory cells in tumors are not completely clarified. The role of tumor lymphocytic inflammatory infiltrate in predicting survival of breast cancer patients is controversial. Our objective was to evaluate the lymphocyte inflammatory infiltrate and its association with clinical, pathological and demographic characteristics in triple-negative mammary carcinomas patients **Methods:** We studied a retrospective cohort of51 stage I to III, operated triple-negative breast cancer patients. Clinical data was recovered from electronic medical charts. Pathological samples were arranged in duplicate in a TMA, with tissue blocks from core biopsies or surgical specimens. Slides were stained with antibodies against CD4 and CD8, FOXP3. The number of positive staining cells for each antibody in each core was counted. The mean value of duplicates was used in all calculations. Fisher's exact and Mann-Whitney tests were used to verify the association between clinical-pathological and demographic data and the number lymphocytes. Overall (OS) and disease free survival (DFS) curves were calculated using Kaplan-Meier method and comparisons between curves was done by log-rank test. **Results:** Median age was 43 years-old. Mean OS was 101 months (87-115) and mean DFS was 87,35 months (71,84-102). There was no association between CD4+ cell counts and any other variable. CD8+ cell counts were associated with tumor size, and larger tumors presented with more intense CD8+ infiltrate. Higher FOXP3+ cell counts were associated with high histological and nuclear grade. There was no statistically significant association between any lymphocyte subset and OS or DFS. **Conclusions:** CD8+ and FOXP3+ lymphocyte infiltration are associated with pathological tumor characteristics and may play a role in tumor development, progression and prognosis.

**1132 General Poster Session (Board #225), Mon, 8:00 AM-11:45 AM**

***BRCA*-mutation status combined with BCL2 protein in prediction of relapse in triple-negative breast cancer (TNBC) treated with adjuvant anthracycline-based chemotherapy.** *Presenting Author: Katerina Bouchalova, Laboratory of Experimental Medicine, Institute of Molecular and Translational Medicine, Palacky University, Olomouc, Czech Republic*

**Background:** The role of BRCA mutation status as a predictor in TNBC is unclear. Data show an association of high BCL2 expression and resistance to anthracyclines. BCL2, size and nodal status are independent predictors for both relaps and death in TNBC treated with adjuvant anthracyclines (Bouchalova et al. ASCO 2012). The objective of this study was to determine whether combination of BCL2 and BRCA1 status predicts outcome in TNBC patients treated with adjuvant anthracycline-based therapy. **Methods:** The study included 187 patients with TNBC, 178 of whom were treated with adjuvant chemotherapy (164 had anthracyclines). BCL2 analysis was performed using IHC. BRCA1 was obtained from patients records: mutation (mut), wildtype (wt) and unknown status were present in 21.39, 19.25, and 59.36 %, respectively. The data were analysed with software Statistica and R. **Results:** Among six BCL2/BRCA1 TNBC subtypes, BCL2high/BRCA1wt predicts the worst, while BCL2low/BRCA1mut the best RFS (logrank $p<0.05$). BCL2high protein expression predicts poor relapse free survival (RFS) in BRCA1wt TNBC patients treated with adjuvant anthracycline-based regimens (logrank $p=0.007$, hazard ratio, HR 13.24, 95%CI 1.19-147.93). Interestingly, there was no significant difference in RFS between BCL2low/BRCA1mut and BCL2high/BRCA1mut, but between BCL2low/BRCA1mut and BCL2high/BRCA1wt (logrank $p=0.009$) TNBC patients treated with adjuvant anthracycline-based therapy. BCL2high/BRCA1wt predicts trend to the worst overall survival (OS) analyzed together with other subtypes treated with adjuvant anthracycline-based regimens (logrank $p=0.065$). **Conclusions:** Dividing TNBC into subtypes according BCL2 protein expression and BRCA1 mutation status predicts good, vs. poor outcome in patients treated with adjuvant anthracycline-based chemotherapy. BCL2 expression together with BRCA1 status could facilitate decision making on adjuvant therapy. Underlying mechanisms could be revealed by further research. In patients with BCL2high/BRCA1wt other types of adjuvant therapy should be considered.

**1133 General Poster Session (Board #226), Mon, 8:00 AM-11:45 AM**

**A randomized, parallel-arm, phase II trial to assess the efficacy of preoperative ixabepilone with or without cetuximab in patients with triple-negative breast cancer (TNBC).** *Presenting Author: Angel Augusto Rodriguez, Houston Methodist Research Institue, Houston, TX*

**Background:** Epithelial growth factor receptor pathway (EGFR) is expressed in TNBC and may be important in a subset of this heterogeneous disease. We evaluated the efficacy and toxicity of an anti-EGFR antibody (cetuximab) combined with ixabepilone given to the TNBC patients (pts) in the neoadjuvant setting. This study was designed to detect an increase in pathological complete response (pCR) rate, defined as no residual disease in the breast, from 20% to 40% in each arm, using a Simon optimal two stage design, with one-sided alpha=10% and power=80%. At least three responses out of 12 patients were needed to proceed with second stage for each arm. **Methods:** All pts received 4 cycles of preoperative ixabepilone 40 $mg/m^2$ every 3 weeks. In addition, patients were randomized to receive either 12 infusions of weekly cetuximab (400$mg/m^2$ on week 1, then 250 $mg/m^2$) or not. Race, proliferation rate, and TILs was correlated with pCR. **Results:** To date, a total of36 pts with stage II-IIIA TNBC were enrolled. Median age was 54 years (range 35-79 years) with median tumor size of 6.1 cm (range 2-18 cm). The median proliferation rate (Ki-67) was 67.2% (range 8%-95%). Pts were Hispanic (36%), White (39%), African-American (19%) and others (6%). In ixabepilone alone arm, pCR was observed in only 14.3%, and this monotherapy arm did not progress to second stage. To date, pCR was observed in 31.3% in ixabepilone/cetuximab arm, with 6 patients still on treatment. Adverse events for the combination arm were modest, mainly grade 1-2 (neutropenia: 4%, skin: 83 %, GI: 50 %, fatigue: 100 %). Grade 3 febrile neutropenia in 3 % were observed. No statistically significant correlation with race, Ki67, and TILs with pCR rate was observed. **Conclusions:** The addition of cetuximab to ixabepilone may improve the rate of pathological complete response in TNBC pts. There was no association between race or proliferation and response to ixabepilone and cetuximab. Evaluation of EGFR, p-EGFR and EGFR pathway -associated genes, PTEN, mutational analysis of PI3K/mTOR pathway and next generation genomic analysis is underway to evaluate for potential predictive biomarkers of response to EGFR inhibition. Clinical trial information: NCT01097642.

**TPS1134 General Poster Session (Board #227A), Mon, 8:00 AM-11:45 AM**

**FINESSE: An open, three-cohort, phase II trial testing oral administration of lucitanib in patients with FGFR1-amplified or nonamplified estrogen receptor-positive metastatic breast cancer.** *Presenting Author: Fabrice Andre, Department of Medical Oncology, Gustave Roussy, Villejuif, France*

**Background:** FGF aberrancy is observed in approximately 25% of breast cancer (BC) patients. Preclinical studies demonstrated that targeting FGFR could lead to antitumor effects. Lucitanib is a multikinase inhibitor targeting FGFR1-2, VEGFR1-3 and PDGFRA/B. In the phase I trial testing lucitanib continuous dosing, 6 objective responses were observed in 12 evaluable patients presenting with FGFR1 and/or FGF3-4-19 (11q) amplification. Based on this, a phase II trial has been initiated. **Methods:** This is a phase II trial testing the efficacy of lucitanib 15 mg daily in patients with ER+/HER2- metastatic BC who have received at least first line endocrine therapy in the metastatic setting. After informed consent, a biopsy of metastatic site is required to assess the presence of FGFR1- and/or 11q-amplification, which will be centrally evaluated using FISH. Testing could be also performed on archived metastatic biopsies. The primary objective is to evaluate the ORR of single agent lucitanib in metastatic BC patients with FGFR1-amplified, FGFR1-non-amplified with neither FGFR1- amplification nor 11q- amplification. Secondary objectives include clinical benefit rate, PFS, safety, pharmacokinetics and exploratory biomarker analyses. A Simon two-stage design will be used for each of the cohorts to test the null hypothesis that the ORR is 5% or less vs 20% using a one-sided test with 5% level of significance and 90% power. In each cohort separately, an initial 21 patients with measurable disease at baseline will be assessed at the end of stage 1. If at least 2 patients respond per the pre-specified criteria, this cohort will accrue additional 20 patients. The null hypothesis will be rejected if there are at least 5 responders among all 41 patients. The trial started in December 2013. It is planned to open in 9 countries and 30 centers. As of January 24, 5 patients have been screened, 1 of them in the FGFR1-amplified arm. **Conclusion:** FINESSE is a phase II trial testing lucitanib, a multikinase inhibitor, in three selected populations in order to define the efficacy of the drug and the predictive value of FGFR1 or 11q amplifications. Clinical trial information: 2013-000288-10.

**TPS1135 General Poster Session (Board #227B), Mon, 8:00 AM-11:45 AM**

**Tailored neoadjuvant epirubicin and cyclophosphamide and nanoparticle albumin bound (*nab*)-paclitaxel for newly diagnosed breast cancer.** *Presenting Author: Mustafa Khasraw, Andrew Love Cancer Centre, Geelong, Australia*

**Background:** Neoadjuvant chemotherapy for breast cancer allows response to be assessed depending on subtype, and to judge impact of response to therapy on progression-free survival (PFS). **Methods:** This study enrols women with breast tumours > 2cm and high likelihood of response, to receive Epirubicin 90mg/m2 and Cyclophosphamide 600mg/m2 Q3 weeks x 4 followed by nab-Paclitaxel (125mg/m2 IV days 1, 8, 15 Q4 weeks) for 12 weeks. Trastuzumab Q3 weeks, will be added to nab-paclitaxel in HER2 positive patients. Forty women; 15 HER2 positive, 15 triple negative and 10 patients with Oncotype DX assay Recurrence Score (RS) >25 will be evaluated for response. We will screen 50 hormone positive women to identify 10 with Oncotype DX assay RS ≥25 and the patients with RS <25 will be included as an exploratory cohort to receive neoadjuvant hormonal treatment. The primary endpoint is rate of pathologic Complete Response (pCR) in the breast. In previous studies, Response Rate (RR) ranged from 12 to 30%. Accordingly, we set RR rate for the null hypothesis (uninteresting) at 30% and for the alternative (worthy of further study) at 50% (CI 95%). Forty patients will be evaluated to discern between RR of 30% and 50% (6% type I error and 87% power). If at the end of the study, 17 or more patients achieve pCR, the regimen will be deemed worthy of further study. Secondary end points include rate of breast conservation, safety and tolerability, PFS and a number of translational endpoints using pre- and post-chemotherapy MRIs and tissue. Translational endpoints include determination of NQO1*2 genotype (P187S) status that may predict anthracycline resistance, isolating cancer stem cells, passing fresh tumour to xenograft, implanting tumours, using aptamers to target implanted tumours and targeting breast cancer stem cells with novel agents including cyclin D and histone deacetylatase inhibitors. Current status: Recruitment began April 2013. A total of 20 patients have been enrolled on to the study as of Feb 2014. Clinical trial information: NCT01830244.

**TPS1136 General Poster Session (Board #228A), Mon, 8:00 AM-11:45 AM**

**A randomized phase II trial of upfront docetaxel and vinorelbine followed by either maintenance oral vinorelbine or observation in patients with HER2-negative locally advanced (LA) or metastatic (M) breast cancer (BC).** *Presenting Author: Fadi Sami Farhat, Lebanese University, Beirut, Lebanon*

**Background:** Vinorelbine (V) and docetaxel (D) are among the most active agents in the treatment of MBC and their combination has a proven efficacy in this setting. V and D both target the tubulin-microtubule system, pre-clinical studies suggest a potential synergy between the 2 drugs. Maintenance therapy has lately demonstrated significant outcome improvement nevertheless the high cost of treatment in developing countries remains an issue. The oral form of vinorelbine (oV) is a convenient and cost-effective treatment, its role as maintenance treatment has not yet been investigated in LA-MBC. The purpose of this study is to assess the efficacy and safety of V+D combination and whether oV used as maintenance therapy can delay cancer progression in patients with LA-MBC. **Methods:** This is a prospective, multicenter, randomized, phase II trial of Docetaxel (60mg/m$^2$ D1) in combination with Vinorelbine (D1, 20mg/m$^2$ I.V and D8, 60mg/m$^2$ Oral), given every 3 weeks for a total of 6 cycles. Patients with objective response or stable disease after 6 cycles are randomized to the arm of maintenance therapy (Oral V 60mg/m$^2$ D1 and D8 at first cycle increased at 2$^{nd}$ cycle to 80mg/m$^2$D1 and D8) or to the observation arm. In the maintenance therapy arm cycles are repeated every 3 weeks until disease progression, unacceptable toxicity or patient refusal. Inclusion criteria were: Pre/post-menopausal women (≥ 18 years) with Her2 negative, LABC or MBC, PS ≤2, disease free survival ≥ 6 months, no symptom or sign of brain metastasis. The primary endpoint (EP) is time to progression (TTP). Secondary EPs include overall response rate (RECIST v1.1), clinical benefit rate, duration of response, 3 years overall survival, safety (CTCAE 4.03) and patient reported outcomes (FACT-B v.4). As of January 2014, 50 patients have been enrolled in the study and 32 randomized. Estimated enrolment is 126 pts. Recruitment is ongoing and planned for 36 months. This study will be the first one to evaluate the role of oral vinorelbine as maintenance treatment in first-line LA-MBC and will provide additional data on the efficacy and safety of D+V combination.

**TPS1137 General Poster Session (Board #228B), Mon, 8:00 AM-11:45 AM**

**MINT: Multi-institutional, neoadjuvant therapy MammaPrint project.** *Presenting Author: Charles E. Cox, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Women with locally advanced breast cancer (LABC) are often treated with neo-adjuvant chemotherapy to reduce the size of the tumor prior to surgery, to enable breast conserving surgery and to observe the clinical effect of therapy in real time. Studies have shown that the 25–27% of individuals who have a pathologic complete response (pCR) to neoadjuvant therapy have a survival advantage of 80% in 5 years, which is double the expected survival of the remaining patients without pCR. If patients who are likely to show a pCR could be identified prior to initiation of therapy, it would enable more informed treatment decisions [von Minckwitz et al. JCO 2006]. Genomic assays, which are widely used to provide prognostic and predictive information in early breast cancer, have the potential to provide information on the likelihood of a patient with LABC responding to neo-adjuvant therapy [Glück et al. BRCRT 2013]. **Methods:** MINT is a prospective study designed to test the ability of molecular profiling, as well as traditional pathologic and clinical prognostic factors, to predict response to neo-adjuvant chemotherapy in patients with LABC. MammaPrint risk profile, BluePrint molecular subtyping profile, TargetPrint ER, PR and HER2 single gene readout, and TheraPrint Research Gene Panel will be analyzed on a fresh or formalin fixed paraffin embedded tumor specimen using the whole genome array. Patients will receive neo-adjuvant chemotherapy pre-specified in the protocol. Response will be measured by pCR and by centrally assessed RCB. The study will include women with histologically-proven invasive breast cancer T2 (≥3.5cm)-T4, N0M0 or T2-T4N1M0, adequate bone marrow reserves and normal renal and hepatic function who signed informed consent. Standard statistical tests such as the Pearson Chi-square test will be used to characterize and evaluate the relationship between chemoresponsiveness and gene expression patterns. A total of 226 eligible patients will be enrolled from 10 US institutions. 85 patients have been enrolled. Clinical trial information: NCT01501487.

**TPS1138 General Poster Session (Board #229A), Mon, 8:00 AM-11:45 AM**

**A phase II study of eribulin in patients with HER2-negative, metastatic breast cancer: Evaluation of efficacy, toxicity, and patient-reported outcomes.** *Presenting Author: Otto Metzger-Filho, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Patient-reported outcomes (PROs) independently and directly describe patient (pt) treatment experiences, are complementary to clinician reports, and are increasingly included in drug development programs. Eribulin (E) has proven activity in metastatic breast cancer (MBC) previously treated with at least two regimens in the advanced setting. However, the clinical activity of E and the pt experience of receiving E in first- and second-line MBC settings, particularly the rates of neuropathy, are not well described, although these data are needed for further drug development. The present study aims to evaluate the activity, safety, and describe PROs of E in an earlier line setting. **Methods:** This is a non-randomized single arm phase II study of E monotherapy for HER2- MBC. Eligible pts have had 0-1 prior lines of chemotherapy for HER2- MBC, and are enrolled into one of two parallel 45 pt cohorts: one HR+ and one triple negative breast cancer (TNBC). E is dosed 1.4 mg/m$^2$ weekly in a 2 wk on/1 wk off schedule; 1 cycle = 3 wks. The primary objective is evaluation of activity by response rate (ORR); additional objectives include progression-free survival and safety. Correlative PRO endpoints include description and comparison of toxicity evaluation by PROs vs provider-report to determine degree of concordance or divergence for each class of toxicity, and description of QOL over time. The experience of neuropathy will be specifically evaluated by the FACT-Neurotoxicity subscale, as well as blood sample collection for exploration of host polymorphisms and the development of neuropathy. PRO instruments (PRO-CTCAE, FACT-B and FACT-Ntx) are administered at cycles 1-3, then every other cycle until end-of-treatment visit; pts complete the surveys on electronic tablets with direct data entry into the database. A sample size of 90 pts is planned, providing 90% power to detect a 22% improvement in ORR for TNBC (22% vs. 44%), and a 23% improvement in ORR for ER+ (30% vs. 53%). Both calculations assume a two-sided, 0.1 type-1 error and an exact binomial test. Clinical trial information: NCT01827787.

**TPS1139 General Poster Session (Board #229B), Mon, 8:00 AM-11:45 AM**

**Use of microRNA to identify stage IV breast cancer patients to be targeted with phospholipase A2 disrupted cisplatin carrying liposomes: An ongoing phase I trial.** *Presenting Author: Ulrik Lassen, Department of Oncology, Rigshospitalet, Copenhagen, Denmark*

**Background:** Cisplatin has shown activity in BRCA associated breast cancer patients but generally the use of cisplatin in breast cancer has been hampered by high toxicity and low response rates of approximately 10% (Baselga et al. JCO, 2013**;** 31:2586-2592.). We address both issues in an ongoing phase 1 study with a third generation liposomal cisplatin which is activated by secretory phospholipase A2 (sPLA2) present on the tumor cells, and in parallel by selecting patients with a companion diagnostic for an optimal cisplatin sensitivity microRNA profile and expression of sPLA2. **Methods:** A validated response prediction method is used in the cisplatin sensitivity prediction. The method uses cell line drug sensitivity data and cell line microarray data and clinical tumor big data analysis (Wang et al. J Natl Cancer Inst; 2013;105:1284–1291.). When the profile was probed on a published cohort of BC there were patients in all breast cancer subgroups that were predicted high likely sensitive. From the literature it is known that 80% of breast cancers are positive for sPLA2 (Yamashita et al. Br J Cancer; 1994;69: 1166-1170.). Methods: sPLA2 is determined by immunohistochemistry, microRNA obtained from formalin fixed paraffin embedded biopsies are assessed by use of Affymetrix chips. After an initial phase 1 dosing d1 q 3 wk reaching 120 mg the dose intensity was increased to d1 and d8 treatment q 3wk, and the 8$^{th}$ dose level has been reached on unselected patients with 120 mg cisplatin administered d1 and d8 and we now plan to extend the phase 1 study and include only biomarker positive patients. Currently 150 formalin fixed paraffin embedded (FFPE) patient biopsies have been screened and only the patients with an optimal profile are treatment candidates. In collaboration with the Danish Breast Cancer Cooperative Group (DBCG) the aim is to screen 600 BC patients with metastatic disease but currently not progressing. At progression only patients with in the highest 10% response likelihood will be candidates for expansion part of the phase 1 trial. Clinical trial information: NCT01861496.

**TPS1140 General Poster Session (Board #230A), Mon, 8:00 AM-11:45 AM**

**Phase I dose-escalating study to evaluate the safety, tolerability, and pharmacokinetic and pharmacodynamic profiles of Foxy-5 in patients with metastatic breast, colorectal, or prostate cancer.** *Presenting Author: Peter Grundtvig Soerensen, Herlev Hospital, Herlev, Denmark*

**Background:** The primary tumor is rarely the cause of death of cancer patients. Instead cancer-associated mortality is generally the result of tumor metastasis. However, most current therapeutic approaches fail to specifically target the dissemination process. A low-level or lack of Wnt-5a protein expression in primary invasive breast carcinomas has been shown to correlate with shortened recurrence-free survival. A similar role for Wnt-5a as a tumor suppressor has been described in thyroid, hematopoietic, prostate and colon cancer tissues. Based on these findings we developed a formulated hexapeptide (Foxy-5) that mimicked the ability of the Wnt-5a molecule to impair cancer cell migration in vitro. Foxy-5 also reduced the metastatic burden in the lungs by 70-90% in vivo in a mouse model (Safholm et al., Clin Cancer Res, 2008). **Methods:** The primary objective of the phase 1 study is to evaluate the safety and tolerability of treatment with Foxy-5. The secondary objectives are to determine the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of Foxy-5 in patients with metastatic breast, colorectal or prostate cancer, to characterize the single and multiple dose pharmacokinetic (PK) profile of Foxy-5, and to characterize the pharmacodynamic (PD) profile of Foxy-5 by assessing evidence of anti-tumor activity of Foxy-5, e.g. by analysing the amount of circulating tumor cells before and after treatment with Foxy-5. All eligible patients are screened for Wnt5a immunoreactivity in their cancer cells and only Wnt5a negative or low patients are enrolled in the study. Clinical trial information: NCT02020291.

**TPS1141 General Poster Session (Board #230B), Mon, 8:00 AM-11:45 AM**

**NSABP B-51/RTOG 1304: Randomized phase III clinical trial evaluating the role of postmastectomy chest wall and regional nodal XRT (CWRNRT) and post-lumpectomy RNRT in patients (pts) with documented positive axillary (Ax) nodes before neoadjuvant chemotherapy (NC) who convert to pathologically negative Ax nodes after NC.** *Presenting Author: Eleftherios P. Mamounas, National Surgical Adjuvant Breast and Bowel Project (NSABP), and the UF Health Cancer Center at Orlando Health, Orlando, FL*

**Background:** This phase III randomized post-NC trial will evaluate if CWRNRT after mastectomy (Mx) or whole breast irradiation (WBI) with RNRT after breast-conserving surgery (BCS) significantly reduces the rate of IBCR-FI in pts who present with histologically positive Ax nodes but become histologically negative Ax nodes →NC. Secondary aims are OS, LRR-FI, DRFI, DFS-DCIS, and second primary cancer. Correlative science will examine the effect of RT by tumor subtype, molecular predictors of outcome for pts with residual disease, and the development of predictors of degree of reduction in loco-regional recurrence. **Methods:** Eligible pts with clinical T1-3, N1 breast cancer with pathologic Ax nodes (positive FNA or core needle biopsy) must complete ≥12 wks of NC (anthracycline and/or taxane-based regimen). HER2-positive pts must receive neoadjuvant trastuzumab or other anti-HER2 therapy (tx). After NC either BCS or Mx will be performed. Ax nodes must be histologically cancer free on sentinel node biopsy with or without axillary dissection (AND) or AND alone. ER/PR and HER-2 neu status before NC is required. All pts will receive additional required systemic tx. Site radiation credentialing with a facility questionnaire and case benchmarking is required. Randomization for Mx pts will be to no CWRNRT or CWRNRT and for BCS pts to WBI or WBIRNRT. 1,636 pts will be enrolled over 5 yrs with definitive analysis at 7.5 yrs. The study is powered at 80% to test the main hypothesis that RT reduces the annual hazard rate of events for IBCR-FI by 35% for an absolute risk reduction in the 5-year cumulative rate of 4.6%. Analysis will be on intent-to-treat with 3 formal interim analyses at 43, 86, and 129 events, with a 4th/final analysis at 172 events. Current accrual is 10. 736 enrolled pts will be evaluated with targeted pt-reported outcome instruments focusing on the effect of RT. Pt assessments will be prior to randomization and then at 3, 6, 12, and 24 mos. Clinical trial information: NCT01872975.

**TPS1142 General Poster Session (Board #231A), Mon, 8:00 AM-11:45 AM**

**Preoperative PARPi and irradiation (POPI) for women with an incomplete response to neoadjuvant chemotherapy (NAC) for breast cancer: A phase I trial.** *Presenting Author: Richard C. Zellars, The Johns Hopkins University School of Medicine, Baltimore, MD*

**Background:** Fifty to seventy percent of breast cancer patients treated with NAC will have an incomplete response and ultimately worse outcomes than those with a pathologically complete response (pCR). Researchers hoping to increase the rate of pCR, added pre-operative radiation to NAC but had little success. One way to further increase the response to neoadjuvant radiation may be the concurrent use of an inhibitor of Poly(ADP-ribose)-polymerase (PARPi). Pre-clinical studies have shown that PARPi sensitizes cancer cells to radiation by inhibiting repair of radiation-induced ssDNA breaks. We hypothesize that POPI will increase the pCR rate in women who have residual disease after NAC. Before we can test this hypothesis, we must determine the max tolerable dose (MTD) of this combined therapy. Thus, we designed and opened a phase I trial of POPI in women with an incomplete response to NAC. **Methods:** Women with pathologically node positive disease before NAC and $>$ 1.0 cm of residual disease after NAC are eligible. After obtaining consent the residual disease is biopsied. Patients with viable disease are enrolled in a standard 3+3 dose finding study of concurrent veliparib and pre-operative radiation. The starting dose of veliparib is 50 mg P.O. BID x 28 days and will increase by 50mg BID to a max of 200 mg BID. Radiation (235 cGy x 16) to the breast and regional nodes overlaps with the first 3 weeks of veliparib. Definitive surgery (lumpectomy/mastectomy) occurs 6 weeks after completion of radiation. The MTD is defined as the dose below the level at which $>$1dose limiting toxicity (DLT) is observed in 3-6 patients. An expansion cohort of 20 patients will be treated at the MTD for further evaluation. Status: This trial opened in 8/2013. Two patients have completed protocol therapy to date. Clinical trial information: NCT01618357.

**TPS1143 General Poster Session (Board #231B), Mon, 8:00 AM-11:45 AM**

**SGN-LIV1A, an antibody-drug conjugate (ADC), in patients with LIV-1–positive breast cancer.** *Presenting Author: Ana Kostic, Seattle Genetics, Inc., Bothell, WA*

**Background:** First identified as an estrogen-inducible gene in a breast cancer cell line, LIV-1 is a multispan transmembrane protein of the solute-carrier family 39 with putative zinc transporter and metalloproteinase activity. As a downstream target of STAT3, it promotes the epithelial-to-mesenchymal transition that is important in the malignant progression to metastasis. LIV-1 is expressed in a number of cancers with the highest prevalence and level of expression in breast, prostate, and melanoma. Additionally, LIV-1 has been linked with malignant progression to metastasis and associated with lymph node involvement in breast cancer. Normal tissue expression is predominantly limited to hormonally regulated tissues, including breast and prostate. SGN-LIV1A is an ADC composed of a humanized anti-LIV-1 monoclonal antibody conjugated to the microtubule-disrupting agent MMAE via a protease-cleavable linker. In vitro, SGN-LIV1A shows target-specific internalization and cytotoxic activity against LIV-1-positive neoplastic cell lines. Significant dose-dependent tumor regression was demonstrated in mouse xenograft models. **Methods:** The primary objective of this phase 1, open label, multicenter study is to evaluate the safety and tolerability, and to identify the maximum tolerated dose of SGN-LIV1A using a 3+3 dose-escalation study design. Pharmacokinetics, immunogenicity, and antitumor activity will also be evaluated. Eligible patients are adult females who have hormone receptor-positive /HER2-negative or triple-negative metastatic breast cancer. Tumor tissue obtained at baseline must be positive for expression of LIV-1 per central assessment. Patients must have received at least 2 prior cytotoxic regimens in the metastatic setting and have measurable disease per RECIST v1.1. Pre-existing neuropathy $\geq$ Grade 2 is not permitted. SGN-LIV1A will be administered IV every 3 weeks at protocol-defined doses starting at 0.5 mg/kg. Patients who achieve an objective response or stable disease will be eligible to continue treatment until disease progression. Enrollment for this US-based trial began in late 2013. Clinical trial information: NCT01969643.

**TPS1144 General Poster Session (Board #232A), Mon, 8:00 AM-11:45 AM**

**A phase 2 single-arm study of the clinical activity and safety of enzalutamide in patients with advanced androgen receptor-positive triple-negative breast cancer.** *Presenting Author: Tiffany A. Traina, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Androgen receptor (AR) expression is observed in 10-30% of patients (pts) with triple-negative breast cancer (TNBC). Experiments using AR+ TNBC cell lines have demonstrated enhanced growth in response to androgen stimulation that is inhibited by enzalutamide (ENZA), a potent oral inhibitor of AR signaling **(**Richer JK. Abstract presented at the AACR Advances in Breast Cancer Research Meeting, San Diego, CA, 2013 October 3-6 and D'Amato NC. Abstract presented at the SABCS, San Antonio, TX, December 4-8, 2012). AR+ TNBC may represent a subtype driven by AR signaling and which may respond to ENZA. **Methods:** Women with advanced AR+ TNBC (ER and PgR $<$1% by IHC and Her2 normal) will receive daily ENZA (160 mg) until disease progression (NCT01889238). The primary endpoint (EP) is clinical benefit rate (CBR) where benefit is defined as complete or partial response (CR or PR) or stable disease (SD) $\geq$16 weeks (wks) as assessed by the Investigator and according to RECIST 1.1. Additional EPs include CBR at 24 wks, safety and tolerability, and the relationship between AR signaling and ENZA activity. If the CBR exceeds 2 in 26 pts, the sample size will increase to 62 pts. Any amount of AR expression (local or central) is allowed, submission of tissue is mandatory. Pts may have bone-only non-measurable disease. Brain imaging is required to exclude patients with CNS metastases. Pts with a seizure history are excluded. The primary EP will analyze pts with centrally defined AR+ TNBC ($\geq$10% nuclear staining by IHC) who have $\geq$1 post-baseline tumor assessment. An ITT analysis will also be reported. The null hypothesis ($H_0$), that the true CBR is 8%, will be tested against a 1-sided alternative. If CBR exceeds 9 in 62 pts in Stage 2, $H_0$will be rejected. This design yields a 1-sided type 1 error rate of 5% and 85% power when the true response rate is 20%. Enrollment is expected to continue through 2014. Clinical trial information: NCT01889238.

**TPS1145 General Poster Session (Board #232B), Mon, 8:00 AM-11:45 AM**

**TBCRC030: A randomized, phase II study of preoperative cisplatin versus paclitaxel in patients (pts) with *BRCA1/2*-proficient triple-negative breast cancer (TNBC)—Evaluating the homologous recombination deficiency (HRD) biomarker.** *Presenting Author: Erica L. Mayer, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Both platinum and taxane chemotherapy have activity in TNBC, however biomarkers predictive for activity of either agent are lacking. The HRD assay detects impaired double strand DNA break repair, and may identify BRCA1/2-proficient tumors with a 'BRCA-like' phenotype suitable for treatment with DNA repair targeted therapies. A significant correlation between HRD score and response to platinum was reported in a preoperative study of gemcitabine, carboplatin and iniparib for TNBC. The current trial will prospectively determine the association between HRD score and response to platinum or taxane preoperative chemotherapy in TNBC, as well as explore other potential novel biomarkers of response. **Methods:** This is a phase II multicenter study randomizing pts with BRCA1/2-proficient, stage I (T1 $>$ 1.5 cm)-III TNBC to preoperative cisplatin 75 mg/m$^2$ q3 wks x 4 or paclitaxel 80 mg/m$^2$ weekly x 12 wks, followed by surgery. Mandatory tissue collection will occur at baseline and surgery. Pts with significant residual disease after 12 weeks will have a tumor biopsy, be classified as a non-responder (RCB$>$1), and can cross-over to alternative treatment. The primary objective is to determine the association of HRD score with pathologic response, defined as RCB 0-1, to neoadjuvant platinum or taxane in TNBC. Secondary objectives include overall clinical and pathologic responses and the positive predictive value of HRD for platinum therapy. Correlative analyses include evaluation of markers: NtAI, LST, HRD combined score, Hereditary Cancer Profile, PMS2 and CHEK2 HCP, RAD17/RAD50 expression values, PAM50, Vanderbilt TNBC subgroups, tumor infiltrating lymphocyte predictor, and signatures of taxane response; whole exome and RNA sequencing will be used to identify novel markers of response. Target accrual is 160 pts randomized 1:1. Assuming response rates of 40% to cisplatin and 30% to taxane and a drop-out rate of 12%, there will be 91% and 87% power, respectively, to detect a difference of 0.75 standard deviations in HRD score by RCB score. Clinical trial information: NCT01982448.

**TPS1146 General Poster Session (Board #233A), Mon, 8:00 AM-11:45 AM**

**tnAcity: A phase II/III trial of weekly *nab*-paclitaxel (*nab*-P) plus gemcitabine (gem) or carboplatin (carbo) versus gem/carbo as first-line treatment for metastatic triple-negative breast cancer (mTNBC).** *Presenting Author: Denise A. Yardley, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** TNBC, which is characterized by a lack of estrogen receptor (ER), progesterone receptor (PgR), and human epidermal growth factor receptor 2 (HER2) overexpression, is associated with a poor prognosis. In combination with gem or carbo/bevacizumab, *nab*-P has demonstrated high response rates as first-line treatment for mTNBC. tnAcity (triple-negative Albumin-bound paclitaxel combination international treatment study) is a phase 2/3 trial evaluating the efficacy and safety profiles of 2 *nab*-P combination regimens (with gem or carbo) as first-line treatment for mTNBC, using gem/carbo as a control. **Methods:** The phase 2 portion of the study will evaluate 240 patients (pts), randomized 1:1:1 (stratified by disease-free interval [DFI]: $\leq$ 1 y vs $>$ 1 y) to *nab*-P 125 mg/m$^2$ plus gem 1000 mg/m$^2$, *nab*-P 125 mg/m$^2$ plus carbo area under the curve (AUC) 2, or the control regimen of gem 1000 mg/m$^2$ plus carbo AUC 2, all given days 1 and 8 of a 21-day cycle. Eligibility criteria include measurable mTNBC (defined as ER and PgR in $<$ 1% of tumor cell nuclei and HER2 IHC 0 or 1+ or 2+ and FISH-negative); no prior chemotherapy for metastatic disease; prior adjuvant/neoadjuvant anthracycline use required if indicated; adjuvant/neoadjuvant treatment with a taxane, platinum, or gem is permitted if completed $\geq$ 12 months prior to randomization; ECOG performance status $\leq$ 1; peripheral neuropathy grade $<$ 2; and absence of brain metastases. The primary objective of the phase 2 portion is to identify the *nab*-P combination arm to be evaluated in the phase 3 study by a ranking algorithm of 5 efficacy and safety parameters. In the phase 3 portion, 550 pts will be randomized 1:1 (stratified by DFI [$\leq$ 1 y vs $>$ 1 y] and prior taxane use) to the *nab*-P combination arm selected from the phase 2 portion or to the control arm. The primary endpoint of the phase 3 portion is PFS by independent radiological assessment; secondary endpoints include ORR, OS, disease control rate, duration of response, and safety. Biomarker and circulating tumor cell analyses will also be performed. As of the submission deadline, 21 patients have been randomized. Clinical trial information: NCT01881230.

**TPS1147 General Poster Session (Board #233B), Mon, 8:00 AM-11:45 AM**

**Concurrent adjuvant systemic therapy and accelerated radiotherapy in triple-negative breast cancer: A feasibility trial.** *Presenting Author: Rene Eleanor Ashworth, New York University Langone Medical Center, New York, NY*

**Background:** Triple-negative breast cancer (TNBC), which comprises ~15% of all diagnosed breast cancers, behaves aggressively and continues to represent a therapeutic challenge. As such, TNBC is associated with a higher rate of early distant recurrence and breast cancer-related death. For early-stage TNBC, conventional systemic chemotherapy has been the mainstay of treatment; however, there is an unmet need for better therapy. Platinum agents have been shown to have activity against TNBC in both neoadjuvant and metastatic settings (Silver et. al., *J Clin Oncol*, 2010). Concurrent chemo-radiation (CCRT) is also being explored; preclinical studies have proven that radiotherapy has unique biological effects that favorably alter the tumor site microenvironment to enhance anti-tumor immunity (Formenti and Demaria, *J Clin Oncol*, 2008). Furthermore, a multi-institutional collaboration of 105 patients demonstrated that 54% of triple-negative tumor carriers achieved pathological response, comparing favorably to their hormone-receptor positive counterparts in both 5-year DFS and OS (Adams et. al., *Breast Cancer Res Treat*, 2010). This phase I/II clinical trial is a single-arm study designed to assess the feasibility of combining Carboplatin with radiotherapy (RT) for the adjuvant treatment of TNBC. **Methods:** Eligibility includes patients with stage I/II TNBC who are eligible for RT after segmental mastectomy. The primary endpoint is acute skin toxicity related to CCRT. Secondary endpoints include additional toxicities-pain and fatigue, quality of life, and late toxicities- fibrosis and telangiectasia. 35 patients are required to achieve a power of 80% in order to detect a significant increase in occurrence of grade II dermatitis or greater; 27 patients have been enrolled to date. Carboplatin, AUC 2.0, is administered weekly for 6 weeks, with 3 weeks of concurrent RT initiated at week 2. RT is delivered prone using 3D-CRT or IMRT. The whole breast is treated to 40.5 Gy in 15 fractions, with a 3 Gy boost to the tumor bed on weeks 2 and 3, for a total dose of 46.5 Gy. Additional adjuvant chemotherapy is given at the discretion of the treating physician. Clinical trial information: NCT01289353.

**TPS1148 General Poster Session (Board #234A), Mon, 8:00 AM-11:45 AM**

**TBCRC028: A phase Ib/II trial of GDC-0941 (a PI3K inhibitor) in combination with cisplatin in metastatic androgen receptor-negative triple-negative breast cancer (TNBC).** *Presenting Author: Vandana Gupta Abramson, Vanderbilt-Ingram Cancer Center, Vanderbilt University, School of Medicine, Nashville, TN*

**Background:** We recently reported six distinct molecular subtypes of TNBC, including two basal-like subtypes with cell cycle and DNA damage response (DDR) gene expression (GE) signatures (BL1 and BL2) and a luminal androgen receptor (LAR) subtype which expresses AR by immunohistochemistry. BL1 and BL2 cell lines respond to DNA damaging agents, including cisplatin. Consistent with the frequent alterations in DDR and PI3K pathways in TNBC, the combination of cisplatin and the pan-PI3K inhibitor GDC0941 was very active against AR-negative TNBC cell lines in preclinical studies. This trial will evaluate the benefit of the addition of GDC-0941 to cisplatin in patients with metastatic AR-TNBC. **Methods:** This is an open-label phase Ib/II multiple institution trial in which patients with metastatic AR-TNBC will be randomized to: a) cisplatin 25 mg/m$^2$ on days 1, 8, and 15 of a 28 day cycle, or b) cisplatin with GDC-0941. Biopsy of a metastatic lesion at baseline, at day 5-10, and at progression is required. Staging scans will be performed at baseline and every 2 cycles thereafter. Upon progression, patients on the cisplatin arm have the option to crossover to the combination arm with GDC-0941. The primary objectives are: to determine the safety and tolerability of cisplatin + GDC-0941 in patients with AR-TNBC (phase Ib) and efficacy, as measured by the overall response rate (phase II). Secondary objectives are to determine the clinical benefit rate and time to disease progression of both study arms. Correlative analyses will evaluate mechanisms of inherent and acquired resistance. Gene expression profiling to assign a TNBC subtype and whole exome analysis will be performed; the predictive effects of PI3K pathway mutations (PIK3CA, AKT, PTEN) will also be examined. Approximately 125 patients will be enrolled (80% power to detect a 20% improvement in the ORR with a type 1 error of 0.05). Clinical trial information: NCT01918306.

**TPS1149 General Poster Session (Board #234B), Mon, 8:00 AM-11:45 AM**

**Phase III study evaluating safety and efficacy of the addition of veliparib plus carboplatin versus the addition of carboplatin to standard neoadjuvant chemotherapy in subjects with early-stage triple-negative breast cancer (TNBC).** *Presenting Author: Gunter Von Minckwitz, German Breast Group/University Frankfurt, Neu-Isenburg, Frankfurt, Germany*

**Background:** Emerging data suggests that TNBC may be sensitive to DNA-damaging chemotherapy agents, including carboplatin (Cb). Veliparib (V; ABT-888), a potent, competitive poly (ADP-ribose) polymerase (PARP)-1 and -2 inhibitor, enhances the activity of several DNA-damaging agents. In I-SPY2, the addition of V and Cb to standard neoadjuvant therapy for early TNBC doubled the pathologic complete response (pCR) rate (52% vs. 26%). This study will evaluate the addition of Cb or V + Cb to neoadjuvant paclitaxel (P) followed by doxorubicin + cyclophosphamide (AC). **Methods:** A phase 3, randomized, placebo-controlled, double-blinded, multinational, multicenter study will enroll 624 patients (pts) with histologically confirmed, invasive, TNBC (T2-T4 N0-2 or T1 N1-2) who are candidates for potentially curative surgery. No prior breast cancer treatment or sentinel lymph node biopsy is permitted. Pts will be stratified by BRCA status, lymph node stage (N0 versus N1-2), and schedule of AC administration (q2 weeks versus q3 weeks), and randomized in a 2:1:1 ratio to: (Arm A) P 80 mg/m$^2$ weekly + Cb AUC 6 mg/mL/min q3weeks x 4 + V 50 mg PO BID for 12 weeks followed by AC (60 mg/m$^2$/600 mg/m$^2$ q2 or 3 weeks x 4); (Arm B) P + Cb + PO placebo followed by AC; (Arm C) P + IV placebo + PO placebo followed by AC. After completing study therapy, pts will undergo surgery with sentinel node sampling or axillary lymph node dissection. Post-op radiotherapy is at MD discretion. The primary objective of the study is to assess the incidence of pCR defined as absence of residual invasive cancer in resected breast tissue and lymph nodes (i.e., ypT0/is N0 per AJCC staging system). Assuming pCR rates in the V + Cb, Cb only and control arms are 60%, 45% and 40%, respectively, the study has $>$ 80% power at 2-sided $\alpha$ level of 0.05 to detect a statistically significant treatment effect in pCR for the V + Cb arm compared to either of the other two arms using chi-square test. Secondary objective is the rate of eligibility for breast conservation after therapy. Other endpoints are residual cancer burden, EFS and OS. The study opened in Jan 2014. Clinical trial information: NCT02032277.

**1501** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Predictors of colorectal cancer screening adherence among African Americans.** *Presenting Author: Praveen Ramakrishnan Geethakumari, Albert Einstein Heathcare Network, Philadelphia, PA*

**Background:** Low colorectal cancer (CRC) screening rates among African Americans (AAs) contribute to higher CRC mortality and lower CRC survival among AAs than whites. We conducted a randomized controlled trial to determine if a preference-based mail and telephone navigation intervention could increase CRC screening adherence among AA patients. **Methods:** The trial included AA patients who were 50-75 years old, eligible for screening, and received care through primary care practices in Philadelphia. Eligible patients (n=764) were consented, surveyed by telephone, and randomized to a Standard Intervention (SI) Group (n=380) or Tailored Navigation Intervention (TNI) Group (n=384). The SI Group was sent colonoscopy instructions and a stool blood test kit, followed by a reminder. The TNI Group received mailed screening contacts keyed to preference, and also received telephone navigation and a reminder. An endpoint survey was administered and an endpoint review of medical records was performed to determine screening adherence status at 6 months. Multivariable analyses were performed to assess intervention impact on adherence. **Results:** Background characteristics of study participants were: female (69%), 50-59 years of age (71%), < high school education (59%), and unmarried (69%). At 6 months after randomization, CRC screening adherence was substantially higher in the TNI Group (38%) than the SI Group (24%), a difference that was statistically significant (OR=2.04, 95% CI: 1.47-2.84). Participants who were > 60 years of age also had a significantly higher screening rate than those who were 50 to 59 years of age (OR=1.92, 95% CI: 1.33, 3.77). Screening adherence was marginally higher among participants who were female, married, and had a higher screening decision stage. **Conclusions:** Exposure to the preference-based mail and telephone navigation intervention increased CRC screening adherence compared to the mailed intervention. Further research is needed to determine how the intervention can be modified to maximize impact and to assess its effect on screening disparity between whites and AAs. To our knowledge, this is the first study to test preference-based tailored navigation for CRC screening in a solely AA patient population. Clinical trial information: NCT00893295.

**1502** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Breast cancer screening in younger women.** *Presenting Author: Nina Beri, Duke University Medical Center, Durham, NC*

**Background:** The 2009 US Preventative Services Task Force (USPSTF) guidelines for breast cancer screening have proven controversial. Previously, annual screening was recommended for women over 40, but new guidelines recommend screening only for high risk women under 50. Other guidelines still recommend annual screening for young women on the basis of reduction in breast cancer mortality. In a population of rural insured women we sought to determine which younger women received mammograms, and the factors that motivate them to do so. **Methods:** Surveys were mailed to 1,000 randomly selected women between the ages of 40 and 49, insured by the National Rural Electric Cooperative Association (NRECA). A study specific survey evaluated screening patterns, knowledge of guidelines, and sociodemographic information. **Results:** Overall, 639 women responded (response rate 63.9%). Median age was 45, 92% were white, 75% resided in rural areas, and 34% reported 4 year college education. The majority (67%) had a screening mammogram within the past year. 81% had their mammograms paid for by NRECA and 66% reported no out of pocket costs. 43% had a family history of breast cancer and 69% had friends with the disease. 71% felt that they understood current guidelines, though less than 1% reported that mammograms for women under 50 were not routinely recommended. 15% were aware that expert recommendations vary. 58% believed that annual mammograms are recommended for women <50. Less than 1% reported that the media coverage of expert recommendations made them less likely to obtain screening, while 44% felt it had no effect. Reported barriers to screening included: lack of time (29%), fear of test (5.6%), fear of diagnosis (4.2%), and discomfort (12%). Women with friends or family with breast cancer were more likely to report screening within the past year (70% vs 54%, *p* 0.003). Education and geographic residence did not correlate with screening. **Conclusions:** The majority of younger insured women in rural America are not aware of USPSTF guidelines and continue to undergo screening mammography. However, modifiable barriers persist and there is a need for consensus and education regarding the current evidence for screening so that younger women can make informed choices about early detection of breast cancer.

**1503** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Menopausal hormone therapy and breast cancer by body mass index (BMI) and African ancestry.** *Presenting Author: Rowan T. Chlebowski, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA*

**Background:** In the Women's Health Initiative (WHI) randomized, placebo-controlled clinical trials, estrogen plus progestin (E+P) increased breast cancer incidence while estrogen alone (E alone) decreased incidence. Nonetheless, some observational studies report breast cancer findings combining these approaches and additionally suggest breast cancer safety for "HRT" use in obese and African American women. **Methods:** We examined E+P and E alone influence on breast cancer incidence by BMI and race/ethnicity in the WHI trials (with 16,608 in the E+P trial, 5.6 yrs intervention and 10,739 in the E alone trial, 7.2 yrs intervention ) with 13 yrs of cumulative follow-up. Hazard ratios (HRs) were estimated using Cox proportional hazards models. Additionally, HRs were estimated in a case-only analysis incorporating African admixture, measured for self-identified African Americans using genetic ancestry information from 656,852 markers. **Results:** Both for the previously reported overall results (E+P HR 1.28 95% CI [1.11-1.48], p < 001; E alone HR 0.79 [0.65-0.97], p = 0.02) (JAMA 2013; 310:2) and by BMI and race/ethnicity, E+P and E alone had opposite effects on breast cancer incidence. There was no interaction with BMI for either E+P (p = 0.58) or E alone (p = 0.86). For Black women in the E+P trial, breast cancer results were similar to White women regardless of % African Ancestry. For Black women in the E alone trial, a somewhat greater reduction in breast cancer incidence for E alone use was seen (HR 0.47 [0.26-0.82]) compared to White women (HR 0.84 [0.67-1.05]). In the case-only analysis, HRs for Black women 0.45 [0.24-0.87]), Black women with < 79% African ancestry (0.62 [0.26-1.48]) and Black women with ≥ 79% African ancestry (0.32 [0.12-0.86]) suggest CEE effect modification on breast cancer risk by African ancestry (p-trend = 0.04). **Conclusions:** Observational study analyses of hormone therapy influence on breast cancer should separately consider E+P and E alone. Current randomized trial findings do not support breast cancer safety for E+P use in obese or African American women. The suggestion that greater African ancestry is associated with greater reduction in breast cancer incidence with E alone use warrants further study. Clinical trial information: NCT00000611.

**1504 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Effects of equivalent weight loss, with or without exercise, on sex hormones related to breast cancer risk in postmenopausal women: The SHAPE-2 trial.** *Presenting Author: Anne Maria May, University Medical Center Utrecht, Utrecht, Netherlands*

**Background:** Physical activity is a known protective factor for postmenopausal breast cancer. Exercise intervention studies suggest that physical activity influences breast cancer related sex hormone levels mainly through concordant weight loss. The aim of this study is to investigate whether there is an additional beneficial effect of exercise beyond the effect of weight loss. **Methods:** After a 5-week run-in period, 243 inactive, overweight and postmenopausal women were randomly allocated to either a diet group (n=97), exercise group (n=98) or stable weight control group (n=48). The aim of both intervention groups was to lose 5-6 kilograms weight. The diet group followed an energy restricted diet. The exercise group participated in a 16-week endurance and strength training program (4 hrs/wk) and were prescribed a small caloric intake restriction. Primary outcomes were assessed at baseline and after 16 weeks, and included serum levels of estron, (free) estradiol, androstenedione, (free) testosterone and sex hormone binding globulin (SHBG). **Results:** Both the diet and exercise group achieved the aimed weight loss (-4.9 kg and -5.5 kg, respectively), while the control group remained stable (+0.06 kg). Compared with control, all estrogens decreased significantly in the exercise group, while in the diet group only free estradiol was significantly decreased ($p<0.05$). Also, compared with diet, the exercise group showed more favorable effects on all estrogens ($p\leq0.05$). For androgens, only the exercise group showed beneficial effects on free testosterone compared with control (p=0.01) and diet (p=0.07). Positive effects on SHBG were significant in both intervention groups ($p<0.0001$) and larger in the exercise group compared with diet (p=0.07). **Conclusions:** Exercise induced weight loss resulted in stronger favorable effects on breast cancer related hormones and SHBG, than diet induced weight loss, demonstrating the importance of exercise for postmenopausal breast cancer risk reduction. Clinical trial information: NCT01511276.

**1505 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Effect of weight loss intervention on inflammatory and metabolic markers in breast cancer survivors: The lifestyle, exercise, and nutrition (LEAN) study.** *Presenting Author: Erikka Loftfield, Yale School of Public Health, New Haven, CT*

**Background:** Obesity and physical inactivity are associated with poorer prognosis among breast cancer survivors. Inflammatory and metabolic pathways may explain these associations. We hypothesized that diet- and exercise-induced weight loss would decrease insulin, glucose, IGF-I, C-reactive protein (CRP), TNF-$\alpha$, IL-6 and leptin, but increase adiponectin in breast cancer survivors. **Methods:** Ninety-seven overweight or obese breast cancer survivors were identified from the Yale-New Haven Hospital Tumor Registry and randomized to usual care (n=33) or weight loss counseling by a registered dietitian (n=64) for 6 months. The usual care group was provided with AICR nutrition and physical activity brochures. Weight was measured and fasting blood samples were drawn at baseline and 6-months by trained staff. We conducted analyses using the intention-to-treat procedure with baseline values imputed for missing 6-month values (n=16). We used analysis of covariance, adjusted for baseline biomarker levels, to evaluate mean biomarker changes across groups. In secondary analyses, we evaluated the effect of weight loss on biomarkers among women randomized to intervention. **Results:** On average, women randomized to intervention and usual care groups lost 6% and 2% body weight (p=0.0003), respectively. Women in the intervention group experienced decreases in insulin, glucose, CRP, leptin and TNF-$\alpha$ and increases in adiponectin and IGF-I. CRP decreased by 30% in the intervention group and 1% in the usual care group (-1.05 mg/L vs. -0.06 mg/L, p=0.05). Compared to intervention women who lost <5% body weight, those who lost ≥5% body weight had larger decreases in CRP (-1.58 mg/L vs. -0.54 mg/L, p=0.02), insulin (-3.21 $\mu$U/mL vs. -0.59 $\mu$U/mL, p=0.048), leptin (11.08 ng/mL vs. -0.76 ng/mL, p=0.002) and IL-6 (-0.20 pg/mg vs. +0.59 pg/mg, p=0.02) but an increase in IGF-I (+9.19 ng/L vs. -11.11 ng/L, p=0.01). **Conclusions:** Weight loss resulting from a 6-month, 11-session counseling program had favorable effects on some inflammatory and metabolic biomarkers associated with breast cancer survival. IGF-I may not be a mechanism through which weight loss improves breast cancer survival.

**1506 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Proportion of *BRCA* mutation frequency in young black women with breast cancer.** *Presenting Author: Tuya Pal, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Young Black women are disproportionately afflicted with breast cancer, a proportion of which may be due to *BRCA1* and *BRCA2* (*BRCA*) gene mutations. Prior studies suggest *BRCA* mutations account for ~5% of breast cancers in young breast cancer survivors. We evaluated the prevalence of *BRCA* mutations and variants detected through full gene sequencing and large rearrangement testing in a population-based sample of young Black women with breast cancer. **Methods:** Black women diagnosed with invasive breast cancer < age 50 between the years 2009-2012 were recruited through the Florida Cancer Registry. Participants completed genetic counseling, a study questionnaire, and consent for medical record release. Saliva specimens were collected for *BRCA* sequencing and large rearrangement testing through MLPA. Data analysis included frequencies and Pearson Chi-square tests. **Results:** Of 283 participants, 28 (9.9%) had *BRCA* mutations (including 26 through sequencing and 2 through MLPA) and 93 (32.9%) had detection of one or more variant of unknown significance (VUS). Of 28 carriers, 18 (64.3%) had a *BRCA1* mutation and 10 (35.7%) had a *BRCA2* mutation. Among all participants, 94 (33%) were clinically tested prior to enrollment; those with prior clinical testing were more likely to have insurance at diagnosis than those not tested previously ($p<0.001$). Compared to those without an identified mutation, those with a *BRCA* mutation were significantly more likely to have: 1) triple negative (TN) cancer (20% vs. 48%); 2) a >10% prior probability of having a mutation based on the Myriad Prevalence Table (31% vs. 54%); and 3) previous genetic testing (31% vs. 50%) (all $p<0.05$). **Conclusions:** Our findings suggest that a higher than expected *BRCA* mutation frequency may partially account for the disproportionately higher incidence of breast cancer observed in young Black women. Furthermore, the high VUS rate is partly attributed to the disparity in *BRCA* testing in Blacks. Thus our results further highlight the importance to increase awareness and access to genetic testing services in Blacks, to help address the growing health disparities in clinical cancer genetics.

**1507 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**The impact of oophorectomy on survival after breast cancer in BRCA1 and BRCA2 mutation carriers.** *Presenting Author: Kelly A. Metcalfe, University of Toronto, Toronto, ON, Canada*

**Background:** Oophorectomy is often recommended to women with BRCA-associated breast cancer in order to prevent a second primary breast cancer and ovarian cancer. However, it is unclear if oophorectomy has an impact on survival in women with BRCA-associated breast cancer. The objective of the current study was to estimate the impact of oophorectomy on survival from breast cancer for women with a BRCA1 or BRCA2 mutation **Methods:** 760 women with Stage I or Stage II breast cancer and a BRCA1 or BRCA2 mutation, between the ages 25 and 65, were followed for up to 20 years from diagnosis. The impact of oophorectomy on survival was evaluated in a Cox proportional hazards model, adjusting for age, gene (BRCA1 versus BRCA2), tumour stage, ER status and other treatments. **Results:** Of the 760 women, 455 had an oophorectomy, either prior to or after the diagnosis of breast cancer. The 20-year survival for the entire patient cohort was 74.3%. The un-adjusted hazard ratio for death associated with oophorectomy was 0.62 (95% CI: 0.42 to 0.90; p = 0.01) and the adjusted hazard ratio was 0.66 (95% CI 0.42 – 1.02; p = 0.06). The hazard ratio was 0.59 (95% CI: 0.34 – 1.01; p = 0.05) for BRCA1 carriers and was 0.81 (95% CI: 0.35 -1.85; p = 0.61) for BRCA2 carriers. The adjusted hazard ratio was 0.77 (95% CI 47 – 1.28; p = 0.29) for women diagnosed under age 50 and was 0.38 (95% CI: 0.12 to 1.15; p = 0.09) for women diagnosed over age 50. The hazard ratio was 1.21 (95% CI: 0.55 to 2.67; p = 0.65) for women with estrogen receptor-positive breast cancer and was 0.27 (95% CI: 0.11 to 0.67; p = 0.005) for women with estrogen receptor-negative breast cancer. **Conclusions:** Oophorectomy is associated with a decrease in mortality in women with early-stage breast cancer and a BRCA1 mutation. Women with estrogen receptor-negative breast cancer and a BRCA1 mutation should consider oophorectomy shortly after diagnosis as part of their treatment plan.

**1508 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Quality of life in BRCA1 and BRCA2 mutation carriers (B1/2) following risk-reducing salpingo-oophorectomy (RRSO).** *Presenting Author: Susan M. Domchek, University of Pennsylvania, Philadelphia, PA*

**Background:** RRSO is associated with a decreased risk of breast cancer, ovarian cancer and improved survival in B1/2. Timing of RRSO must balance the known benefits against the impact of early menopause. A better understanding of the long term impact of RRSO is required to aid decision making. **Methods:** B1/2 were ascertained from FORCE, a national advocacy group for hereditary breast and ovarian cancer. Demographics and medical history were obtained by online questionnaires. QOL measures evaluated executive cognition function (BADDS), menopausal symptoms (Greene), sexual function (FSFI), sleep (PSQI), stress (PSS), anxiety (HADS-A), and depression (HADS-D). **Results:** 637 B1/2 with RRSO were enrolled. Median age was 47. Median age of RRSO was 45. 43% had prior cancer history (of whom 87% had breast cancer and of these 60% chemotherapy). 27% were currently using HRT. Self reported HTN was present in 14%, osteopenia/osteoporosis in 32%, and depression in 36%. Suboptimal scores were present in the majority of patients for the majority of measures: specifically 60% of BADDS, 57% of Greene vasomotor, 73% of FSFI, 61% of PSQI, 56% of PSS, 16% of HADS-A, and 15% of HADS-D scores fell in the abnormal range. Earlier age of oophorectomy predicted suboptimal scores in sleep, stress, menopausal symptoms, anxiety and depression scales ($p<0.04$ for each). High school education or less (compared to some college or more) predicted poorer results in stress, anxiety, sexual functioning and menopausal symptoms ($p<0.02$ for each). Single status (as opposed to married or living as married) was associated with poorer scores on stress and sleep scales ($p<0.01$). In the subgroup of B1/2 with no cancer history and RRSO $<50$ years-old, current HRT use was associated with improved sleep ($p=0.02$) and vasomotor symptoms ($p<0.0001$). **Conclusions:** In this large series of B1/2 ascertained through FORCE, the majority of women reported sexual dysfunction, menopausal symptoms, cognitive issues, and poor sleep. Interventions are needed to mitigate the negative impact of RRSO.

**1509 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM**

**Multigene panel testing in patients suspected to have Lynch syndrome.** *Presenting Author: Matthew B. Yurgelun, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Multigene panels are increasingly used for assessing hereditary cancer risk due to their ability to analyze numerous cancer susceptibility genes in parallel. Our aim was to study the outcomes of multi-gene panel testing in patients undergoing clinical testing for Lynch syndrome (LS). **Methods:** The study cohort was 1,260 consecutive patients with a history of LS-associated cancer and/or polyps who had undergone clinical genetic testing for LS in a commercial laboratory. Genomic DNA mutations were identified using a 25-gene hereditary cancer panel based on emulsion PCR and next generation sequencing. Germline sequence variations and large rearrangements were classified for pathogenicity. Patients' personal/family histories of cancer were obtained from test request forms submitted with clinical LS testing. **Results:** Panel testing found $\geq$1 pathogenic mutation in 160/1,260 (13%) patients and $\geq$1 variant of uncertain significance in 552/1,260 (44%) patients. Of the 160 mutation carriers, 116 (73%) had a mutation in one of the 5 LS genes, whereas 48 (30%) had a mutation in one of the 20 non-LS genes tested including 4 (3%) with both LS and non-LS mutations. Of the 48 non-LS mutations, 15 (31%) were in *BRCA1/2*, 10 (21%) were in genes underlying other hereditary colorectal cancer syndromes (*APC*, biallelic *MUTYH*, *PTEN*, and *STK11*), and the remaining 23 (48%) were in other cancer susceptibility genes (*ATM*, *BARD1*, *BRIP1*, *CHEK2*, *NBN*, *PALB2,* and *RAD51C*). Based on their personal/family histories, a large majority of patients met NCCN criteria for LS testing but not hereditary breast/ovarian cancer (HBOC) testing (Table). **Conclusions:** In this large cohort of patients suspected to have LS, 30% of mutation carriers identified by panel testing had non-LS cancer susceptibility gene mutations. With more comprehensive genetic testing approaches, many unexpected mutations will be found in patients who do not fulfill classic clinical criteria for their syndrome.

| | Met NCCN LS criteria | Met NCCN HBOC criteria |
|---|---|---|
| **Total cohort** | 1112/1,260 (88%) | 312/1,260 (25%) |
| **All mutation carriers** | 150/160 (94%) | 30/160 (19%) |
| **LS carriers** | 111/116 (96%) | 20/116 (17%) |
| **All non-LS carriers** | 43/48 (90%) | 11/48 (23%) |

**1510 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM**

**Prevalence of mutations in a panel of breast cancer susceptibility genes in patients with early onset breast cancer.** *Presenting Author: Kara Noelle Maxwell, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

**Background:** Approximately 5-10% of breast cancers are attributable to inherited single gene mutations. Clinical testing for germline variation in multiple cancer susceptibility genes is available using massively parallel sequencing. However, data is needed on the spectrum of mutations and variants of uncertain significance (VUSs) in defined patient populations. **Methods:** We performed massively parallel sequencing using targeted capture of 19 cancer susceptibility genes in 277 *BRCA1/2* negative patients with early onset breast cancer (EOBC). **Results:** Excluding synonymous variants, 60% of patients were identified to have at least one rare variant. Twenty-eight patients (10%) were found to have a pathogenic mutation (Class 5 variant) or likely deleterious VUS (Class 4). Seven of these patients (2.5% overall) were found to have Class 4/5 variants in genes for which clinical guidelines exist for management, namely *TP53* (4), *CDKN2A* (1) and *MSH2* (2). Twenty-one patients (7.6%) had Class 4/5 variants in a moderate penetrance cancer susceptibility gene for which clinical guidelines are lacking. Four patients (1.4%) were heterozygous carriers of a pathogenic *MUTYH* mutation. In addition, 49 patients (18%) were found to carry a Class 3 VUS in a high penetrance or moderate penetrance gene. **Conclusions:** These data show that massively parallel sequencing identifies reportable (Class 3, 4 or 5) variants in known cancer susceptibility genes in 30% of patients with early onset breast cancer. However, only rare patients (2.5%) have definitively actionable mutations given current clinical management guidelines. Large-scale cooperative group studies are therefore needed to determine the clinical utility of multiplex panel testing in patients with early onset breast cancer.

**1511 Clinical Science Symposium, Mon, 8:00 AM-9:30 AM**

**A study of ovarian cancer patients tested with a 25-gene panel of hereditary cancer genes.** *Presenting Author: Lucy R. Langer, Northwest Cancer Specialists, Portland, OR*

**Background:** With advances in next-generation sequencing, patients receiving hereditary cancer testing can be tested for more genes, more efficiently. Patients with ovarian cancer are at risk for several different hereditary cancer syndromes—Hereditary Breast and Ovarian Cancer (HBOC) and Lynch syndrome (LS) in particular. **Methods:** We queried a laboratory database for patients affected with ovarian cancer and tested with a 25-gene panel of hereditary cancer genes from September 4, 2013 through December 27, 2013. All patient data regarding clinical history was obtained by health care provider report on test requisition forms. **Results:** We identified 263 patients with a personal history of ovarian cancer who received genetic testing using a 25-gene hereditary cancer panel. Of these patients, 77.2% met NCCN guidelines for HBOC, 0.8% met for NCCN guidelines for LS and 22.1% met guidelines for both syndromes. Deleterious or suspected deleterious mutations were identified in at least one gene in 16.3% of ovarian cancer patients. These included mutations in *BRCA1* or *BRCA2* (11%) and *ATM* (3.4%). Positive mutations were also identified in *APC* (3 patients), *BRIP1* (2 patients), and 1 patient each in *RAD51C*, *MSH6*, *CHEK2*, and *NBN*. We detected 137 variants of uncertain significance (VUS) in 263 patients with a range of 0 to 4 VUS identified per patient. No VUS were detected in the majority (61.6%) of patients. **Conclusions:** Testing patients using a 25-gene hereditary cancer panel increased the number of positive test results in ovarian cancer patients by 48% over *BRCA1* and *BRCA2* testing alone, showing the benefit of using a panel approach in this population.

**1512 Poster Highlights Session (Board #1), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Patient-reported outcomes and behavioral risk factors as predictors of chemoprevention adherence among women in the National Surgical Adjuvant Breast and Bowel Program (NSABP) Breast Cancer Prevention P-1 trial.** *Presenting Author: Stephanie R. Land, National Cancer Institute, Rockville, MD*

**Background:** Despite a 50% reduction in the risk of breast cancer (BC) for tamoxifen (T) vs. placebo (P), many women at risk of BC do not adhere to the 5 year course. Using prospectively-collected data from the double-blind NSABP P-1, we evaluated whether patient-reported outcomes were associated with drug adherence, and whether baseline behavioral risk factors modified those associations. **Methods:** 13,338 women at high risk of BC were randomly assigned to T vs. P (20 mg/day); we analyzed the 11,064 enrolled more than 3 years before trial unblinding 5/98. Mixed effects logistic regression was used to evaluate whether baseline and 3-month (mo) SF-36 mental (MCS) and physical (PCS) quality of life scales, depressive symptoms (CES-D), and possible treatment-related symptoms (BCPT symptom scales) predicted 12-mo drug adherence (using over 75% of assigned medication), accounting for Gail model estimated breast cancer risk and education; and whether associations were modified by baseline smoking status, alcohol consumption, body mass index (BMI, continuous variable), T vs. P, and age (continuous variable). **Results:** At 12 mo, 10,572 women were expected to be on therapy (excluding patients who never initiated therapy or experienced protocol required discontinuation); 84.2% were adherent. Sexual symptoms at 3 mo were associated with reduced adherence, but only among younger women (for example at age 45, odds ratio (OR) 0.8, p=.048); other symptoms predicted greater adherence among normal weight (OR=1.5 per 1 point, p=.016) but not among overweight women; 3-mo PCS predicted higher adherence among smokers (OR=1.4 per 10 points, p=.02), 3-mo MCS predicted adherence among women assigned to P (OR=1.4 per 10 points, p<.001). No significant associations were found with CES-D. **Conclusions:** Quality of life and symptoms at 3 months were associated with chemoprevention adherence at 12 months, and the associations differed according to age, treatment, BMI, and smoking status. Behavioral risk factors and patient-reported outcomes will help identify particular patients who may need greater adherence support. Clinical trial information: NCT00003906.

**1513 Poster Highlights Session (Board #2), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Risk of tobacco-related cancers in *CDKN2A* mutation-positive melanoma families.** *Presenting Author: Hildur Helgadottir, Department of Oncology-Pathology, Stockholm, Sweden*

**Background:** Germline mutations in the tumor suppressor gene *CDKN2A* occur in 5-20% of familial melanoma cases. A single founder mutation, p.Arg112dup, accounts for the majority of *CDKN2A* mutations in Swedish carriers. This mutation alters the peptide sequences of tumor suppressors p16-INK4A and p14-ARF. The aim of this study was to assess cancer risks in *CDKN2A* p.Arg112dup carriers and their first (FDRs) and second degree relatives (SDRS). **Methods:** In this prospective cohort study, cancer diagnoses in *CDKN2A* p.Arg112dup mutation carriers (n=120), non-carriers (n=111), carriers' FDRs (n=275) and SDRs (n=321) and controls (n=3976) were obtained from the Swedish Cancer Registry. Relative risks (RR) for cancers were calculated (number of cancers/person years). Due to the finding of high risks in mutation carriers of cancers that are normally associated with tobacco smoking, data was retrospectively collected on smoking history in carriers. Odds ratios were calculated to compare smoking (ever-smoker/never-smoker) in carriers with or without a diagnosis of non-melanoma cancer. Two-sided 95% confidence intervals (95% CI) were calculated for all RRs. **Results:** In carriers prospective RR for non-melanoma cancers was 5.0 (95% CI=3.7-7.3), for pancreatic cancer 43.8 (95% CI=13.8-139.0), for cancers in upper digestive tissues 17.1 (95% CI=6.3-46.5), and in respiratory tissues 15.6 (5.4-46.0). In FDRs and SDRs, RRs were significantly elevated for cancers in pancreas, respiratory and upper digestive tissues. In ever-smoking carriers compared with never-smoking carriers, the odds ratio of cancers in pancreas, respiratory or upper digestive tissues was 9.3 (95% CI= 1.9-44.7). **Conclusions:** *CDKN2A* p.Arg112dup mutation carriers from melanoma-prone families and their FDRs and SDRs have elevated risk for pancreatic, lung, head and neck and gastro-esophageal carcinomas. These cancers were mainly seen in ever-smoking carriers. This is the first study that shows association between smoking history and cancer diagnoses in *CDKN2A* mutation carriers. Germline *CDKN2A* mutations may confer an increased sensitivity to carcinogens in tobacco smoke. *CDKN2A* mutation carriers should be counseled to abstain from smoking.

**1514 Poster Highlights Session (Board #3), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Effect of exercise and dietary fish consumption on risk of recurrence in colon cancer: A multinational study.** *Presenting Author: Mohammed Shaik, Michigan State University, East Lansing, MI*

**Background:** Dietary factors and physical activity have been associated with the risk of occurrence of colon cancer(CCa) but their role in the recurrence of colon cancer(rCCa) has not been established. The aim of our study was to examine the association between dietary intake, exercise, and other risk factors with the rCCa. **Methods:** Data were obtained from the Global Epidemiological Study(GES), a multinational database to assess disease risk factors. Patients(pts) were recruited from Poland, Vietnam, Western Europe and the USA. Pts diagnosed with CCa gave informed consent to provide data including their exercise activity and dietary intake. Chi-square and t-test were used for categorical and continuous variables. The association[adjusted odds ratio(aOR)] between rCCa and risk factors was obtained using logistic regression. **Results:** A total of 1,515 pts were surveyed, of which 188 pts had rCCa later in life. The average age and the no. of current smokers with rCCa and those without rCCa were, 63 yrs *vs.* 64 yrs and 21(11.1%) *vs.*164(12.3%), respectively. There were 54.3% males and 46.7% females. Those with and without rCCa were compared regarding food intake, exercise, tobacco and alcohol use. In LR, food intake besides fish did not influence rCCa, neither did smoking duration or alcohol consumption. Fish intake of less than 2 servs per week had an aOR of 2.58 (1.07-6.29) and exercise less than 60 minutes per week had an aOR of 2.68 (1.02-7.0, Table). **Conclusions:** Fish consumption of more than 2 servs per week and also 60 minutes of weekly exercise, were each independently associated with a reduced risk of recurrence of colon cancer.

**Predictors of rCCa.**

| Variables | Adjusted OR (CI) | p-value |
|---|---|---|
| **Fish (< 2/wk *vs.* > 2/wk)** | 2.58 (1.07-6.29) | 0.03 |
| **Whole grain (<3/day *vs.* >3/day** | 1.44 (0.40- 5.17) | 0.57 |
| **Dairy (< 2/day *vs.* > 2/day)** | 1.16 (0.63-2.14) | 0.62 |
| **Vegetables (< 2/day *vs.* > 2/day)** | 0.75 (0.43-1.32) | 0.32 |
| **Fruits (< 2/day *vs.* > 2/day)** | 0.82 (0.47-1.43) | 0.49 |
| **Meat (< 2/wk *vs.* > 2/wk)** | 1.07 (0.68-1.69) | 0.74 |
| **BMI** | 1.02 (0.99-1.05) | 0.18 |
| **Nonsteroidal use (no *vs.* yes)** | 0.94 (0.59-1.51) | 0.82 |
| **Total years of smoking (<25 yrs *vs.* >25 yrs)** | 0.90 (0.56-1.43) | 0.66 |
| **Alcohol (no *vs.* yes)** | 1.23 (0.77-1.98) | 0.37 |
| **Exercise (<60 min/wk *vs.* > 60 min/wk)** | 2.68 (1.02-7.0) | 0.04 |

**1515 Poster Highlights Session (Board #4), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Antioxidant micronutrients and renal cell carcinoma: Results from the Women's Health Initiative.** *Presenting Author: Won Jin Ho, Department of Internal Medicine, University Hospitals Case Medical Center, Cleveland, OH*

**Background:** Renal cell carcinoma (RCC) is the 8$^{th}$leading cancer in women, commonly diagnosed at more advanced stage. Oxidative stress has been considered to play an important role in the pathogenesis of RCC. Various dietary micronutrients have antioxidant properties, including carotenoids, vitamin C, and vitamin E, and thus diets rich in these nutrients have been evaluated in relation to renal cancer prevention. The aim of this study is to explore the relationship between antioxidant micronutrient and RCC risk in the Women's Health Initiative (WHI). **Methods:** A total of 91,913 postmenopausal women enrolled between 1993 and 1998 and followed through July 2013 were included in the analysis. Dietary micronutrient intake was estimated from the baseline WHI food frequency questionnaire, and data on supplement use was collected via interview-based inventory procedure. RCC cases were ascertained from medical records and centrally adjudicated. Risk for RCC associated with $\alpha$-carotene, $\beta$-carotene, $\beta$-cryptoxanthin, lutein+zeaxanthin, lycopene, vitamin C, and vitamin E was analyzed using Cox proportional hazards analysis, adjusted for confounders. **Results:** There were 383 RCC cases identified in the WHI during follow-up. Lycopene intake was inversely associated with RCC risk (p = 0.001); compared to the quartile of lowest lycopene intake, the quartile with highest lycopene intake was associated with a 45% lower risk of RCC (HR 0.55; 95% CI, 0.38 to 0.80). There were no significant associations with RCC for any of the other micronutrients. No substantial correlation was found among micronutrients to suggest multicollinearity. **Conclusions:** These results suggest that further investigation into the relationship between dietary lycopene intake and RCC risk is warranted.

**1516 Poster Highlights Session (Board #5), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Atypical glandular cells and atypical cells of unknown origin in screening and subsequent risk of cervical cancer.** *Presenting Author: Par Sparen, Department of Medical Epidemiology and Biostatistics, Karolinska Institute, Stockholm, Sweden*

**Background:** Atypical glandular cells (AGC) in cervical screening may signal a wide range of conditions from reactive changes to malignancies in the cervix. Atypical cells of unknown origin (AUO) is a rare cytological finding in the Swedish cervical screening program which currently is referred to colposcopy. We set out to investigate the epidemiological evidence for AGC and AUO to be treated as high grade findings that should prompt a direct referral to colposcopy and endocervical evaluation and sampling. **Methods:** A population-based cohort study was defined as all Swedish resident women who had AGC and AUO findings, respectively, in cervical screening program from 1969 to 2011, retrieved from the National Quality Register for cervical Cancer prevention. Information on subsequent cervical cancer between 1969 and 2011 was obtained from the National Cancer Register. Prevalent cancers and long-term cancer risks after AGC and AUO diagnoses, respectively, were examined, and compared with low-grade and high-grade squamous intraepithelial lesions (LSIL and HSIL). Risk ratios (RR) and hazard ratios (HR) with 95% confidence intervals (CI) were calculated as effect measures. **Results:** 20,041 women diagnosed with AGC, and 33,253 women diagnosed with AUO, in Pap smear without any other abnormalities before were identified. Among these, 262 were diagnosed with invasive cervical cancer within half a year after AGC (1.31%), and 303 within half a year after AUO (0.91%), which implies possibly prevalent cancers. RR compared to LSIL was for AGC 6.83 (CI=5.92, 7.88), and for AUO 4.76 (CI=4.16, 5.46). RR compared to HSIL was 0.53 (CI=0.47, 0.60) for AGC and 0.37 (CI=0.33, 0.41) for AUO. HR half a year after AGC was 1.91 (CI=1.64, 2.23), compared to LSIL, and 1.32 (CI=1.12, 1.55), compared to HSIL. Correspondingly for AUO, HR=1.67 (CI=1.46), compared to LSIL, and HR=1.15 (CI=1.01, 1.33), compared to HSIL. **Conclusions:** Both AGC and AUO implies high risk of prevalent or long-term invasive cervical cancer, which warrants direct diagnostic measures and close follow up to find precursors or early carcinomas in the endocervix. We are currently exploring the possibility of increased risk also for endometrial cancer.

**1517 Poster Highlights Session (Board #6), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Thailand experiences on cervical cancer prevention using vinegar.** *Presenting Author: Khunying Kobchitt Limpaphayom, Department of OB& GYN, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*

**Background:** Cervicare Thailand is a visual inspection using acetic acid(VIA)and cryotherapy in a single visit approach(SVA) project that was initiated by Jhpiego,an affiliate of the Johns Hopkins University, and funded by Bill and Melinda Gates Foundation. Since 2002 the program has been supported locally. Purpose of this paper is to report of the results of scale up of the cervical cancer prevention initiative. **Methods:** The cervical cancer screening and treatment data were retrieved from service statistics that were routinely report in national health information system.We focused our data capture and analysis on 34 provinces where SVA is available. Additionally we utilized reports of training to supplement our data review. **Results:** Since 2000, there were 63 courses for SVA resulted in 1388 nurses qualified provide SVA in 34 of 77 provinces across Thailand. Another 149 clinical trainers were prepared to assist in training more providers and also conduct supportive supervision .Up to December 2013,749,407(22.8%)from a total of 3,285,585 women aged 30-45 have been screened with VIA. Positive VIA result were found in 27,978(3.7%) of which 15,396(55.0%) received treatment with cryotherapy at the same visit. The number of VIA positive cases referred for additional care was 12,582(45%).The referral were gynecologic problem and/or lesion ineligible for cryotherapy. Another 9,101(1.2%) women had suspicious cervical cancer finding, which required further diagnosis and treatment. **Conclusions:** SVA can be provided and made sustainable in Thailand. This approach increased accessibility and addresses health inequity for women in remote area.The scaled up has also identified the challenges and issue attendant to scaling up as well as the key lesson learned in improving the cervical cancer prevention in Thailand. While impact has yet to be measured nationally, the report from one of the province is promising. Roi-et where they have fully scaled up SVA, hospital based cancer registry show a declining trend for invasive cervical cancer year 2006 and 2011, reporting a drop from 65 cases to 54 cases.

**1518 Poster Highlights Session (Board #7), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Estimating the impact of screening on three decades of cervical cancer incidence.** *Presenting Author: Daniel Xiao Yang, Yale School of Medicine, New Haven, CT*

**Background:** In the U.S., the Pap smear has become a widely practiced, effective tool for the early detection and prevention of cervical cancer. However, the total number of cervical cancer cases that have been prevented by screening is unknown, as well as the impact of screening on racial disparities. **Methods:** We estimated national cervical cancer incidence from 1976 to 2009 using the Surveillance, Epidemiology, and End Result database. Screening data from 1951 to 2010 were obtained from literature and National Cancer Institute Progress Reports. We examined trends in early (localized) and late (regional, distant) stage cancer incidence and estimated the number of cancers prevented due to screening over the past three decades. Race was categorized as white, black, and other (Asian/Pacific Islander, Alaskan Native, and American Indian). **Results:** After rising steadily from 1951-1981, the percentage of all adult women who received cervical cancer screening stabilized at 71.7% in 1982 to 73.8% in 2010. Overall, from 1976 to 2009, there was a significant decrease in the incidence of early stage cervical cancer, from 10.2 to 5.4 cases per 100,000 women ($p < .001$). Late stage disease incidence also decreased, from 5.2 to 3.7 cases per 100,000 women ($p < .001$). After adjusting for "pre-screening era" rates of cervical cancer, we estimate that Pap smears were associated with a reduction of between 105,000 to 492,000 cases of cervical cancer over the past three decades in the U.S. The combined incidence among black women decreased from 26.9 to 9.7 cases per 100,000 women ($p < .001$), a greater decline compared to that of white women (13.7 to 8.5 cases per 100,000, $p < .001$), and women of other races (16.0 to 7.4 cases per 100,000, $p < .001$). **Conclusions:** We estimate that a large number of early and late stage cervical cancers were prevented, and the racial disparity in cancer rates was reduced during an era of increased screening. Given disparate access to the HPV vaccine, it will be important to continuously assess national cervical cancer incidence to measure the additional benefit of the vaccine against the known benefit of screening, and to ensure equal access and outcomes for all women.

**1519 Poster Highlights Session (Board #8), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Use of a SNP panel to refine risk estimates in women at high risk of breast cancer: Results from two randomized tamoxifen prevention trials.** *Presenting Author: Jack M. Cuzick, Centre for Cancer Prevention, Wolfson Institute of Preventive Medicine, London, United Kingdom*

**Background:** An assessment of how panels of single-nucleotide polymorphism (SNP) breast cancer risk factors might improve risk assessment among high-risk women is needed for better targeting of preventive therapy and other risk reduction measures. **Methods:** A case-control study was designed using leukocytic or tissue DNA from two tamoxifen prevention trials (IBIS-I and Marsden). SNPs were assayed on the Sequenom platform and a relative risk score for 15 SNPs (SNP15) was formed using the most recent iCOGS SNP risk estimates. Baseline questionnaires were used to estimate 10-year relative risks from the Tyrer-Cuzick model (TC). Conditional logistic regression was used to assess performance. An updated panel using all validated risk SNPs (approx. 70) is also being evaluated and will be presented at the meeting. **Results:** 440 cases and 686 controls had median age at baseline of 49 (inter-quartile range 45 - 54). Hardy-Weinberg equilibrium was verified. SNP15 and TC appeared uncorrelated (Spearman 0.037, P=0.209). The odds ratio (OR) between 25$^{th}$, 75$^{th}$ percentiles of SNP15 was 1.24 (95% CI 1.05 - 1.46) with AUC 0.568; TC had OR 1.41 (1.21 - 1.64), AUC 0.578; combined OR 1.54 (1.30 - 1.83), AUC 0.600. The observed risk was 48% (11 – 84) of predicted for SNP15 and 77% (42 – 110) for TC. SNP15 was more predictive for estrogen receptor (ER) positive tumours (318 cases, OR 1.36 (1.12 – 1.64), AUC 0.587, 67% (25-109) of predicted) but not for estrogen-receptor (ER) negative cancer (122 cases, P = 0.76); TC was significantly associated with both ER types. Little difference in performance was seen between tamoxifen and placebo treatment arms. The proportion of untreated women with 10-yr predicted risk above 8% was <1% for SNP15, 18% for TC and 25% for the combined risk score. **Conclusions:** A SNP panel is useful for refining risk estimates in women with phenotypic risk factors for breast cancer, and adds important information to classic phenotypic factors but does not appear to vary according to potential to benefit from tamoxifen. Clinical trial information: ISRCTN91879928 (ref: CCT-NAPN-14839).

**1520 Poster Highlights Session (Board #9), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Frequency of occult findings in contralateral prophylactic mastectomy as it relates to preoperative MRI or BRCA testing.** *Presenting Author: Lillian M. Erdahl, Mayo Clinic Rochester, Rochester, MN*

**Background:** Contralateral prophylactic mastectomy (CPM) rates in patients with unilateral breast cancer are increasing in the U.S. Preoperative MRI screening and genetic testing may influence surgical planning for patients undergoing CPM. The aim of our study was to determine the impact of breast MRI and BRCA mutation status on the rate of finding an occult high risk lesion (HRL) or occult malignancy (OM) in a CPM. **Methods:** We identified 740 women with unilateral breast cancer undergoing concurrent therapeutic mastectomy and CPM from 10/2008 to 6/2013 with no history of cancer in the CPM breast. We reviewed medical records for use of preoperative bilateral breast MRI and genetic testing for a BRCA 1 or 2 mutation. Likelihood ratio chi-square tests and multivariate logistic regression were used to assess potential impact of MRI and genetic testing on the likelihood of occult findings in the CPM breast. **Results:** Of 740 patients, 494 (67%) had a preoperative breast MRI and 244 (33%) had BRCA testing [197 (80.7%) BRCA 1/2 negative, 38 (15.6%) positive for BRCA 1/2 deleterious mutation, and 9 (3.7%) variant of unknown significance (VUS)]. Both MRI and BRCA testing were more likely to be performed in younger patients ($p<0.0001$). A clinically occult HRL or OM was identified in 108 (14.6%) CPM breasts: 78 (10.5%) HRL and 30 (4.1%) OM. There was no difference in the rate of occult lesions by use of MRI (14.2% MRI vs 15.5% no MRI, $p = 0.63$). BRCA 1 or 2 mutation was not associated with a higher rate of occult findings: 10.5% for BRCA 1/2 positive, 11.1% for VUS, 11.2% for BRCA 1/2 negative, and 16.4% for not tested ($p = 0.28$). A multivariate model adjusted for age, index breast cancer characteristics, and neoadjuvant chemotherapy, showed that neither preoperative breast MRI or BRCA 1/2 mutation was associated with occult findings on CPM. **Conclusions:** Patients not undergoing preoperative MRI were not more likely to have an occult malignancy or HRL identified in the CPM. The presence of a deleterious mutation in BRCA 1 or 2 is not associated with a higher rate of occult finding on CPM. Factors other than preoperative MRI or mutation status should be used to guide operative management of patients electing CPM.

**1521 Poster Highlights Session (Board #10), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**RPFNA cytologic atypia and short-term breast cancer risk in the prevention era.** *Presenting Author: Whitney L. Michaels, University of Kansas Medical Center, Kansas City, KS*

**Background:** In 2000 we published our initial observation from a high risk cohort of 480 women that cytologic evidence of hyperplasia with atypia in tissue obtained by random periareolar fine needle aspiration (RPFNA) was associated with a 5 fold increased risk of developing DCIS or invasive breast cancer (IBC) at a median follow-up (FU) of 45 months (Fabian et al. JNCI 2000). Few women had any exposure to prevention agents as NSABP-P1 was not reported until 1998. We began a new high risk cohort in 2002 as our tissue processing methods changed to Thin Prep which provided better nuclear detail. Women in the 2$^{nd}$cohort, in addition to counseling about standard prevention options, were given information about clinical trials and told that RPFNA atypia was a risk factor. The purpose of this initial analysis was to determine the predictive value of RPFNA atypia in the prevention era. **Methods:** A total 1,162 women, eligible on the basis of family history, prior LCIS or atypical hyperplasia and/or prior contralateral DCIS or IBC were enrolled in our 2$^{nd}$ cohort between 2002 and 2012. We used the same methods as with our earlier cohort where the first two aspiration results within 21 months were combined. The same cytopathologist (CZ) and same primary aspirator (CF) were utilized for both cohorts. Women were censored at the time of prophylactic mastectomy, development of other site cancer or death. 5 year Gail model risk, instead of 10 year Gail risk, was calculated for women 35 or older who did not have prior LCIS, DCIS or IBC. Kaplan-Meier hazard plots and Cox regression analysis were used for time to development of DCIS or IBC and effects of joint variables, respectively. **Results:** Median age at entry was 47 and 59% were premenopausal. 32% had cytologic evidence of atypia. At median FU of 55 months, neither 5 year Gail risk nor cytologic atypia was significantly predictive of subsequent development of breast cancer. However, 33% of women with atypia had taken a SERM or AI as part of a prevention trial and/or as standard of care and 12% of women <50 had a prophylactic oophorectomy. **Conclusions:** In a setting where many women with RPFNA atypia undergo a prevention intervention, cytologic atypia does not predict short term risk for breast cancer.

**1522 Poster Highlights Session (Board #11), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Founder effect and a high prevalence of BRCA1 mutations among young Mexican triple-negative breast cancer (TNBC) patients.** *Presenting Author: Cynthia Mayte Villarreal-Garza, Instituto Nacional de Cancerologia, Mexico City, Mexico*

**Background:** Previous studies have shown that the prevalence of BRCA mutations among young TNBC patients is elevated. Current guidelines recommend that women ≤60 years with TNBC be referred for genetic counseling. Different studies in Mexico have shown an early age of onset of BC and a high prevalence of TNBC, which suggests that BRCA mutations may account for a higher proportion of breast cancers in this population. However, there is limited information regarding BRCA mutation prevalence mainly due to lack of access to clinical BRCA gene analyses in Mexico. **Methods:** The purpose of this study is to analyze BRCA mutation frequency in a cohort of young Mexican TNBC patients using a panel assay of 114 recurrent BRCA mutations found in women of Hispanic ancestry (HISPANEL) on the Sequenom platform. Mexican women diagnosed with TNBC at or before age 50 were prospectively recruited from the National Cancer Institute in Mexico City. Patients were screened by HISPANEL and by PCR for the Mexican founder BRCA1 ex9-12del large rearrangement. **Results:** Among 190 consecutive TNBC cases, the median age of diagnosis was 42 years old and 69% were younger than 45 years. The majority of patients presented with locally advanced disease (69%). A BRCA mutation was detected in 43/190 (23%) of patients (42-BRCA1, 1-BRCA2), and BRCA1 ex9-12del accounted for 42% of the mutations. Only 45% of the BRCA mutation carriers had a family history of breast and/or ovarian cancer. Samples were processed in a two-week period, with a total cost of $4,000 USD. **Conclusions:** There is a remarkable prevalence of BRCA1 mutations among young TNBC patients in our population. The first documented Mexican founder mutation, BRCA1 ex9-12del, was the most frequent BRCA mutation and is likely responsible for a significant burden of disease in women from Southern Mexico. The HISPANEL can be completed within 72 hours from sample collection, at a modest cost of $20 USD per sample, and implementation among women of Mexican ancestry could reduce overall genotyping cost and increase access to cancer prevention among underserved women in Mexico and the U.S.

**1523 Poster Highlights Session (Board #12), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Association of the single nucleotide polymorphism TNRC9 rs3803662 on mammographic density and estrogen receptor-positive breast cancer risk in Japanese women.** *Presenting Author: Nobuyasu Yoshimoto, Oncology, Immunology and Surgery, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

**Background:** The incidence of breast cancer in Japanese women has doubled in all age groups over the past two decades. We recently created risk prediction models for estrogen receptor (ER)-positive breast cancer in both pre- and post- menopausal women using genetic factors (single nucleotide polymorphisms (SNPs)), environmental risk factors, serum hormones and growth factors, by logistic regression analysis. However, mammographic density is also considered to be a risk factor for breast cancer. To acquire some insight into the relationships among SNPs, mammographic density and breast cancer risk, we analyzed the correlation between these factors. **Methods:** The study population comprised 913 consecutive Japanese women with breast cancer, and 278 control Japanese women. We analyzed the correlation between genetic factors (14 SNPs) and breast cancer risk in both premenopausal and postmenopausal women. We also analyzed differences in mammographic density between the SNP genotypes (homozygotes of major alleles, heterozygotes and homozygotes of minor alleles) in the combined population of both premenopausal and postmenopausal women. **Results:** CYP19A1 rs10046 TT genotype and TNRC9 rs3803662 AA genotype were both found to have a significant association with ER-positive breast cancer in premenopausal women (OR 0.55: $P = 0.019$, OR 1.59: $P = 0.027$), while ESR1 rs6905370 GG genotype and TP53 rs1042522 CC genotype were significantly associated with ER-positive breast cancer in postmenopausal women (OR 1.83: $P = 0.033$, OR 0.54: $P = 0.045$). Mammographic density differed significantly among CYP2C19 rs4917623 genotypes (CC 50.23 +/- 18.82%, CT 46.69 +/- 20.03%, TT 49.04 +/- 19.22%, $P = 0.009$), among ESR1 rs827421 genotypes (AA 49.97 +/- 20.77%, AG 47.63 +/- 18.51%, GG 45.19 +/- 19.20%, $P = 0.048$) and among TNRC9 rs3803662 genotypes (AA 49.35 +/- 18.43%, AG 48.43 +/- 20.45%, GG 44.12 +/- 18.41%, $P= 0.026$). **Conclusions:** TRNC9 rs3803662 AA genotype was considered to confer an increased risk of ER-positive breast cancer by increasing mammographic density. ESR1 rs827421 AA genotype might also increase ER-positive breast cancer risk by the same mechanism.

**1524 Poster Highlights Session (Board #13), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Pharmacokinetic analysis of tamoxifen metabolites in premenopausal women with early breast cancer: A substudy of NCIC CTG MA.12 randomized clinical trial.** *Presenting Author: Shahbal Bill Kangarloo, Alberta Health Services, Tom Baker Cancer Centre, Calgary, AB, Canada*

**Background:** The clinical impact of CYP2D6 genetic polymorphisms on tamoxifen (Tam) remains unclear. Active metabolite levels of Tam can be influenced by drug interaction and compliance. This study evaluated the association of steady state plasma levels of Tam and its metabolites with clinical outcomes in samples collected in MA.12. Premenopausal women (n=672) with high risk node negative and node positive breast cancer following adjuvant chemotherapy were randomized to Tam or placebo. There was an improvement in DFS (HR 0.77; p=0.056) but not OS (HR 0.78; p=0.12) favoring Tam. **Methods:** TAM, N-desmethyl-tamoxifen (NDM), 4-hydroxy-tamoxifen (4-OH), and endoxifen (Endo) were quantified in serum by liquid chromatography–tandem mass spectrometry. Samples collected after 120 days on Tam were analyzed, (n=121 Tam, n=121 Placebo). Exploratory analyses assessed the association of DFS and OS with each metabolite level, as a continuous variable, as well as a categorical variable using an optimal cut point. Cut points were determined using the minimum p-value. Factors associated with DFS or OS were evaluated in a multivariate Cox model adjusting for age, performance status, chemotherapy, receptor status, nodal status, histology and tumor stage. **Results:** Baseline characteristics of the substudy were similar to the full trial population. Descriptive metabolite levels in the Tam cohort are listed in the Table. There was no crossover at 120 days. As a continuous measure, none of the metabolite values were significantly correlated with DFS or OS. As a categorical variable, only 4-OH was associated with clinical outcomes. In a multivariate Cox model, the optimal 4-OH cutpoint (1.72 ng/mL) was significantly correlated with 5 year DFS HR 0.30 [95% CI(0.10-0.95), p=0.04)] and 5 year OS HR 0.21 [95% CI(0.05-0.93), p=0.04]. **Conclusions:** In this exploratory, hypothesis generating analysis of MA.12, wide ranges in serum concentrations of Tam metabolites were observed. Only 4-OH levels were associated with clinical outcomes.

| Metabolite | Mean serum [ng/mL], (range) | % Coefficient of variance |
|---|---|---|
| **NDM** | 126.6, (0.61-293.1) | 50.2 % |
| **4-OH** | 1.47, (0-4.26) | 56.9 % |
| **Endo** | 16.6, (0-52.7) | 65.9 % |

**1525 Poster Highlights Session (Board #14), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Mammographic density and breast cancer in women from high-risk families.** *Presenting Author: Marina Pollán, National Center of Epidemiology, Instituto Salud Carlos III, Madrid, Spain*

**Background:** Mammographic density (MD) is one of the strongest determinants of breast cancer (BC). In this case-control study, we compared MD in *BRCA1/2* mutation carriers and non-carriers from *BRCA1/2* mutation-positive families and investigated the association between MD and BC among *BRCA1/2*mutation carriers per type of mutation and tumor subtype. **Methods:** The study was carried out in female members of *BRCA1* and *BRCA2* mutation-positive families followed-up at 16 Spanish Genetic Counseling Units. A total of 1039 women signed the informed consent and answered the questionnaire. Participants´ density was scored retrospectively from available mammograms by a single blinded radiologist using a 5-category scale (<10%, 10-25%, 25-50%, 50-75% and >75%). In cancer cases, mammograms were selected among those taken prior to diagnosis or from the contralateral breast. In controls, the last screening mammogram was evaluated. MD distribution in carriers and non-carriers was compared using ordinal logistic models, and the association between MD and BC in *BRCA1/2* mutation carriers was studied using logistic regression. Huber-White robust estimators of variance were used to take into account correlations between family members. A similar multinomial model was used to explore this association by BC subtype. **Results:** We identified and scored mammograms from 353 *BRCA1*, 360 *BRCA2* mutation carriers and 247 non-carriers. MD was associated with subsequent development BC (OR per category of MD: 1.41; 95%CI: 1.15-1.73, p = 0.001), with no significant differences between *BRCA1* and *BRCA2* mutation carriers (p = 0.69). However, MD was significantly lower among *BRCA2* mutation carriers compared to non-carriers (OR=0.70; p = 0.031). Finally, no statistically significant differences were observed in the association of MD with specific BC subtypes. **Conclusions:** *BRCA1/2* mutation carriers do not present higher MD compared to non-carriers, but our work confirms that MD is also an independent risk factor for BC in this population.

**1526 Poster Highlights Session (Board #15), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**EGFR mutation screening in non-small cell lung cancer: Results from an access program in Brazil.** *Presenting Author: Luciola De Barros Pontes, HCor Onco, Sao Paulo, Brazil*

**Background:** Epidermal growth factor receptor (EGFR) mutation testing allows for optimal selection of therapy with tyrosine kinase inhibitors in patients with non-small-cell lung cancer (NSCLC). Previous studies have shown a variation in EGRF genotype according to ethnic background, with scarce data about EGFR mutation status among brazilian patients with NSCLC. **Methods:** Between 2011 and 2013, as part of a program sponsored by a pharmaceutical company in Brazil, tumor samples of patients with stage IIIb/IV NSCLC were submitted, at the discretion of the attending physicians, for EGFR mutation testing. All analysis were performed at 02 reference laboratories, as follows: after microdissection, DNA was isolated from serial sections of formalin-fixed, paraffin-embedded tumor tissue to obtain at least 70% tumor cells. Exons 18, 19, 20 and 21 of the EGFR gene were analysed using Sanger sequencing. EGFR mutation rate was calculated and its frequency compared between clinical subgroups using chi-square test. Data about smoking status was incomplete and thus not included in this analysis. **Results:** 3,771 (1,799 male; 1,942 female) samples were analysed, of which 3364 provided informative results. Frequency of EGFR mutation was 25.5% (857/3364). Deletions in exon 19 were the most frequent alterations detected (54%; 463/857), followed by point mutations in exon 21 (28%; 240/857), exon 20 (9.7%; 83/857) and, less frequently, mutations in exon 18 (8.3%; 71/857). The median age for patients with a positive test was 66 years (range, 28-95). The most important predictors for the presence of EGFR mutations were adenocarcinoma histology (p<0.001), with 89% of positive tests occurring in this histology (331/370 - available data), and female gender (p<0.001), in which 30.2% of the patients tested were positive. No differences in EGFR mutation frequency were found between age groups. **Conclusions:** To the best of our knowledge, this is the largest study to assess EGFR mutation status in Latin America and in Brazil. Our findings suggest that the frequency of EGFR mutation in this cohort was lower than that found in Asia, but higher than in Caucasian populations, confirming findings seen in other Latin American countries.

**1527 Poster Highlights Session (Board #16), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Clinical and molecular characteristics of non-small cell lung cancer patients harboring PIK3CA mutations.** *Presenting Author: Sebastian Yves Friedrich Michels, University of Cologne, Cologne, Germany*

**Background:** Somatic mutations of the *PIK3CA* gene have been described in non-small cell lung cancer (NSCLC), but limited data is available on their biological relevance. This study was performed to characterize PIK3CA-mutated NSCLC clinically and genetically. **Methods:** Tumor tissue collected consecutively from 1,144 NSCLC patients within a molecular screening network between March 2010 and March 2012 was analyzed for *PIK3CA* mutations using dideoxy-sequencing and next-generation sequencing (NGS). Clinical, pathological, and genetic characteristics of these patients are described and compared with a control group of *PIK3CA*-wildtype patients. **Results:** Among the total cohort of 1,144 patients we identified 42 (3.7%) patients with *PIK3CA* mutations in exon 9 and exon 20. These mutations were found with a significant higher frequency in sqamous cell carcinoma (8.9%) compared to adenocarcinoma (2.9%, p<0.001). Overall, they were significantly associated with smoking (p=0.012). The most common *PIK3CA* mutation was exon 9 E545K. The majority of patients (57.1%) had additional oncogenic driver aberrations. Further, *PIK3CA*-mutated patients had significantly higher incidence of malignancy prior to lung cancer (p<0.001). The median overall survival of these patients treated with systemic medication at stage IV was 9.5 months (95% CI, 2.3 – 16.8 months) and 32.1 months (95% CI, 17.9 – 46.3 months) for the local stages. **Conclusions:** Analysis of the largest cohort of *PIK3CA*-mutated NSCLCs described so far shows clinical and genetic heterogeneity of this subgroup in adenocarcinomas as well as in squamous cell carcinomas. In addition, we found that *PIK3CA* mutation positive lung cancer frequently develops in patients with prior malignancies.

**1528 Poster Highlights Session (Board #17), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Racial/ethnic variations in lung cancer incidence and mortality, adjusted for smoking behavior: Results from the Women's Health Initiative.** *Presenting Author: Manali I. Patel, Stanford University Medical Center, Menlo Park, CA*

**Background:** It is unclear whether there are racial/ethnic disparities in lung cancer incidence and mortality among women. Therefore, we examined lung cancer incidence and mortality in the Women's Health Initiative (WHI), a prospective cohort of post-menopausal women. **Methods:** Lung cancer diagnoses were centrally adjudicated by pathology review. Logistic regression models estimated odds of incidence and mortality by race/ethnicity adjusted for age, education, calcium/vitamin D, BMI, smoking (status, age at start, duration and pack-years), alcohol, family history, oral contraceptive, hormones, physical activity, and diet. **Results:** The analytic cohort included 129,951 women -108,487 (83%) white (47.5% current/past smoker); 10,892 (8%) Black (47.7% current/ past smoker); 4,882 (4%) Hispanic (33.7% current/past smoker); 3,696 (3%) Asian/Pacific Islander (A/PI) (26.2 % current/past smoker); 534 American Indian/Alaskan Native (48.3% current/past smoker) and 1994 (1.4%) other (41.6% current/past smoker). In unadjusted models Hispanics had 66% lower odds of lung cancer compared with whites (OR 0.34 95% CI (0.2-0.5)), followed by A/PI (OR 0.45 95% CI (0.27-0.75)) and blacks (OR 0.75 95% CI (0.59-0.95). In fully adjusted multivariable models, decreased risk of lung cancer for blacks, Hispanics, and A/PI compared to whites was no longer statistically significant. In unadjusted models Hispanics and A/PI had decreased risk of death from compared to whites (OR 0.3 95% CI (0.15-0.62), OR (0.3 95% (0.16-0.75)), respectively); however, no significant racial/ethnic differences were found in risk of death from lung cancer in fully adjusted models. **Conclusions:** We found no racial/ethnic disparities in lung cancer incidence or mortality in a population of post-menopausal women after adjusting for socio-demographic, clinical, and behavioral factors. Clinical trial information: 1757.

**1529 Poster Highlights Session (Board #18), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Circulating microRNA signature and lung cancer outcome in low-dose computed tomography (LDCT) screening.** *Presenting Author: Stefano Sestini, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** The efficacy of low-dose computed tomography (LDCT) screening is currently being tested in prospective randomized trials worldwide. Some of these trials are also investigating the value of non-invasive biomarkers, to improve the cost-benefit ratio of LDCT by individual risk assessment. In the present study, we have analyzed the capacity of a miRNA signature classifier (MSC) based on 24 previously refined microRNAs circulating in plasma to predict the outcome of lung cancer patients within the LDCT screening program. **Methods:** Between 2000 and 2010, 3411 heavy smokers were enrolled in a screening program, with annual (2225) or biennial (1186) LDCT. During the first five years of screening, a total of 111 consecutive subjects developed lung cancer. The actuarial five-year survival according to clinical and pathological characteristics was calculated for all patients, and for the subset of 76 patients suitable for plasma MSC analysis, according to three different risk groups (High, Intermediate or Low). Median follow-up of the alive patients was 4.5 years (Inter Quartile Range = 6.5). **Results:** Five-year survival was 55% in overall (median 7.9 yrs), 63% for LDCT-detected cases (median nc), 90% for pStage I (median nc), 9% for pStage II-IV (median 1.5 yrs, $p<0.001$), 68% for cancers detected in the initial two years of screening (median nc), and 38% for years 3 to 5 (median 3.0 yrs, $p<0.004$). None of the 13 interval cancers survived 4 years (median 0.8 yrs, $p<0.001$). In the subset suitable for plasma MSC analysis , survival was 76% for low- to intermediate risk MSC (median nc), and 35% for High risk MSC (median 2.9 yrs, $p=0.002$). The prognostic power of MSC persisted when the analysis was restricted to LDCT-detected cases after exclusion of interval cancers (85 vs. 38% respectively, $p<0.001$). No cancer deaths were observed in the subset of 28 patients with pStage I and low- to intermediate risk MSC. **Conclusions:** Patients developing interval lung cancer or with a Stage higher than I had a very poor outcome, despite LDCT monitoring. Plasma MSC predicted lung cancer outcome effectively, and might improve the individual risk assessment and performance of LDCT screening in the near future. Clinical trial information: INT 05-53.

**1530 Poster Highlights Session (Board #19), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Lung cancer detection by low-dose computerized tomography (LDCT) and digital tomosynthesis (DT) for lung cancer screening in a high-risk population: A comparison of detection methods.** *Presenting Author: Natthaya Triphuridet, Chulabhorn Hospital, Bangkok, Thailand*

**Background:** Low-dose computerized tomography (LDCT) recommended as a screening tool for lung cancer in a high risk population has some limitations with respect to its high false positive rate, accumulated radiation exposure and relatively high costs. Digital tomosynthesis (DT) is a multi-section imaging technique which can improve detection ability of small lung nodules and renders much lower radiation dosage and operation costs. **Methods:** 624 Thai heavy smokers (>30 pack-years) were enrolled in a prospective study starting from July 2012 to October 2013. All participants underwent LDCT and DT on the same day while the results were independently viewed with 1-week interval apart. Abnormal findings were categorized into 3 groups: negative, indeterminate (maximum diameter of pulmonary nodule 5-9.9 mm or volume 50-500 $mm^3$), and suspicious for primary lung cancer (maximum diameter of pulmonary nodule >10 mm or volume >500 $mm^3$, consolidation, obstructive atelectasis, pleural effusion, or mediastinal lymphadenopathy). **Results:** Ten lung cancer cases were detected in this high-risk group (10/624, 1.6%). LDCT and DT classified 23 and 20 cases, respectively, as suspicious for primary lung cancer. DT detected 8 primary lung cancers as frequently as did LDCT. LDCT classified 68 cases as indeterminate while DT classified 21 as such cases. Two additional primary lung cancers were detected at a 3-month follow-up; all were identified as indeterminate by baseline LDCT and only one case was indeterminate by baseline DT. The positive predictive value (PPV) for all suspicious for primary lung cancer findings by LDCT and DT was 34.8% and 40%, respectively. The sensitivity and specificity of LDCT and DT was comparable at 80% and 98%, respectively. The PPV for pulmonary nodule >10 mm or volume >500 $mm^3$ was 30% and 42% in LDCT and DT, respectively. The PPV for pulmonary nodule >5mm or volume 50-500 $mm^3$ was 9% and 22.5% in LDCT and DT, respectively. **Conclusions:** DT is a lung cancer screening modality that is comparable to LDCT, particularly for pulmonary lesions of 10 mm. and larger.

**1531 Poster Highlights Session (Board #20), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Death less than one month from diagnosis in children with cancer: A population-based analysis.** *Presenting Author: Adam L. Green, Dana-Farber Cancer Center Institute/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

**Background:** Childhood cancer outcomes continue to improve, but a proportion of patients still die soon after diagnosis. While many of these deaths may be preventable, this group of patients has not been well characterized and may be underreported. **Methods:** We retrieved data from SEER 13 on the 34,878 patients 0-19 yrs with cancer diagnosed between 1992 and 2010. Early death (ED) was defined as death within the first month from diagnosis. Demographic, clinical, and socioeconomic factors were analyzed using chi-square testing. Socioeconomic data for each county were derived from Census 2000 and divided into two categories according to the median value for the cohort. **Results:** 1.8% (n=644) patients died within one month of diagnosis. Compared with the entire cohort, the ED group had a significantly higher percentage of infants (25.3% vs.7.2%, $p<0.0001$). In comparison to the whole cohort, diseases overrepresented in the ED group included infant ALL (2.0 vs 0.6%, $p<0.0001$), AML (18.2 vs 5.0%, $p<0.0001$), CNS tumors (24.8 vs 17.7%, $p<0.0001$), and hepatic tumors (3.7 vs 1.4%, $p<0.0001$). Diseases underrepresented included ALL, lymphomas, and renal, bone, and soft tissue tumors. Patients in the ED group were more likely to be of non-white race (24.5% vs. 20.4%, $p=0.03$) or Hispanic ethnicity (33.8% vs. 26.1%, $p<0.0001$). These patients were also more likely to live in counties with high rates of poverty ($p<0.0001$), unemployment ($p=0.03$), language isolation ($p=0.0004$), and immigration ($p=0.003$), and a low rate of high school education ($p=0.02$). Early death rate decreased over the period of analysis (APC -2.6%). **Conclusions:** Risk factors for ED in childhood cancer include infancy, specific diagnoses such as AML and CNS tumors, racial and ethnic minority, and disadvantaged socioeconomic status. The disease-specific rates of early death found in this population analysis were uniformly higher than those reported in large cooperative clinical trials, suggesting that many ED patients are lost to the medical literature. This group should be described prospectively, and initiatives to identify patients at risk and develop preventive interventions should be undertaken in the primary and specialty settings.

**1532 Poster Highlights Session (Board #21), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Influence of metformin use on the transformation of monoclonal gammopathy of undetermined significance into multiple myeloma.** *Presenting Author: Su-Hsin Chang, St. Louis Veterans Affairs Medical Center, St. Louis, MO*

**Background:** Multiple myeloma (MM) is the second most common hematologic malignancy in the United States and is preceded by monoclonal gammopathy of undetermined significance (MGUS). Stimulation of the insulin-like growth factor receptor pathway is a hypothesized mechanism for the progression of MGUS to MM; therefore, alteration of this pathway with metformin could reduce the risk of progression. We evaluated the influence of metformin use on the transformation of MGUS to MM in a retrospective cohort. **Methods:** Patients with MGUS and diabetes mellitus diagnosed between 1998 and 2009 were identified in the U.S. Veterans Health Administration (VHA) database. Unique identifiers were used to link data to the pharmacy database to obtain diabetes medications. Two investigators reviewed patient-level clinical information to verify dates of MGUS and MM diagnoses, and abstract additional data, including size of baseline M protein, immunoglobulin (Ig) subtype, and serum-free light-chain ratio, when available. The duration of metformin use was determined by the dates of the first and last prescription before 2013 or MM diagnosis. Several threshold values for dichotomization around the median duration of metformin use for patients developing MM were examined. Cox proportional hazard models, adjusting for age, body mass index, race, sex, Ig subtype, and size of M spike, were used to analyze the association between metformin use and the time from MGUS diagnosis to MM diagnosis. **Results:** 2,116 MGUS patients with diabetes were identified after excluding those with IgM MGUS. Among them, 38% were not treated metformin and 113 patients developed MM. We found that metformin use over 46 months (median duration of metformin use for MM patients) was protective, but not statistically significant (HR: 0.83; 95% CI: 0.55-1.24). However, metformin use over 4.5 years (54 months) was significantly protective with HR: 0.60 and 95% CI: 0.38-0.94. Patients with M protein concentration ≥1.5 g/dL (HR: 6.32; 95% CI: 3.7-10.8) and IgA monoclonal protein (HR: 1.82; 95% CI: 1.15-1.90) had a higher risk of progression. **Conclusions:** Prolonged metformin use was associated with a reduced risk of transformation from MGUS to MM.

**1533 Poster Highlights Session (Board #22), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Risk factors for melanoma among survivors of non-Hodgkin lymphoma in the U.S. elderly population.** *Presenting Author: Clara JK Lam, National Cancer Institute, Rockville, MD*

**Background:** Non-Hodgkin lymphoma (NHL) survivors have increased risk of developing melanoma compared with the general population. Although immune dysfunction may play a role, no previous study has investigated immune-related factors and melanoma risk after NHL. **Methods:** We used the SEER-Medicare linkage to identify a cohort of 44,875 individuals who were diagnosed with first primary NHL during 1992-2009 at ages 65-84 years and survived ≥1 year. Cox regression quantified melanoma risk associated with NHL treatments as well as autoimmune conditions and infections occurring at age ≥65. **Results:** A total of 202 second primary melanomas occurred during 248,917 person-years, including 91 after chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) and 111 after other NHL subtypes. Melanoma risk after CLL/SLL was significantly increased among patients who received fludarabine- and rituximab-containing chemotherapy (hazard ratio [HR]=2.99, 95% confidence interval [CI]=1.68-5.33, versus no chemotherapy), whereas risk was not evident for rituximab-containing therapy without fludarabine. Among non-CLL/SLL patients, melanoma risk was significantly elevated for patients receiving cyclophosphamide-containing chemotherapy without rituximab (HR=2.15, 95%CI=1.26-3.65) or rituximab and cyclophosphamide-containing chemotherapy (HR=1.66, 95%CI=1.00-2.75). Occurrence of autoimmune diseases after NHL diagnosis was associated with increased risk of melanoma (B-cell activating diseases: HR=1.43, 95% CI=1.02-2.01; T-cell activating diseases: HR=1.39, 95%CI=0.94-2.04), with particularly elevated risks for asthma occurring after CLL/SLL (HR=2.11, 95%CI=1.09-4.08). In contrast, localized scleroderma was associated with increased melanoma risk both prior to (HR=1.47, 95% CI=1.00-2.16) and after NHL (HR=1.44, 95%CI=0.87-2.39). Similarly, urinary tract infection was associated with increased melanoma risk prior to (HR=1.39, 95%CI=0.99-1.94) and after NHL (HR=1.59, 95%CI=1.05-2.41), but no significant associations were observed for other infections. **Conclusions:** These findings support a role for immune perturbation in the development of melanoma after NHL.

**1534 Poster Highlights Session (Board #23), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Risk of death from cardiovascular disease in long-term breast cancer survivors: A comparison with women from the general population.** *Presenting Author: Milada Cvancarova, Oslo University Hospital Radiumhospitalet, Oslo, Norway*

**Background:** As a result of modern cancer treatment such as surgery, chemotherapy and radiation therapy there is a growing number of cancer survivors. However, it comes at a cost. Cardiovascular disease (CVD) after cancer treatment has gained growing attention in the medical community during the recent decades. Our aim was to compare CVD-related mortality in long term breast cancer (BC) survivors to that in the general population taking into account the competing risk of dying of cancer or other non-CVD causes. We aimed to study the effect of more recent radiotherapy techniques comparing left and right sided BC, and the effect of socioeconomic status measured as the level of income at the time of diagnosis on the risk for dying from CVD. Sosioeconomic status indicators such as low income have been associated with higher prevalence of CVD. **Methods:** In total, 18614 BC patients diagnosed from 1984 to 2002 who survived at least ten years after their cancer diagnosis were matched with 10 women randomly selected from the general population. Each BC case was matched on date of birth and the selected controls had to be alive and cancer free at the time of their case's diagnosis. Income at diagnosis was categorized as low, medium and high. The risk of dying of CVD-related cause was modeled using stratified Cox regression. Separate models were fitted for women irradiated on the left and right body side. **Results:** There was no statistically significant difference in risk of dying due to CVD-related causes between BC cases and their matched controls (HR=1.05, 95%CI[0.98 to 1.12]. However, left-sided irradiated BC survivors had increased risk of CVD-related death compared to their controls (HR=1.17, 95%CI [1.02 to 1.23]. There was no difference between right-sided irradiated cases and their controls (HR=0.99, 95%CI[0.90 to 1.08]. Income at diagnosis was not associated with CVD-related mortality. **Conclusions:** Recent radiotherapy techniques still imply increased CVD-related mortality among left-sided irradiated BC survivors. Therefore further reduction of cardiac radiation doses should be implemented, particularly in women with left sided breast cancer.

**1535 Poster Highlights Session (Board #24), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Cancer patients' preferences for return of somatic and germline whole-exome sequencing results: Data from the CANSEQ study.** *Presenting Author: Stacy W. Gray, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The introduction of whole-exome sequencing (WES) into routine cancer care presents novel challenges for patient education and informed consent. In light of the recent American College of Medical Genetics and Genomics recommendations for the return of actionable germline incidental findings, it is imperative to understand patients' preferences for the return of WES findings. **Methods:** Advanced lung and colorectal cancer patients were offered WES. Preferences for the return of somatic and germline findings were obtained at consent. Attitudes about genetic testing and genetic knowledge were elicited through a baseline survey. **Results:** We approached 97 patients for participation, of whom 92 (95%) enrolled. Eighty-six patients completed the survey (completion rate 93%); 49% lung, 58% female, mean age 65 (standard deviation (sd) 11.4), 79% white, 21% ≤ high school education, 22% ≥ advanced degree. The vast majority of patients wanted to learn about somatic and germline WES findings. Preferences for return of results were highest for somatic findings that can be used to select a clinical trial (97%) and for positive prognostic findings (99%). Most patients also wanted return of germline pharmacogenetic (cancer-related 99%; non-cancer related 94%), cancer risk (96%), and treatable non-cancer risk (96%) results. Preferences for the return of somatic results with negative prognostic implications (86%), results indicating germline risk for non-treatable, non-cancer conditions (85%), and carrier status (88%) were slightly lower. Patients had highly positive attitudes about genetic testing but relatively low genetic knowledge, answering a mean of 54% of items correctly on a 7-item scale (sd 24.7). **Conclusions:** Patients with advanced lung and colorectal cancer express strong preferences for the return of somatic and germline WES findings. Despite patients' positive attitudes about genetic testing, relatively low levels of genetic knowledge may present challenges to adequate informed consent and highlight the need for high-quality sequencing-related patient education.

**1536 Poster Highlights Session (Board #25), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Survival after second primary lung cancer following non-Hodgkin lymphoma: A U.S. population-based study.** *Presenting Author: LINA INAGAKI, Rollins School of Public Health, Emory University, Atlanta, GA*

**Background:** Cancer survivors are known to have a higher risk of developing second primary cancer (SPC). While Hodgkin lymphoma attracts more attention, non-Hodgkin lymphoma (NHL) survivors account for a larger population of those who develop SPC, and lung cancer accounts for the largest risk of SPC among NHL-survivors. Although a follow-up care plan for cancer survivors has been recommended, concrete guidelines for screening for SPC have not been established. **Methods:** Study patients were identified from the SEER program from 1990 through 2009. A total of 863 NHL survivors who developed second primary lung cancer and 3,452 patients among 232,202 first primary lung cancer patients without a history of malignancy were randomly sampled and included in the analysis. The overall survival (OS) between the two groups were compared using a Log-rank test, followed by subset analysis for estimated survival among patients with localized stage lung cancer, in which OS was significantly different, using Cox proportional hazard regression, controlling for sex, race, year of diagnosis, age at diagnosis, histology, tumor grade and marital status. **Results:** NHL survivors experienced significantly inferior survival after lung cancer compared to patients without a history of malignancy at localized stage disease: 5-year OS was 33.0% vs. 44.8% ($p < 0.001$), whereas the survival did not differ significantly for regional stage: 13.9% vs. 19.2% ($p = 0.38$), and distant stage: 0% vs. 2.9% ($p = 0.10$). The subset analysis for patients with localized stage showed that the adjusted Hazard Ratio for death among NHL survivors was 1.38 (95% CI, 1.10-1.73; $p = 0.005$). **Conclusions:** NHL survivors were shown to have inferior survival when diagnosed with localized stage lung cancer compared to the general population. Because NHL survivors may not benefit from screening, the promotion of lung cancer screening to reduce mortality among NHL survivors warrants careful assessment.

**1537 General Poster Session (Board #319), Sun, 8:00 AM-11:45 AM**

**Genetic variant in the microRNA binding site of *DOK3* (rs2279398G>A) and susceptibility to colorectal cancer.** *Presenting Author: Jong Gwang Kim, Kyungpook National University Hospital, Daegu, South Korea*

**Background:** Single nucleotide polymorphisms (SNPs) located in the 3'-UTR of miRNA target genes could affect miRNA-mediated gene regulation, thereby contributing to the susceptibility or prognosis of colorectal cancer. Docking protein 3 (DOK3) is adapter protein that acts as tumor suppressor through modulating RAS signaling pathway. The present study analyzed SNPs located at putative miRNA-binding sites of the 3'-UTR of various genes and investigated their impact on the susceptibility of colorectal cancer. **Methods:** One hundred thirty five SNPs were selected in Silicoanalysis for the current study from 3'UTR SNPs of SNP database, which was based on several miRNA database, calculating miRNA bind efficiency on polymorphism, and HapMap database. Here independent two set of study was designed, 380 healthy controls and 371 colorectal adenocarcinoma patients were enrolled in discovery set, and 524 healthy controls and 521 colorectal adenocarcinoma patients were enrolled in replication set. The SNP genotyping was performed using the Sequenom MassARRAY. **Results:** In discovery set, 16 SNPs were significantly associated with the risk of colorectal cancer in any genetic model from 135 SNP genotyping. Among 16 SNPs, *DOK3* rs2279398G>A was significantly associated in replication set as recessive model (adjusted odds ratio (OR) = 0.65, 95% confidence interval (CI) = 0.44-0.97, $P = 0.03$). In combined analysis, *DOK3* rs2279398G>A was associated with significantly decreased risk of colorectal cancer in codominant and recessive model (adjusted OR = 0.84, 95% CI = 0.73-0.96, P = 0.012, adjusted OR = 0.65, CI = 0.49-0.88, P= 0.004, respectively). **Conclusions:** *DOK3* rs2279398G>A may affect the expression of *DOK3* by altering miRNA binding efficiency on miRNA-binding sites of the 3'-UTR of *DOK3* and impact on colorectal cancer tumorigenesis. This finding suggests that *DOK3* rs2279398G>A may be a useful biomarker for determining the susceptibility to colorectal cancer.

**1538 General Poster Session (Board #320), Sun, 8:00 AM-11:45 AM**

**Analysis of somatic copy number alterations in pediatric solid tumors using array comparative genomic hybridization.** *Presenting Author: Alanna Church, Boston Children's Hospital, Boston, MA*

**Background:** Somatic structural changes in tumor genomes are known to be significant in the diagnosis, prognosis, and therapy of pediatric solid tumors. Translocations, focal deletions and amplifications, whole arm and whole chromosome gains and losses are routinely assayed by karyotype and FISH at the time of diagnosis. Array comparative genomic hybridization (aCGH) is another technique to interrogate somatic copy number alterations (SCNAs). aCGH has the advantage of being compatible with formalin-fixed, paraffin-embedded (FFPE) tissue, and offers higher resolution for SCNAs than other techniques. Here we investigate the clinical utility of copy number assessment in pediatric solid tumors. **Methods:** Patients were enrolled on a multi-institutional translational research study, designed to test the feasibility of using somatic genetic analysis to guide the therapy of advanced pediatric solid tumors. For each patient with adequate available material, tumor tissue was analyzed for both sequence variants and SCNAs. This analysis focuses on copy number changes at 38 pre-selected oncology-related genes. aCGH results were reviewed by an expert panel of oncologists and molecular pathologists. **Results:** Of the 100 patients enrolled, 32 cases have been analyzed by aCGH: 3 carcinomas, 16 sarcomas, 7 embryonal tumors, 4 undifferentiated malignancies, and 2 others. 26 cases (81%) had SCNAs reported, of which 6 cases had focal (<1Mb) changes, and 20 had only large-scale changes. Focal changes included MYC, MYCN, SMARB1 (INI1), CDKN2A, and ERBB2 (Her2). In addition it was occasionally possible to visualize chromosomal translocations, such as EWSR1 rearrangements, with this methodology. 9/32 (28%) of cases had findings with diagnostic, prognostic or therapeutic significance. **Conclusions:** Copy number assessment of pediatric solid tumors by aCGH on FFPE tissue is feasible and reveals clinically relevant findings in a significant number of cases.

**1539 General Poster Session (Board #321), Sun, 8:00 AM-11:45 AM**

**Argentinean Jewish population frequencies for common mutations in BRCA1, BRCA2, and CHEK2.** *Presenting Author: Paola Jablonski, Centro Nacional de Genética Médica, ANLIS, Ministerio de Salud de la Nación, Buenos Aires, Argentina*

**Background:** Specific founder mutations 187_188delAG; 5385_5386insC and A1708E in BRCA1 and 6174delT and IVS2+1G>A in BRCA2 have been reported in Jews of Israel and United States. Moderate penetrance alleles 1100 delC, p.I157T and c.IVS2 +1G>A in CHEK2 gene explain part of non-BRCA aggregation of breast cancer (BC) in this ethnic group. The Jewish population of Argentina is the largest in Latin America and the third in the American continent and their genetic epidemiology is unknown. The aim of this study was to screening for these alleles in an Argentinean series of Jewish high risk families for BC/ovarian cancer (OC). **Methods:** A total of 183 DNA samples were genotype by sequencing for BRCA1/2 mutations and by PCR-RFLP for CHEK2 variants. **Results:** Among 135 unrelated proband cases, 67% were only BC, 4% BC and OC, 6% BC and other cancer; 8% OC, 2% Melanoma, 2% other cancer and 11% asymptomatic individuals. Overall, 20% were mutation carriers, 65,4% in BRCA1, 11/187_188delAG, 6/5385_5386insC and 34,6% in BRCA2, 9/6174delT. One patient was double heterozygous for 187_188delAG-6174delT. Five of the seven OC were in 187_188delAG probands. All the 5385_5386insC carriers with BC were bilateral or associated with other cancer. The 5385_5386insC mutation was found in carriers in whom the diagnoses of BC/OC were made at an earlier age. Seven intronic BRCA1/BRCA2 variants including two previously unreported IVS1-106 A>G in BRCA1 and IVS1-36 C>T in BRCA2 and the missense variant c.6100 C>T in BRCA2 were observed. Bioinformatics predictions suggested that the non coding variants could be polymorphisms and the missense mutation could modify the structure of the BRCA2 protein and their function. The BRCA1/BRCA2 A1708E and c.67+1G>A mutations and the CHEK2 variants were not found in this series. **Conclusions:** This study demonstrates that 187_188delAG; 5385_5386insC and 6174delT mutations were seen in a significant proportion of Argentinean Ashkenazim high risk families of undergoing genetic testing for BC/OC. The two founder mutations A1708E and c.67+1G>A in Jews of Sephardic origin and the three of most predisposing variants of *CHEK2* did not have major contribution in our population.

**1540 General Poster Session (Board #322), Sun, 8:00 AM-11:45 AM**

**Using next-generation sequencing (NGS) to identify causative mutations in Asian cancer (CA) patients with suspected Lynch syndrome.** *Presenting Author: Samuel Guan Wei Ow, Department of Haematology-Oncology, National University Cancer Institute, Singapore, National University Health System, Singapore, Singapore*

**Background:** Although at least 6 known genes are implicated in the causation of Lynch Syndrome (LS), up to 50% of suspected cases are due to undefined genes. We utilised NGS to characterize the mutation profile of high risk CA patients suspected with LS. **Methods:** We enrolled 96 Asian CA patients from our CA Genetics Clinic from 2000 to 2012 with family history (FH) suspicious for LS, and obtained germline DNA for targeted sequencing of 94 CA-predisposition genes using TruSight Cancer (Illumina Inc, San Diego, USA) on the MiSeq platform. Polymorphisms at >1% frequency were removed using 1000 Genomes (Asian) and the remaining non-synonymous variants were classified with reference from InSiGHT database. **Results:** Of the 96 index patients, 81.3% were Chinese, median age at CA diagnosis was 45.5 (range 18-82), 85.4% and 8.3% each had colon CA (CRC) and a LS-like CA. 5/96 patients had FH that fulfilled Amsterdam I/II Criteria (AC), 38 had FH of CRC and at least 1 first degree relative (FDR) with LS-like CA, 28 had CRC with histopathological features suggestive of LS, 30 had young-onset CA <50y (26 CRC, 4 LS-like CA), and 4 had more than 1 primary LS-related CA. 24 cases (not fulfilling AC) have been sequenced to date with a minimum depth of 400X. Among classical LS-related genes, 2/24 patients were found with deleterious mutations in *MSH2* (nonsense mutation at *1255C*>T; splicing mutation at *942G>A*), 2/24 with insertion mutation in *MSH6* resulting in frameshift (*4065_4066insTTGA*) and 1/24 had a possibly deleterious missense mutation in *MLH1* (*1058C>T*). In addition, 18 nonsense mutations were found in the coding regions of *AIP*, *BRIP1*, *BMPR1A*, *CEP57, CHRNA3, ERCC2*, *FANCD2*, *FANCM*, *GATA4*, *GPC3*, *MLPH*, *NSD1, PTCH1, TIMM10B* and *XPC* which warrant further investigations. 15 novel variants in the classical LS-related genes were detected (2 *MLH1*, 6 *MSH2*, 2 *MSH6*, 1 *PMS1*, 1 *PMS2*, 3 *EPCAM*) of which *EPCAM 344T>A* and *515C>A* occurred in 21 and 6 index patients respectively. **Conclusions:** Genetic variants unique to Asian high risk CA patients have been revealed in this study. NGS is a feasible and cost-efficient way to screen for causative mutations in a spectrum of genes in CA patients suspected to have a hereditary predisposition.

**1541 General Poster Session (Board #323), Sun, 8:00 AM-11:45 AM**

**Evaluation of breast cancer incidence in Lynch syndrome patients by MMR gene.** *Presenting Author: Jamie Willmott, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

**Background:** The current literature is divided as to whether or not breast cancer (BC) is a feature of Lynch syndrome (LS). The aim of this analysis was to investigate the prevalence of BC in patients with mutations in the individual mismatch repair (MMR) genes that cause LS. **Methods:** A retrospective review of patients' personal and family history of cancer was performed on patients with LS-causing mutations. All patients that underwent full sequencing and/or large rearrangement testing for mutations in *MLH1*, *MSH2*, *MSH6*, *PMS2* or *EPCAM* at Myriad Genetic Laboratories between September 2006 and October 2013 were included. Patients were excluded if they only had single site testing for a known LS mutation or if they were known to have a mutation in *BRCA1* or *BRCA2*. A Pearson chi-square test was performed to determine if the prevalence of breast cancer was significantly different among individual MMR genes. Exact confidence limits for binomial proportions were then computed. **Results:** A total of 5,638 patients with a LS-causing gene mutation were identified and the proportion of patients with BC was calculated for each gene. A chi-square test shows that at least one of these proportions is statistically significantly different from the others (p=0.007). The percentages (with 95% confidence intervals (CI)) of patients with BC by gene are 5.9% (4.6% - 7.5%) for *MSH6*, 4.0% (2.2 % - 6.8%) for *PMS2*, 3.7% (3.0% - 4.5%) for *MSH2*, 3.2% (2.5% - 4.1%) for *MLH1*, and 1.8% (0.05% - 9.7%) for *EPCAM*. **Conclusions:** The confidence interval for the proportion of *MSH6* carriers with BC does not overlap with those for *MLH1* and *MSH2*. Our results suggest that a personal history of BC is more prevalent in *MSH6* mutation carriers than in LS patients with mutations in other MMR genes. This may explain some of the confusion surrounding the inclusion of BC as a Lynch syndrome-associated cancer. Rather than taking an approach of accepting or rejecting that BC is associated with LS as a whole, it may be more appropriate to define BC risks by specific MMR gene or a broader panel of genes.

| | *MLH1* N=1857 | *MSH2* n=2372 | *MSH6* n=1032 | *PMS2* n=322 | *EPCAM* n=55 |
|---|---|---|---|---|---|
| Personal history of breast cancer - n (%) [95% CI] | 60 (3.2%) [2.5% - 4.1%] | 87 (3.7%) [3.0% - 4.5%] | 61 (5.9%) [4.6% - 7.5%] | 13 (4.0%) [2.2% - 6.8%] | 1 (1.8%) [0.05% - 9.7%] |

**1542 General Poster Session (Board #324), Sun, 8:00 AM-11:45 AM**

**Analysis of patients with two hereditary cancers (breast/ovarian or colon/endometrial) who met NCCN genetic testing criteria after their first cancer.** *Presenting Author: Jennifer Saam, Myriad Genetic Laboratories, Inc., Salt Lake City, UT*

**Background:** Patients with Hereditary Breast and Ovarian cancer (HBOC) or Lynch syndrome (LS) hereditary cancer syndromes are at a greater risk for developing second cancers after an initial cancer diagnosis. The identification of these patients after the first cancer can lead to the prevention or early identification of second cancers. **Methods:** We surveyed a commercial laboratory database for *BRCA1* and *BRCA2* mutations detected among patients with both breast and ovarian cancer tested from Sept. 2006-Oct. 2013. We also reviewed the database for the presence of LS mutations among patients diagnosed with both colon and endometrial cancers who received testing from May 2008-Oct. 2013. We evaluated the prevalence of mutations based on age of diagnosis of the first cancer and examined patient personal cancer history to determine what percentage of the positive patients would have met NCCN guidelines based on the diagnosis of their first cancer (defined as ovarian cancer at any age, breast cancer at age of 45 or less for HBOC, and endometrial or colon cancer less than age 50 for LS). Personal and family history was provided by the health care provider on the test order form. **Results:** For patients diagnosed with both breast and ovarian cancer (N=9982), the prevalence rate of *BRCA1* and *BRCA2* mutations was 22.4% (peak mutation rate of 35.8% for patients in their 30s). Of *BRCA1* and *BRCA2* mutation carriers, 56.0% met criteria for genetic testing after their first cancer—20.5% diagnosed with ovarian cancer first and 35.5% with breast cancer at or under age 45 as their first cancer. Patients diagnosed with colon and endometrial cancer (N=941) had mutations in the LS genes at a prevalence rate of 28.1% (peak mutation rate of 46.7% for patients in their 40s). Of mutation carriers, 65.2% met guidelines for LS testing after the first cancer, 30.7% with colon cancer at age 49 or younger and 34.5% with endometrial cancer younger than age 50. **Conclusions:** This review of commercial testing data for hereditary cancer syndromes shows the importance of diagnosing patients with hereditary cancer syndromes after their first cancer so a second cancer can be prevented or detected early with improved screening.

**1543 General Poster Session (Board #325), Sun, 8:00 AM-11:45 AM**

**Predictors of weight gain in breast cancer survivors.** *Presenting Author: Iram T. Azam, Northwestern University, Chicago, IL*

**Background:** Obesity and weight gain are important risk factors in the development of breast cancer. Weight gain in breast cancer patients is associated with a decreased response to adjuvant chemotherapy, increased cancer recurrence, and worse overall prognosis. Recent genomic studies indicate specific single nucleotide polymorphisms (SNPs) of the fat mass and obesity-associated gene (*FTO*) are associated with obesity and breast cancer risk. Little is known about factors contributing to weight gain in breast cancer patients receiving different treatment regimens. **Methods:** We performed a prospective cohort study of 120 women recruited from Northwestern University, Robert H. Lurie Cancer Center. Measurements of body mass index, nutritional status, and exercise levels were obtained at baseline and 6 month increments over a 24-month period. Chart review was conducted to obtain demographics, tumor characteristics (ER/PR/HER2 status, tumor size, stage, lymph node metastases), and treatment regimens. Blood samples were genotyped for 4 single nucleotide polymorphisms in *FTO*. **Results:** The percentage of patients gaining weight after diagnosis was 45.3% and 60.9% at the 12 and 24 month follow up, respectively. Chemotherapy and endocrine therapy were not associated with weight gain, even after controlling for age, race, baseline BMI, nutritional status, and exercise levels. PR+ patients were more likely to gain weight (p=0.02). FTO SNPs rs9939609 (A/T) and rs1477196 (A/G) were associated with weight gain. **Conclusions:** The majority of women with breast cancer gained weight after diagnosis, and this was most frequently observed in women with PR+ status and 2 of the identified FTO SNPs. Future studies should explore if the risk for weight gain associated with these factors may be attenuated by specific lifestyle interventions and treatment regimens.

**1545 General Poster Session (Board #327), Sun, 8:00 AM-11:45 AM**

**Effect of reproductive factors and lifestyle on the onset of breast cancer in female BRCA 1 and 2 mutation carriers.** *Presenting Author: Christian F. Singer, Medical University of Vienna, General Hospital, Vienna, Austria*

**Background:** We have recently demonstrated that the onset of breast cancer (BC) in BRCA 1 and 2 mutation carriers is influenced by their birth year, thus indicating a risk-modifying role for reproductive and life style factors. We now examined possible associations between potential risk factors, birth cohorts, and the onset of BC in BRCA1 and 2 mutation carriers. **Methods:** 130 female BRCA1 and 67 BRCA2 mutation carriers who had been identified at the Vienna University Hospital between 1995 and 2013, and who had developed BC were included in the analysis. Individual reproductive and life style factors were identified by questionnaires. Cox regression analysis and log-Rank testing were used to estimate the effect of potential risk factors on the onset of BC. **Results:** BRCA mutation carriers who had never been pregnant developed BC at a younger age than those who had been pregnant at least once (36.4 vs 40.9; p=0.001). Similarly, women who had used oral contraceptives, or had smoked, developed BC earlier than never users (39.3 vs. 44.9 years; p=0,0001, and 39.0 vs. 41.4 years; p=0,05, respectively). In Multivariate analysis oral contraceptive use (HR:1.7; p=0.006), and date of birth ≥1965 (HR:4.5; p=0.001) were associated with an earlier BC-onset. Conversely, the more full-term pregnancies a woman had experienced, the longer her BC-onset was delayed (HR:0.2; p=0.04). Mutation carriers born ≥1965 developed BC at a median age of 42 years whereas the median age at diagnosis for women born <1965 was 58 years (p<0.0001 log Rank test). These women were also more likely to have experienced multiple pregnancies and to have breastfed, but were less likely to have used oral contraceptives or to have smoked. **Conclusions:** We here demonstrate that in BRCA1 and 2 mutation carriers the birth-cohort-associated differences in the onset of BC are profound and largely influenced by reproductive factors such as the number of pregnancies and the use of oral contraceptives.

**1546 General Poster Session (Board #328), Sun, 8:00 AM-11:45 AM**

**How are young women 18-24 counseled on hereditary breast and ovarian cancer (HBOC) testing?** *Presenting Author: Amy Abramowitz, Feinberg School of Medicine, Northwestern University, Chicago, IL*

**Background:** Women often learn about their HBOC risk before the age of 25 (Bradbury 2009), and women 18-24 are often interested in genetic testing (Werner-Lin 2012). While guidelines do not preclude this, they do not provide specific guidance on genetic counseling or testing for women 18-24 (18-24s). We aim to identify how genetic counselors (GCs) counsel these women, what challenges they experience, and how these challenges may be addressed. **Methods:** IRB approved interviews with GCs at NCCN centers. The framework approach of qualitative research and simple frequencies were used for analyses. **Results:** Phone interviews were conducted with GCs from 11 NCCN centers. Although 73% of GCs use age and life stage considerations in counseling, only 45% routinely recommend testing for 18-24s. Those who test 18-24s routinely, cite the following reasons: studies show these women handle testing with maturity; women need genetic information for family / health planning; some 18-24s are diagnosed with cancer; and women consider recommendation to wait until 25 paternalistic. GCs who do not routinely recommend testing to 18-24s (55%) cite these barriers: lack of screening guidelines for 18-24s beyond self-exams; concern that families coerce 18-24s into testing; and perceived lack of understanding of available options by 18-24s. However, 80% of those who do not routinely test 18-24s, may do so on exception: very young HBOC family history, patient requests testing multiple times and demonstrates understanding of implications, or a woman needs the information for family planning. GCs provided recommendations for improving the genetic services for 18-24s: formal training and standardized approach to counseling (55%), frequent and long term follow-up using a "medical home" model (45%), involvement of psychosocial and fertility specialists (27%), and access to 18-24 peer support (27%). **Conclusions:** Lack of guidelines on genetic counseling and testing of women 18-24 result in variability of HBOC counseling and testing practices and potentially sub-optimal care for these women. Counselors and patients would benefit from formalized guidelines and training on genetic assessment for women 18-24.

**1547 General Poster Session (Board #329), Sun, 8:00 AM-11:45 AM**

**The landscape of precision medicine cancer clinical trials in the United States.** *Presenting Author: Nitin Roper, New York Presbyterian Hospital-Cornell & Hospital for Special Surgery, New York, NY*

**Background:** Advances in tumor biology and high throughput genomic analysis have ushered in the era of precision cancer medicine. Little is currently known, however, about the landscape of prospective "precision medicine" cancer clinical trials in the U.S. **Methods:** We identified all adult interventional cancer trials registered on clinicaltrials.gov between September 2005 and May 2013. Trials were classified as "precision medicine" if testing for a specific genomic or protein alteration in tumor tissue was required for enrollment. Characteristics such as type of genomic/proteomic alteration tested, masking, phase, sponsor, accrual and cancer subtype were ascertained for each trial. **Results:** Of the initial 18,797 trials identified, 9,094 (48%) were eligible for inclusion. 905 (10%) were classified as precision medicine trials and 8,189 (90%) were non-precision medicine trials. Compared with non-precision medicine trials, precision medicine trials were more likely to be phase II (OR 1.44 (1.25-1.65), p<0.0001) or phase III (OR 1.27 (1.01-1.60), p=0.0419), randomized (OR 1.19 (1.02-1.38), p=0.0270), sponsored by industry (OR 1.37 (1.19-1.58), p<0.0001), and multi-center (OR 1.63 (1.41-1.88), p<0.0001). The percentage of precision medicine trials compared to the total number of trials increased from 5% in 2006 to 17% in 2013. Precision medicine trials required testing for 33 unique genomic/proteomic aberrations for enrollment. The most common cancer subtypes were breast (40%), skin (15%), lung (9%), and hematologic (6%). **Conclusions:** The proportion of adult cancer clinical trials in the U.S. requiring the presence of a specific genomic/proteomic tumor aberration for enrollment has increased substantially over the past several years. However, such trials still represent a small minority of studies performed within the cancer clinical trials enterprise.

**1548 General Poster Session (Board #330), Sun, 8:00 AM-11:45 AM**

**The clinical experience: Hereditary cancer testing by a 25-gene panel.** *Presenting Author: Elias Obeid, Fox Chase Cancer Center, Philadelphia, PA*

**Background:** Prior to next generation sequencing (NGS) technology, genetic testing for hereditary cancer risk was gene and syndrome-specific. Fox Chase Cancer Center began offering patients a 25-gene panel, utilizing NGS, through a commercial early access clinical program in September of 2013. This panel includes *BRCA1/2* and other high/moderate risk genes for breast, colon, and other cancers. The utilization of this panel test compared to syndrome-specific testing has not been assessed in a clinical setting. Here we describe our clinical experience with this new testing option. **Methods:** Patients were offered a choice between syndrome-specific testing and a 25-gene panel from Myriad Genetics Laboratories. Of 152 tests ordered from September 4, 2013 to January 24, 2014, results were available for 144 patients. All tested patients met NCCN criteria for genetic testing or were deemed appropriate for testing after assessment by a certified genetic counselor. **Results:** Of 144 test results available, 87 had 25-gene panel testing, 26 had syndrome-specific testing for *BRCA1/2*, and 31 had targeted testing (Ashkenazi panel, single site, or deletion/duplication analysis). In the *BRCA1/2* test group, a deleterious mutation was seen in 3/26. Of note, 12/26 patients declined the 25-gene panel. From 87 patients in the 25-gene panel, 8 had clinically positive results for a deleterious gene mutation of which 3 (3/8, 37.5%) were unanticipated test results that influenced clinical management (mutations in *ATM*, *APC*, and *RAD51D*). All 8 individuals were affected with cancer. We found a high rate of variants of unknown significance (VUS) (29/87, 33.3%), as well as a high rate of monoallelic deleterious mutations in *MYH* (5/87, 5.7%). **Conclusions:** Multigene panel testing is now available for patients seeking genetic identification of an inherited predisposition to cancer. Our experience indicates that such a multigene panel may yield results that would not otherwise be discovered through syndrome-specific testing, and may provide additional clinical guidance. However, results can have uncertain clinical impact given the high VUS rate as well as other findings, such as monoallelic *MYH*, for which there is no clear medical management at the present time.

**1549 General Poster Session (Board #331), Sun, 8:00 AM-11:45 AM**

**Implications of following the guidelines for genetic testing and MRI use for breast cancer.** *Presenting Author: Fernanda C. G. Polubriaginof, Massachusetts General Hospital, Boston, MA*

**Background:** Evidence-based medicine is based upon the use of established guidelines and algorithms to increase the quality and decrease the cost of medical care. Genetic testing for breast cancer gene mutations is offered to women who have a risk ≥ 10% of carrying a mutation or that meet the NCCN Guidelines. Screening with breast magnetic resonance imaging (MRI) is recommended for women who have a lifetime risk ≥ 20% of developing breast cancer. Our purpose is to evaluate the impact of using guideline based care for these medical issues. **Methods:** With institutional review board approval, we performed a retrospective analysis of data obtained from consecutive women who presented for breast imaging to the Newton Wellesley Hospital Breast Imaging Center from September 3, 2013 to December 31, 2013. Demographic characteristics and breast cancer risk factors were entered into software to evaluate risk (HughesRiskApps) for BRCA mutation, for genetic testing eligibility, for lifetime risk of breast cancer and for MRI eligibility. Risk of mutation was evaluated by Tyrer Cuzick Versions 6 and 7, BRCAPRO and the Myriad Model. Genetic testing eligibility was determined by risk of mutation ≥ 10% or by meeting the NCCN Guidelines. Lifetime risk of breast cancer was evaluated by Tyrer Cuzick Versions 6 and 7, BRCAPRO and Claus. Eligibility for MRI was determined by a lifetime risk ≥ 20% (Per ACS and NCCN Guidelines). **Results:** A total of 10,604, were evaluated, of whom 9,976 (94.08%) had no personal history of breast cancer and 628 (5.92%) had a personal history of breast cancer. See Table. **Conclusions:** Following the guidelines for BRCA testing and for MRI screening will result in a large number of women undergoing these services. It would be useful to evaluate whether following these guidelines does increase quality and decrease the cost of care.

| Genetic testing eligibility | No. of patients (%) |
|---|---|
| **Without breast cancer (n=9,976)** | |
| **Risk of mutation ≥ 10%** | 346 (3.50%) |

**Genetic anticipation in *BRCA1/2* families after controlling for ascertainment bias and cohort effect.** *Presenting Author: Rodrigo Santa Cruz Guindalini, Instituto do Câncer do Estado de São Paulo, Universidade de São Paulo, São Paulo, Brazil*

**Background:** Although genetic anticipation has been reported in hereditary breast and ovarian cancer syndrome (HBOCS), little is understood about the underlying genetic and molecular mechanisms for *BRCA1/2* families. Two previously unaddressed biases affecting the accuracy of previous studies are ascertainment bias and cohort effect. **Methods:** We retrospectively reviewed 178 pedigrees of *BRCA1/2* families who had at least two consecutive generations of the same cancer (breast or ovarian) in our Cancer Risk Clinic registry. Using paired t-test and BRCAPRO scores as analytical weights in a parametric anticipation model, the calculation of generational differences in breast/ovarian cancer age of onset was performed. This model was then modified to control for ascertainment bias by excluding probands. Multilevel linear regression using breast cancer age of onset, birth year cohort, and generation was applied to study potential cohort effect. **Results:** Earlier onset of breast cancer and ovarian cancer in successive generations was found (Table). After controlling for ascertainment bias, statistically significant anticipation phenomenonpersisted only for breast cancer. In the cohort effect analysis, generational differences in age of breast cancer onset were not significant but earlier onset in later birth cohorts was significant. **Conclusions:** To our knowledge, this is the largest study that exclusively included families with deleterious *BRCA1/2* mutations, controlled for ascertainment bias, and used individual risks of having *BRCA1/2*mutations as analytical weights to address and report significant anticipation phenomenon in HBOCS. The observed anticipation effect is due to a decrease in age of onset in the cohort over time and not generational differences. Future studies are warranted to confirm these findings.

**Anticipation phenomenon in BRCA1/2 families.**

**Are immunohistochemical (IHC)/microsatellite instability (MSI) testing necessary as part of Lynch syndrome work-up in the era of multiplex genetic testing?** *Presenting Author: Ahmad Fitri Idris, Mater Misericordiae University Hospital, Dublin, Ireland*

**Background:** IHC for mismatch repair proteins and MSI are commonly used to direct genetic testing for Lynch Syndrome. Abnormal results in the setting of a positive family history often lead to genetic testing for Lynch syndrome. The often cumbersome process of completing IHC/MSI requires obtaining stored tissue +/- blood from a family member affected with cancer. Upfront genetic testing is not favoured due to concerns about identifying variants of uncertain significance. We performed a review of Lynch syndrome work-up in Ireland, and propose a model that is the reverse of the current international standard, and may expedite and simplify work up of these families. **Methods:** Data was ascertained from three cancer genetics services in Dublin and included the following variables: Date of birth, date of request and reporting results for IHC, MSI and genetic tests. Time intervals were determined for LS work-up for all patients who had the process initiated in these 3 centres. **Results:** Probands from 50 families referred for LS work-up were included.The median time from date of IHC request to date of IHC report (total of 50 patients) was 4 weeks (range: 4 days to 36 weeks). The median time between date of IHC request to date of MSI report (n = 32 patients) was 20 weeks (Range: 4 to 56 weeks). The median time from date of genetic test request to date of result (n = 9 patients) was 9 weeks (Range: 2 to 26 weeks). The median time for completion of all 3 tests in one individual (n=3 patients) was 14 weeks (Range: 10 to 60 weeks). **Conclusions:** The diagnostic pathway for Lynch syndrome is cumbersome and often lengthy. Appropriate upfront multiplex genetic testing would expedite the identification of mismatch repair gene mutation carriers. IHC/MSI testing could be used to characterise variants of uncertain significance.

**1552 General Poster Session (Board #334), Sun, 8:00 AM-11:45 AM**

**Impact of an interventional counseling procedure in BRCA families: Efficacy and safety.** *Presenting Author: Erica Sermijn, Familial Cancer Clinic and Medical Oncology, Brussels University Hospital, UZ Brussel, Brussels, Belgium*

**Background:** Predictive genetic testing has high impact on cancer prevention for BRCA carriers. Passing information in BRCA families on the availability of testing is important. In most countries this is mainly proband - mediated, but this path is defective, and denies relatives lifesaving information.This study assessed the safety/ efficacy of an intervention, aiming at actively informing relatives. **Methods:** Sequential prospective study in new BRCA families. First the proband told relatives about the hereditary trait/predictive testing (standard procedure; phase I). After 6 months a letter was sent to adult relatives, who had not been reached (study; phase II). The letter provided vital information, preserving the probands' anonymity. Contact info and an inquiry form probing the acceptability were provided. After the letter a phone call was made to obtain a final notion of their wishes. All subjects received a psychometric test (State - Trait Anxiety Inventory, STAI), an interview, and routine counseling. **Results:** Twenty families were included. Of 172 relatives at risk, 89 participated: 47 by the proband, 42 by the letter as the major trigger to seek counseling. Nearly all of these subjects (98 %) opted for predictive testing, of which 30 were mutation carriers. Subjects were satisfied with the intervention. Twenty-four of the eligible relatives could not be reached; 59 were 'decliners'. Reasons for not participating were: age, being male, having no child, prevention elsewhere, no interest. The intervention is psychologically safe: the 95 % CI for the estimated mean difference in STAI DY1 between phase II/I subjects, ( mean difference - 1.07, 95 % CI (-4.48;2.35), p=0.53), shows that the mean STAI DY1 score for phase II is at most 2.35 units higher than for phase I, which is not relevant. **Conclusions:** The practice of proband - based information tranfer in BRCA families is highly defective. A protocol in which relatives are directly informed by the counselor nearly doubles the number of relatives tested. This approach is psychologically safe and allows more carriers to adopt effective prevention. These results should lead to a change in counseling guidelines in families with a strong germline predisposition for cancer. Clinical trial information: 2005/087.

**1553 General Poster Session (Board #335), Sun, 8:00 AM-11:45 AM**

**Impact of 25-gene panel testing and integrated risk management tool on medical management in hereditary cancer syndrome evaluation.** *Presenting Author: Lucy R. Langer, Northwest Cancer Specialists, Portland, OR*

**Background:** The identification of patients (pts) with hereditary cancer syndromes such as Hereditary Breast and Ovarian Cancer (HBOC) or Lynch syndrome (LS) leads to profound clinical management changes. Using next generation sequencing, more comprehensive gene panels with greater sensitivity have been developed. However, most pts still receive a negative genetic test result. Integrating personal and family cancer history identified during the screening process with genetic test results can offer refined management recommendations. **Methods:** Patients identified using criteria for HBOC or LS were tested using a 25-gene hereditary cancer panel. Recommendations from testing incorporated the genetic test result and a personalized cancer risk and management tool (CRMT) based on a patient's personal and family history and professional guidelines. Health care providers (HCPs) were surveyed for their management advice to the patient for four cancers (breast, ovarian, endometrial and colon) before and after testing. Pre-test surveys were received from 1414 patients at the time of the data analysis. We report data from matched pre and post-test survey pairs for a preliminary 100 pts to be updated upon presentation. Interventions were ranked from least aggressive (surveillance) to most aggressive (surgery). **Results:** In this sample set, 48% of pts had a diagnosis of breast, ovarian, colorectal, endometrial, pancreas, melanoma, stomach and/or prostate cancer, 3% had a history of other cancers and 49% had no personal history of cancer. 65% of pts met NCCN guidelines for HBOC, 10% for LS and 18% met guidelines for both syndromes. Overall, HCPs used the genetic test result with the CRMT to guide their management decisions in 91% of cases. After testing, 25% of pts received a change in management recommendations, 60% of pts with a positive result and 23% of pts with a negative result. Of the management changes, 72% were in surveillance, 16% in chemoprevention, 20% in surgery and 28% other. **Conclusions:** Integrating expanded genetic panel test results with a personalized cancer risk and management tool aids HCPs in providing tailored cancer risk management in both gene positive and negative populations.

**1554 General Poster Session (Board #336), Sun, 8:00 AM-11:45 AM**

**Shortened telomere length to predict initiation of carcinogenesis in Lynch syndrome.** *Presenting Author: Grainne O'Kane, Mater Misericordiae University Hospital, Dublin, Ireland*

**Background:** Lynch Syndrome (LS) is an autosomal dominant cancer predisposition syndrome conferring a 60-80% lifetime risk of developing colorectal cancer in addition to a spectrum of other malignancies. This occurs as a consequence of germline mutations in DNA mismatch repair (MMR) genes. Significant phenotypic heterogeneity exists among LS families. Anticipation has also been reported but remains poorly understood. We investigated an association between age of tumour onset and telomere length in Irish LS families. **Methods:** Family pedigrees were reviewed and parent-child pairs (PCPs) with LS-associated malignancy identified. Patients with genetically confirmed LS were invited to participate in the study. Peripheral blood mononuclear cells were isolated from affected mutation carriers (AC) and unaffected mutation carriers (UAC). DNA was extracted and relative telomere length (RTL) measured by quantitative polymerase chain reaction. Pearson's correlation was used to compare age-adjusted RTL and age at tumour diagnosis. **Results:** Forty-four LS families were identified containing fifty-four PCPs with LS-associated malignancies. Anticipation was present in 90%; the median age of cancer diagnosis occurred 14.5 years earlier in mutation carriers (range 1-45 yrs). Telomere length has been analysed in fifty-one mutation carriers to date. (Table) As expected increasing age at blood withdrawal correlated with shorter telomere length ($p<0.05$). In AC the mean age-adjusted RTL was 1.281 and in UAC 0.980. In AC there was a strong correlation between earlier onset malignancy and shorter age-adjusted RTL ($p=0.004$). **Conclusions:** Anticipation is evident in Irish LS families and patients who develop earlier onset malignancy have shorter telomere lengths. We plan to validate our findings in a larger cohort and compare telomere length in an age and sex matched control cohort.

**Classification of somatic variants in solid tumors detected by next-generation sequencing (NGS) and the need for clinical guidelines.** *Presenting Author: Antonios Papanicolau-Sengos, University of Utah, Salt Lake City, UT*

**Background:** NGS approaches to clinical mutation testing reveal previously uncharacterized, or poorly characterized, somatic variants. A major challenge in reporting is categorization of these variants in the absence of formal guidelines. The process is subjective and the potential for variation between molecular pathologists is significant. **Methods:** To better characterize variation between molecular pathologists we retrospectively reviewed 95 clinical cases sequenced with the Ion Ampliseq Cancer Hotspot Panel v2 at ARUP Laboratories. We focused on variants that were reclassified upon re-review by three molecular pathologists. **Results:** Ninety eight mutations and 31 variants of unknown significance (VUS) were reported in 72 total tumors. There were seven reclassifications (5% of total classifications) in seven different tumors (3 urothelial carcinomas, 1 bladder adenocarcinoma, 1 melanoma, 1 lung carcinoma, and 1 unknown). Most of these were point mutations and involved *FGFR1* (x1), *FGFR3* (x1), *CTNNB1* (x1), *RB1* (x1) and *PIK3CA* (x3). Six of seven were reclassified from mutation to VUS based upon insufficient evidence of oncogenicity. **Conclusions:** Five of the reclassifications involved actionable genes (*FGFR1*, *FGFR3*, and *PIK3CA*). The original classification of these as "mutation" was primarily based on in vitro data. A "mutation" classification implies there is sufficient evidence for an oncogenic change that may be amenable to targeted therapy. In vitro biochemical and cell biologic assays are artificial systems which may not fully recapitulate in vivo tumor behavior. This study emphasizes the subjective nature of variant classification and the need for the development of weighted criteria devised by a multidisciplinary panel of experts. Until then, it is of utmost importance that molecular pathologists develop systematic methods to determine the quality of available data. We propose a simple checklist to optimize the way variants are classified. We suggest that medical oncologists critically scrutinize the classification of variants as they appear in clinical reports.

**1556 General Poster Session (Board #338), Sun, 8:00 AM-11:45 AM**

**The clinicopathologic significance of FOXC1 in *BRCA*-mutant breast cancer.** *Presenting Author: Michael Phillip Choi, Cedars-Sinai Medical Center, Los Angeles, CA*

**Background:** BRCA1 breast cancer (BC) has been associated with the basal molecular subtype and BRCA2 with the luminal subtype but the biological basis for this is unknown. The forkhead box C1 (FOXC1) transcription factor has been identified as a marker of sporadic basal-like BC which correlates with a poor prognosis. Furthermore, loss of BRCA1 function has been shown to increase FOXC1 expression in BC cell lines resulting in aggressive cellular behavior. We investigated the clinicopathologic associations of FOXC1 expression in BRCA1/2 mutant BC. **Methods:** Review of our institutional database identified 37 BRCA1 and 35 BRCA2 mutation carriers treated for BC from 1995 to 2013. Immunohistochemical (IHC) staining of paraffin-embedded tissue sections was performed using a monoclonal FOXC1 antibody against nuclear FOXC1 protein and evaluated by two independent, blinded pathologists. The association of FOXC1 expression with clinical and pathologic variables was analyzed. **Results:** FOXC1 expression was identified in 21/37 BRCA1 mutant BC and 6/35 BRCA2 mutant BC on IHC (Table 1). Univariate analysis showed FOXC1 expression to be associated with younger age, higher tumor grade, higher Ki67%, triple negative/basal molecular subtype, and a lower number of positive lymph nodes. FOXC1 expression correlated with increased locoregional recurrence rates ($p = 0.05$) however there was no significant difference in overall survival between FOXC1 positive and negative BC. **Conclusions:** FOXC1 expression is more commonly seen in BRCA1 mutant BC than in BRCA2 mutant BC and is associated with aggressive pathological tumor characteristics and a higher rate of locoregional recurrence.

**1557 General Poster Session (Board #339), Sun, 8:00 AM-11:45 AM**

**Familial clustering and predisposition to HPV-associated malignancy.** *Presenting Author: Judith Conroy, University College Dublin, Dublin, Ireland*

**Background:** Familial clustering of cervical cancer occurs, with a likely heritable component, but the genetic etiology of this disease is poorly understood. Human Papilloma Virus (HPV) is ubiquitous and HPV infection is common. The majority of infected individuals are asymptomatic. A minority of individuals fail to clear HPV infection and a subset of this cohort develop HPV-associated malignancy. We hypothesized the presence of an inherited predisposition to carcinogenesis following HPV infection in an Irish family with a striking number of HPV-related malignancies, and performed a linkage analysis to identify a susceptibility region. **Methods:** DNA was extracted from blood samples ascertained from an Irish family with multiple individuals affected by HPV-associated malignancies.Twenty-four samples were genotyped using the Illumina HumanCytoSNP-12 microarray (Illumina Inc., San Diego, California). Non-parametric linkage was performed in two phases. The first phase of analysis included only those individuals who had a clinical diagnosis of Cervical or head and neck cancer (n=5) and individuals with no cancer diagnosis, and no abnormal smear tests to date (n=2). The second phase of analysis included an additional 7 female patients who have had positive smear tests. **Results:** One early onset head and neck cancer, 4 cervical cancer, and 7 cases of cervical dysplasia occurred in this family. For phase 1 analysis, five loci with LOD scores >0.5 were identified on chromosomes 2p11.2-q13, 7q32.3-34, 11q23.3-25, 12p13.33-13.2 and 17q12-23.2 (LOD>0.5). Non-parametric linkage ruled out all but one of the Phase 1 linkage peaks. A single linkage peak of length was identified on chromosome 17q21.31-33 (6Mb, Z score > 2.3, LOD >1.13, p<0.01). **Conclusions:** We identified an association between 17q21.31-33 and HPV-associated malignancy in an Irish family with multiple affected individuals. Fine mapping of this region is underway and will be reported.

**1558 General Poster Session (Board #340), Sun, 8:00 AM-11:45 AM**

**Association of the *HOXB13 G84E* mutation with increased risk for prostate cancer and other malignancies.** *Presenting Author: Jennifer Beebe-Dimmer, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

**Background:** A rare non-conservative substitution (G84E) in the highly conserved MEIS-interacting domain of the homeobox transcription factor gene *HOXB13* has been shown to be associated with an increased risk of prostate cancer. The gene is involved in human embryonic development including the prostate gland, but its role in carcinogenesis is unknown. DNA samples from 9,012 male patients included in the Mayo Clinic Biobank (MCB) were genotyped to determine the frequency of the G84E mutation in this population and its association with various reported cancers. **Methods:** Subjects were genotyped using a custom TaqMan (Applied Biosystems) assay for G84E (rs138213197). In addition to donating a blood specimen, all MCB participants completed a baseline questionnaire to collect information on medical history, family history, and behavioral characteristics. The frequency of the allele was determined according to both self-report of invasive cancer diagnoses and report of cancer history among first-degree relatives. **Results:** Forty-nine of 9,012 male patients in the MCB were carriers of G84E (0.5%). Analyses were restricted to those patients with information on history of specific cancers based upon either self-report or electronic medical record. Thirty-one percent (n=2,595) of participants had been diagnosed with cancer, including 46.9% of G84E carriers compared to just 28.7% of non-carriers (p=0.006). G84E was most frequently observed among men with prostate cancer with a carrier frequency of 1.3% compared to 0.4% of men with no history of any invasive cancer (p<0.0001). However, the mutation was also more commonly observed in men with bladder cancer (p=0.06) and leukemia (p=0.01). G84E carriers were more likely to have a positive family history of prostate cancer in a first degree relative compared to non-carriers (43.6% v. 18.6%, p=0.0003). **Conclusions**: Our study confirms the association between the rare *HOXB13* G84E variant and prostate cancer. We have also shown novel associations between G84E and both bladder cancer and leukemia. Future investigation is warranted to confirm these associations in a larger data set in order to improve our understanding of the role of germline *HOXB13* mutations in human cancer.

**1559 General Poster Session (Board #341), Sun, 8:00 AM-11:45 AM**

**BRCAPRO 6.0 model validation in male patients presenting for *BRCA* testing.** *Presenting Author: Zahi Ibrahim Mitri, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Male breast cancer accounts for < 1% of male cancers. Patients carrying a BRCA mutation are at higher risk of developing breast, pancreatic and prostate cancers among others. BRCAPRO is a risk model used during counseling to estimate risk of being BRCA+. The purpose of this analysis is to evaluate the accuracy of BRCAPro 6.0 in estimating the risk of a man carrying a BRCA mutation. **Methods:** This IRB-approved retrospective chart review was of 147 male patients who presented to MD Anderson Cancer Center between 02/1997 and 09/ 2011 for genetic counseling and had BRCA testing performed. All patients had their BRCAPRO risk assessment calculated by using the BRCAPro 6.0 clinical cancer gene assessment software (http://www4.utsouthwestern.edu/breasthealth/cagene/). The statistical software SPSS 20.0 was used to obtain results including descriptive statistics, independent sample t-test and receiver operating curve (ROC). **Results:** The median age of the cohort was 59 years (18-87). Of the 147 patients, 53 (36%) tested positive and 94 (64%) tested negative for a BRCA mutation. Among those who tested positive, 22 patients had a positive BRCA1 mutation, 30 had a positive BRCA2 mutation, and one patient was positive for both BRCA1 and BRCA2 mutation. Of the 147 patients, 50 (36%) underwent predictive testing for a known family mutation. Median BRCAPro score for all patients was 12.16 (range: 0.02-100), 48.93 (range: 0.02-100) for patients who tested positive, and 5.96 (range: 0.05-51.16) in those who tested negative. Forty-five patients (31%) had breast cancer, 16 of which tested positive for a BRCA mutation. 37 patients (25%) had no cancer diagnosis, and 65 patients (44%) carried a different cancer diagnosis: pancreatic (26%) and prostate (12%) cancer were the most common. There were 23 patients (16%) with multiple cancer diagnosis. Independent samples Mann-Whitney test revealed a significant difference between positive and negative test results for BRCAPro 6.0 ($p<0.001$). The ROC curve had an AUC of 0.819 and a standard error of 0.038. **Conclusions:** Given the results of the analysis, BRCAPro 6.0 appears to be a good predictive test to determine BRCA carrier risk in male patients. These results should be further evaluated in a larger cohort.

**1560 General Poster Session (Board #342), Sun, 8:00 AM-11:45 AM**

**Women from certain BRCA1/2-mutation–negative hereditary breast ovarian cancer families and consideration of prophylactic saplingo-oophorectomy before menopause.** *Presenting Author: Rozumna-Martynyuk Nataliya, Mater Misericordiae University hospital, Dublin, Ireland*

**Background:** Prophylactic salpingo-oophorectomy (PSO) is recommended at 35-40 years for BRCA1 mutations carriers and 40-45 years for BRCA2 mutation carrier. The optimal timing of PSO is less certain for women from BRCA1/2 mutation negative hereditary breast ovarian cancer (HBOC) families. There is an increasing trend to defer this surgery until after menopause. We explored the safety of this approach if it were to be adopted in BRCA1/2 wild-type HBOC families. **Methods:** BRCA1/2 mutation negative families with at least one case of ovarian cancer were identified in an Irish cancer genetics clinic. Four generation family pedigrees were reviewed and clinical data recorded including cancer diagnosis, and age at diagnosis. **Results:** 680 women underwent BRCA1/2 diagnostic testing. Forty-four families with breast and ovarian cancer were BRCA1/2 mutation wild-type. 113 (age range: 28-77, median=47.9 years) of 936 women in these families developed breast cancer. There were 40 cases of ovarian cancer (age range: 27-79, median=53.9 years). Sixty-six percent of ovarian cancer occurred at </=60 years and 34% occurred at < /=50 years. Seven families had more than one case of ovarian cancer (OC)(table 1). In one family there were 7 cases. In 5 of these 7 families ovarian cancer was diagnosed at ages </= the average age of menopause (51 years). **Conclusions:** Pre-menopausal prophylactic salpingo-oophorectomy should be considered for women from BRCA1/2 mutation wild-type HBOC families.

**Biologic pathways, candidate genes, and molecular markers associated with quality-of-life domains.** *Presenting Author: Jeff A. Sloan, Mayo Clinic, Rochester, MN*

**Background:** There is now compelling evidence of a genetic foundation for patient-reported quality of life (QOL) domains. This work reports the results of a systematic review of thebiological pathways, candidate genes and molecular markers involved in fatigue, pain, negative (depressed mood) and positive (well-being/happiness) emotional functioning, social functioning, and overall QOL. **Methods:** We followed a purposeful search algorithm of existing literature to capture empirical papers investigating the relationship between biological pathways and molecular markers and the identified QOL domains. We conducted a computerized literature search on PubMed for the years November 2007- November 2012 to build on our previous work (Sprangers, QOLR, 2009). A gene or molecular marker was included if there is at least one publication (either empirical, meta-analysis or review) reporting a significant association with a QOL domain. **Results:** More than 200 articles were identified and reviewed. Multiple major biological pathways are involved in each QOL domain, summarized into a series of seven tables describing each biological pathway and candidate gene. The inflammatory pathway has the strongest evidence as a controlling mechanism underlying fatigue. Inflammation and neurotransmission are key processes involved in pain perception and the COMT gene is associated with multiple sorts of pain. The neurotransmitter and neuroplasticity theories have the strongest evidence for their relationship with depression. Oxytocin-related genes and genes involved in the serotonergic and dopaminergic pathways play a role in social functioning. Inflammatory pathways, via cytokines, also play an important role in overall QOL. In total, more than 50 candidate genes were identified as having previously published evidence of at least a preliminary relationship with patient-reported QOL-related domains. **Conclusions:** We have produced a set of candidate genes and biological pathways for researchers to use when embarking on studies relating candidate genes and/or molecular markers to QOL.

**1562 General Poster Session (Board #344), Sun, 8:00 AM-11:45 AM**

**Analysis of global gene expression in adrenocortical tumors from Li-Fraumeni syndrome *TP53* germline mutation carriers.** *Presenting Author: Fernanda Fortes, A. C. Camargo Cancer Center, São Paulo, Brazil*

**Background:** Li Fraumeni Syndrome (LFS) is a rare autosomal dominant hereditary cancer syndrome. In Brazil, a variant form of LFS is often due to a founder mutation p.R337H *TP53*. The occurrence of cancer in patients and the age of onset may vary even in patients who carry the same mutation. Patients with mutations in *TP53* gene may develop a broad spectrum of tumors, including adrenocortical carcinomas (ADR). The objective of this study was to evaluate the global gene expression profile of ADR in patients with and without p.R337H *TP53* mutation. **Methods:** Analysis of global gene expression was evaluated by microarray (4x44K, Agilent Technologies). **Results:** The presence of 135 differentially expressed genes between the ADR patients with and without p.R337H *TP53*mutation was detected. Genes which have increased expression and are related to a worse prognosis in adrenocortical carcinoma were identified with decreased expression in carriers of p.R337H mutation. **Conclusions:** This study suggests that a differential expression profile of transcripts in ADR p.R337H *TP53* germline mutation carriers may act as modifiers and exert a protective effect in Li-Fraumeni syndrome patients.

**1563 General Poster Session (Board #345), Sun, 8:00 AM-11:45 AM**

**Single nucleotide polymorphisms and smoking status for prediction of non-small cell lung cancer.** *Presenting Author: Junjie Wu, School of Life Sciences, Fudan University, and Changhai Hospital of Shanghai, Second Military Medical University, Shanghai, China*

**Background:** Lung cancer has become the leading cause of death in all cancer. The 5-year survival rate of lung cancer is less than 15%, but the 5-year survival rate of up to 87.7% after treatment of early stage lung cancer. Therefore, timely detecting early stage lung cancer is the key to influence survival rate. However, the current level of lung cancer diagnosis did not increase the rate of detection of lung cancer. The objective of the current study is to introduce genetic factors SNPs to build predictive models of lung cancer for improving the detection rate of early stage lung cancer. **Methods:** SNPs that were identified of associations to NSCLC in several recent studies were reassessed using a pooled sample size of 3,637 Chinese subjects, with 1,597 cases and 2,040 controls from these studies. Multivariate logistic regression models were used to predict NSCLC using SNPs, age, with or without sex, with or without smoking status as predictors. The performance of prediction was assessed using the area under the receiver operating characteristic (ROC) curve (AUC). **Results:** Overall, the AUC from a logistical regression model using all 6 SNPs plus smoking status and demographics as predictors was 0.63(95% CI: 0.61–0.65; P=1.6×10-38), higher than that of 0.60 (95% CI: 0.59–0.62; P=4.5×10-25) from a non-genetic model using smoking status and demographics. For female group and ever smoking group, the AUC from models only using 5 SNPs and 4 SNPs as predictors was 0.61(95% CI: 0.57–0.65;P=8.44×10-9) and 0.57 (95% CI: 0.55–0.60; P=1.53×10-7) respectively. For Adenosquamous group, the AUC from a model using 3 SNPs plus sex as predictors was 0.71(95% CI: 0.62–0.80; P=3.91×10-5), higher than that of 0.57 (95% CI: 0.48–0.66; P=0.157) from a non-genetic model using sex only. **Conclusions:** The combination of SNPs improved the performance of risk models for lung cancer. This study displays an significative role to integrate SNPs in predictive models for lung cancer risk. These findings show the importance of stratifying analysis by sex, smoking status and histology, to improve the performance of specific risk models for lung cancer.

**1564 General Poster Session (Board #346), Sun, 8:00 AM-11:45 AM**

**Contribution of extended family history in assessment of risk for breast and colon cancer.** *Presenting Author: Benjamin Lev Solomon, University of Vermont, Burlington, VT*

**Background:** Family history is important for identifying candidates for advanced screening and referral for cancer genetic counseling. We identified the percentage of individuals who would not receive recommended screening or referral if only a 1st degree family history was obtained. **Methods:** Family histories were obtained from 626 women getting mammography at the University of Vermont between 5/00-5/01 using a validated questionnaire. ACS guidelines were used to determine eligibility for advanced breast and colon cancer screening. Eligibility for referral for genetic counseling for hereditary breast and colon cancer was determined using FHS-7 and Amsterdam II screening criteria, respectively. **Results:** 499 histories were reviewed (127 histories were excluded due to incorrect completion, personal history of cancer or no family history of cancer). For high risk breast cancer screening, 8 individuals met guidelines using 1st degree family history with an additional 10 meeting criteria when family history was extended. For high risk colon cancer screening, 50 individuals met criteria using 1st degree family history with an additional 12 meeting criteria when the family history was extended. Using only 1st degree family history misses candidates for advanced screening: 55% for breast and 24% for colon cancer screening. 63 individuals met criteria for counseling for hereditary breast cancer using 1st degree family history with an additional 51 and 52 when 2nd and 3rd degree family history were included, respectively. Ten individuals met guidelines for referral for counseling for hereditary colon cancer using 1st degree family history with 21 additional meeting criteria when including 2nd degree family history. 62% of candidates for genetic counseling for hereditary breast cancer and 67% of candidates for hereditary colon cancer were missed when using only 1st degree family history. **Conclusions:** This is one of the first studies to demonstrate that 1st degree family history alone is not adequate for identification of all candidates for high risk screening and referral for genetic counseling for hereditary breast and colon cancer syndromes. Given our small sample, larger studies are required to confirm these findings.

**1565 General Poster Session (Board #347), Sun, 8:00 AM-11:45 AM**

**Cost-effectiveness of aromatase inhibitors versus selective estrogen-receptor modulators for breast cancer prevention in postmenopausal women.** *Presenting Author: Amy Grace Groom, Department of Medicine, Dalhousie University, Halifax, NS, Canada*

**Background:** The selective estrogen-receptor modulators (SERMs) tamoxifen (TAM) and raloxifene (RAL), and more recently the aromatase inhibitor (AI) exemestane (EXE) have all been shown to reduce the risk of breast cancer (BC) in post menopausal (PM) women at high risk. As significant differences in adverse effect profiles and costs exist amongst these agents, determining the preferred strategy for clinical use requires consideration of both the risk-benefit profile and overall cost-effectiveness (CE) of each strategy. Prior studies have examined the CE of SERMs in this setting but similar evaluations of AIs have not yet been performed. **Methods:** We examined the probabilities of various BC prevention strategies, including 1) SERMs (TAM or RAL) relative to placebo and 2) AI relative to SERMs and placebo, meeting the $100,000 per quality-adjusted life year (QALY) gains threshold. A Markov model was constructed for a hypothetical cohort of PM women with varying elevated risks of developing BC and treatment related adverse events. Costs, utilities and probabilities were derived from the literature and relevant BC prevention trials including NSABP-P1, STAR and MAP 3. The analysis took a third-party payer perspective and reports costs in 2013 CDN dollars. **Results:** Substantial variability in the relative CE of each strategy was observed when probabilistic sensitivity analysis was performed and thus cost effectiveness acceptability frontiers (CEAFs) were used to compare the relative CE of each strategy. Both SERMs were associated with incremental gains in QALYs as well as incremental costs compared to no treatment but AI was most often the preferred BC prevention strategy at a willingness-to-pay threshold of $100,000/QALY. **Conclusions:** The use of EXE for BC prevention is associated with incremental QALY gains and is a cost-effective strategy in PM women at high risk of BC. The strategy of choice is dependent upon BC risk as well as the risk of adverse effects and the willingness-to-pay for a QALY gain.

**1566 General Poster Session (Board #348), Sun, 8:00 AM-11:45 AM**

**Low-dose CT lung cancer screening in the community: A prospective cohort study.** *Presenting Author: Vincent K. Lam, University of Maryland Greenebaum Cancer Center, Baltimore, MD*

**Background:** Results from the National Lung Screening Trial (NLST) in 2011 showed that low-dose CT screening in high-risk groups reduces lung cancer deaths. Major professional organizations, as well as the USPSTF, have endorsed low-dose CT screening in these select populations. However, major questions remain about whether widespread deployment of CT screening can achieve results similar to the NLST, especially in the community setting. **Methods:** A prospective cohort study was initiated in November 2010. High-risk participants (age at least 50 years old and history of cigarette smoking of at least 20 pack-years) underwent low-dose CT screening, performed and interpreted at El Camino Hospital in Mountain View, California. Diagnostic follow-up for positive scans were recommended per International Early Lung Cancer Action Program (I-ELCAP) guidelines. Participants were followed for events that occurred through December 31, 2013. **Results:** 157 participants underwent low-dose CT screening with mean follow-up of 2.2 years. Median age at entry was 64 (range 50-95). 59% of the participants are women and 94% are Caucasian. Over 80% also satisfied the more stringent NLST inclusion criteria for smoking history. The rate of positive initial screening tests was 35.7%. One positive screen (3.2%) required invasive diagnostic follow-up, which was uncomplicated. No interval lung cancer was detected. One incident case of small cell lung cancer resulted in death. The rate of timely adherence to diagnostic follow-up was only 43%. Late follow-up was often due to participant or primary care provider preference (68%), with participants lost to follow-up (18%) and lack of insurance (10%) also contributing. **Conclusions:** To our knowledge, this is the first community-based prospective study of low-dose CT lung cancer screening. Compared to the NLST, the higher rate of positive initial screening tests (36% vs 27%), higher overall false positive rate, and significantly decreased adherence (43% vs 95%) in this study highlight the difficulties of generalizing the NLST mortality benefits in the broad deployment of CT screening. Our results support current recommendations that CT screening be performed in a highly structured and integrated setting.

**1567 General Poster Session (Board #349), Sun, 8:00 AM-11:45 AM**

**A population-based comparison of outcomes among screening, symptom, and emergently-detected colorectal cancer (CRC).** *Presenting Author: McKyla McIntyre, University of British Columbia, Vancouver, BC, Canada*

**Background:** CRC screening is recommended in average-risk individuals aged 50 years or older. Our aims were 1) to evaluate the proportion of CRC in a large population-based setting that were diagnosed by screening, symptoms, or emergent presentation; and 2) to examine the characteristics and outcomes of CRC based on their method of detection. **Methods:** All sporadic CRC cases diagnosed and referred in 2008 to any 1 of 5 regional cancer centers in British Columbia, Canada were reviewed and analyzed. Screening-eligible patients were classified into CRC diagnosed by 1) screening endoscopies or stool tests; (2) symptoms prompting outpatient workup; and (3) emergent presentations to the hospital. Using Kaplan-Meier methods and Cox regression, 5-year CRC-specific survival (CRC-SS) and overall survival (OS) were compared. **Results:** A total of 992 CRC patients were included: median age was 69 years (range 50-95), 58% were men, and 54% were colon. Among them, 12% were diagnosed by screening, 75% by symptoms, and 13% by emergent presentation. Comparing across the 3 cohorts, patients who presented emergently tended to be older ($p=0.06$), women ($p=0.02$) and have colonic tumors ($p<0.001$) while individuals with either emergently or symptom-detected tumors were more likely to manifest with metastatic disease ($p<0.001$). In the group that underwent screening, stool tests were the most frequent screening modality. Compared to CRC diagnosed by screening, emergently detected disease showed worse CRC-SS (HR 1.34), but symptom-detected disease showed better CRC-SS (HR 0.66) (p for trend $=0.0095$). Both emergently and symptom-detected CRC were correlated with worse OS relative to screening-detected disease (HRs 2.28 and 1.25, respectively) (p for trend$<0.001$). **Conclusions:** Despite screening guidelines, CRC was more commonly diagnosed by symptoms or emergent presentations. Screening was associated with improved OS, but its impact on CRC-SS was variable. Thus, the observed benefits of screening may be more strongly driven by the presence of other associated preventive or healthy behaviors. Interventions that harness these healthy behaviors may be more effective in improving CRC screening uptake and outcomes.

**1568 General Poster Session (Board #350), Sun, 8:00 AM-11:45 AM**

**Correlation between risk benefit index and uptake of breast cancer chemoprevention.** *Presenting Author: Parijatham S. Sivasubramanian, Columbia University Medical Center, New York, NY*

**Background:** Chemoprevention with antiestrogens, tamoxifen and raloxifene, is under-utilized partly due to concerns regarding side effects such as uterine cancer and thromboembolism. Tamoxifen is indicated for women with ductal and lobular carcinoma in situ (DCIS/LCIS) and has a favorable risk-benefit ratio for high-risk women under age 50. For women 50 years and older, a Risk Benefit Index (RBI) developed by Freedman et al. takes into account a woman's age, race, breast cancer risk, and prior hysterectomy. We examined the correlation between RBI and chemoprevention uptake among high-risk women. **Methods:** From 2007 to 2013, new high-risk women seen at an urban, academic breast clinic were enrolled. Eligibility for chemoprevention included a 5-yr Gail risk$\geq$1.67%, DCIS/LCIS, or BRCA mutation. RBI scores for tamoxifen and raloxifene based upon published algorithm tables were calculated for high-risk women $\geq$50 yrs and classified as strong/moderate evidence of benefits outweighing risks and benefits do not outweigh risks. Women with DCIS/LCIS/BRCA mutation and age$<$50 were excluded from the analysis. **Results:** Among 403 women enrolled, 311 (77%) were eligible for chemoprevention. Among women with DCIS/LCIS/BRCA mutation and age$<$50, 62% (124/201) and 31% (10/32) took an antiestrogen, respectively. Among 60 women with an RBI score, 82% had strong/moderate benefit; 33% took an antiestrogen with 65% in agreement with their RBI score. Among women who did not take an antiestrogen, 80% would have had a benefit to raloxifene or both. **Conclusions:** Among high-risk women who took an antiestrogen, the majority of treatment decisions were in agreement with their RBI score. Most women who refused an antiestrogen would have benefited. High-risk postmenopausal women now have the option of aromatase inhibitors, which may improve the risk-benefit profile for chemoprevention.

| | Took tamoxifen | Took raloxifene | Took neither | Total, N (%) |
|---|---|---|---|---|
| Strong/moderate benefit for both | 0 | 3 | 6 | 9 (15) |
| Strong/moderate benefit for raloxifene | 4 | 9 | 26 | 39 (65) |
| Strong/moderate benefit for tamoxifen | 1 | 0 | 0 | 1 (2) |
| No benefit for both | 1 | 2 | 8 | 11 (18) |
| Total, N (%) | 6 (10) | 14 (23) | 40 (67) | 60 (100) |

**1569 General Poster Session (Board #351), Sun, 8:00 AM-11:45 AM**

**Characteristics of HIV+ lung cancer cases in a large clinical population: Implications for lung cancer screening.** *Presenting Author: Marina Shcherba, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY*

**Background:** Lung cancer (LCa) accounts for ~30% of cancer deaths and 10% of non-HIV-related deaths among HIV(+)s. Compared to those in the general population, even after accounting for smoking, HIV(+)s have a 2.5–5-fold higher risk of LCa, and are diagnosed younger. The National Lung Screening Trial (NLST) demonstrated survival improvements with low dose CT (LD-CT) screening in persons at high lung cancer risk (age 55-74 with ≥30 pack-years [pys] of smoking). We examined the age and smoking histories of HIV+ LCa patients to determine who would have met NLST screening eligibility. **Methods:** The Cancer Registry (42,967 cancer cases) and the HIV Integrated Clinical Database (14,927 HIV+s) at Montefiore Medical Center – Einstein (Bronx, NY) were linked to identify HIV+ cancer cases between 2000-2012. Chart review was performed for those with LCa. **Results:** Of the 935 invasive cancers in HIV+s, 90 (9.6%) were LCa (62% men, 38% women). Histology was 11% small cell, 20% squamous and 37% adenocarcinoma, 2% large cell, and remaining 30% were classified as non-small cell carcinomas. Median age at LCa diagnosis was 54 years ([y]; range: 24–72), with 2% <35y, 52% 35-54y, 46% ≥55y. 4% were never smokers, and 3% had <15pys, 24% 15-29pys, 68% ≥30pys. Overall, 66 cases (73%) did not meet NLST age or smoking criteria. Most cases (85%) had been followed for HIV care. The median CD4+ was 238 cells/$\mu$L, and median HIV viral load was 81 copies/mL. LCa was stage I in 8%, stage II in 11%, stage III in 23%, and stage IV in 58%. All stage I/II cases underwent surgical resection. **Conclusions:** Most HIV+ LCa cases failed to meet NLST criteria for LD-CT screening due to age <55y or pys <30. If LD-CT is to be utilized in this high-risk population, age and smoking thresholds may need to be lowered. Notably, 19% of tumors were diagnosed at stage I/II without routine screening, reinforcing the potential to identify LCa at a treatable stage in HIV(+) persons.

**1570 General Poster Session (Board #352), Sun, 8:00 AM-11:45 AM**

**Randomized trials on mammography screening and the left-to-nature design.** *Presenting Author: Philippe Autier, University of Strathclyde Institute for Global Public Health at iPRI, Lyon, France*

**Background:** Population data suggest that mammography screening does not play a major role in breast cancer mortality declines. The six randomized trials that found decreased risks of breast cancer death with mammography screening were all based on the left-to-nature design where women allocated to control groups were unaware that they were part of a trial. We hypothesized that factors other than mammography screening contributed to reductions in breast cancer mortality seen in the trials. **Methods:** We systematically searched in publications on mammography trials for data on factors other than mammography screening that could have influenced breast cancer size or mortality. We extracted or computed reductions in risks of breast cancer death predicted by reductions in cancer size observed in trials multiplied by size-specific fatality rates observed in trials. We then compared predicted and reported risk reductions. We searched for causes of death other than breast cancer among breast cancers during trials. **Results:** Predicted and reported relative risks of breast cancer death were 0.84 (95% CI: 0.84-0.96) and 0.68 (0.59-0.80) in the Swedish Two-County trial, 0.89 (0.69-1.16) and 0.76 (0.56-1.04) in the Swedish Goteborg trial, 0.96 (0.76-1.22) and 0.71 (0.55-0.93) in the Greater New York Health Insurance Plan trial, and 0.90 (0.80-1.01) and 0.79 (0.78-1.01) in the English Age trial. In the Two-County trial, breast cancer women in the intervention group had a 33% (20 to 63%) increased risk to die from a cause other than breast cancer. Lower predicted reductions in risks of death and more deaths not due to breast cancer reflect the contribution of factors other than earlier detection in reduced risks of breast cancer death. In several trials, interval breast cancers were smaller and more frequently in situ than cancers in control groups indicating that factors other than mammography screening played a role in breast cancer earlier detection. We found evidence that in the Two-County trial, the intervention also consisted in promoting breast awareness and breast self-examination. **Conclusions:** Randomized trials based on the left-to-nature design have overestimated the capacity of mammography screening to reduce the risk of breast cancer death.

**1571 General Poster Session (Board #353), Sun, 8:00 AM-11:45 AM**

**One hundred years of cancer mortality in Scotland (1911-2010).** *Presenting Author: Peter Boyle, University of Strathclyde Institute for Global Public Health at iPRI, Lyon, France*

**Background:** Mortality data by age and gender are available for Scotland for one hundred years, 1911-2010. This allows a unique insight into the changing patterns of cancer over a complete century. **Methods:** Bridging was established manually to ensure that each rubric contained the same cancer sites throughout the period studies. Population data were available throughout the time period. Age-standardised mortality rates per 100,000 could be calculated. It was possible to follow the observed death rates in certain cohorts of men and women born in the late 1800s and the early 1900s. **Results:** Data are available for 20 individual sites of cancer in addition to the combined all cancers. Notable findings include the dramatic reduction in stomach cancer, which fell in men from38 per 100,000 around 1930 to 6 per 100,000 in 2006-2010 (in women the rates fell from 30 to 4 over the same time period). Lung cancer in men fell from its peak of 80 in 1960 to 30 in 2005-2010. One quarter of men born between 1900-1910 died of lung cancer in their lifetime (over 80% of men in Scotland smoked in 1950). Breast cancer mortality in women is now lower than at any other time point during the last century. Downward trends are apparent in birth cohorts at all ages indicating that this favourable trend will continue. Colorectal cancer mortality has declined markedly in both gender groups: in men the rate fell from 39 (1930-34) to attain 15 (2006-2010). The effects of treatment advances in Testis Cancer and Hodgkin's Lymphoma are clearly reflected in the declining mortality rate. **Conclusions:** These data provide insights into the changing pattern of cancer over the last century. The impact of tobacco-smoking on cancer mortality throughout the century has been dramatic although the declines in tobacco-related cancers is confirmation of the effectiveness of anti-tobacco policies. It is harder to explain the substantial declines in stomach, colorectal and breast cancer although they are very welcome.

**1572 General Poster Session (Board #354), Sun, 8:00 AM-11:45 AM**

**A population-based analysis of the impact of physicians on cancer screening.** *Presenting Author: Leo Chen, University of British Columbia, Vancouver, BC, Canada*

**Background:** Despite its ability to reduce morbidity and mortality, participation in cancer screening continues to be suboptimal. Our aims were to 1) characterize the frequency of breast (BR), colorectal (CR), cervical (CV) and prostate (PR) cancer screening in a US population-based setting, 2) describe the clinical factors associated with screening uptake, and 3) examine the effect of patient contact with their physicians and the quality of these interactions in modifying screening behavior. **Methods:** Average risk patients considered eligible for cancer screening were identified from the US Health Information National Trends Survey. We developed a scoring system based on patient-reported patterns of care to characterize the quality of their interactions with physicians. Determinants of screening were assessed with multivariate logistic regression analyses and joint effects models that accounted for the frequency and quality of contact with physicians were developed to explore their influence on screening. **Results:** A total of 7,327 patients were included. In each of the BR (n=1,696), CR (n=2,377), CV (n=2,240) and PR (n=1,014) cancer cohorts, screening rates were suboptimal at 72%, 69%, 76% and 61%, respectively. Advanced age, family history of any cancers, high income earners, individuals who visited their physicians frequently and those who rated the interactions with their physicians highly were generally more likely to have undergone screening (Table). Joint effects models revealed that the quality rather than the frequency of physician contact was a stronger predictor of screening, but the odds of screening were greatest for patients who experienced both frequent and high quality interactions with their physicians. **Conclusions:** Participation in cancer screening remains poor. Contact with physicians and the quality of this interaction were associated with screening behavior. Interventions to improve these provider-related factors may optimize screening.

**Odds ratios for cancer screening.**

| | BR | CR | CV | PR |
|---|---|---|---|---|
| **Advanced age** | 0.99 | 1.05* | 0.96 | 1.06* |
| **Family history** | 1.26* | 1.17 | 1.10 | 1.82* |
| **High income** | 1.08 | 1.22* | 1.18* | 1.22* |
| **Frequent visits with MD** | 1.41* | 1.36* | 1.06 | 1.39* |
| **Good quality interactions with MD** | 1.87* | 1.27* | 1.67* | 1.19 |

*means $p < 0.05$.

**1573 General Poster Session (Board #355), Sun, 8:00 AM-11:45 AM**

**Risk-reducing salpingectomy at the time of benign gynecologic surgery: A survey of ACOG members in New York State.** *Presenting Author: Joshua Stewart, Weill Cornell Medical College, New York Presbyterian Hospital, New York, NY*

**Background:** To determine if Obstetricians and Gynecologists in New York state would offer risk-reducing salpingectomy (RRS) at the time of benign hysterectomy with ovarian preservation or permanent sterilization. **Methods:** An anonymous survey was administered to Ob/Gyn physicians at the 2013 Annual American College of Obstetricians and Gynecologists district II meeting. Physicians-in-training were excluded. The survey instrument assessed provider practice to offer RRS before and after reading a brief summary of the clinical position by the Society of Gynecologic Oncology of Canada, entitled "Salpingectomy and Ovarian Cancer Prevention." **Results:** Ninety physicians completed the survey. Median age was 52 years (range 30-87), and 91% practiced general Ob/Gyn. Median annual surgical volume was 10 hysterectomies (range 0-150) and 11 surgical sterilizations (range 0-100). More physicians were willing to offer RRS at the time of hysterectomy than at the time of permanent sterilization (54% vs. 14%, $p < 0.05$). After reading the position statement, there was a 27% increase in the number of physicians who would offer RRS at the time of benign hysterectomy ($p<0.01$) and 42% at the time of surgical sterilization (p=NS). On univariate analysis, physician practice to offer RRS at the time of hysterectomy was associated with previous knowledge of evidence for RRS (96% of physicians aware vs. 82% not aware, $p = 0.04$), surgeon age ($p<0.05$), and practice setting (academic > community, $p<0.5$). Willingness to perform RRS at time of permanent sterilization was associated with the method of sterilization (laparoscopic, 82%, hysteroscopic, 18%, postpartum tubal, 0% $p < 0.07$) and volume of sterilization cases per year ($p<0.05$). On multivariate analysis, the only factor associated with offering RRS was the number of years in practice, 1.6 (95% CI 1.01-1.53, $p<0.05$). **Conclusions:** Our data suggest that obstetricians and gynecologists would offer RRS at the time of benign hysterectomy in those women who elect ovarian conservation. The link between fallopian tube as the origin of ovarian serous cancer needs to be elaborated to potentially offer high-risk patients a method of prevention with few long-term consequences.

**1574 General Poster Session (Board #356), Sun, 8:00 AM-11:45 AM**

**Vulnerable populations and overconfidence in cancer screening.** *Presenting Author: François Eisinger, Institut Paoli Calmettes, Marseille, France*

**Background:** The EDIFICE surveys have been conducted every 3 years since 2005. The aim is to characterize behavior related to recommended, organized screening services (breast and colorectal). However, we recently focused on levels of confidence in screening efficacy for cancer locations for which only opportunistic screening is available. Results from vulnerable and non-vulnerable populations were compared. **Methods:** Phone interviews were conducted among a representative sample of 1,600 individuals (age 40-75 years), using the method of quotas. Opinions on efficacy of cancer screening were assessed for 8 anatomical locations. Data were analyzed according to a validated vulnerability score. **Results:** For cancer locations with no organized screening services, the level of confidence in screening efficacy is surprisingly high, and significantly higher in vulnerable than in non-vulnerable populations; in decreasing order: lung cancer, 85% vs. 78% ($P<0.05$), leukemia, 69% vs. 60% ($P<0.05$), gastric cancer, 67% vs. 56% ($P<0.05$), liver cancer, 63% vs. 48% ($P<0.05$), esophageal cancer, 59% vs.52% ($P<0.05$), and central nervous system cancer, 34% vs. 27% ($P<0.05$), respectively. In contrast, organized screening programs inspire very similar high levels of confidence in both populations: breast cancer, 95% vs. 96% (NS) and colorectal cancer, 92% vs. 94% (NS), respectively. Risk factors for cancer are more prevalent in vulnerable populations: higher BMI, more active smokers and less frequent sports activities. **Conclusions:** Our results demonstrate an excess of confidence in the efficacy of cancer screening, particularly by vulnerable populations. We have put forward two opposing mechanisms to potentially explain the paradoxical coexistence of overconfidence in cancer screening and greater exposure to cancer risk factors. Firstly, individuals may (wrongly) feel protected within the safe net of screening and therefore allow themselves greater exposure to known risk factors. This has been termed the "Moral Hazard". On the other hand, although they realize they have a high risk of being affected by cancer, they ignore the facts and adopt an attitude of wishful thinking.

**1575 General Poster Session (Board #357), Sun, 8:00 AM-11:45 AM**

**Prevalence of smoking in cancer survivors: National Health and Nutrition Examination Survey (NHANES) III data analysis.** *Presenting Author: Mohammed Shaik, Michigan State University, East Lansing, MI*

**Background:** Smoking is an important risk factor for many cancers. Studies have shown a lower prevalence of smoking in cancer survivors. However, we wanted to determine whether this prevalence is constant or changes the longer the patient is cancer free. **Methods:** Data was obtained from NHANES III, a nationally representative health survey conducted from 1988-1994. Subjects who were diagnosed with solid tumors were included in this study. These subjects were divided into two groups, Group A(GpA) were those within 3 yrs of diagnosis of cancer and group B(GpB) included those more than 3 yrs from diagnosis of cancer. Prevalence of smoking in these groups was analyzed using the chi-square test (proc surveyfreq in SAS 9.3). **Results:** Of 33,994 subjects in the NHANES III database, 780 subjects were diagnosed with solid tumors. Of these, 415 subjects had data regarding their current smoking status. There were 138 subjects who were within 3 years and 183 subjects beyond 3 years of their cancer diagnosis. There were 38.1% males and 62% females, and 83%, 16% and 1% were white, black and other races, respectively. Current smoking in subjects without cancer was 52.3% and 30.1% in subjects with cancer which was consistent with prior studies. The cancer survivors within 3 years of diagnosis had a 22.4% (31/138) prevalence of smoking, and subjects with more than 3 years since diagnosis had a 34%(94/277) prevalence of smoking (p=0.01). (Table) **Conclusions:** The prevalence of smoking in cancer survivors was lower than in the general population as expected. Subjects who survived more than 3 yrs from their diagnosis had a statistically significant higher prevalence of smoking when compared to survivors less than 3 yrs from their diagnosis. Health care providers need to continue to counsel against smoking in cancer survivors for a longer period of time.

**Characteristics of cancer survivors.**

| Variables | Subj <3 yrs from cancer diagnosis (GpA) n=251 | Subj >3 yrs from cancer diagnosis (GpB) n= 480 | p-value |
|---|---|---|---|

**1576 General Poster Session (Board #358), Sun, 8:00 AM-11:45 AM**

**Breast cancer incidence among young women of urban China (Shanghai) and in Canada: Implications for prevention.** *Presenting Author: Joseph Ragaz, School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada*

**Background:** Objective of this study: to evaluate, in Urban China and Canada, the long-term BrCa incidence trends, with emphasis on rates among young women age <50. Shanghai, one of the largest regions of Urban China, enjoyed since the late 1970's rapid rates of westernization, i.e. confluence of western lifestyles, urbanization and industrialization. While a good association between the westernization and BrCa incidence has been reported in past studies, BrCa age-specific incidence analyses comparing urban China to western regions such as Canada, are not available. **Methods:** Data were received from Shanghai Municipal Centre for Disease Control and Prevention and from the Public Health Agency of Canada based on the Canadian Cancer Registry database at Statistics Canada. For each region, 5-year age specific BrCa incidence rates [ASIRs] in 5 year cohorts starting at age 35 were estimated and expressed as percent difference between years 1973-79 [baseline, 100%] and the last five years 2000-2004. ASIRs were age-standardized annual new incident cases per 100,000 population, and standardized using the 1960 world population as reference. **Results**: See Table. **Conclusions:** For any age group [including those age >65], ASIR increases were much greater in urban Shanghai than in Canada, but they were particularly dramatic for the very young age 35-39. Incidence rates were however still very high also for the whole group of young women age 40-60. As most women in these young age groups of urban China, as in the western countries, receive [western] BrCa diagnostic and therapeutic approaches, a systematic implementation of BrCa preventive strategies and their larger scale research will be required, particular targeting young adolescent women or school age girls. Our data suggest that these are the age groups who are at sizable risk of subclinical carcinogenesis related to western life-style, and for whom prevention research and interventions may have most meaningful cost/benefit, and overall impact.

| | ASIR | |
|---|---|---|
| **Age group at diagnosis** | **Canada** | **Shanghai** |
| **35 – 39** | 0% | +46% |
| **40 – 44** | -4% | +106% |
| **45 – 49** | -1% | +170% |
| **50 – 54** | +22% | +157% |
| **55 – 59** | +30% | +132% |
| **60 – 64** | +32% | +85% |
| **65+** | +23% | +91% |

**Cancer screening behaviors among spouses in a nationally representative sample.** *Presenting Author: Ashwin A Kotwal, University of Chicago, Department of Medicine, Chicago, IL*

**Background:** Spouses are known to behave similarly across a range of health behaviors, however, little is known about how each spouse influences the other's cancer screening behavior. Using a unique national sample of older couples with detailed information on both partners, we assess whether screening colonoscopy, PSA screening, and mammography rates of each spouse are associated, and identify characteristics of each partner and their relationship that influence cancer screening likelihoods. **Methods:** We use the National Social life Health and Aging Project (NSHAP) Wave 2 sample (2010), a nationally-representative sample of matched older male-female couples (n=953). We use multivariate logistic regression models for each of the four outcomes (PSA screen in last 1 year for husbands, mammography in last year for wives, and screening colonoscopy in last 5 years for both), as a function of sociodemographic, health status, spouses' cancer screening behavior, and relationship quality covariates. **Results:** Controlling for covariates, husbands with wives who had screening mammograms in the last year are more likely to have had screening PSAs in the last year (64% vs 50%; p=0.001). Husbands are more likely to have received screening colonoscopies when their wives have received screening colonoscopies (69% vs 54%; p<0.001), when their wives are more educated (69% vs 55%; p=0.037), and when their wives are happier with the marital relationship (65% vs 49%; p=0.006). Similarly, wives are more likely to receive a screening colonoscopy when their husband has received a screening colonoscopy (67% vs 51%; p<0.001). For mammography, wives are more likely to have had a mammogram in the last year if their husbands have had recent PSA screens (68% vs 56%; p=0.002) or if their husbands have had recent screening colonoscopies (68% vs 54%; p=0.001). **Conclusions:** In a national sample, older spouses' cancer screening behaviors are significantly associated with one another after adjusting for shared sociodemographics. Recognizing how spouses mutually influence screening rates can help providers deliver more effective screening recommendations and improve adherence, particularly when different screening recommendations exist for each cancer.

**Identfying barriers to providing tobacco cessation support for cancer patients.** *Presenting Author: James Roger Marshall, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** The 2014 Surgeon General's Report concluded that smoking caused increased mortality in cancer patients, but data demonstrate that most physicians do not regularly provide tobacco cessation support. The purpose of this study was to identify predictors of providing tobacco cessation support through a large physician provider survey administered through the International Association for the Study of Lung Cancer (IASLC). **Methods:** An online survey was developed and administered to IASLC members asking about tobacco assessment and cessation practices. Barriers to providing cessation support were also asked. Responses were analyzed to identify demographic, perception, and practice related correlates of decreased cessation support. **Results:** A total of 1,507 respondents replied to the survey representing a 40.5% response rate. Respondents from the United States (US) , in an academic practice, and devoting more time to patient care were associated with higher rates of asking about tobacco use. However, only practice in the US predicted for higher rates of providing cessation assistance. Respondents reporting clinicians need more education on cessation and respondents stating they had sufficient education was predictive of regularly providing cessation support. Believing that tobacco cessation does not affect cancer treatment outcome predicted for lower rates of assisting with cessation support. Reimbursement concerns and belief that patients were not receptive to cessation support did not affect physicians regularly providing cessation support. However, lack of resources, lack of training and experience with cessation, and lack of time were all predictive of decreased tobacco cessation support by respondents. **Conclusions:** Lack of time, training, and resources were the primary determinants of providing tobacco cessation support for cancer patients. Efforts are needed to address these issues to improve tobacco cessation support in the standard clinical care of cancer patients.

**1579 General Poster Session (Board #361), Sun, 8:00 AM-11:45 AM**

**Cervical cancer screening: Twelve years experience with high-risk population of southern Mexico.** *Presenting Author: Francisco Gutierrez-Delgado, Centro de Estudios y Prevencion del Cancer, Juchitan, Mexico*

**Background:** Cervical cancer is still the main cause of death from cancer in indigenous population and rural communities in Mexico. We have evaluated both screen-and-treat colposcopy and oncogenic human papilloma virus (HPV)-DNA testing as potential screening programs in high-risk population. Our experience has been previously reported (2006 and 2008 ASCO Annual Meetings; Abstracts 5012 and 16519, respectively). In this study we report a follow-up of both strategies. **Methods:** Between 12/2002 and 11/2013, women were offered colposcopy. From 08/2006 to 11/2013, HPV-DNA testing (Hybrid Capture II (hC2) assay (Digene Corp, Gaithersburg, MD, USA) was offered to women aged 14 to 89 years. Criteria for colposcopy diagnosis, cervical cytology, therapy for HPV diagnosis, CIN2 and CIN 3, and the methodology for (Hybrid Capture II (hC2) assay has been reported elsewhere. Women were followed in their communities **Results:** 17,471 women (median age 39 years, range: 14–87) were underwent colposcopy. 14,487 (83%) of them were evaluated between 2002 and 2008, and 2985 (17%) from 2009 to 2013. The median follow-up was 8 years (range 5-11) and 3 years (range 0-5), respectively. Abnormal colposcopy (HPV, CIN 1, CIN 2 or CIN 3), was diagnosed in 2,528 (14%) out of 14,487 women and 45 (0.31%) had carcinoma. 411 (14%) out of 2,985) women were diagnosed as having an abnormal colposcopy and 11 (0.36%) had carcinoma. 1,110 women were evaluated with the oncogenic HPV-DNA testing. 807 (73%) women were ≥ 30 years old years and 303 (27%) were younger 30 years old. HPV-DNA testing was positive in 134 (16%) and 97 (32%) women, respectively. In women ≥ 30 years old who had a normal colposcopy (n=681), 96 (11.8%) of them had a positive HPV test and in 38 (4.7%) of those who had an abnormal colposcopy. In women younger 30 years old HPV test was positive in 45 (14.85%) women who had a normal colposcopy (n=179) and in 52 (17.16%) diagnosed as having abnormal colposcopy. No new cervical cancer cases have been reported in the follow-up. **Conclusions:** Screen-and-treat colposcopy and oncogenic HPV testing are feasible strategies for cervical cancer screening in selected high-risk population and an alternative to cytology-based screening programs

**1580 General Poster Session (Board #362), Sun, 8:00 AM-11:45 AM**

**The effect of current smoking on mortality in cancer patients.** *Presenting Author: Graham Walter Warren, Medical University of South Carolina, Buffalo, NY*

**Background:** Smoking is the largest preventable health behavior associated with the development of cancer. An evidence-based estimate is needed to assess the effect of current smoking at diagnosis on mortality for cancer patients. **Methods:** A MEDLINE literature search was performed to identify studies between 1990-2012 evaluating the effect of current smoking at or following a cancer diagnosis on overall mortality. Only studies collecting tobacco information in close proximity to diagnosis and with at least 200 patients in the analysis were included. **Results:** A total of 83 studies met criteria reporting on 129,346 patients including 60 studies comparing the effects of current smoking with never smoking and 23 studies reporting the effects of current smoking with former and never smoking combined. Overall 60 studies (72.3%) demonstrated one or more statistically significant negative associations between current smoking and mortality, 6 studies (7.2%) reported near significant negative associations, and 17 studies (20.5%) demonstrated no association. The risks of current smoking were observed across all treatment modalities (surgery, chemotherapy, radiotherapy). Current smoking increased the risk of mortality as compared with never smoking by a median of 52%, as compared with former smoking by a median of 41%, and as compared with former and never smoking combined by 50%. **Conclusions:** Current smoking increases the risk of overall mortality for cancer patients independent of cancer treatment. The effects of current smoking are distinct from the effects of former or ever smoking.

**1581 General Poster Session (Board #363), Sun, 8:00 AM-11:45 AM**

**Pioglitazone as a candidate chemoprevention agent for lung cancer: A pilot window trial in early stage NSCLC.** *Presenting Author: Dennis A. Wigle, Mayo Clinic, Rochester, MN*

**Background:** Multiple lines of evidence support the use of PPARγ ligands in the treatment and prevention of lung cancer. Pioglitazone is a PPARγ ligand that is FDA-approved for type-II diabetes mellitus, and used by millions of diabetic patients worldwide. We evaluated pioglitazone as a candidate chemo-preventive agent for NSCLC by investigating the effects on Ki-67 in NSCLC tumor tissue using a pilot window trial design. **Methods:** Patients with known or suspected stage IA-IIIA NSCLC who were current or former smokers with a ≥ 10 pack-year smoking history were enrolled. Patients underwent fluorescence bronchoscopy with targeted biopsies (normal, suspicious/dysplastic areas) bronchial brushings, and additional tumor sampling to asses Ki67 staining. Patients also underwent a pre-treatment PET scan, followed by pioglitazone, 45 mg once/day for 14-42 days prior to surgical resection. Ki67 staining along with other secondary biomarker endpoints were assessed in repeat bronchoscopy and surgical resection specimens after pioglitazone treatment. **Results:** Of the 10 pre-registered participants, 3 did not have biopsy-confirmed NSCLC and 1 had metastatic NSCLC; a total of 6 participants received pioglitazone. Mean age 64.0 years, 5 males, 1 female; with 2nadenocarcinomas, 3 squamous cell carcinomas, and 1 mixed adenosquamous tumor. Median %change in Ki67 staining in the primary tumor of the 5 eligible participants (1 participant excluded with a solitary non-lung cancer metastasis) was -20% (p=0.06), with all patients having a reduction in Ki67 post-intervention. Gene expression analysis of histologically normal bronchial airway epithelium pre- and post-pioglitazone treatment revealed a number of upregulated genes enriched for complement activation and chemokine signaling (GSEA p <0.05). Genes that were repressed were related to inflammatory and B cell survival pathways (GSEA p<0.05). **Conclusions:** These preliminary data are suggestive of a potential effect for pioglitazone in early stage NSCLC, despite the small sample size. These results need to be confirmed in a larger cohort of patients. Clinical trial information: NCT01342770.

**1582 General Poster Session (Board #364), Sun, 8:00 AM-11:45 AM**

**Lung cancer characteristics in 762 never- and 6,246 ever-smoker patients: Study KBP-2010-CPHG.** *Presenting Author: Daniel Coëtmeur, Centre Hospitalier de Saint Brieuc-Hôpital Yves Le Foll, Saint-Brieuc, France*

**Background:** In 2010, the French College of General Hospital Respiratory Physicians performed a prospective multicenter epidemiological study to describe the baseline characteristics and management of all new cases of primary lung cancer and evaluate survival. The present abstract compares characteristics according to smoking. **Methods:** 7,051 patients ≥18 years presenting with primary lung cancer, histologically or cytologically diagnosed between 1 January and 31 December 2010, and followed-up in the respiratory department of one of the 104 general hospitals participating in the study, were included. A standardized form was completed for each patient at diagnosis. A steering committee checked inclusion exhaustiveness. **Results:** 762 patients were never-smoker and 6,246 ever-smoker (43 missing data). Respectively, 222, 635, and 5,088 of ever-smokers claimed to consume or to have consumed 1-10, 11-20, and >20 pack-year; their median smoking duration was 40 years. Former-smokers stopped smoking 12 years ago (median). 158 never-smokers claimed to have been exposed to passive-smoking. At diagnosis, statistical significant differences between never- and ever-smoker patients (p<0.0001) were found for sex (women: 70%/19%); age (median: 73/64 years); stage of cancer (IV: 71%/59%); cancer type (adenocarcinoma: 69%/43%; small-cell lung cancer: 5%/14%; squamous-cell carcinoma: 8%/28%); EGFR mutation exploration (51%/28%) and positivity (37%/5%). For all these characteristics, significant trends (p<0.0001) were also observed when patients were graded according to consumption: e.g., percentage of adenocarcinoma was 63%, 54%, 50%, and 41% in the 0, 1-10, 11-20, and >20 pack-year groups, respectively. **Conclusions:** This study confirms the main differences between never-smokers and ever-smokers, in particular on histological type and EGFR-mutation, two characteristics that impact treatment.

**1583 General Poster Session (Board #365), Sun, 8:00 AM-11:45 AM**

**Multiple primary malignancies involving primary sporadic colorectal cancer in Japan: Incidence of gastric cancer with colorectal cancer patients may be higher than previously recognized.** *Presenting Author: Takaharu Kato, Department of Surgery, Saitama Medical Center, Jichi Medical University, Saitama, Japan*

**Background:** Improvement in the prognosis of colorectal cancer (CRC) patients has led to increasing occurrences of multiple primary malignancies (MPMs) alongside CRC but little is known about their characteristics. This study was undertaken to clarify the clinical and pathological features of MPMs, especially those at extra colonic sites, in patients with CRC. **Methods:** We reviewed 1,076 patients who underwent operations for primary sporadic CRC between 2007 and 2012. Familial adenomatous polyposis, Hereditary Non-Polyposis Colorectal Cancer, colitic cancer and any metastasis from CRC were excluded. We extracted patients who had developed at least one MPM in an extracolonic site while having synchronous or metachronous CRC. Synchronous MPMs were defined as malignancies detected within 6-month interval before and after the detection of CRC. We compared the clinicopathological features of CRC patients with and without MPMs. As a control, we used a database compiled of patients with gastric cancer (GC) that were detected by mass screening performed in Saitama prefecture, Japan 2010 and compared these with CRC patients with synchronous GC. **Results:** MPMs at extracolonic sites were identified in 134 of 1,076 CRC patients (12.5%). Average age was 67.0 (range, 29-96) versus 71.3 (50-92) (P < 0.001). The incidence of GC (40.0% (53 of 134)) was the highest of all MPMs. All CRC patients with GC were older than 57 years of age. Synchronous GC was detected in 26 patients. On the other hand, out of 200,007 screened people, 225 people were diagnosed as GC in Saitama prefecture. The age-standardized incidence ratio of synchronous GC in CRC patients (0.54%) was significantly higher than in the control group (0.03%) (odds ratio 18.7, 95% confidence interval 18.5-18.9; P < 0.001). **Conclusions:** CRC patients preferentially developed GC synchronously and metachronously when they are older than 50 years. Thus, this patient group should undergo careful perioperative screening for GC.

**1584 General Poster Session (Board #366), Sun, 8:00 AM-11:45 AM**

**A population-based study of incidence and survival trends of 1,261 thymic malignancies (TM): Results from the California Cancer Registry (CCR).** *Presenting Author: Jonathan Riess, Department of Internal Medicine, Division of Hematology/Oncology, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

**Background:** TMs are rare with sparse population-based epidemiologic literature. **Methods:** We used data from the CCR, a comprehensive population-based state registry to examine TM incidence and survival trends in California from 1988 to 2011. Cases were specified by site (thymus), histology (thymic carcinoma and thymoma), and behavior (malignant). Primary endpoint was cause-specific survival (CSS). Hazard ratios (HR) for CSS were calculated using a Cox proportional-hazards model controlling for relevant baseline variables including age, gender, stage, and year of diagnosis, among others. **Results:** We identified 1,261 TM cases with an incidence of 0.17 per 100,000 person-years. Average annual increase was 2% (95% CI 1-3.1%). Earlier stage was associated with improved CSS in the crude (localized HR=0.17, 95% CI 0.11-0.28; regional HR=0.37, 95% CI 0.28-0.49) and multivariate models (localized HR=0.30, 95% CI 0.157-0.567; regional HR=0.44 (95% CI 0.29-0.67). Thymic carcinoma histology was associated with worse CSS in both the crude (HR=2.42, 95% CI 1.74-3.37) and multivariate models (HR=2.57, 95% CI 1.1-6.1). Patients diagnosed between 1995-2001 had improved CSS compared to 1988-1994 (crude HR=0.49, 95% CI 0.35-0.70), even in the multivariate model (HR=0.35, 95% CI 0.18-0.71). Radiotherapy was associated with improved CSS (multivariate HR=0.45, 95% CI 0.21-0.97) for patients treated with partial or total removal of tumor. **Conclusions:** This is the first population-based study of TMs from the CCR that identifies baseline variables significantly associated with CSS. TM incidence appears to be increasing over time: this was also associated with improving CSS over the same period. In addition to stage and non-thymic carcinoma histology, treatment with radiotherapy after partial or total removal of tumor was found to be associated with improved CSS. These findings provide a more contemporary database for future TM outcomes research and generate new hypotheses for clinical evaluation.

**1585 General Poster Session (Board #367), Sun, 8:00 AM-11:45 AM**

**The incidence of testicular cancer in the United States and Europe from 1992 to 2009.** *Presenting Author: Manas Nigam, University of Chicago Pritzker School of Medicine, Chicago, IL*

**Background:** Testicular germ cell tumors (TGCTs) are the most commonly diagnosed cancer in men between 15 and 35 years in the United States and in most European populations. The incidence of TGCTs increased in White, Black, and Hispanic men in the U.S. through 2003. We sought to determine current trends in TGCT incidence in the U.S. and Europe. **Methods:** TGCT incidence data covering the U.S. and European populations were extracted from the Surveillance, Epidemiology and End Results-13 registry and the EUREG database, respectively. Age-standardized incidence rates (ASIRs) were derived from SEER*Stat 8.0.1. Trends were determined using JoinPoint. **Results:** TGCT incidence among U.S. males over 15 years old increased from 1992 (5.7/100,000) to 2009 (6.8) with a significant annual percentage change (APC) (1.1%, $p<0.001$). TGCT ASIRs were highest in White men (1992: 7.5/100,000; 2009: 8.6/1000) followed by Hispanic men (1992: 4.0; 2009: 6.3) and lowest among Asian (1992: 2.0/100,000; 2009: 2.8) and Black men (1992: 0.7; 2009: 1.7). Significantly increasing ASIRs were observed in White men (APC: 1.2%, $p<0.001$) and most prominently in Hispanic men, especially from 2002-2009 (APC: 5.6%, $p<0.01$). Significant increases were observed for localized (APC: 1.2%, $p<0.001$) and metastatic TGCTs (APC: 1.4%, $p<0.01$). Incidence of testicular cancer increased in 15 of 19 (79%) European countries analysed ($p < 0.05$). **Conclusions:** Between 1992 and 2009, testicular cancer incidence in the U.S. continued to increase, notably among Hispanic men, and testicular cancer incidence increased in 79% of European countries analyzed.

**Incidence rates for TGCTs among U.S. men, SEER-13, 1992-2009.**

| | All GCTs | Age-adjusted incidence rate (per 100,000) | | Annual percentage change (APC) |

**1586 General Poster Session (Board #368), Sun, 8:00 AM-11:45 AM**

**Cancer patients' acceptability of incorporating an epidemiology questionnaire within a clinical trial: A patient preference study and subanalysis of the NCIC clinical trials group HN.6 clinical trial.** *Presenting Author: Sinead Cuffe, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Understanding the influence or impact of epidemiological factors on cancer outcomes in clinical trials can broaden our knowledge of disease, trial populations and therapeutic effects thus leading to improved patient care. However, there is a lack of data on cancer patients' compliance with an epidemiology questionnaire in the context of a clinical trial. **Methods:** A wide spectrum of cancer patients from three community, academic and tertiary cancer centres in Ontario, Canada were provided with a hypothetical scenario and surveyed regarding their willingness and preferences to complete an epidemiology questionnaire if incorporated into a cancer therapy trial. Patient compliance with completing a voluntary epidemiology questionnaire was separately determined in the pan-Canadian, multicentre phase III HN.6 clinical trial (NCT00820248) in patients with locoregionally advanced head and neck cancer. **Results:** Of 617 cancer patients surveyed, the vast majority were willing to complete an epidemiology questionnaire; 45% would do so unconditionally; 31% would do so provided it did not inconvenience them too much; just 4% would refuse. Patients preferred shorter questionnaires of up to 30-50 questions requiring 10-20 minutes to complete, and administered over 1-3 sessions. Patients were less willing, but still compliant, to answer questions relating to sexual history (71%), and household income (66%) relative to other epidemiological questions (all >90%). 18% of patients thought that epidemiology questionnaires should be a mandatory component of clinical trials, with 31% believing that they may benefit personally from such research. Among the 320 HN.6 study participants, 268 (84%) completed the voluntary epidemiology questionnaire, and compliance averaged 94.8 (+/-1.0)% per question. **Conclusions:** Cancer patients appear to be very willing to participate in clinical trials that incorporate epidemiology questionnaires in trial design. The high compliance rates with completion of an epidemiology questionnaire in a phase III multicentre study confirmed this finding. Clinical trial information: NCT00820248.

**1587 General Poster Session (Board #369), Sun, 8:00 AM-11:45 AM**

**Rising incidence of young-onset colorectal cancer in Texas, 1995-2010.** *Presenting Author: Daniel Wang Ying, Baylor College of Medicine, Houston, TX*

**Background:** Although colorectal cancer (CRC) has traditionally been considered a disease of the elderly, the incidence of CRC among young adults in the US has been steadily rising. Examining CRC trends in Texas may, by virtue of its diverse population, shed light on future CRC epidemiology in the US. **Methods:** In this retrospective cohort study, we used 1995-2010 Texas Cancer Registry data to calculate the annual percentage change (APC) of CRC incidence by age, race/ethnicity, and anatomic site. **Results:** Of the 125,987 cases identified, 11% occurred in people <50 years old. The APCs of CRC incidence for individuals >50, 40-49, and 20-39 years old were -2.1% (CI -2.7 to -1.5, $p<.05$), 0.2% (NS), and 1.7% (CI 1.0 to 2.4, $p<.05$), respectively. In the >50 cohort, the incidence of CRC in all colon subsites progressively decreased (see Table). In the 20-39 group, sigmoid/rectum tumors became increasingly more common among Hispanics (APC 2.7% [CI 1.1 to 4.2, $p<.05$]) and non-Hispanic whites (APC 3.4% [CI 1.9 to 4.6, $p<.05$]) but not among African-Americans (APC -0.7% [CI -2.9 to 1.7, NS]), and there was a non-significant rise in right-sided tumors among African-Americans (APC 2.4% [CI -0.5 to 5.4, NS]). Compared to the >50 cohort, patients 20-39 were more likely to present with Stage III/IV disease (65.8% vs 53.2% [$p<.01$]). **Conclusions:** While the incidence of CRC in older Texans has fallen, CRC has become progressively more common in individuals 20-39 years old, a trend largely attributable to a rise in distal tumors in Hispanics and non-Hispanic whites. Younger patients tend to present with more advanced disease, likely due to lack of routine screening and/or more aggressive biology. Young-onset CRC is an emerging disease that warrants further investigation.

**APCs in CRC incidence, 1995-2010.**

| Age | Race/ethnicity | Whole colon | Right colon | Left colon | Sigmoid/rectum |
|---|---|---|---|---|---|
| **20-39** | All | 1.7* | 1.5* | 2.1* | 2.3* |

**1588 General Poster Session (Board #370), Sun, 8:00 AM-11:45 AM**

**Frequency and clinical significance of extramammary findings on breast magnetic resonance imaging.** *Presenting Author: Catherine Elizabeth Moore, University of Iowa Hospitals and Clinics, Iowa City, IA*

**Background:** Breast magnetic resonance imaging (MRI), often obtained for management of newly diagnosed breast cancer, or other indications, uncovers extra-mammary findings (EMF) with some frequency. These results often prompt further work-up and cause pt concern. **Methods:** We retrospectively reviewed 1322 breast MRI reports performed at the University of Iowa between 2007 and 2012. We completed a chart review of the radiology reports, patient characteristics, and breast cancer characteristics. We then focused specifically on the EMFs that were detected on breast MRI. The EMFs in the field of breast MRI include lesions in the chest (lung, heart, mediastinum, and chest wall), liver, bone, spleen, lymph nodes, blood vessels, and bones. **Results:** A total of 1,322 MRI reports were reviewed. EMFs were reported in 130 (9.8%). An EMF was more likely to occur in postmenopausal pts ($p = 0.021$) or if the MRI indication was for breast cancer ($p <0.001$). EMFs were more frequent in pts with hormone receptor (HR) positive disease. HER2 status did not impact rate of EMFs. Most EMFs occurred in liver and bone. Of the 130 EMFs, 5 (3.8%) resulted in pts with active breast cancer being upstaged to stage IV disease. Of these 5 lesions, 3 were sternal and 2 were hepatic. One pt had an MRI for a high-risk indication and a sternal lesion was found which represented recurrence of previously treated breast cancer. These 6 studies represented 0.5% of all breast MRIs in this series. There were 2 additional cases where both the MRI and staging studies obtained the same day showed metastatic disease. **Conclusions:** Unexpected EMFs occurred with some frequency on breast MRI. Postmenopausal state, a diagnosis of breast cancer and HR positive disease, were associated with a higher EMF rate. These findings very rarely represented distant breast cancer.

**1589 General Poster Session (Board #371), Sun, 8:00 AM-11:45 AM**

**Age-related change in breast cancer stage at diagnosis relative to increased mammography detection over time: 1990-2012.** *Presenting Author: Judith April Malmgren, HealthSTAT Consulting, Inc., Seattle, WA*

**Background:** The United States does not have a national mammography screening program and relies on recommendations from the United States Preventive Services Task Force (USPSTF), the American Cancer Society (ACS) and other organizations to encourage screening. It has been hypothesized that mammography screening has not reduced advanced stage breast cancer (BC) from analysis of stage III and IV BC in a national database. **Methods:** Using our institutional breast cancer registry database, we reviewed change in stage distribution (0-IV) over time (OT) related to changes in detection method in the same time period. We restricted our analysis to age groups that have or have had screening recommendations during the time period (age 40 to 74) (N=8754). Pearson chi square tests were used to assess significance. Method of detection was categorized as patient (PtD) (N=3171), physician (PhysD) (n=460) or mammography (MamD) (n=5123) detected as recorded by the physician at time of diagnosis. Patients with unknown or other method of detection were excluded (n= 140). Stage for all years was converted to AJCC 7. **Results:** From 1990-2012 mammography detection of BC increased from 8% in 1990 to 22% in 2012 (+14%) ($p<.001$). MamD BC differed by age, presenting more often among older than younger women ($p<.001$) [age 40-49 = 45%, age 50-64 = 62%, age 65-74 = 68%]. For all groups combined stage shifted increasing 14% for stage 0 and decreasing 15% for stage I/II/III BC combined [stage I -4%, stage II -4%, stage III -7 %] with no change in stage IV ($p<.001$). By the three age groups, stage 0 BC change over time was +16% age 40-49, +14% age 50-64, and +11% age 65-74, stage I was 0% age 40-49, -6% age 50-64, -5% age 65-74; stage II was -10% age 40-49, 0% age 50-64/65-74; stage III -9% age 40-49, -7% age 50-64, -5% age 65-74; with no significant change in stage IV. **Conclusions:** A significant shift to lower stage disease was observed concurrent with increased mammography detection not restricted to stage III BC or including stage IV BC. Evaluation of association between screening recommendations and stage shift have to include change in all BC stages (0-IV) adjusted to a single AJCC grading standard and stratified to account for age related differences.

**1590 General Poster Session (Board #372), Sun, 8:00 AM-11:45 AM**

**Multicenter observational study of reactivation of hepatitis B virus (HBV) caused by chemotherapy for solid tumors (ST).** *Presenting Author: Shunsuke Kondo, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital, Tokyo, Japan*

**Background:** Reactivation of HBV has often been reported in patients (pts) with malignant lymphoma administered combination chemotherapy regimens containing rituximab. Recently, HBV reactivation has been reported even in pts with STs. However, the incidence of HBV reactivation in pts with STs and the treatment outcomes in pts with HBV reactivation have not yet been fully elucidated. Therefore, we prospectively investigated the incidence of HBV reactivation in pts with STs receiving first-line chemotherapy and the clinical outcomes of these patients. **Methods:** ST pts with seropositivity for HBsAg [sAg(+)], or seronegativity for HBsAg and seropositivity for HBcAb and/or HBsAb [c/sAb(+)], receiving first-line chemotherapy including neoadjuvant or adjuvant chemotherapy, were enrolled. HBV DNA was at least measured at the termination of the first-line chemotherapy, and at 3, 6, and 12 months after the termination of first-line chemotherapy. It was also measured in cases where HBV reactivation was suspected, such as based on increase in the serum levels of transaminases. HBV reactivation was defined as a 10-fold or greater increase in the titer of HBV DNA. **Results:** A total of 379 pts [sAg(+), 35 pts; c/sAb(+), 344 pts] were enrolled in this study. Any cancer types and regimens were included, and the median period of measurements of HBV DNA was 74 days (range, 13-248 days). Among the pts with sAg(+), HBV reactivation occurred in 9 pts, and the incidence rates at 6, 12 and 18 months were 6.8%, 30.0%, and 35.8%, respectively. Among pts with c/sAb(+), HBV reactivation occurred in 7 pts, and the incidence rates at 6, 12 and 18 months were 0.6%, 2.0% and 3.1%, respectively. Four of the seven pts with c/sAb(+) showing HBV reactivation improved without antiviral therapy, and there were no pts with increased serum transaminase levels or fulminant hepatitis in this series. **Conclusions:** HBV reactivation in ST pts with c/sAb(+) was rare, and no case with clinically significant HBV reactivation was detected by periodic measurement of HBV DNA and proper management at the first sign of reactivation. Clinical trial information: UMIN000005369.

**1591 General Poster Session (Board #373), Sun, 8:00 AM-11:45 AM**

**A comparative analysis of the association between health expenditure and cancer survival in 168 countries.** *Presenting Author: Felipe Ades, Institut Jules Bordet, Brussels, Belgium*

**Background:** Whereas cancer incidence is higher in high and middle income countries, cancer survival is lower in low income countries. In this analysis we investigated the relationship between health expenditure and cancer-related survival in 168 countries. **Methods:** Health expenditure data from 168 countries and cancer indicators data from 28 cancer types from the same countries were extracted from the World Bank (WB) and the World Health Organization (WHO) databases. The mortality/incidence (M/I) ratio was calculated to evaluate the fraction of patients dying after a cancer diagnosis. A regression analysis was conducted using a lin-log functional form that accounts for a non-linear relationship between (M/I) ratio and health expenditure. The coefficient of determination ($R^2$), indicates the proportion of outcomes explained by the model. **Results:** Health expenditure was significantly higher in high income countries than in middle and low income countries. For cancers with effective screening and/or effective treatment options higher expenditure was strongly correlated with improved survival. For cancers with no screening and moderately efficient treatment options survival was moderately correlated with health expenditure. For cancers with no screening and poor treatment options survival was poorly correlated to health expenditure. The estimated non-linear relationship shows that increases in health expenditure have a much more significant effect when health expenditure is low, especially for the first two groups of diseases. Significant survival improvements are expected from increasing health expenditure of low and middle income countries as in South America, Africa and parts of Asia, and only marginal incremental improvements, if any, in high income countries as the USA and Western Europe. **Conclusions:** Higher health expenditure is correlated with improved survival in cancers with available effective screening methods and/or treatment options. For cancer with no effective treatment options health expenditure has little impact on survival.

**The prevalence of severe vitamin D (vitD) deficiency and its effect on tumour indices and clinical outcomes in patients with early breast cancer (EBC).** *Presenting Author: Kasia M. Owczarczyk, Mount Vernon Cancer Centre, Middlesex, United Kingdom*

**Background:** VitD deficiency is a common occurrence in the UK, affecting nearly a quarter of British women. Emerging data suggests that this proportion may be higher in pts with EBC; however, screening and vitD supplementation is currently not recommended in this population. This study was carried out to assess the prevalence of severe vitD deficiency in an ethnically diverse UK EBC cohort and its association with tumour indices and clinical outcomes. **Methods:** Serum vitD levels were prospectively recorded in a consecutive cohort of pts with newly diagnosed EBC presenting to our oncology department from 2006-2010. Severe vitD deficiency was defined as serum total 25-hydroxyvitD <10ng/mL, a threshold for which high dose supplementation is recommended, according to revised national guidelines. $X^2$tests and multiple logistic regression were used to investigate association between vitD and clinical factors, with Cox PH models used to investigate the effect of vitD on time to tumour recurrence. **Results:** Data was available for 259 patients. Median vitD level was 17.6ng/mL 61 patients (23.6%) were severely vitD deficient. vitD deficiency was associated with age <50 years, non-White ethnicity and ER-ve receptor status. In multiple logistic regression, ethnicity and ER were independently associated with vitD deficiency. After a relatively short follow up of 33 mths (IQR 25-42), 33 (12.7%) pts had a local or distant recurrence. Risk of recurrence was increased in pts with vitD<10ng/mL (HR=1.58, 95%CI 0.75–3.32) which is consistent with a recent meta-analysis. **Conclusions:** In this study, nearly a quarter of pts (and more than a third of Asian pts) were severely vitD deficient at diagnosis, more than in most published studies. Given revised supplementation recommendations, both routine testing and adequate supplementation of vitD is recommended.

**Effect of CHRNA9 polymorphisms and passive smoking on the risk of breast cancer in Taiwan.** *Presenting Author: Yi-Chen Hsieh, Taipei Medical University, Taipei, Taiwan*

**Background:** Previous studies have indicated that smoking exposure is associated with increased breast cancer risk, and $\alpha$9-nicotine acetylcholine receptors ($\alpha$9-nAChRs) were involved in breast tumorigenesis. However, there are no studies exploring the $\alpha$9-nAChRs genes (CHRNA9) and cigarette smoking exposure together on breast cancer risk. **Methods:** A case-control study was conducted on 737 breast cancer patients and 719 age-matched healthy controls. Three single nucleotide polymorphisms (SNPs) of CHRNA9 located on promoter were genotyped and compared between cases and controls to identify these SNPs associated with breast cancer susceptibility. A dual-luciferase reporter assay was used to analyze the promoter activity of these SNPs of CHRNA9 gene. **Results:** CHRNA9 -885A/T and -823A/G polymorphisms showed a significant association with susceptibility of breast cancer. Passive cigarette smoking and risk genotypes of -823A/G of CHRNA9 gene had synergistic effects on the risk of breast cancer. The odds ratio for the interaction and the attributable proportion from the interaction and synergy index were 6.3, 0.56 and 2.6, respectively. These findings indicated a multiplicative interaction between passive cigarette smoking and CHRN9 gene. The results further confirmed that the risk genotype of -823A/G of CHRNA9 exhibited stronger transcriptional activation activity than the wild type ($P<0.05$). **Conclusions:** Our findings support that a significant interaction effect exists between CHRNA9 gene and passive cigarette smoking on breast cancer patients.

**1594 General Poster Session (Board #376), Sun, 8:00 AM-11:45 AM**

**The risk of second primary malignancy among male breast cancer patients: A population-based study.** *Presenting Author: Man-Hsin Hung, Division of Hematology and Oncology, Department of Internal Medicine, Taipei Veterans' General Hospital, Taipei, Taiwan*

**Background:** Male breast cancers, thought rare, are in a trend of increasing in recent years. Owning to advances in diagnostic and therapeutic modalities, outcomes for breast cancer have been greatly improved. Therefore issues regarding second primary malignancy in these long-term breast cancer survivors become more important than before and should be further investigated. **Methods:** From the Taiwan National Health Insurance Program Database, patients with newly diagnosed breast cancer from January 1997 to December 2011 were recruited for analysis. The standardized incidence ratios (SIRs) of secondary non-breast primary cancer in male breast cancer patients were calculated and compared with the cancer incidence in the general male population. **Results:** Within a follow-up of 2,773 person-years, there were 73 primary non-breast cancers developed in 578 male breast cancer patients. Compared with the general population, the SIRs of second primary malignancy in male breast cancer patients were 2.17 [95% confidence interval (CI) 1.70- 2.73], which were particularly higher in patients with breast-cancer-diagnosis-age younger than 40 (SIR 29.70, 95% CI 6.12- 86.80; Table) furthermore, the SIRs of thyroid cancer (SIR 13.2, 95% CI 1.60- 47.69), skin cancer (SIR 8.24, 95% CI 3.02 – 17.94) and head and neck cancer (SIR 4.41, 95% CI 2.35 – 7.54) were the highest among all types of second primary malignant diseases observed. **Conclusions:** Compared with the general population, the SIRs of secondary non-breast-cancer malignant disease were significantly higher in male breast cancer patients, particularly in patients with breast cancer diagnosed younger than 40 years of age. Therefore, more intensive surveillance of second primary malignancy may be needed for male breast cancer survivors, particularly for those with high riskfeatures.

**1595 General Poster Session (Board #377), Sun, 8:00 AM-11:45 AM**

**A nomogram associated with high probability of invasive carcinoma on the surgical specimen in patients with preoperative diagnosis of ductal carcinoma in situ of the breast.** *Presenting Author: Takafumi Kondo, St. Luke's International Hospital, Tokyo, Japan*

**Background:** Sentinel node biopsy is frequently performed for patients with preoperative diagnosis of ductal carcinoma in situ (DCIS) by needle biopsy because of a possibility of postoperative diagnose of invasive ductal carcinoma (IDC) on the surgical specimen. Inessential sentinel node biopsy would be omitted, if final postoperative diagnosis could be predicted DCIS accurately. The aim of this study are to determine clinicopathological factors associated with postoperative diagnosis of IDC regardless of preoperative diagnosis of DCIS, and to conduct a model to predict IDC on surgical specimen. **Methods:** Pre- and postoperative pathological diagnosis and radiological findings on 1,251 consecutive patients who were diagnosed DCIS by preoperative core needle biopsy (CNB) or vacuum-assisted breast biopsy and underwent surgical resection from 2003 to 2012 were retrospectively assessed. Multivariate logistic regression was applied to generate the nomogram to predict IDC. **Results:** Of the 1,251 patients, 318 (25.4%) were diagnosed IDC on surgical specimen. On multivariate analysis, no evidence of sclerosing adenosis on preoperative biopsy specimen (odds ratio (OR) 0.46, 95%CI 0.25-0.85, $p = 0.013$), pleomorphic calcifications on mammogram (OR 1.68, 95%CI 1.14-2.47, $p = 0.009$), suspicious of invasive carcinoma on ultrasound and/or MRI (OR 2.13, 95%CI 1.51-3.00, $p = 0.000$), tumor size≧2cm on ultrasound (OR 1.80, 95%CI 1.05-3.06, $p = 0.032$) were independent predictive factors. HER2-positive (OR 1.54, 95%CI 0.98-2.41, $p = 0.062$) and comedo necrosis (OR 1.42, 95%CI 0.99-2.03, $p = 0.056$) were also same trend. A nomogram using these factors predicted the correlation with AUC of 0.67 (95% CI 0.63-0.71). **Conclusions:** Our nomogram showed the correlation of the presence of invasive breast carcinoma on surgical specimen regardless of preoperative diagnosis of DCIS. Prospective external validation is needed before being implemented in clinical practice.

**1596 General Poster Session (Board #378), Sun, 8:00 AM-11:45 AM**

**Incidence and mortality rates of breast and gynecologic cancers and human development index in the pan-American region.** *Presenting Author: Jeovany Martínez-Mesa, Latin American Cooperative Oncology Group (LACOG), Porto Alegre, Brazil*

**Background:** Breast and gynecologic cancers incidence and mortality rates differ between geographical regions. We aim to evaluate if disparities in incidence and mortality cancer rates among women in the Pan-American countries could be related to the country human development index (HDI). **Methods:** This ecological analysis includes 28 countries from the Pan-American region. Age-standardized incidence and mortality rates per 100.000, mortality/incidence ratios for breast , cervical cancer, ovarian cancer and corpus uteri cancer obtained from GLOBOCAN 2012. Data were log-transformed because of strong skewness. The information on HDI was gathered from the UNDP 2012 report. Pearson's correlation test and simple linear regression were performed in Stata 12. **Results:** HDI was strongly and positively associated with breast and ovarian cancers incidence and mortality rates. HDI was negative associated with cervical cancer incidence and mortality rates and also with breast and cervical cancers ratio. HDI was not associated with corpus uteri cancer estimative. Linear regression coefficients ($\beta$) between HDI and each cancer log-rate are shown in the Table. **Conclusions:** HDI should be considered as an indicator explaining inequalities in incidence and mortality rates of breast, cervical and ovarian cancer in women between countries in the Pan-American region.

| | Linear regression coefficient | |
|---|---|---|
| Cancer rates per 100,000 (log-transformed) | $\beta$ (95%CI) | p-value* |
| **Breast cancer incidence** | 4.03 (2.61;5.45) | <0.001 |
| **Breast cancer mortality** | 1.76 (0.32;3.21) | 0.019 |
| **Breast cancer mortality/incidence ratio** | -0.26 (-0.42;-0.10) | 0.003 |
| **Cervical cancer incidence** | -3.28 (-4.78;-1.78) | <0.001 |
| **Cervical cancer mortality** | -4.63 (-6.1;-3.17) | <0.001 |
| **Cervical cancer mortality/incidence ratio** | -0.89 (-1.16;-0.62) | <0.001 |

**1597 General Poster Session (Board #379), Sun, 8:00 AM-11:45 AM**

**Obesity-induced alteration in iron metabolism via elevated hepcidin and the risk of postmenopausal breast cancer among Caucasians.** *Presenting Author: Puja Agarwal, University of Illinois at Chicago, Chicago, IL*

**Background:** Obesity is an established risk factor for postmenopausal breast cancer and also induces iron dysregulation via elevated hepcidin (hepatic peptide hormone). Hepcidin degrades ferroportin (Fp-only known iron exporter) and traps iron that enhances carcinogenesis within the cell. Breast tumors with high hepcidin and low Fp have poor prognosis. The purpose of this study was to determine if systemic hepcidin independently enhances the established obesity and postmenopausal breast cancer risk. **Methods:** A nested case (n=44)-control (n=44) study was conducted from an ongoing cohort on women seeking breast biopsies enrolled in a study to develop blood-based biomarkers. White postmenopausal women with incident breast cancer were matched for age and BMI to women with a non-proliferative benign lesion. Both cases and controls were stratified by obesity status (50% had a BMI $>$ 30 & 50% $<$ 30). Blood samples, anthropometric and other information were collected prior to biopsy. C-reactive protein, IL-6, leptin, adiponectin, estradiol, soluble transferrin receptor and hepcidin were measured using ELISA and cases and controls were compared with T-test, Wilcoxon Rank test and conditional logistic regression. **Results:** Hepcidin (p=0.02) along with other obesity related factors for breast cancer (inflammation (CRP, IL-6); leptin and estrogen; (all p values $\leq$ 0.05)) significantly differed with obesity status among the controls. Among the cases hepcidin levels were similar in obese and non-obese. Hepcidin ($\beta$=0.04; p value=0.043) was a significant independent predictor of disease (p value) status when controlled for age, leptin, family history of breast cancer, age of menarche and use of hormone replacement therapy and IL-6 in multivariable conditional logistic regression**. Conclusions:** Influence of obesity on hepcidin reported in premenopausal women also occurs post menopause. Hepcidin level is associated with breast cancer and may represent a novel mechanism to explain the link between obesity and breast cancer. Further study of this association is warranted.

**1598 General Poster Session (Board #380), Sun, 8:00 AM-11:45 AM**

**Incidence trends of keratinocytic skin cancers and melanoma in Israel 2006-2011.** *Presenting Author: Tal Sella, Sheba Medical Center, Ramat Gan, Israel*

**Background:** The incidence of skin cancer, both melanoma and keratinocyte cancers (KC) is rising throughout the world, specifically squamous cell carcinomas(SCC) and basal cell carcinoma(BCC), being the most common of all cancers. Objective: To determine trends in incidence of Melanoma, BCC and SCC among 1.7 million members of Maccabi Healthcare Services from 2006 to 2011. **Methods**: Data on newly diagnosed Melanoma, SCC and BCC cases was collected from the MHS Cancer Registry and based on histology reports from the centralized pathology lab. Age-specific and overall age-adjusted European standardized rates were computed. Trends were estimated by calculating Average Annual Percentage Change(AAPC). **Results**: During the six year study period, a total of 16,079 subjects were diagnosed with at least one BCC, 4,767 with SCC and 1,264 with invasive melanoma. Age-standardized incidence rates were 188, 58 and 17 per 100,000 person years for BCC, SCC and melanoma, respectively. All lesions were more common among males and primarily affected the elderly. BCC rates were stable throughout the study period(AAPC -0.7%, 95%CI -4.5% to 3.2%) while SCC incidence increased significantly(AAPC 15.5%, 95%CI: 2.6% to 30.0%). In contrast, melanoma rates showed a continuously decreased with a significant AAPC of -3.0%, 95%CI (-4.5 to -0.1). **Conclusions**: Previously unreported, the incidence of KC in Israel is one of the highest in the world. The disparities in incidence trends between SCC, BCC and melanoma allude to their different etiologies. These findings underscore the importance of continuous monitoring, education and prevention programs in a growing high risk population.

**1599 General Poster Session (Board #381), Sun, 8:00 AM-11:45 AM**

**Impact of antibiotic exposure on the risk of colorectal cancer.** *Presenting Author: Shimon Ben Boursi, Sheba Medical Center, Ramat Gan, Israel*

**Background:** Previous reports revealed colonic dysbiosis in tumor tissue from cases with colorectal cancer (CRC) showing lower levels of microbial diversity and an enrichment of certain bacterial strains. It was suggested that the composition of the microbiota might serve, among other genetic and environmental factors, as a significant promoter of the multistep process of CRC formation. Antibiotic therapy reduces the overall bacterial diversity, with substantial consequences for the resultant functional stability of the colonic microbiota. Aim: To evaluate the association between the type and cumulative dose of antibiotic exposure and CRC risk. **Methods:** We conducted a nested case-control study using The Health Improvement Network (THIN), a large population-based medical records database from the United Kingdom (UK) that contains information on 11.7 million patients with follow up of up to 18 years. Study cases were defined as those with any medical code of CRC. Subjects with known familial colorectal cancer syndromes or IBD were excluded from the study. For every case, 4 eligible controls matched on age, sex, practice site, and duration of follow-up before index date were selected using incidence density sampling. Exposure was defined as any antibiotic therapy at least 6 month before index date. The OR and 95%CI were estimated using conditional logistic regression analysis adjusted for BMI, alcoholism, smoking history, Diabetes mellitus and chronic NSAIDs use. **Results:** 22,023 CRC patients and 85,981 controls were identified with a mean follow up time of 6 years (SD 3.53). The adjusted OR for CRC among user of penicillins, quinolones and metronidazole was 1.08 (95%CI 1.04-1.12), 1.08 (95%CI 1.03-1.14) and 1.11 (95%CI 1.05-1.18) respectively with p$<$0.0001 for all. The modest risk increase remained statistically significant only for remote exposure to penicillins (OR 1.05, 95%CI 1.001-1.09, for exposure 10 years before index date). There was no statistically significant effect with other antibiotic classes, anti-viral or anti-fungal therapy. **Conclusions:** Past exposure to Penicillins is related to a modest elevation in CRC risk, possibly through effects on the colonic microbiota.

**1600 General Poster Session (Board #382), Sun, 8:00 AM-11:45 AM**

**Thyroid hormone replacement and the risk for colorectal cancer.** *Presenting Author: Shimon Ben Boursi, Sheba Medical Center, Ramat Gan, Israel*

**Background:** The association between thyroid hormones and cancer risk was evaluated in several studies with conflicting results. While thyroid hormones can stimulate cancer growth, hypothyroid function can lead to reduced risk and a more favorable outcome in cancer patients. Aim: To evaluate the risk for colorectal cancer (CRC) in patients treated with thyroid hormones replacement. **Methods:** We conducted a nested case-control study using The Health Improvement Network (THIN), a large population-based medical records database from the United Kingdom (UK) that contains information on 11.7 million patients with follow up of up to 18 years. Study cases were defined as those with any medical code of CRC. Subjects with known familial colorectal cancer syndromes or IBD were excluded from the study. For every case, 4 eligible controls matched on age, sex, practice site, and duration of follow-up before index date were selected using incidence density sampling. Exposure was defined as any thyroid hormone therapy at least 6 month before index date. The odds ratio (OR) and 95%CI were estimated using conditional logistic regression analysis adjusted for BMI, alcoholism, smoking history, Diabetes mellitus and chronic NSAIDs use. **Results:** 22,023 CRC patients and 85,981 controls were identified with a mean follow up time of 6 years before index date (SD 3.53). The adjusted OR for CRC associated with use of thyroid hormones was 0.87 (95%CI 0.82-0.93, p$<$0.0001) and remained reduced 5 and 10 years after initiation of therapy (OR 0.84, 95%CI 0.78-0.91 and 0.83, 95%CI 0.74-0.92 respectively). There was no change in OR when analyzing all durations of therapy, including patients treated for less than 6 months (OR 0.88, 95%CI 0.82-0.93). **Conclusions:** Patients using thyroid hormone replacement drugs have a statistically significant reduction in CRC risk. Further research is required in order to evaluate whether this effect is secondary to the primary thyroid disease or direct effects of therapy.

**1601 General Poster Session (Board #383), Sun, 8:00 AM-11:45 AM**

**Long-term breast cancer outcomes in Canada with special analyses of cancer care access and mortality reduction.** *Presenting Author: Joseph Ragaz, School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada*

**Background:** The objective of this study is to compare main Breast Cancer outcomes in two regions of Canada with different access to Provincial Guideline-based cancer care [GCC]. Since the 1960's, British Columbia has had a centralized provincially funded Cancer program, coordinating GCC care. Adjuvant therapies started in late 1970's; and of screening mammography in late 1980's. Both Programs were implemented province-wide, and at least a decade earlier than in Atlantic Provinces (Atl. Prov.). Both regions have had comparable BrCa registry since 1970. **Methods:** From 1970-2007 datawere obtained in collaboration with Public Health Agency of Canada and Canadian Cancer Registry database at Statistics Canada. Estimates for annual age standardized rates /100,000 [with Canada 1991 as population reference] were evaluated for BrCa in-situ [ASR-IS]; incidence of invasive BrCa [ASIRs]; and BrCa-specific mortality [ASMRs]. Results were averaged q 10 years. ASMRs were also expressed [in percent] relative to baseline years 1970-75. **Results:** See Table. **Conclusions:** (1) While in the 1970's the rates of both in-situ and invasive BrCa in Atl. Prov. were significantly lower than in B.C., subsequently both rates have increased to approximate rates in B.C.( 20 ASMR reduction in B.C. is more substantial and observed many years earlier than in Atl. Prov. (3) These results show that uniform guideline-coordinated cancer care favorably impacts BrCa outcomes, and should be implemented in regions with unequal access to cancer care. **1602 General Poster Session (Board #384), Sun, 8:00 AM-11:45 AM**

**Breast cancer risk among women following lifestyle recommendations: A case-control study in Spain.** *Presenting Author: Marina Pollán, National Center of Epidemiology, Instituto Salud Carlos III, Madrid, Spain*

**Background:** In 2007, the World Cancer Research Fund (WCRF) and the American Institute of Cancer Research (AICR) issued 8 general and 2 special recommendations for cancer prevention based on available evidence. The objective of this study was to explore the association between the WCRF/AICR recommendations and breast cancer risk. **Methods:** EpiGEICAM is a nation-wide case-control study, 1019 cases from 23 hospitals were matched to 1019 controls by age and municipality of residence. The cases were sub classified by tumor subtype: 1) Estrogen Receptor(ER)+ or Progesterone Receptor(PR)+ with Human Epidermal Growth Factor Receptor 2(HER2)-; 2) HER2+; and 3) ER-,PR-&HER2- tumors. We constructed a score (0-9) based on 9 of the 10 WCRF/ AICR recommendations. The score was grouped in 4 categories (0 to $<4$, 4 to $<5$, 5 to $<6$ and $\geq 6$) and its association with BC risk was evaluated using conditional logistic regression models adjusted by total calorie intake, smoking habit, age at first delivery, education, history of breast problems, family history of BC and menopausal status. Multinomial logistic regression models were used to evaluate the association of the WCRF/AICR score with each of the intrinsic BC subtypes. These models were adjusted by age, hospital, and the same set of potential confounders described above. **Results:** The women with higher score showed a decreased risk of BC ($OR_{[6\text{-}9]vs[0\text{-}4]}$ =0.51; 95%CI=0.36-0.73 and $OR_{unit\text{-}increase}$=0.82; 95%CI =0.74-0.91; p-trend$<$0.001). This preventive effect was slightly more pronounced in postmenopausal women ($OR_{[6\text{-}9]vs[0\text{-}4]}$ =0.43; 95%CI=0.26-0.70 and $OR_{unit\text{-}increase}$=0.81; 95%CI=0.71-0.93, p-trend=0.001) and in women with ER+/PR+&HER2- tumors ($OR_{[6\text{-}9]vs[0\text{-}4]}$ =0.43; 95%CI =0.30-0.62 and $OR_{unit\text{-}increase}$=0.78; 95%CI=0.70-0.87; p-trend$<$0.001). However, none of the differences in the magnitude of risk by menopausal status and intrinsic tumor subtypes was statistically significant. **Conclusions:** Adherence to the WCRF/AICR recommendations for cancer prevention might reduce breast cancer risk in both pre and postmenopausal women and all cancer subtypes.

**1603 General Poster Session (Board #385), Sun, 8:00 AM-11:45 AM**

**Importance of durational hormone therapy in breast cancer patients in Germany: Retrospective database analysis.** *Presenting Author: Nina Schmidt, Department of Gynecology, Endocrinology and Oncology, Philipps-University of Marburg, Marburg, Germany*

**Background:** The ATLAS trial demonstrated an additional benefit in the extension of treatment of breast cancer patients from 5 to 10 years. However, the longer therapy requires good compliance by the patients. The aim of this study is to investigate the actual duration of therapy of breast cancer patients until treatment discontinuation or scheduled termination of therapy. **Methods:** We used data from the IMS Disease Analyzer database that entails a dataset of more than 20 million patients. Out of this dataset, breast cancer patients with first time tamoxifen (TAM) or aromatase inhibitors (AI) prescriptions between January 1995 to December 2012 in 1,264 genral practitioner and 387 gynecological practices were identified. Treatment discontinuation of hormonal therapy was defined as 180 days without any treatment or switch to an alternative hormonal therapy. Only women, who still visited their physician more than 180 days after therapy end were included in the analysis. For the current persistence analyses, 8,837 women on tamoxifen or aromatase inhibitors met the inclusion/ exclusion criteria. **Results:** The average hormonal therapy duration was 915 days (SD: 784). 88.1% of women discontinued their therapy before the end of the 5th year. Discontinuation rate was 35.4% within first year and increased to 61.4 % within 3 years of follow-up. The compliance rate decreased with increasing age of the patient. **Conclusions:** The retrospective data analysis showed that the share of patients who stay on hormonal therapy for five years is very small. Therapy discontinuation can be due to side effects, suboptimal communication between physicians and patients or other reasons. Compliance in breast cancer therapy needs to be significantly increased for improved outcome in clinical practice.

**1604 General Poster Session (Board #386), Sun, 8:00 AM-11:45 AM**

**Association of diabetes and cancer-diagnoses in primary care practices in Germany.** *Presenting Author: Nina Schmidt, Department of Gynecology, Endocrinology and Oncology, Philipps-University of Marburg, Marburg, Germany*

**Background:** Previously published studies suggest that type 2 diabetes is associated with an increased risk of cancer, particularly in the case of breast, colorectal, bladder and pancreatic cancers. In the present study the incidence of 14 different cancer types was compared among diabetes vs. none-diabetes patients. **Methods:** We used data from the IMS Health Disease Analyzer database focusing on two different groups of patients: patients diagnosed with diabetes and patients without diabetes who were treated in a general practice in Germany. The analysis was performed retrospectively. The proportion of patients with a primary cancer diagnosis following initial diagnosis of diabetes (or in the same period for patients with no diabetes) was determined. The Hazard ratios (HR; Cox regression) for the risk of cancer in diabetic versus none-diabetic patients (follow-up:. maximum of 12 years) were adjusted for demographic and clinical variables. **Results:** 78,599 patients diagnosed with diabetes and 392,995 patients without diabetes were identified. The study population was matched in terms of age (68 $\pm$ 11 years) and gender (male: 47%). The overall risk of cancer was slightly higher in diabetes-patients than in patients without diabetes (HR: 1.06; CI: 1.04 to 1.09). The risk of getting cancer was significantly increased for patients with diabetes with regard to pancreatic cancer (HR: 2.17; CI: 1.86 to 2.52), esophageal cancer (HR: 1.32; CI: 1.03 to 1.69), kidney cancer (HR: 1.30; CI: 1.11 to 1.52), lung cancer (HR: 1.15; CI: 1.05 to 1.28), colorectal cancer (HR: 1.13, CI: 1.04 to 1, 22) and endometrial cancer in women (HR: 1.43; CI: 1.08 to 1.90). In breast, prostate, liver, stomach, thyroid, urinary bladder, gall bladder cancer and non-Hodgkin lymphoma no significant increase in risk was observed. **Conclusions:** In this retrospective database analysis, with a maximum of 12 year observation period, type 2 diabetes was associated with an increased risk of cancer. However, it is not yet clear at this point whether the diabetes or rather certain antidiabetic drugs increase the risk of cancer. Further research is required to understand these correlations.

**1605 General Poster Session (Board #387), Sun, 8:00 AM-11:45 AM**

**Incidence of cardiovascular events in the real-world population of cancer patients treated with targeted therapies.** *Presenting Author: Jonathan G Zaroff, Kaiser Permanente, Oakland, CA*

**Background:** Population-based risks of cardiovascular events (CV) among cancer patients treated with targeted therapies (tyrosine kinase inhibitors (TKIs) or drugs with similar mechanism of action (MOA)) are not available. Most estimates derive from case-series or trials. The study objective was to estimate the incidence of specific CV events in this population. **Methods:** A population-based cohort study of Kaiser Permanente Northern California (KPNC) members. KPNC is an integrated health program with 3.2 million members (~30% of the insured population) in 14 Northern California counties. Inclusion criteria: Cancer registry diagnosis (1997-2009) of any solid tumor excluding non-melanoma skin cancer, and with treatment with any of the following: sunitinib, sorafenib, imatinib or bevacizumab. Main (adjudicated) outcome measures: Acute coronary syndrome, heart failure (HF), ischemic stroke, hemorrhagic stroke, cardiac arrest, hypertension (HTN), deep venous thrombosis (DVT), pulmonary embolus, and CV death. Statistical analysis: The incidence rate (IR) of each CV outcome was measured as the rate of events per 1000 person years (PY) and reported with 95% confidence intervals (CI). Two follow-up periods were defined: early (treatment duration of the targeted therapy plus 60 additional days) and unrestricted (at any time after a prescription until censoring or the end of follow-up). **Results:** In total, ~3,000 patients met inclusion criteria for this analysis including 294 patients with renal cell carcinoma (RCC) and 80 patients with gastointestinal stromal tumor (mean age=59.5 years, 66.8% White and 2005 as a median year of cancer diagnosis). Highest IRs were observed for HTN, DVT and HF for both the early and unrestricted follow-up periods for all cancer types. For early follow up, the IR of HTN was 0 for prostate cancer, 14.6 (95%CI: 9.7-22.0) for breast cancer, and 25.7 (95%CI: 17.0-38.6) for RCC. These IRs increased to 1.8 (95%CI: 0.2-10.4), 20.7 (95%CI: 14.6-29.2), and 30.6 (95%CI: 20.9-44.4), respectively, for unrestricted follow up. **Conclusions:** This was the first population-based study to estimate incidence of CV events among those treated with targeted therapy, by cancer type.

**1606 General Poster Session (Board #388), Sun, 8:00 AM-11:45 AM**

**Gender disparity in breast cancer: A veteran population-based comparison.** *Presenting Author: Anita Aggarwal, VA Medical Center, Washington, DC*

**Background:** Male breast cancer (MBC) is <1% of all cancers in men and continues to rise. Because of rarity, there is paucity in literature. Management of MBC is generalized from female breast cancer (FBC). The Veterans Affairs (VA) Central Cancer Registry (VACCR) provides a unique source for the study of MBC. The objective of this retrospective analysis was to compare and contrast the characteristics and outcome of MBC with FBC in the VA population. **Methods:** VACCR data from 153 VA medical centers were used to analyze the database of VA patients who had breast cancer diagnosed between 1998 and 2013. Primary site codes were identified for breast cancer (50.0-50.9). Data were entered and analyzed using biostatistical software (SAS 9.3). **Results:** In total, 6443 patients' records were reviewed, and 1123 MBC were compared with 5320 FBC patients. The mean age at diagnosis was 70 and 57 years for MBC and FBC, respectively ($P < .0001$). Higher number of MBC (95%) as compare to FBC ( 72%) were age >50years. 75% patients with breast cancer were white in both genders. More MBC (40% vs 24%) presented with higher disease stage (III and IV) in comparison to FBC (21% had DCIS and 53% stage I). The dominant histology was ductal carcinoma. No difference in laterality was observed. Estrogen and progesterone receptor-positive tumors were more common in MBC compared with FBC. 45% and 36% of MBC and FBC, respectively, received hormonal treatment as first course but fewer MBC received chemotherapy and radiation. The mean follow up time was 754 days. As of Dec 2013, 355 (32%) MBC and 791 (15%) FBC died during the course of the study. Males had higher odds of death compared to females after adjusting for age, race, stage, and grade (OR 1.656, 95% CI 1.347, 2.037). **Conclusions:** To the authors' knowledge, this is the largest series of MBC and FBC to date in the Veterans population. The results suggested that males were older at presentation and had higher stage of breast cancer as compare to FBC. The higher mortality rate in MBC may be due to higher stage and /or tumor biology.

**1607 General Poster Session (Board #389), Sun, 8:00 AM-11:45 AM**

**Burden of HPV infection in the United States: NHANES (1999-2012).** *Presenting Author: Erin Dunn, University of Miami, Miller School of Medicine, Miami, FL*

**Background:** Human Papilloma Viruses (HPVs) are a group of over 150 viruses. When certain types of HPV persist, benign tumors such as warts or papillomas can result. Other persistent HPV infections can play a role in causing cancer of the cervix, penis, anus, vagina, vulva, and oropharynx. National population-based surveys of HPV infection provide estimates of population-specific prevalence, trend, and determinants to identify the burden of HPV. Determining the burden of HPV infection is crucial for future public health efforts. **Methods:** We looked at prevalence of HPV infections, both by DNA (females only) and oral testing (females and males) in the US from 1999-2012 National Health and Nutrition Examination Survey (NHANES) to obtain a representative sample of the US non-institutionalized civilian population. NHANES performs in-person interviews and physical examinations and collects biological samples at homes and at mobile examination centers. We provided epidemiology of HPV infection and its types for females and males. Analysis was performed by SAS v9.3 (SAS Institute Inc, Cary, NC USA) with survey procedures to take into account the sampling design. **Results:** Orally-measured HPV infection affected 7.3% of the US population with the most frequent being HPV 16 (n=276,335) and HPV 62 (n=221,320) and least frequent being HPV 26 (n=736.615). Using the oral test, men had the highest prevalence of general HPV infection (74.4%) and high risk HPV (79.4%). Whites had the highest prevalence of HPV infection (61.7%) and of high risk HPV (69.2%). "Other races" had the lowest HPV infection (4.7%) and high risk HPV (3.5%). DNA-measured HPV affected 42.9% of US women, with HPV 62/53 most and HPV 64 least frequently. DNA-measured HPV showed non-Hispanic White women had the highest prevalence in general (62.0%) and for high risk HPV (62.5%). "Other races" had the lowest prevalence of overall HPV (5.1%), while "other Hispanic" had the lowest burden of high-risk HPV (4.9%). **Conclusions:** Using a large population-based survey-,our results show the variation of HPV by test and type. Understanding the burden of HPV infection, especially the types that are linked to cancer, may provide a base for future cancer prevention programs via screening, vaccination, health promotion and literacy.

**1608 General Poster Session (Board #390), Sun, 8:00 AM-11:45 AM**

**The decrease in global cancer mortality.** *Presenting Author: Paolo Boffetta, Ichan School of Medicine at Mount Sinai, New York, NY*

**Background:** A decrease in cancer mortality has been reported in the United States, Europe and other developed regions of the world during the last two decades. Whether similar trends apply to less-developed countries – and globally – is unclear. **Methods:** We aimed at describing the global patterns of cancer mortality by conducting a systematic analysis of the WHO mortality database for countries for which high- or intermediate-quality data on death certifications are available for a period of at least 10 years (typically 2003-2012). We included 60 countries in the analysis, and calculated age-specific and age-adjusted mortality rates. **Results:** A decrease in overall cancer mortality of approximately 1% per year was present in both developed and less-developed regions, and in both genders. For cancers of the esophagus, stomach, larynx and thyroid, the average decrease in global mortality rate was greater than 2% per year. Individual cancers which showed an increase in mortality rates on a global scale are limited to pancreas and brain (both genders), lung (women), melanoma and kidney (men) and endometrium. **Conclusions:** Reasons for the decrease in cancer mortality in less-developed countries may include decrease in cancer incidence, shift in the stage distribution, shift in the proportional contribution of individual cancers, and improved therapy. The increase in the number of cancer deaths, globally and in less-developed countries, is primarily driven by changes in the demographic structure of the population, but the risk of the individual of dying from cancer appears to decrease in all countries with reliable data. Cancers with increasing mortality rates should be given priority for research.

**1609 General Poster Session (Board #391), Sun, 8:00 AM-11:45 AM**

**Prevalence of COPD in a lung cancer case-control study: Variability by assessment method and by race.** *Presenting Author: Ann G. Schwartz, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

**Background:** The association between lung cancer risk and a history of self reported COPD (Chronic Obstructive Pulmonary Disease) is well established, but the association is less consistent when based on CT scan evidence of emphysema. We evaluated the effect of COPD ascertainment method on lung cancer risk estimates in a case-control study focused on genomic variation in lung cancer patients with and without COPD. **Methods:** A total of 899 participants (280 lung cancer cases and 619 controls) have been enrolled; 45% are African American (AA). Participants completed a questionnaire, spirometry and CT scans to assess COPD by radiology assessment and quantitative imaging analysis. Enrollment to the study to analyze genomic variation is ongoing. **Results:** 20% of cases and 10% of controls reported a physician diagnosis of emphysema; lung cancer risk was significantly associated with self-report (OR=2.1; 95%CI 1.4-3.1). A larger percentage of cases (63%) and controls (53%) were classified as having emphysema based on radiology assessment, reducing the association with lung cancer (OR=1.5, 95% CI 1.1-2.1). The percentage of false positives ("yes" on self-report and "no" on the CT) at ~ 3% and false negative reports (self-report "no" and "yes" on CT) at ~ 45% were consistent across racial groups. Risk of lung cancer based on self reported COPD compared to spirometry defined COPD ($FEV_1/FVC < 70\%$) was similar. 40% of cases self reported COPD as did 24% of controls (OR = 2.0; 95% CI 1.4-2.7), while 52% of cases and 35% of controls had a COPD diagnosis based on spirometry (OR = 2.0; 95% CI 1.4-2.7). Significant differences in self-reported versus spirometry-defined COPD were observed in both cases ($p=0.03$) and controls ($p<0.001$), driven by findings in AA. AA cases ($p=0.01$) and controls ($p<0.001$) had evidence of under-reporting of COPD. ORs associated with emphysema on CT were 1.2 (95% CI 0.7-1.8) for whites and 2.1 (95% CI 1.3-3.5) for AA ( $p=0.053$). Quantitative imaging for COPD is underway. **Conclusions:** These results indicate participants under-report emphysema and COPD, under-reporting differs by race, and regardless of measurement method, there is a significant effect of emphysema and COPD on lung cancer risk.

**1610 General Poster Session (Board #392), Sun, 8:00 AM-11:45 AM**

**Statins and survival in a cohort of veterans with chronic lymphocytic leukemia (CLL).** *Presenting Author: Abdullah Mohammad Khan, Rutgers New Jersey Medical School, Newark, NJ*

**Background:** CLL is the most prevalent leukemia in the Veteran (V) population but there is limited information on the clinical characteristics and risk factors in this population. We hypothesized that statins might have a protective effect based on earlier work (ASCO 2013). **Methods:** In an IRB approved protocol, a retrospective cohort of 130 V diagnosed with CLL from 2001 to 2013 were reviewed for demographic, clinical, and laboratory data. Comorbidity was assessed using Charlson Comorbidity Index (CCI), The Kaplan-Feinstein Index (KFI), and the Cumulative Illness Rating Scale (CIRS). Cox regression analysis was performed using STATA 13. **Results:** The median (M) age was 72 years (34-94), height 69.5 inches (60-99), weight 190 pounds (99-287.5), and BMI 27.4 $kg/m^2$ (15.54-42). 42 (32.3 %) served in the Vietnam War and 88 (67.7%) served during World War II and the Korean conflict. At diagnosis, 129 (99%) V had an ECOG Performance Status (PS) of 0-2, 111 (85%) had Rai stage 0-2 disease, and 81 (62%) were on statins. M hemoglobin was 13.6 g/dl (7.3-17.2), white blood cell count 15.8 K/cmm (3.6-282), absolute lymphocyte count 9.35 K/cmm (1.6-161.1), blood urea nitrogen (BUN) 19 mg/dL (4-88), creatinine 1.1 mg/dl (0.4-3.6), albumin 4.2 (2-4.8), lactate dehydrogenase 182 IU/L (101-1635), and beta 2-microglobulin 2.3 mg/dl (0.9-10.9). By immunophenotyping 35 (26.9%) were CD38/ ZAP-70 positive. The CCI was 4.1 (0-9.0), KFI 1 (0-3), CIRS 15 3 (1-6), CIRS 16 6 (1-14), CIRS 17 2 (0-4.5), CIRS 18 0 (0-1), CIRS 19 0 (0-1). The M survival was 1625 days (4-7502). In univariate analysis, age ($p<0.04$), height ($p<0.05$), BUN ($P<0.02$), and albumin ($P<0.01$) predicted survival. In multivariate analysis, statin use ($p< 0.017$), CD38/ZAP 70 ($p<0.013$) and CIRS 17 ($p<0.022$) were able to predict survival. **Conclusions:** In our study, patients with older age, good PS, and early CLL, statin use was a significant predictor of survival. These findings need to be evaluated in a larger cohort. Statin use may be an important stratification criteria for future trials.

**1611 General Poster Session (Board #393), Sun, 8:00 AM-11:45 AM**

**Comparison of false-negative probabilities for digital and film mammography within a large health care organization.** *Presenting Author: Firas M Dabbous, Division of Epidemiology and Biostatistics, University of Illinois at Chicago, School of Public Health, Chicago, IL*

**Background:** Screening mammography as an early detection tool is susceptible to both false positive and false negative results. We compared false negative probabilities (FNP) for Full Field Digital Mammogram (FFDM) and Screen Film Mammography (SFM) in a single large healthcare organization. **Methods:** Screening mammograms between 2001 and 2009 were linked to incident breast cancer cases for the period 2001-2010 from the Illinois State Cancer Registry using probabilistic linkage methods. The linkage rate in a validation subsample of known breast cancers was 99%. A false negative mammogram ("interval cancer") was defined as a normal finding by the original interpreting radiologist in a woman diagnosed with breast cancer in the subsequent 12 months. **Results:** There were 669,222 screens and 4,058 breast cancer cases (3,071 screen-detected, 988 interval cancers). As expected, overall FNP decreased with increasing age and increased with increasing breast density. Contrary to expectation, FNP was higher for FFDM vs. SFM (27% vs. 23%, $p=0.01$), though marginally lower for FFDM vs. SFM among women under age 50 (24% vs. 27%, $p=0.28$). FFDM was not associated with improved FNR for women with denser breasts or for tumor characteristics suggesting more aggressive disease (hormone receptor negative and higher grade). **Conclusions:** Our results run counter to other studies that have foundFFDM to be more accurate than SFM generally and specifically among women with dense breasts. Differences between studies may be in part a reflection of the community based nature of this sample of women and practicing radiologists.

**1612 General Poster Session (Board #394), Sun, 8:00 AM-11:45 AM**

**Is digital mammography associated with a higher risk of false-positive results? Findings from a community setting.** *Presenting Author: Firas M Dabbous, Division of Epidemiology and Biostatistics, University of Illinois at Chicago, School of Public Health, Chicago, IL*

**Background:** Compared to screen film mammography (SFM), full field digital mammography (FFDM) may improve detection of lesions in younger women with denser breasts but may also increase false positives. We compared false positive probabilities (FPP) for FFDM and SFM in a single large healthcare organization. **Methods:** Screening mammograms during 2001 and 2009 were linked to incident breast cancers diagnosed from 2001-2010 from a state cancer registry using probabilistic methods, and 664,342 screens without a cancer diagnosis in the subsequent 12 months were identified. False positive probability was defined as the proportion of screening mammograms without a subsequent breast cancer diagnosis that were nonetheless interpreted as abnormal. Due to the very large sample size, we focus on clinical rather than statistical significance. **Results:** FPP decreased from 16% in women under 50 to 9% for women aged 70 and above. FPP was lower for women with less dense vs. more dense breasts (11% vs. 14%). Non-White ethnicity (13% vs. 12%) was not associated with FPP, whereas a woman's first screen was associated with higher FPP than subsequent screens (17% vs. 10%). In multivariable models, FPP was 1.3 percentage points lower for FFDM than SFM ($p<0.001$) and the difference did not vary substantially by age, race/ethnicity or breast density. **Conclusions:** It does not appear that FFDM as practiced in this community setting comes with a higher risk of false positive results, which should be reassuring to community-based institutions that have or are shifting away from SFM towards FFDM.

**1613 General Poster Session (Board #395), Sun, 8:00 AM-11:45 AM**

**Gastric cancer: Clinical differences among Hispanic and non-Hispanic whites at the John Theurer Cancer Center (JTCC), Hackensack University Medical Center.** *Presenting Author: Narjust Perez-Florez, Department of Internal Medicine, Rutgers University-New Jersey Medical School, Newark, NJ*

**Background:** Gastric cancer is a leading cause of cancer death worldwide and has significant geographical, ethnic, and socioeconomic differences in distribution. The aim of this study was to compare clinicopathological characteristics and survival between Hispanics and non-Hispanic whites with gastric cancer. **Methods:** We reviewed the records of all patients diagnosed with gastric cancer between January 1999 and March 2013 at the JTCC. A total of 638 patients were studied. Demographics, histology, anatomic site, recurrence and survival rate among both Hispanics and non-Hispanic whites were analyzed. Chi-square test was used to estimate differences in categorical data; Kaplan-Meier and Wilcoxon methods were used for the survival analysis. **Results:** There were 101 Hispanics (H) and 537 non-Hispanic whites (NHW). The mean age at diagnosis was 63 years (21-88) in H and 69 years (39-95) in NHW. A significant difference in age at diagnosis was found in the Stage IV subgroup, with a mean of 54 years for H and 67 years for NHW. At diagnosis, 48 (47.5%) of H patients had stage IV disease compared with 195 (36.3%) of NHW ($p<0.003$). H were more likely to have distal cancers and poorly differentiated tumors compared to NHW (43.8% vs. 15.4%, $p<0.0001$; 70.8% vs. 50.1%, $p<0.0001$, respectively). H had a higher recurrence rate than NHW (17.8% vs 8.7%, $p<0.003$). There was a significant difference in median survival between the two groups, being 51 months for H (95% CI: 34.6-66.9) and 99 months for NHW (95% CI: 77.3-120.7) $p<0.0001$. Gastric cancer was the primary cause of death in 66.2% of H vs. 33.0% of NHW ($p<0.0001$). From the entire cohort, 17.8% of H vs. 33.0% of NHW were free of disease at the time of death ($p<0.007$). **Conclusions:** In our cohort, Hispanic patients were diagnosed with gastric cancer at a younger age, were more likely to have distally located and poorly differentiated tumors, to present with advanced disease at diagnosis, and had shorter overall survival when compared to non-Hispanic whites. Further research should aim to elucidate the basis of these differences, as this could potentially impact management and improve survival.

**1614 General Poster Session (Board #396), Sun, 8:00 AM-11:45 AM**

**Ethnic disparities in pediatric Ewing sarcoma and osteosarcoma.** *Presenting Author: Adam L. Green, Dana-Farber Cancer Center Institute/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

**Background:** Ewing sarcoma (ES) and osteosarcoma (OST) are primarily pediatric tumors that become more difficult to cure when they present with locally advanced disease or metastases. The role of socioeconomic disparities in presentation and outcome of patients with ES and OS has not been well studied. **Methods:** We analyzed all patients in the SEER 18 dataset less than 19 years of age at diagnosis with ES or OST between 2004 and 2010. Comparisons were done using the Fisher exact test. Socioeconomic data for each county were derived from Census 2010 and divided into two categories according to the median value for the cohort. **Results:** Hispanic patients were significantly more likely to have metastatic disease at presentation of OST than non-Hispanic patients (27.2 vs 20.3%, $p=0.014$); there was a trend toward higher likelihood of metastatic presentation for Hispanic ES patients (33.1 vs 27.0%, $p=0.07$). No differences in metastatic disease at presentation were observed in either disease based on race, insurance status, or other socioeconomic variables. Hispanic patients with ES had a significantly poorer 2-year overall survival (OS) than non-Hispanics (75.4 vs 85.3%, $p=0.003$); there was a trend toward poorer 2-year OS for Hispanic patients with OST (80.4 vs 84.9%, $p=0.06$). Hispanic patients with localized ES also had a significantly poorer 2-year OS than non-Hispanics (85.7 vs93.6%, $p=0.008$). No OS difference was seen based on race or insurance status. Significantly poorer 2-year OS for all ES stages, and for localized disease, was also found in patients living in counties with higher than average percentage of people with less than a high school education, foreign born, and living in language isolation. No significant differences in 2-year OS between socioeconomic groups were found in OST. **Conclusions:** Hispanic patients are more likely to present with advanced disease in ES and OST; for ES, this extends to poorer survival. The absence of disparities based on race and insurance, and presence of disparities in other groups with potential limited English proficiency, raise the possibility of language-based barriers to care contributing to these differences. These issues merit further study with primary data in order to determine appropriate intervention.

**TPS1615 General Poster Session (Board #397A), Sun, 8:00 AM-11:45 AM**

**A multicenter phase II study of docosahexaenoic acid (DHA) in patients (pts) with a history of breast cancer (BC), premalignant lesions, or benign breast disease.** *Presenting Author: Ayca Gucalp, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Obesity is a risk factor for the development of BC and is associated with poorer cancer outcomes irrespective of BC subtype. Obesity is associated with diffuse white adipose tissue (WAT) inflammation manifest histologically as crown-like structures (CLS). The presence and severity of CLS in breast WAT (CLS-B) are associated with several proinflammatory mediators known to be involved in development of BC including TNF-$\alpha$/COX-2/IL-1$\beta$ and aromatase. DHA, an omega-3 fatty acid, can suppress inflammation by multiple mechanisms including inhibition of TLR4-activated signaling pathways that induce TNF-$\alpha$ and COX-2. We hypothesize that DHA will decrease the expression of key inflammatory mediators and down-regulate aromatase in breast WAT of overweight/obese women. **Methods:** This is a randomized placebo-controlled, double-blinded phase II study of DHA in overweight/obese pts with a history of stage I-III BC, DCIS/LCIS, Paget's disease, or proliferative benign breast disease (NCT01849250). We aim to determine whether oral DHA for 12 weeks at 1,000 mg twice daily as compared to placebo reduces normal breast tissue levels of TNF-$\alpha$. Secondary objective: To evaluate the effect of DHA on the change from baseline in levels of COX-2/IL-1$\beta$/aromatase/CLS-B. Inclusion:1) BMI $\geq$ 25. 2) $\geq$ 6 months from all prior BC treatment. 3) No clinical evidence of disease. 4) One breast unaffected by invasive cancer, which has not been radiated or surgically augmented. Exclusion: 1) DHA supplementation ($>$ 200 mg/day). 2) Daily aspirin/NSAID use in the week preceding the trial. 3) Regular use of steroids or immunomodulators.Percent change in TNF-$\alpha$ mRNA levels in normal breast tissue between DHA and placebo arm will be compared using two-sample t-test. If normality assumptions are violated, a two-sample Wilcoxon rank-sum test will be used. With 30 subjects in each arm, we will have 80% power to detect effect size as small as 0.74 at 0.05 significance level using a two-sided, two-sample, Student t-test. Assuming a 10% dropout rate and 10% non-evaluable rate, up to 76 pts will be randomized. To date, 17 pts have been consented and 9 have been randomized to participate. Clinical trial information: NCT01849250.

**TPS1616 General Poster Session (Board #397B), Sun, 8:00 AM-11:45 AM**

**MELO-D: Antiproliferative effects of melatonin and vitamin D in breast cancer.** *Presenting Author: Punam Rana, Juravinski Cancer Center, Hamilton, ON, Canada*

**Background:** Vitamin D and melatonin have been associated with anticancer activity in epidemiological and experimental studies. However, evidence from controlled trials on their efficacy in cancer prevention is inconsistent, in part related to lack of knowledge on the mechanism of preventive activity. The MELO-D study is the first to use an innovative pre-operative chemoprevention approach to examine the potential anticancer role of vitamin D and melatonin. We hypothesize that vitamin D and separately, melatonin, decreases the proliferative activity in a breast cancer tumor, as measured by Ki67. **Methods:** Using a 2x2 factorial design, 144 women diagnosed with invasive breast cancer are randomized to receive Vitamin D3 (2000 IU daily) or placebo, and to melatonin (20 mg/day) or placebo. The duration of study medication is 3-4 weeks while the subjects wait for definitive breast cancer surgery. The primary outcome is difference in Ki67 between the initial core biopsy and final surgical specimen. The mean difference in Ki67 from baseline to definitive surgery will be compared between groups. The effect of Vitamin D and melatonin will also be examined in relation to other factors including serum vitamin D levels, genetic factors (e.g. VDR polymorphism), and tissue factors (e.g. p53 status). Patients are currently being recruited from the Juravinski Cancer Centre (JCC) and St. Joseph's Healthcare Hamilton. Clinical trial information: NCT01965522.

**TPS1617 General Poster Session (Board #398A), Sun, 8:00 AM-11:45 AM**

**Add-Aspirin trial: A phase III, double blind, placebo-controlled, randomized trial assessing the effects of aspirin on disease recurrence and survival after primary therapy in common nonmetastatic solid tumors.** *Presenting Author: Ruth E Langley, Medical Research Council, Clinical Trials Unit at University College London, London, United Kingdom*

**Background:** Pre-clinical data demonstrate that aspirin inhibits tumour growth and prevents metastases. Meta-analyses of individual patient data from randomized trials evaluating cardiovascular (CV) effects of aspirin show reduced metastases and cancer deaths for those on aspirin. Toxicity concerns have limited aspirin use as a primary anti-cancer prevention agent. In the adjuvant setting, the risk:benefit ratio differs, with higher morbidity and mortality from recurrence potentially outweighing risks. Aspirin, an inexpensive drug with a potential therapeutic role in several common cancers, could have a large impact on the global cancer burden. The Add-Aspirin trial investigates if aspirin use after curative treatment for non-metastatic solid tumours prevents recurrence and prolongs survival. **Methods:** Add-Aspirin is a double blind, placebo-controlled, multicentre, international trial. Eligible participants (n=9,920) from the UK and India will have had potentially curative treatment for non-metastatic cancer. There are 4 separate tumour cohorts – breast (BC), colorectal (CRC), gastro-oesophageal (GOC) and prostate cancer (PC). Following an 8 week active run-in period of aspirin 100mg daily to assess adherence and tolerability, participants are randomised to aspirin 100mg, 300mg or placebo daily for $>$ 5 years. Each tumour specific cohort is individually powered and has a separate disease-specific primary outcome measure: BC (n = 3,100) invasive disease-free survival (DFS); CRC (n = 2,600) DFS; GOC (n = 2,100) overall survival (OS); and PC (n = 2,120) biochemical recurrence-free survival. Secondary outcome measures include adherence, toxicity and CV events. OS across the 4 cohorts is a co-primary outcome measure. Sub-studies include assessment of thromboxane B2 for compliance and methodological work to assess the utility of long-term passive follow up. Blood/tissue specimens collected at enrolment will allow tumour-specific mutations to be used as stratification factors. Recruitment will commence by May 2014. Funder CRUK; Sponsor University College UK. Clinical trial information: 2013-004398-28.

**TPS1618 General Poster Session (Board #398B), Sun, 8:00 AM-11:45 AM**

**Community-based cluster randomized trial of screening with visual examination of oral cavity and double-contrast barium swallow for upper aerodigestive tract cancers.** *Presenting Author: Conjeevaram S Pramesh, Tata Memorial Center, Mumbai, India*

**Background:** Oral, esophageal and hypopharyngeal cancers are common and important public health problems in India. They are highly aggressive neoplasms and are associated with a poor prognosis especially because most patients are diagnosed at late stages of disease. Certain high risk factors like tobacco, betel and arecanut and alcohol use have been associated with the causation of these cancers. Screening may offer the opportunity to reduce the incidence of invasive lesions and also help in decreasing the mortality rates associated with these cancers. **Methods:** We are currently doing a large cluster randomized trial in Ratnagiri district, Maharashtra, India to ascertain whether screening of oral cancers with visual examination by trained health workers and hypopharyngeal and esophageal cancers with double contrast barium swallow (DCBS) will reduce mortality from these diseases. The population between 35 and 65 years of age who have used tobacco and/or alcohol for more than five years are eligible for the trial. The area has been divided into 16 clusters (7,500 individuals per cluster) of which 8 clusters will receive two rounds of screening at three year intervals while all 16 clusters will receive health education about tobacco and alcohol cessation. Individuals with abnormal findings on oral examination or DCBS will undergo clinical examination by a clinician (trained in diagnosing early cancers and precancerous lesions of the oral cavity) or direct laryngoscopy or upper gastrointestinal endoscopy with biopsy of suspicious or definite abnormalities at the base hospital. Patients with a biopsy proven oral, esophageal or hypopharyngeal cancer will undergo routine staging investigations and standard treatment as per the stage at diagnosis. The primary outcome measure is mortality from oral, hypopharyngeal and esophageal cancers. Secondary outcome measures will include overall survival, diagnostic sensitivity of DCBS and cost effectiveness of screening. We have so far completed screening of 17,258 out of 24,398 eligible individuals (70.7% compliance) and detected 27 cancers. The study is expected to be completed in 2010. Clinical trial information: Not yet assigned.

**2000 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Phase III study of radiation therapy (RT) with or without procarbazine, CCNU, and vincristine (PCV) in low-grade glioma: RTOG 9802 with Alliance, ECOG, and SWOG.** *Presenting Author: Jan C. Buckner, Mayo Clinic, Rochester, MN*

**Background:** Early results of R9802 (Shaw et al: J Clin Oncol. 2012; 30(25):3065-70) demonstrated that PCV given with RT at the time of initial diagnosis prolongs progression-free survival (PFS), but not overall survival (OS), compared with RT alone. Herein, we report long term follow up results. **Methods:** Eligibility criteria included age <40 years with subtotal resection or biopsy, age >40 with any extent of resection, and supratentorial grade II astrocytoma (A), oligo-astrocytoma (OA), or oligodendroglioma (O). Patients were stratified by age, histology, Karnofsky Performance Status, and presence versus absence of contrast enhancement on the preoperative imaging study and randomized to RT alone (54 Gy in 30 fractions) or RT followed by 6 cycles of PCV chemotherapy. Wilcoxon test was used to compare survival distributions. Cox proportional hazard models were used to identify prognostic variables. **Results:** 251 eligible patients were accrued from 1998 to 2002. Median follow up is 11.9 years; 55% of patients have died. Patients in the RT + PCV arm have significantly longer median survival time (MST) compared to the RT alone arm (13.3 vs. 7.8 years, p=0.03; HR=0.59) and longer median PFS (10.4 vs. 4.0 years, p=0.002; HR=0.50). 5 and 10 year OS for RT + PCV vs RT alone are 73% vs 64%, and 62% vs 41%, respectively. Cox model identified RT + PCV treatment arm as a favorable prognostic variable for OS (p=0.003; HR 0.60) and PFS (p<0.001; HR=0.49). A or A-dominant OA histology (vs O or O-dominant OA) was prognostic for worse OS (p<0.001; HR=2.16) and PFS (p<0.001; HR 1.85). Male OS but not PFS was worse than females (p=0.02; HR 1.51). Analyses of 1p/19q co-deletions and IDH mutations have not yet been completed. **Conclusions:** For grade 2 glioma patients with less than gross total tumor resection or >40 years of age, PCV + RT prolongs both OS and PFS compared with RT alone. Patients with A or A-dominant OA have worse outcomes, as do males. Multivariable models that incorporate 1p/19q co-deletion and IDH mutational analyses may more fully elucidate the magnitude of treatment benefit for patients with tumors identified by specific histologic type and molecular markers. Clinical trial information: NCT00003375.

**2001^ Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Correlation of molecular subtypes with survival in AVAglio (bevacizumab [Bv] and radiotherapy [RT] and temozolomide [T] for newly diagnosed glioblastoma [GB]).** *Presenting Author: Heidi Phillips, Genentech Inc., South San Francisco, CA*

**Background:** Factors that correlate the extent of clinical benefit with anti-VEGF therapy are poorly understood. Two phase 3 trials in newly diagnosed GB (AVAglio and RTOG-0825) reported that Bv+RT/T prolonged PFS but not OS *v* placebo (P)+RT/T. Specific GB pt subgroups may derive OS benefit from 1st-line Bv; tumor profiling has uncovered intrinsic and prognostic GB molecular subtypes. Bv efficacy in molecular subtypes was evaluated as an exploratory objective in AVAglio. **Methods:** An 800 gene platform capable of reliable gene expression (GE) measurement in formalin-fixed, paraffin-embedded samples was developed/validated. In AVAglio, randomizedpts (n=921) received: RT/T+Bv or P, 6 wks; 28-day break; maintenance T+Bv or P (x6); Bv or P until PD/unacceptable toxicity. Samples from 342 AVAglio pts (Bv/P; biomarker evaluable population) were profiled and classified into known GB molecular subtypes (pre-defined hypothesis); assigned subtypes were correlated with OS. An exploratory outcome-driven analysis to discover novel predictor subtypes more directly associated with OS benefit from Bv was then performed. **Results:** Per recent data from The Cancer Genome Atlas (TCGA), pts with proneural tumors with wild-type isocitrate dehydrogenase 1 (IDH1) had the worst prognosis among all GB subtypes (defined by TCGA [Verhaak, Cancer Cell 2010]/ Phillips, Cancer Cell 2006). Importantly, this analysis uncovered a relationship between molecular subtype and extent of OS benefit in Bv-treated pts. Exploratory outcome-driven GE analyses identified novel gene clusters associated with prolonged OS with Bv *v* P. Pt groups predicted to derive Bv benefit in the outcome-driven method overlapped with, but were not identical to, groups defined by known GB subtypes; thus, novel OS-associated candidate predictors may more precisely identify pts likely to derive benefit from Bv. **Conclusions:** Candidate molecular predictors were identified in AVAglio, suggesting that a subgroup of newly diagnosed GB pts may derive OS benefit from Bv; these data could impact pt stratification and therapy and give insights into Bv mode of action, and warrant further validation in other datasets. Clinical trial information: NCT00943826.

**2002 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**A 6-gene signature for outcome prediction of grade II/III glioma.** *Presenting Author: Tim Lautenschlaeger, Department of Radiation Medicine, The Ohio State University, Columbus, OH*

**Background:** Grade II and III gliomas are very heterogeneous in their outcome, leaving some uncertainty as to what the best treatment is for the individual patient. **Methods:** We used multiple datasets totaling 756 glioma patients to develop a prognostic 6-gene signature for grade II and III gliomas. Three risk groups were defined (low, medium, and high risk). This 6-gene classifier was then validated in multiple independent glioma data sets totaling over 500 patients and translated into a PCR-based assay. **Results:** The classifier was validated in a 214 grade II/III glioma patient independent validation set (TCGA, HR=4.03; 95% CI, 1.82-8.92; p= 0.001, for low vs high risk group) and a 287 patient grade IV glioblastoma set (updated TCGA, HR, 2.42; 95% CI, 1.69-3.47; p< 0.001, for low vs high risk group). The classifier was then translated into a PCR based assay in an independent 32 grade II/III glioma patient pilot cohort (multi-institutional, HR=6.3; 95% CI, 1.7-23.6; p= 0.006, for low vs high risk group). Multivariate Cox regressions validated the risk classifier independent of other clinical or molecular factors (grade, histology, IDH1 status) in all three data sets. ROC analysis for 3 year overall survival demonstrate that the classifier can predict 3 year survival better than grade, histology or IDH1 mutation status (AUC, 0.82; 95% CI, 0.70-0.93; p< 0.0001) in patients with grade II/III tumors. Of note, ROC analysis for 3 year overall survival demonstrated that the 6-gene classifier was also an excellent predictor of 3 year survival in glioblastoma (AUC, 0.84; 95% CI, 0.76-0.91; p< 0.0001). **Conclusions:** The 6-gene classifier can reliably predict 3-year outcome for patients older than 40 years and 7-year outcome for patients younger than 40 years old with grade 2 and 3 gliomas independent of histology, grade or IDH1 mutation status.

**2003 Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Radiation therapy and concurrent plus adjuvant temsirolimus (CCI-779) versus chemoirradiation with temozolomide in newly diagnosed glioblastoma without methylation of the *MGMT* gene promoter.** *Presenting Author: Wolfgang Wick, Neurooncology, University of Heidelberg Medical Center, Heidelberg, Germany*

**Background:** Preclinical data indicate activity of mammalian target of rapamycin inhibitors and synergistic activity together with radiotherapy in glioblastoma. The aim of this trial is to assess the therapeutic activity of temsirolimus (CCI-779), an intravenous mTOR inhibitor, in patients with newly diagnosed glioblastoma with unmethylated *O6 methlyguanine-DNA-methlytransferase (MGMT)*promoter. **Methods:** Patients (n=257) with newly diagnosed glioblastoma after open surgical biopsy or resection fulfilling basic eligibility criteria underwent a central *MGMT* promoter analysis using quantitative methylation specific PCR. Patients with glioblastoma harboring an unmethylated *MGMT* promoter (n=111) were randomized 1:1 between radiotherapy (60 Gy; 5 times 2 Gy per week) plus concomitant and six cycles of maintenance temozolomide or radiotherapy plus weekly temsirolimus at 25 mg flat dose to be continued until progression or undue toxicity. Primary endpoint was overall survival at 12 months (OS12). Sample size of the investigational treatment arm required 54 patients to assess adequacy of temsirolimus activity set at 80%. More than 38 patients alive at 12 months in the *per protocol* population was considered a positive signal. A control arm of 54 patients treated with the standard of care was implemented to evaluate the assumptions on OS12. **Results:** Between December 2009 and October 2012, 111 pts in 14 centers were randomized and treated. Median age was 55 and 58 years in the temsirolimus and standard arm, respectively. Most patients (95.5%) had a WHO performance status of 0 or 1. Both therapies were properly administered with a median of 13 cycles of maintenance temsirolimus. In the *per protocol*population, exactly 38 patients treated with temsirolimus (out of 54 eligible) reached OS12. In the intention to treat population OS12 was 72.2% [95% CI (58.2, 82.2)] in the temozolomide arm and 69.6% [95% CI (55.8, 79.9) in the temsirolimus arm [HR=1.16 95% CI (0.77, 1.76), p=0.47]. **Conclusions:** The therapeutic activity of temsirolimus in patients with newly diagnosed glioblastoma with an unmethylated MGMT promoter is too low. Clinical trial information: NCT01019434.

**2004** **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**A randomized, placebo-controlled pilot trial of armodafinil for fatigue in patients with gliomas undergoing radiotherapy.** *Presenting Author: Eudocia Quant Lee, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Fatigue is a common symptom among glioma patients and affects quality of life. Armodafinil, a wakefulness-promoting medication, benefits patients with fatigue of various causes. This study evaluates the effects of armodafinil on fatigue in glioma patients undergoing radiation therapy (RT). **Methods:** Eligibility criteria included age ≥ 18; Karnofsky Performance Status (KPS) ≥ 60; grade 2-4 glioma undergoing RT to a total dose of 50-60 Gy with or without chemotherapy. Patients were randomized 1:1 to armodafinil (A) or placebo (P). Fatigue assessments were made at baseline, Day 22, Day 43, and Day 56 with the FACIT-F Fatigue Scale, Brief Fatigue Inventory (BFI), and Cancer Fatigue Scale (CFS). The primary aim is to detect a difference in the 42-day change in FACIT-F fatigue subscale scores between the two groups using a 2-sample Wilcoxon statistic. Secondary outcomes include a 42-day change in CFS and BFI. **Results:** Data is available for 77 of the 80 patients (40 in A and 37 in P). In the armodafinil arm, median age was 56 (25-79), median KPS was 90 (70-100), 57.5% had glioblastoma (GBM), 35% had anaplastic glioma (AG), 7.5% had another glioma histology. In the placebo arm, median age was 54 (19-78), median KPS was 90 (70-100), 51.4% had GBM, 32.4% had AG, and 16.2% had another glioma histology. The median 42-day change in the FACIT-F fatigue subscale scores in the armodafinil arm was 2 (range -40 to 26) and in the placebo arm was -6.665 (range -65 to 28) with Wilcoxon p-value of 0.066. There was a statistically significant improvement in fatigue in the armodafinil arm vs. the placebo arm based on median 42-day change in the BFI (Wilcoxon p-value of 0.008). Toxicity was rare and similar between arms. There were no cardiac toxicities attributed to treatment. One patient experienced insomnia in the armodafinil arm. **Conclusions:** Treatment with armodafinil is well tolerated in glioma patients undergoing RT. There is a trend towards fatigue reduction in the armodafinil group. Updated results will be presented. Study Sponsored by: Cephalon, Inc., a wholly owned subsidiary of Teva Pharmaceuticals, and the National Brain Tumor Society. Clinical trial information: NCT00766467.

**2005** **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**A randomized, double-blind, placebo-controlled phase 2 trial of dendritic cell (DC) vaccination with ICT-107 in newly diagnosed glioblastoma (GBM) patients.** *Presenting Author: Patrick Y. Wen, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The trial investigated whether adding tumor-antigen-loaded DC vaccine to surgery and chemoradiation would improve overall survival (OS) or progression free survival (PFS). **Methods**: HLA-A1+ and/or -A2+ resected patients with residual tumor $<1$ $cm^3$ received 6 weeks of concurrent temozolomide (TMZ) and radiation. 124 patients were randomized 2:1 to receive ICT-107 (autologous PBMC-derived DC pulsed with 6 synthetic peptide CTL epitopes targeting the GBM tumor and tumor stem cell-associated antigens MAGE-1, HER-2, AIM-2, TRP-2, gp100, and IL-13R$\alpha$2) or its matching control (unpulsed DC). Patients then received induction ICT-107 or control QWx4 followed by maintenance TMZ, 5 days/mo for 12 mos. Booster vaccinations occurred at 1, 3, and 6 mos after induction, and every 6 mos thereafter. The trial concluded and data were evaluated at 67 events. **Results:** ICT-107 was generally safe and well tolerated, with no imbalance in AEs between the treated and control groups. PFS improved by 2 mos in the ICT-107 ITT group (p=0.02 two-sided, hazard ratio (HR)=0.56). In the per-protocol (PP) group (117 patients receiving all 4 induction vaccinations), p=0.01 two-sided, HR=0.53, and the difference in median PFS increased to 3 mos. The median OS favored ICT-107 by 2 mos in the ITT and 3 mos in the PP groups. However, the number of events was small and OS did not reach statistical significance (p=0.58 two-sided, HR=0.87, and p=0.40 two-sided, HR=0.79, respectively). Median follow-up from randomization was 13.6 mos. In the ICT-107 group, vaccine activation markers IL12 and HLA-DR were predictive of OS (p-values $<$ 0.05). There were no correlations in the placebo group. **Conclusions:** This is the first randomized, placebo-controlled immunotherapy trial in GBM to positively affect a clinical outcome, PFS. Although OS improvement was not statistically significant at the 67/124 event point, patients continue to be followed for OS, allowing periodic updating of the primary endpoint and assessment of long-term survival. Analysis of QOL, and correlation of both tumor antigen expression and vaccine immunologic response with OS are in process.

**2006^** **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Final results of APG101_CD_002: APG101 plus reirradiation versus reirradiation in the treatment of patients with progressive glioblastoma.** *Presenting Author: Michael Platten, Neurooncology, University of Heidelberg Medical Center, Heidelberg, Germany*

**Background:** Preclinical data indicate antiinvasive activity of APG101, a CD95-ligand (CD95L)-binding fusion protein, and synergistic activity with radiotherapy in glioblastoma. In healthy volunteers, single doses of up to 20 mg/kg APG101 are safe. **Methods:** Patients (N=91) with progressive glioblastoma after standard radiochemotherapy (± 1 second-line chemotherapy), provided a tumour diameter of 1-4 cm and time since the end of radiotherapy ≥ 8 months, were randomised 1:2 stratified for tumour diameters ≤ or > 2.5 cm between radiotherapy (36 Gy; 5 times 2 Gy per week; rRT) or rRT+APG101 (400 mg weekly i.v.) to be continued until progression. CD95L was evaluated in tumour tissue. This open-label, non-comparative phase II trial (NCT01071837) sought to demonstrate a doubling in the 6-months progression-free survival (PFS-6) rate with rRT+APG101 assuming a 15% PFS-6 rate with rRT alone. The control arm with rRT alone was added to calibrate for the PFS-6 assumption. **Results:** Patient characteristics in the intention-to-treat population [N=84 (26 patients rRT, 58 patients rRT + APG101)] were balanced. The PFS-6 rates were 3.8% (95%-CI: 0.1 - 19.6) rRT and 20.7% (95%-CI: 11.2 - 33.4) for rRT+APG101 (p=0.04). Median PFS was 2.5 (95%-CI: 2.3-3.8) months and 4.5 (95%-CI: 3.7-5.4) months with a hazard ratio (HR) of 0.49 (95% CI: 0.27-0.88, p=0.0162). Cox regression analysis adjusted for tumour size revealed a HR for rRT+APG101 for death of any cause of 0.60 (95% CI: 0.36-1.01)] (p=0.0559). Patients with lower methylation levels at CpG2 in the *CD95L* promoter in the tumour tissue had a stronger risk reduction (HR=0.13 95% CI: 0.03-0.52) when treated with APG101. **Conclusions:** CD95 pathway inhibition in combination with rRT is an innovative concept with clinical efficacy. It warrants further clinical development. *CD95L* promoter methylation in the tumour may be developed as a biomarker. Clinical trial information: NCT01071837.

**2007** **Oral Abstract Session, Sun, 8:00 AM-11:00 AM**

**Validation of rano criteria: Contribution of T2/FLAIR assessment in patients with recurrent glioblastoma treated with bevacizumab.** *Presenting Author: Raymond Yi-kun Huang, Dana-Farber Cancer Institute/Brigham and Women's Cancer Center, Boston, MA*

**Background:** Since its introduction, the RANO criteria have been widely adopted in clinical trials for evaluating treatment response in high-grade gliomas. To date, the criteria have not been validated using outcome data from prospective trials. We examined the radiologic data of patients with recurrent glioblastoma treated with bevacizumab from the randomized phase II BRAIN trial (AVF3708g) to determine the effect of including T2/FLAIR evaluation in the RANO criteria on measurements of objective response rates (ORR) and progression free survival (PFS). **Methods:** The imaging data of 163 patients with recurrent glioblastoma from the BRAIN trial were evaluated by 6 readers blinded to clinical information. The ORR and median PFS were determined using the RANO criteria and compared to those obtained without evaluating the T2/FLAIR abnormality (Macdonald criteria). Landmark analyses were performed at 2, 4 and 6 months, and Cox proportional hazard models were used to determine the associations between OR and progression with subsequent survival. **Results:** The ORRs were 0.433 (95% CI: 0.373 - 0.494) and 0.451 (95% CI: 0.391 – 0.513) by RANO and Macdonald criteria, respectively (p = 0.78). The median PFS was 4.21 months (95% CI: 3.68-5.49) using RANO criteria, compared to 5.52 months (95% CI: 4.27-6.83) as determined by Macdonald criteria (p=0.04). At 2-, 4-, and 6-month landmarks, both OR status and PFS determined by RANO criteria were predictive of overall survival (OS) (hazard ratios for 4-month landmark; OR HR= 2.12, p = 0.0003, PFS HR=4.08, p<0.0001). **Conclusions:** The inclusion of T2/FLAIR assessment in the RANO criteria results in a small difference in median PFS but no significant difference in ORR. The associations of OR and PFS with survival using the RANO criteria at 6 months and earlier time points following therapy potentially support their possible roles as surrogates for OS.

**2008^ Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Contrast-enhanced T1-weighted digital subtraction maps combined with diffusion MRI to identify recurrent glioblastoma patients that benefit from bevacizumab therapy.** *Presenting Author: Benjamin M. Ellingson, Department of Radiological Sciences, Biomedical Physics, and Bioengineering; University of California, Los Angeles, Los Angeles, CA*

**Background:** Bevacizumab is an anti-angiogenic therapy approved for recurrent glioblastoma (GBM); however, use of bevacizumab remains controversial. In the current study we demonstrate that recurrent GBM patients with a particular imaging phenotype identified on diffusion MRI who also show an early response on contast-enhanced T1-weighted digital subtraction maps (delta T1) have a significant survival advantage when treated with bevacizumab. **Methods:** A total of 105 patients with recurrent GBM enrolled in a multicenter clinical trial (BRAIN Trial, AVF3708g) with apparent diffusion coefficient (ADC) data from diffusion MRI available were included. Delta T1 maps were calculated by subtracting post-contrast from pre-contrast T1-weighted images, leaving only areas of enhancement visible. ADC histogram analysis was performed prior to therapy by fitting a double mixed Gaussian model to ADC histograms in contrast-enhancing areas. Patients were stratified into three groups based on their imaging phenotype: (1) Pro-Bev – patients with a high pre-treatment ADC in the lower Gaussian curve who show more than a 25% reduction in enhancement after therapy; (2) Anti-Bev – a low pre-treatment ADC who also do not show a change in contrast enhancement after therapy; and (3) Mixed Response – patients with only a single prognostic factor, either by diffusion MRI or delta T1. **Results:** Patients with both a favorable pre-treatment diffusion MRI phenotype and an early response after bevacizumab therapy demonstrated a significantly longer PFS (Cox, P=0.01; c-index = 0.61) and OS (P=0.001; c=index=0.60) compared with the other groups. Patients with an unfavorable pre-treatment diffusion MRI phenotype who do not have an early response were more likely to progress and expire early. **Conclusions:** A combination of pre-treatment diffusion MRI analysis and response assessment using delta T1 maps can be used as an early indicator of GBM patients that will benefit from bevacizumab therapy at recurrence. Such a combination technique may be useful for patient stratification for clinical trials involving bevacizumab combination therapies. Clinical trial information: NCT00345163.

**2009 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Prospective analysis of serial FLT-PET scanning to discriminate between true and pseudoprogression in glioblastoma.** *Presenting Author: Martha W. den Hollander, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Response evaluation in glioblastoma (GBM) patients after concomitant radiotherapy and temozolomide (TMZ) is hampered by the occurrence of progressive contrast enhancing lesions on MRI that do not reflect true tumor progression. $^{18}$F-fluorothymidine (FLT) is a Positron Emission Tomography (PET) tracer that is taken up by proliferating cells. The goal of this study was to prospectively assess the value of FLT-PET in discriminating between true progression and pseudoprogression in patients with primary GBM treated with radiotherapy and TMZ (NTR3680). **Methods:** FLT-PET scans were performed before start and 4 weeks after radiochemotherapy. MRI scans were performed at these time points and after 3 cycles of adjuvant TMZ. Macdonald criteria were used for response evaluation on MRI. Pseudoprogression was defined as progressive disease on MRI after radiochemotherapy, with stabilization or improvement of enhancing lesions after 3 cycles of adjuvant TMZ. Changes in $SUV_{max}$ and tumor to normal brain tissue ratios were calculated for FLT-PET and compared between patients with true progression and pseudoprogression. In case of multiple lesions, the mean of the $SUV_{max}$of lesions was calculated. Ki67 staining in the primary tumor and overall survival data were analyzed. **Results:** Thirty patients, 28 patients with GBM and two with gliosarcoma (WHO grade IV), were included. Of the 19 patients assessed for pseudoprogression, 6 showed pseudoprogression and 6 showed true progression. There was no difference in (changes in) $SUV_{max}$ and tumor to normal brain tissue ratios on FLT-PET between patients with true progression and pseudoprogression. Baseline FLT uptake correlated with overall survival ($P = 0.002$) but not with Ki67. **Conclusions:** FLT-PET scans do not discriminate between true progression and pseudoprogression in patients with GBM, but baseline FLT uptake does correlate with overall survival. Clinical trial information: NTR3680.

**2010 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Diagnosis of pseudoprogression using ferumoxytol perfusion MRI in patients with glioblastoma to predict better outcome.** *Presenting Author: Edward A. Neuwelt, Oregon Health & Science University, Portland, OR*

**Background:** This retrospective IRB approved study determined the survival of GBM patients with or without pseudoprogression. **Methods:** Patients with histologically-proven newly diagnosed GBM at Oregon Health and Science University from January 2006 to June 2012 after standard CRT received adjuvant temozolomide (TMZ) until tumor progression. Diagnosis of pseudoprogression was made by perfusion MRI with ferumoxytol (an iron oxide nanoparticle) and updated Response Assessment in Neuro-Oncology Working Group (RANO) criteria. Survival was determined using Kaplan-Meier product limit analysis and Cox regression model. **Results:** A total of 68 patients were included. The overall median survival was 19.9 months (95% CI 15.1-22.5). Median survival in 24 (35.3%) patients with pseudoprogression was 34.7 months (95% CI 20.3-54.1), significantly longer than the 13.4 months (95% CI 11.1-19.5) in 44 (64.7%) patients without pseudoprogression ($P<0.0001$). The longest survival was seen in patients with combination of pseudoprogression and MGMT promoter methylation, 54.1 months (Table). **Conclusions:** Pseudoprogression is associated with better survival, especially if concurs with MGMT promoter methylation. The patients that experienced true tumor progression had poor survival. This study emphasizes the importance of differentiating tumor progression and pseudoprogression using ferumoxytol to assess perfusion.

| | Death/patients | Hazard ratio (95% CI) | Median survival (months; 95% CI) |

**PD1 and PD-L1 expression in glioblastoma.** *Presenting Author: Anna Sophie Berghoff, Institute of Neurology, Medical University of Vienna, Vienna, Austria*

**Background:** We aimed to investigate programmed cell death (PD)1 and PD-ligand (L)1 expression and relevance in glioblastoma. **Methods:** 135 specimens of 117 patients (median age 60); median KPS 90 (range 10-100) with glioblastoma were included. In 18 patients, resection specimens of the first local recurrence in addition to tumor tissue from the initial resection were available. Analyses of PD1, PD-L1, CD3 and CD8 expression were performed by immunohistochemistry and previously published semiquantitative evaluation criteria. *O6-methylguanine DNA methyltransferase* (*MGMT*) promoter methylation was analyzed using pyrosequencing and a cut-off at 8%. **Results:** We found sparse to moderate density of tumor-infiltrating lymphocytes (TILs) in a total of 100/135 (74.1%) cases (CD3+ 92/135, 68.1%; CD8+ 64/135, 47.4%). PD1 expression was found on scattered TILs, both in the perivascular compartment and within the tumor tissue, in 20/135 (14.8%) cases. PD-L1 expression was evident on tumor cells and macrophages/microglial cells throughout the tumor tissue with occasional focal accentuation in 116/135 (85.9%) specimens, with 44.5% showing PD-L1 staining of more than 50% of the viable tumor tissue. *MGMT* methylation was found in 37/99 (37.4%) analyzed samples. There was no significant correlation of expression of PD1 or PD-L1 with the density of TILs or *MGMT* methylation status (p>0.05), respectively. Younger age (p=0.009), high KPS (p=0.035) and *MGMT*hypermethylation (p=0.008) showed a significant correlation with favorable overall survival, while TIL density or expression of PD1 (p=0.783) and PD-L1 (p=0.866) did not associate with patient outcome. Table 1 compares expression of PD1, PD-L1, CD3 and CD8 between matched specimens of the initial tumor and the first local recurrence. **Conclusions:** PD1 and/or PD-L1 are immunohistochemically detectable in a majority of glioblastoma samples. A clinical study with specific immune checkpoint inhibitors seems to be warranted in glioblastoma.

**Association of tumor-infiltrating lymphocytes with brain edema and overall survival in brain metastases.** *Presenting Author: Matthias Preusser, Medical University of Vienna, Vienna, Austria*

**Background:** Density of tumor-infiltrating lymphocytes (TILs) has a prognostic impact in various extracranial solid tumors. We characterized TILs in patients with brain metastases (BM). **Methods:** We immunostained neurosurgical specimens of patients with newly diagnosed single brain metastasis for CD3, CD8, CD45RO and FOXP3 and used previously published semiquantitative evaluation criteria. **Results:** 118 BM specimens of patients with lung cancer (62/118; 52%), breast cancer (17/118; 14%), melanoma (6/118; 5%), kidney cancer (10/118; 8%) or another primary tumor (23/118; 19%) were available for this study. Dense infiltration with CD3+ TILs was observed in 64/118 (54%) specimens, with CD8+ TILs in 70/118 (59%), with CD45RO+ TILs in 72/118 (61%) and with FOXP3+ TILs in 26/118 (22%) specimens. Dense CD3+ TILs infiltration was more frequently observed in lung cancer, melanoma and kidney cancer BM than in breast cancer BM ($p=0.024$; Chi square test). Melanoma BM had more frequently dense infiltration with FOXP3+ TILs ($p=0.003$; Chi square test) than other BM subtypes. Density of CD3+, CD8+, CD45RO+, or FOXP3+ TILs did not correlate with preoperative steroid application ($p>0.05$; Chi Square test). Patients with dense infiltration of CD3+ TIL had significantly improved OS (27 vs. 12 months; $p=0.002$; log rank test). Further, dense infiltration with CD8+ TILs was associated with improved OS (16 vs. 12 months; $p=0.048$; log rank test) and large peritumoral edema on the preoperative MRI ($p=0.03$; Chi Square test). Dense infiltration with CD45RO+ TILs was correlated with improved survival prognosis (18 vs. 8 months; $p=0.01$; log rank test). Patients with dense infiltration of FOXP3+ TILs had an impaired survival prognosis (6 vs. 16 months; $p=0.05$; log rank test). A composite "immuno score" showed a strong association with median OS (27 months for cases CD8+/CD45RO+/FOXP3- infiltrates and 6 for cases with CD8-/CD45RO-/FOXP3+ infiltrates; $p=0.001$ log-rank test). **Conclusions:** Dense TILs infiltrates are common in BM and correlate with the amount of peritumoral brain edema and improved survival prognosis. Further studies should investigate the therapeutic impact of immunomodulatory agents in patients with BM.

**2013 Poster Highlights Session (Board #3), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Results of comprehensive molecular profiling of gliomas and the potential therapeutic implications.** *Presenting Author: Santosh Kesari, University of California, San Diego, La Jolla, CA*

**Background:** Gliomas are the most common type of primary brain tumors with underlying molecular heterogeneity contributing to differential treatment response. Our retrospective study was designed to interrogate biomarkers from a large cohort of glioma patients to identify alterations with therapeutic implications. **Methods:** 871 glioma tumor samples (79% WHO grade IV glioblastoma, GBM) were analyzed with a multi-platform approach including sequencing, IHC, FISH/CISH and methylation assay to investigate actionable biomarker aberrations. Retrospective data analysis was performed on the complete cohort and molecular subgroups of patients. **Results:** In the 871 patient samples, mutations in 27 genes were seen. Both common TP53 (39%), IDH1 (22%), PTEN (13%) and previously unreported mutations in gliomas were observed, including JAK3, SMO and ABL1. Co-mutation of 2 or more genes occurred in 37% of cases. TP53 mutation was suggestive of genetic instability and was frequently associated with other concurrent mutations ($p=0.0006$). IDH1 mutations were associated with MGMT promoter methylation, low expression of TS, RRM1 and TOP2A (p from $<0.0001$ to 0.0036), suggesting different responses to temozolomide, fluoropyrimidine, gemcitabine and etoposide. IDH1 mutation was also associated with TP53 mutation; whereas wild type IDH1 was associated with PTEN mutation ($p=0.0309$) and showed some association with EGFR mutations ($p=0.0543$). Distinct biomarker profiles by IHC, FISH and sequencing were also observed when comparing GBM to grade II/III gliomas, suggesting different biology from GBM and thus different treatment implications. 20 GBM patients were identified with pre and post treatment analyses performed (comparative analysis ongoing). **Conclusions:** Gliomas exhibit a high degree of molecular heterogeneity as revealed by multi-platform profiling. IDH1 mutation identifies molecular subgroups of patients with different responses to therapeutic agents; while TP53 mutation suggests increased genetic instability. These results highlight the benefits of profiling in consideration of treatment options for glioma patients.

**2014 Poster Highlights Session (Board #4), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Do host factors determine long-term survival in glioblastoma? A genome/transcriptome profiling study by the German Glioma Network.** *Presenting Author: Michael Weller, Department of Neurology, University Hospital Zurich, Zurich, Switzerland*

**Background:** The prognosis of glioblastoma remains poor: only a minority of patients experience long-term survival beyond three years after diagnosis. Previously identified predictors of long-term survival include younger age, gross total surgical resection, $O^6$-methylguanine DNA methyltransferase (MGMT) promoter methylation and isocitrate dehydrogenase (IDH) 1 or 2 mutation (Hartmann et al. Clin Cancer Res 2013; 19:5146-5157), but these parameters do by no means fully account for long-term survival. **Methods:** Accordingly, to identify specific molecular signatures of glioblastomas with long-term survival, we performed genome- and transcriptome-wide molecular profiling of 94 glioblastoma samples, including 28 long-term survivors with >36 months overall survival (OS), 20 short-term survivors with <12 months OS, and 46 patients with intermediate OS. Integrative bioinformatic analyses were used to characterize molecular aberrations in the distinct survival groups stratified by MGMT and IDH1/2 status. **Results:** Glioblastoma patients with long-term survival were younger and more often had *IDH1/2*-mutant and *MGMT*-methylated tumors. Gene expression profiling revealed over-representation of a distinct (proneural-like) expression signature in long-term survivors that was linked to *IDH1/2* mutation. However, *IDH1/2*-wildtype glioblastomas from long-term survivors did not show distinct gene expression profiles and included proneural, classical and mesenchymal glioblastoma subtypes. Genomic imbalances differed between *IDH1/2*-mutant and *IDH1/2*-wildtype tumors, too, but not between survival groups of *IDH1/2*-wildtype patients. **Conclusions:** These data strongly suggest that host-derived rather than tumor-derived factors allow for long survival in glioblastoma. Ongoing studies on long-term survival in glioblastoma of the German Glioma Network therefore focus on immune responses, notably autoantibody profiling, to corroborate the hypothesis that immune control of glioblastoma may contribute to long-term survival.

**2015 Poster Highlights Session (Board #5), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

***MGMT* promoter methylation as a prognostic biomarker for benefit from dose-intensified temozolomide rechallenge in progressive glioblastoma: First results from the randomized phase II DIRECTOR trial.** *Presenting Author: Ghazaleh Tabatabai, Department of Neurology, University Hospital Zurich, Zurich, Switzerland*

**Background:** Rechallenge with temozolomide (TMZ) at first progression of glioblastoma after radiotherapy with concomitant and maintenance temozolomide (TMZ/RT→TMZ) has been studied in retrospective and single-arm prospective studies, applying TMZ continuously or using 7/14 or 21/28 days schedules. Progression-free survival rates have been in the range of 10-30% without any major prognostic impact of $O^6$-methylguanine DNA methyltransferase *(MGMT)*. **Methods:** Glioblastoma patients at first progression after TMZ/RT→TMZ and at least 2 maintenance TMZ cycles were randomized to Arm A (one week on (150 mg/sqm TMZ per day) / one week off) or to Arm B (three weeks on (100 mg/sqm TMZ per day) / one week off). The primary end point was median time to treatment failure defined as progression, premature (< 12 months) TMZ discontinuation for toxicity, or death from any cause; 166 patients were deemed necessary to show a meaningful difference between arms. **Results:** Because of withdrawal of support, the trial was prematurely closed to accrual after 105 patients.The outcomes in Arm A and Arm B for the primary endpoint of median time to treatment failure (56 days [95% CI 55-98] vs. 59.5 days [95% CI 56-105]) and for overall survival (OS) (298 days [95% CI 202-395] vs. 322 days, [95% CI 246-356]) were similar. These endpoints differed, however, by *MGMT* promoter methylation status, which was informative for all patients. Median time to treatment failure in patients with *MGMT*-methylated tumors was 98 days [95% CI 56-223] vs. 56 days [95% CI 56-60] in *MGMT*-unmethylated glioblastoma. PFS-6 was 39.7% vs. 6.9% with vs. without *MGMT* promoter methylation; OS with *MGMT*-methylated glioblastoma was 382 days [95% CI 300-531] vs. 241 days [95% CI 191-313] in *MGMT*-unmethylated glioblastoma. Hematological toxicity > grade 3 was similar (27% Arm A vs. 30.7% Arm B). **Conclusions:** TMZ rechallenge is an active treatment for *MGMT* promoter-methylated glioblastoma progressive after standard therapy. The best TMZ regimen remains to be defined. Alternative strategies are warranted for patients with progressive *MGMT*-unmethylated glioblastoma. Clinical trial information: NCT00941460.

**2016 Poster Highlights Session (Board #6), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**MGMT gene promoter methylation in plasma of glioma patients receiving temozolomide.** *Presenting Author: Riccardo Soffietti, Department of Neuro-Oncology, University and City of Health and Science Hospital of Turin, Turin, Italy*

**Background:** MGMT gene promoter methylation in tumor tissue of gliomas is now recognized as a predictive biomarker for response to temozolomide. Up to date there is lack of studies investigating MGMT methylation status in the circulating DNA of glioma patients undergoing chemotherapy with temozolomide. In this prospective study on a cohort of patients with gliomas of different grades of malignancy we aimed to: (1) evaluate the concordance between MGMT methylation status in tumor tissue and plasma; (2) monitor MGMT methylation status in plasma before and during temozolomide, and explore its value as a predictive biomarker. **Methods:** We enrolled 58 patients who underwent surgical resection, followed by radiotherapy and/or temozolomide. Blood samples were collected at baseline and every 3 cycles of temozolomide up to 12 months. MGMT promoter methylation status was assessed in both paraffin-embedded tumor tissue and plasma by real-time PCR. **Results:** MGMT promoter methylation status was concordant in tumor tissue and plasma at baseline in 42 out of 48 patients (87.5%, Kappa=0.75, 95%CI: 0.57-0.93). When considering glioblastomas only we obtained a 93.7% concordance and a Kappa of 0.87 (95%CI: 0.70-1.00). Mortality was higher for patients with MGMT unmethylated promoter both in tumor tissue (HR=2.21, 95%CI: 0.99-4-95) and plasma (HR=2.19, 95%CI: 1.02-4.68). Progression-free survival was shorter for patients with unmethylated MGMT promoter both in tumor tissue (HR=2.30, 95%CI: 1.19-4.45) and plasma (HR=1.77, 95%CI: 0.95-3.30). The cumulative incidence of unmethylated MGMT promoter in plasma was 58% at baseline and reached virtually 100% at 12 months. **Conclusions:** The assessment of MGMT promoter methylation in plasma can be useful when adequate tumor tissue (i.e. in stereotactic biopsy or in inoperable tumors) is not available. Moreover, the analysis of MGMT promoter methylation in plasma could be particularly useful to monitor methylated patients, helping to establish when the tumor switches from a methylated to an unmethylated status, thus predicting the emerging of a treatment resistance.

**2017 Poster Highlights Session (Board #7), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Determining the glioma CpG island methylator phenotype, 1p/19q codeletion, and *MGMT* promoter methylation from epigenome-wide methylation data in the biomarker cohort of the NOA-04 trial.** *Presenting Author: Benedikt Wiestler, Neurooncology, University of Heidelberg Medical Center, Heidelberg, Germany*

**Background:** Molecular biomarkers, including *isocitrate dehydrogenase 1* or *2* (*IDH1/2*) mutation, 1p/19q codeletion and *$O^6$-methylguanine-DNA-methyltransferase* (*MGMT)* promoter methylation, improve prognostication and may even guide treatment decisions in patients with World Health Organization (WHO) grade III gliomas. At present, each marker is individually tested by distinct assays. Illumina Infinium HumanMethylation450 BeadChip arrays (HM450) allow the determination of large-scale methylation profiles and genome-wide DNA copy number changes, enabling molecular subgrouping of tumors. Algorithms have been developed to detect the glioma CpG island methylator phenotype (G-CIMP) associated with *IDH1/2* mutation, as well as 1p/19q codeletion and *MGMT*promoter methylation, using this assay. **Methods:** Here, we investigated the diagnostic and prognostic performance of these algorithms in the biomarker cohort (n=115 patients) of the NOA-04 trial, which centrally assessed *IDH*, 1p/19q and *MGMT*status using established single marker tests. **Results:** Concordance for *IDH* and 1p/19q status was very high: In 92% of cases, the HM450 and the reference data agreed. In discordant cases, survival analysis by Kaplan-Meier and Cox regression analyses suggested a more accurate assessment of the biological phenotype by HM450 analysis. The HM450-derived MGMT-STP27 model to calculate *MGMT* promoter methylation probability revealed this aberration in a significantly higher fraction of cases than conventional methylation-specific PCR (MSP), with 87/91 G-CIMP positive tumors predicted as *MGMT*promoter-methylated. Fitting a new model for these tumors resulted in an area under the curve of 0.84. **Conclusions:** G-CIMP and 1p/19q codeletion are reliably detectable by HM450 analysis and associated with prognosis in the NOA-04 trial. Efforts are required to resolve the discrepancy between the MGMT-STP27 and MSP data for *MGMT* promoter methylation status. Overall, our data suggests that HM450 analysis may be able to replace individual marker tests for routine assessment of anaplastic gliomas.

**2018 Poster Highlights Session (Board #8), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Randomized phase II study of axitinib versus standard of care in patients with recurrent glioblastoma.** *Presenting Author: Bart Neyns, Universitair Ziekenhuis Brussels, Brussels, Belgium*

**Background:** Vascular endothelial growth factor receptor (VEGFR) signal transduction mediates glioblastoma (GB) associated neo-angiogenesis. Axitinib is an oral small molecule tyrosine kinase inhibitor with high affinity and specificity for the VEGF-receptors, approved for the treatment of metastatic renal cell carcinoma. **Methods:** Axitinib (5 mg BID starting dose) vs. best alternative choice of therapy was studied in an open label, randomized, phase II clinical trial in patients (pts) with recurrent GB. Six-month progression-free survival (6mPFS) was the primary endpoint. **Results:** Between Sep 2011 and Oct 2013, 44 pts who failed surgery, RT and temozolomide were randomized 1:1 at 3 sites. Median age 54y (range 20-79), 33M/11F, WHO-PS 0/1/2/3: 6, 26, 11, and 1 pt. In the control arm 20 pts received bevacizumab and 2 pts received lomustine at standard doses. Axitinib (n=22) was generally well tolerated. Most common axitinib related AEs consisted of dysphonia (3x G2), fatigue (6x G2, 2x G3), hypertension (5x G2), oral hyperesthesia (7x G2, 1x G3), diarrhea (2x G2, 2x G3), and hypothyroidism (3x G2). In 4 pts axitinib dosing was interrupted and subsequently dose reduced because of toxicity; in 4 other pts axitinib was dose escalated to 7 or 10 mg BID (2 pts each). Tumor response by RANO criteria was 28% in the axitinib arm vs. 23% in the control arm (Table). All pts had an increased uptake on 18F-FET PET at baseline. A decrease (-26 to -100%) of SUVmax/background was documented in 6/7 pts on axitinib at the time of response on MRI. Corticosteroids could be stopped in 4/12 and tapered in an additional 5/12 pts in the axitinib arm. After a median follow-up of 10.5 mths, the 6mPFS for axitinib was 22% (95% CI 5-40) vs. 19% (95% CI 2-36) for the control arm. Median PFS and OS were respectively 2.9 vs. 2.6 mths, and 10.3 vs. 7.4 mths for pts treated in the axitinib vs. control arm. **Conclusions:** Axitinib has single-agent activity and manageable toxicity in pts with recurrent GB. The survival on the axitinib arm was comparable to that on the contemporary control arm. Further evaluation of axitinib for recurrent GB is warranted. Clinical trial information: NCT01562197.

**Phase II trial of the phosphatidyinositol-3 kinase (PI3K) inhibitor buparlisib (BKM120) in recurrent glioblastoma.** *Presenting Author: Patrick Y. Wen, Dana-Farber Cancer Institute, Boston, MA*

**Background:** The PI3K pathway is activated in most GBMs and represents a potential therapeutic target. Buparlisib is an oral, pan-Class I PI3K inhibitor that enters the brain at therapeutic concentrations and inhibits the growth of U87 and GBM PDX models. **Methods:** The Ivy Consortium conducted a phase II study of buparlisib in recurrent GBM patients with activation of the PI3K pathway (mutation, homozygous deletion or loss of immunohistochemistry (IHC) of PTEN, PIK3CA or PIK3RI mutations, or detectable pAKT). Additional eligibility criteria included radiologic progression, 1st or 2nd relapse, > 18 yrs, KPS > 60, adequate bone marrow and organ function, no prior bevacizumab or enzyme-inducing antiepileptic drugs. Patients received buparlisib 100mg daily. The study consisted of 2 concurrent cohorts. In Cohort 1 (up to 15 patients) buparlisib was given for 8-12 days prior to surgery for recurrent disease. Patients underwent FDG PET, pharmacokinetic studies, and tumor obtained for drug concentrations and pharmacodynamic effects. In Cohort 2, 50 patients with unresectable GBM received buparlisib with a . primary endpoint of PFS6. **Results:** 13 patients have been enrolled into cohort 1, 50 into cohort 2. Treatment was well-tolerated with no grade 4 toxicities. Grade 3 toxicities were asymptomatic lipase elevation (6), rash (4), hyperglycemia (3), fatigue (4), elevated ALT/AST (2), and 1 each of depression, anxiety, hypophosphatemia, thrombocytopenia and lymphopenia. Analysis of tumor specimens from Cohort 1 showed reduction of pAKTS473 by IHC in 4/6 (67%) of evaluable patients. The combined cohorts showed minimal efficacy with median PFS of 1.8 months and median OS of 10.9 months. Best response was stable disease. Only 1 patient in each cohort achieved PFS6. Of the first 40 patients who underwent exome sequencing, there were 4 PIK3CA (10%), 2 PIK3R1 (5%), and 13 PTEN (33%) mutations. Patients with PTEN loss and or PI3K mutations paradoxically had a worse outcome. **Conclusions:** Buparlisib is well-tolerated in patients with recurrent GBM and achieves adequate tumor concentration to inhibit pAKTS473. However, single agent efficacy was minimal. Final correlation of tumor genotype with outcome will be presented.

**2020 Poster Highlights Session (Board #10), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Panobinostat in combination with bevacizumab for recurrent glioblastoma and anaplastic glioma.** *Presenting Author: Eudocia Quant Lee, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Bevacizumab is frequently used to treat recurrent high-grade gliomas, but responses are generally not durable. Panobinostat is a histone deacetylase inhibitor with anti-neoplastic and anti-angiogenic effects in glioma and may work synergistically with bevacizumab. We conducted a multicenter phase II trial of panobinostat in combination with bevacizumab in patients with recurrent grade III and IV gliomas. **Methods:** Two cohorts were enrolled: one with recurrent glioblastoma (GBM) as the primary study and one with recurrent anaplastic glioma (AG) as the exploratory study. Patients were treated with oral panobinostat 30 mg 3 x per week, every other week, in combination with bevacizumab 10 mg/kg every other week. The primary endpoint was 6-month progression-free survival (PFS6) in the GBM cohort and the study was powered to discriminate between a 35% and 55% PFS6 rate (85% power at an alpha level of 0.07). **Results:** At planned interim analysis, 13 of the first 21 patients accrued to the GBM cohort had progressed within 6 months of initiating study treatment. The GBM cohort did not meet criteria for continued accrual and was closed early. In the GBM cohort, PFS6 rate was 30.4% [95% confidence interval: 12%, 51%], median PFS was 5 months [3, 9], and median OS was 9 months [6, 19]. Accrual in the AG cohort continued to completion and a total of 15 patients were enrolled. In the AG cohort, PFS6 was 46.67% [21%, 73%], median PFS was 7 months [2, 10], and median OS was 17 months [5, 27]. The most common grade 3 or 4 toxicities related to treatment in the GBM arm were hypophosphatemia (12.5%), thrombocytopenia (12.5%), lymphopenia (8.3%), neutropenia (8.3%), and ALT elevation (8.3%). In the AG arm, the most common grade 3 or 4 toxicities were thrombocytopenia (20.0%) and hypophosphatemia (13.3%). There were no deaths related to study treatment. **Conclusions:** Although reasonably well-tolerated, this phase II study of panobinostat and bevacizumab in recurrent GBM did not meet criteria for continued accrual and the GBM cohort of the study was closed. However, in the recurrent AG cohort, bevacizumab in combination with LBH589 may delay progression. Updated outcome and safety data will be presented. Study supported by Novartis and Genentech. Clinical trial information: NCT00859222.

**2021 Poster Highlights Session (Board #11), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 1 study evaluating ABT-414 in combination with temozolomide (TMZ) for subjects with recurrent or unresectable glioblastoma (GBM).** *Presenting Author: Hui Kong Gan, Austin Health and Ludwig Institute for Cancer Research, Melbourne, Australia*

**Background:** Patients (pts) with recurrent GBM have few treatment options and a very poor prognosis. GBM tumors often exhibit aberrant epidermal growth factor receptor (EGFR) proliferative signaling. ABT-414 is an antibody drug conjugate consisting of a unique antibody targeting active EGFR or mutant EGFRvIII linked to a potent, toxic anti-microtubule agent monomethylauristatin F (MMAF). ABT-414 has demonstrated high antitumor activity in preclinical GBM tumor models harboring either wild type EGFR or EGFRvIII. **Methods:** Objectives were to evaluate the toxicities, pharmacokinetics (PK), and the recommended phase 2 dose of ABT-414 when administered every other week (QOW) in combination with TMZ in pts with recurrent or unresectable GBM. Assessments include adverse events (AEs, NCI-CTCAE), PK parameters, objective response (RANO criteria) and tumor tissue EGFR biomarkers. **Results:** As of Jan 1, 2014, safety data was compiled for 12 pts (6/6, Male/Female, median age 48). Common ($\geq$ 3 pts) adverse events include blurred vision (n=5), corneal deposits (n=4), foreign body sensation in the eye, nausea, pyrexia, and headache (n=3 each). Grade 3/4 AEs include lymphopenia, corneal deposits, skin infection, and blood cholesterol increase (n=1 each). Three cohorts have been treated to date (0.5, 1.0, 1.5 mg/kg). One dose limiting toxicity of grade 3 corneal deposits was reported at 1.0 mg/kg with improvement of symptoms after a dose reduction. ABT-414 PK results in 7 pts appeared to be dose proportional from 0.5-1.0 mg/kg, with mild accumulation using QOW dosing, and a half-life of 7-8 days. As of Jan 9, best responses for 9 pts with measurable disease at baseline include 1 complete response (CR) and 2 partial responses (33%). Patient samples are being evaluated for EGFR amplification, EGFR VIII status and expression of EGFR mRNA to determine which marker best associates with clinical response. **Conclusions:** Preliminary safety data demonstrate a unique toxicity pattern related to MMAF-induced corneal epithelial microcysts. Preliminary responses in 3/9 pts with TMZ refractory GBM, including 1 CR, warrant further study. Phase 2 studies with ABT-414 in GBM are being planned. Clinical trial information: NCT01800695.

**2022 Poster Highlights Session (Board #12), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Can average-risk medulloblastoma adult patients be treated with radiotherapy and plus chemotherapy?** *Presenting Author: Enrico Franceschi, Medical Oncology Department, Bellaria-Maggiore Hospital, Azienda USL of Bologna - IRCCS Institute of Neurological Sciences, Bologna, Italy*

**Background**: The standard treatment in children with average-risk medulloblastoma (MB) is chemotherapy after reduced-dose radiotherapy (23.4 Gy of craniospinal irradiation and a posterior fossa boost to 55.8 Gy). However, in adults, there is no agreement on the use of adjuvant chemotherapy in this setting. **Methods**: We performed a retrospective analysis of adult MB pts with average-risk disease, defined as no postsurgical residual (or $<1.5$ $cm^2$) and no metastatic disease (M0). Main inclusion criteria were: age $>$ 16 years, post-surgical treatment with standard craniospinal irradiation with or without adjuvant chemotherapy (cisplatin and etoposide $\pm$ cyclophosphamide). **Results**: From 1988 to 2012 were accrued 43 average-risk MB pts treated with surgery and adjuvant radiotherapy. Fifteen (34.9%) pts received also chemotherapy: 7 before radiotherapy (RT), 5 after RT, and 3 before and after RT. Median age was 31 years (range: 16-57), M/F ratio 27 (62.8%)/16 (37.2%). Histology was classic in 24 pts (55.8%), desmoplastic in 12 pts (27.9%), extensive nodularity in 5 pts (11.6%), large cell/anaplastic in 2 pts (4.7%). Reasons to administer chemotherapy were residual disease $<1.5$ cm in 9 pts (60.0%), delay in RT start in 6 pts (40.0%). After a median follow up time of 10 years (range: 8-13), median overall survival (OS) was 18 years (95%CI: 9 – 28) in pts who receive RT alone, and was not reached in pts treated with radiotherapy plus chemotherapy. The survival rates at 5,10 and 15 years were 100%, 78.6% (95% CI: 60.0-97.2%) and 60.2% (95%CI: 36.9-83.5%), in pts treated with RT alone, and 100%, 100% and 100%, in pts treated with RT plus chemotherapy (p=0.079). To date, all pts receiving adjuvant chemotherapy are alive. Univariate analyses did not show significant differences in survival by gender (P=1.000), age (P=0.070) and T stage (T1-Ta vs T3b-T4, P=0.881) between groups. **Conclusions**: Our findings suggest a role for adjuvant chemotherapy in the treatment of average-risk MB adult pts. Due to the extreme rarity of MB in adults, prospective trials remain a challenge. Further improvements might drive to add chemotherapy in average-risk setting with less favorable biological signatures (large cell/anaplastic MB and non-WNT group).

**2023 Poster Highlights Session (Board #14), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 2 study of orally administered PLX3397 in patients with recurrent glioblastoma.** *Presenting Author: Nicholas A. Butowski, University of California, San Francisco, San Francisco, CA*

**Background:** PLX3397 is an oral, small molecule that potently and selectively inhibits CSF1R, Kit, and Flt3-ITD kinases. CSF1R is expressed on microglia/macrophages and tumor cells within glioblastoma (GB). Many glioma cell lines express the CSF1R ligands, CSF-1 and IL-34 and the KIT ligand, SCF, and depletion of microglia in preclinical GB models reduces tumor burden and spread. **Methods:** This study of recurrent GB measured the 6-month PFS rate (PFS6), median duration of response, overall response rate (ORR), overall survival (OS), safety, and plasma and tumor pharmacokinetics (PK) and pharmacodynamics (PD) during PLX3397 treatment. **Results**: 38 recurrent GB patients were treated with PLX3397 at 1000 mg daily, with Cohort 1 (14 patients) treated 7 days in advance of recurrent surgery and Cohort 2 (24 patients) without surgery. PLX3397 was well tolerated; common (>10%) treatment-related adverse events included fatigue, constipation, nausea, hair color change, elevation in AST/ALT, anorexia, and headache. The primary endpoint of PFS6 was 11.4% with no complete or partial responses. 7/38 (18%) of patients experienced stable disease.Plasma PK Cmax was median 8090 ng/mL (range 3100-13400) with Tmax of 2 hr. Cohort 1 tumor tissue PK was median 5500 ng/g (range 1320-69400). PD effects observed in blood in both Cohorts included elevated plasma CSF-1 and reduced $CD14^{dim}/CD16^{+}$ monocytes. In pre-surgical patients (Cohort 1), tissue PD effects observed included possible changes in tumor macrophage/microglia morphology, IBA1 IHC, FACS, and pERK IHC compared to control patient tissues. PDGFRA amplification was seen in 13/36 archival samples. **Conclusions**: PLX3397 is a potent inhibitor of tumor-associated macrophages and microglia, readily entered GB tissue, and demonstrated expected PD effects. As a single agent, PLX3397 showed no significant improvement in PFS, although further research toward identifying a responsive subset of GB patients is ongoing. PLX3397 is well-tolerated and its safety profile is conducive to testing its combination with other treatments; A Phase 2 trial combining PLX3397 with RT and Temodar in newly diagnosed GB has been initiated. Clinical trial information: NCT01349036.

**2024 Poster Highlights Session (Board #15), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Primary malignant brain tumours (PMBT) in phase I studies: Barriers to treatment and patient outcomes.** *Presenting Author: Scheryll Paula Alken, Departments of Neuro Oncology/Drug Development, Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

**Background:** Primary malignant brain tumours (PMBT) are a rare tumour group with a poor outcome and limited options at relapse. Despite recent incremental gains from multimodal therapy and an emerging understanding of underlying genetic alterations, patients (pts) with PMBT have traditionally been excluded from phase I trials due to a number of concerns including blood-brain barrier penetration; it is recognised that such concerns are less relevant in the molecular era. We examined the outcomes of and barriers to participation of these pts on phase I studies. **Methods:** We reviewed the case records of pts with PMBT referred to the Neuro Oncology and Clinical Pharmacology Units of the Royal Marsden Hospital between 2004 and 2013 for consideration of a phase I study. Pt characteristics including demographics and details of prior treatment were examined. Kaplan-Meier estimator and Cox regression were used to evaluate progression free survival (PFS) and overall survival (OS). All tests performed were two-sided with an alpha of 0.05, and a power of 80% was used. Surviving patients were censored at date of last follow-up. **Results:** Seventy three pts with PMBT were identified. Of these, 50 (68.5%) were allocated to a phase I trial and 38 (52%) of these patients received at least one dose of the study drug. 9 pts (18%) failed screening, 3 pts (6%) withdrew consent. 11 pts (15%) were not allocated to a study due to a lack of suitable trials, 9 (12%) were not allocated due to poor performance status (PS). Factors influencing enrolment were examined; only Karnofsky PS (KPS) was statistically significant (HR 1.09, 95% CI 1.04 – 1.15, p=0.001). The median PFS of pts dosed was 7.3 months. The median OS of these pts was 7.9 months versus 4.2 months in those not dosed (p=0.024). Grade 3 drug related toxicities were seen in 9.6% of patients. **Conclusions:** Patients with PMBT can be safely treated in phase I trials. A lack of suitable trials remains the main barrier to enrolment, as does KPS, which is similar to other rare malignancies. Based on our results these patients tolerate investigational agents similar to other groups. This study adds to the growing body of evidence encouraging investigators to enrol such patients.

**2025 Poster Highlights Session (Board #16), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Results of stage 1 of the oparatic trial: A phase I study of olaparib in combination with temozolomide in patients with relapsed glioblastoma.** *Presenting Author: Anthony J. Chalmers, University of Glasgow, Glasgow, United Kingdom*

**Background:** Drug delivery is a major problem in the treatment of glioblastoma (GBM). Tumour pharmacokinetics (PK) of small molecule targeted agents in GBM are not well understood, and poor activity may result from lack of biological efficacy or adverse PK. Olaparib, a small molecule inhibitor of the DNA repair enzyme poly(ADP-ribose) polymerase (PARP), has potential to overcome treatment resistance of GBM. Despite radiological responses in brain metastases, GBM penetration by olaparib has not been studied. **Methods:** Preclinically, blood-brain barrier penetration was assessed by directional transport of [$^{14}$C]-olaparib across MDCKII cells expressing MDR1 and autoradiography of rats and mice treated with [$^{14}$C]-olaparib. Clinically, 8 patients with recurrent GBM underwent dynamic contrast enhanced (DCE) MRI at baseline followed by tumour resection after 4 days of oral olaparib (tablet: 100 mg QD, n=5; 200 mg BID, n=3). Olaparib levels were measured in tumour and plasma by LC-MS. **Results:** Olaparib was a substrate for MDR1 and efflux was blocked by the MDR1 inhibitor ketoconazole. Radioactivity was not detected in the central nervous systems (CNS) of rats or mice after single dose [$^{14}$C]-olaparib, but significant levels were measured in subcutaneous HCT-116 tumour xenografts up to 96 hrs. Olaparib was detected in 24/24 resected GBM specimens from 8 patients (Table) at concentrations similar to those in previous breast cancer studies in which PARP inhibition and tumour responses were observed. Pre-treatment DCE-MRI showed increased vascular permeability in tumours, and tumour cellularity parameters correlated with olaparib levels. **Conclusions:** Olaparib is excluded from the CNS under normal conditions but reliably penetrates recurrent GBM at therapeutic levels. Small molecule PK in GBM are poorly predicted by standard pre-clinical models. Clinical trial information: NCT01390571.

**Targeting glioma-initiating cells in GBM: ABTC-0904, a randomized phase 0/II study targeting the Sonic Hedgehog-signaling pathway.** *Presenting Author: Andrew E. Sloan, University Hospital Case Medical Center, Cleveland, OH*

**Background:** The prognosis for GBM, which appears to be driven by glioma initiating cells (GIC), remains poor. Our hypothesis was that interrupting sonic hedgehog signaling (SHh) would inhibit GIC activity and improve PFS (PFS6). **Methods:** A two armed, randomized phase 0/II study of Vismodegib, an inhibitor of SMO, was performed in 40 patients undergoing resection for recurrent GBM (rGBM). The trial hypothesis was to achieve 25% PFS6 rate compared to a null of 10 % with a 90% power and a 10% type I error rate (1-sided). Arm I received Vismodegib for 7 days pre-operatively; Arm II was not treated pre-operatively. All patients were treated with Vismodegib post-operatively. Primary objective was to assess PFS6, with secondary endpoints of median overall survival, response and toxicity. Secondary objectives included determination of: intra-tumoral PK and PD; inhibition of SHh signaling by RT-PCR and immunohistochemistry; and inhibition of GIC proliferation and self-renewal by neurosphere proliferation and limited dilution assay. **Results:** PK/PD data and tumor specimens were obtained from 39 of the 40 patients. Median drug levels in plasma and tissue were7638 and 3270 ng/ml respectively for patients in Arm I. SHh signaling intermediates (Gli-1, Gli-2, PTCH-1b) were 3.3 to 110-fold decreased in Arm I vs. Arm II (p<0.0002). Finally, proliferating CD133$^+$ neurospheres were derived from 14 of the 39 cultures assessed and array CGH suggested GIC (vs. NSC) as the cells of origin. The proportion of tumor-derived CD133$^+$neurospheres undergoing proliferation and self-renewal was decreased in Arm I vs. II (p <0.005 and p < 0.003 respectively). PFS6 and OS were 1.8m and 8.3m respectively; but there was no difference between the two arms. **Conclusions:** Vismodegib was well tolerated but not efficacious as a single agent in rGBM. However, this agent achieved therapeutic intra-tumoral concentration in rGBM and had biological activity on proliferation and self-renewal of GBM derived CD133$^+$neurospheres. Combinatorial therapy targeting SHh pathway in GBM should be pursued. Clinical trial information: NCT00980343.

**2027 Poster Highlights Session (Board #18), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase II study of monthly pasireotide LAR (SOM230C) for recurrent or progressive meningioma: Final results.** *Presenting Author: Andrew David Norden, Dana-Farber Cancer Institute, Boston, MA*

**Background:** No medical therapy for recurrent meningioma has proven effective, yet a subset of these tumors recur after surgery and radiation. A pilot study of sustained-release somatostatin yielded promising results. Pasireotide LAR is a long-acting somatostatin analog with higher affinity for most somatostatin receptor subtypes than octreotide. **Methods:** This was a phase II trial of monthly pasireotide LAR 60 mg IM in patients with recurrent or progressive meningioma. Patients were stratified by histology (cohort A: atypical [grade 2] and malignant [grade 3] meningiomas; cohort B: benign [WHO grade 1] meningiomas). Treatment cycles were 28 days. Restaging MRIs were performed every 3 cycles and response was assessed using Macdonald criteria. Octreotide scanning was performed at baseline. Tumor tissue was obtained for somatostatin receptor immunohistochemistry. Serum IGF-1 levels were checked serially. **Results:** 18 patients in cohort A and 16 in cohort B were accrued. Cohort A had median age 59 (range 39-74), 8 men (44%), median KPS 80 (range 60-100), 17 (94%) with previous radiation therapy. Cohort B had median age 52 (range 36-81), 9 men (56%), median KPS 90 (range 70-100), 11 (69%) with previous radiation therapy. There were no responses. Twelve patients in cohort A (67%) achieved stable disease for a median of 4 cycles, and 13 patients in Cohort B (81%) achieved stable disease for a median of 7 cycles. In Cohort A, PFS6 was 17% and median PFS 15 weeks (95% CI: 8-20). In Cohort B, PFS6 was 50% and median PFS 26 weeks (12-43). Toxicity was mild except for grade 3 hyperglycemia in 5 (15%) patients, grade 4 hyperglycemia in 1 (3%) patient, grade 4 hypoglycemia in 1 (3%) patient, grade 3 hypokalemia in 1 (3%) patient, grade 3 fatigue in 2 (6%) patients, grade 3 amylase elevation in 1 (3%) patient, and grade 3 lipase elevation in 2 (6%) patients. Neither octreotide uptake nor IGF-1 levels predicted outcome. Staining for sst3 was predictive of favorable OS (HR 0.44, p=0.02) and PFS (HR 0.64, p=0.04). **Conclusions:** Pasireotide LAR is inactive in most recurrent meningiomas. Tumors with increased sst3 expression may be particularly sensitive to pasireotide, for reasons that remain to be determined. Clinical trial information: NCT00813592.

**2028 Poster Highlights Session (Board #19), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A multicenter randomized study comparing temozolomide (TMZ) versus TMZ-plus-bevacizumab (BEV) before standard treatment in unresectable glioblastoma (GBM) patients (p): The GENOM 009 study by the GEINO group.** *Presenting Author: Carmen Balana, Catalan Institute of Oncology Hospital Germans Trias i Pujol, Barcelona, Spain*

**Background:** We compared the efficacy and safety of treatment with TMZ or TMZ+BEVprior to and concomitant with radiotherapy in unresectable(GBM) patients. **Methods:** Between December 2009 and April 2013, p with unresectable GBM, PS<3 and MMS ≥25 were randomly assigned to receive eitherTMZ (85 mg/m², days 1–21, for 2, 28-day cycles), followed by standard TMZ with concomitant radiotherapy (60Gy) and then adjuvant TMZ for 6 cycles (TMZ Arm), or the same regimen but with the addition of BEV (10mg/kg /15 days) during pre-radiotherapy and concomitant treatment (BEV Arm). The primary endpoint was response according to RANO criteria after the 2 pre-radiotherapy cycles.The study was powered to detect a 30% difference between arms ($\alpha$ and $\beta$ errors of 0.05 and 0.20). Secondary endpoints included toxicity, neurological deterioration before radiation, progression-free survival (PFS), overall survival (OS) and 1-year survival. **Results:** 103 p were registered and 93 randomized – 45 to the TMZArm and 48 to the BEV Arm.Partial response (PR) was attained in 7.1% of p in the TMZ Arm vs 25.6% in the BEVArm(P=0.001), and clinical benefit (PR + stable disease) in 26.1% vs 65%, respectively Neurological deterioration before radiotherapy was more frequent in the TMZ Arm (48.9% vs 20.8% of p; P=0.004). PFS was 2.2 months (m) in the TMZ Arm vs 4.8 m in the BEV Arm (HR, 0.79; P=0.29). OS was 7.7 m vs 10.8 m (HR, 0.71; P=0.12) and 1-year survival was 29.6% vs 48.9% (HR, 0.60; P=0.06), respectively. MGMT methylation was an independent prognostic factorfor longer PFS (P=0.01), OS (P=0.001) and 1-year survival(P=0.004). More toxicities occurred in the BEV Arm, but a significant difference was observed only for stomatitis (P=0.02). **Conclusions:** The primary endpoint was met. The response rate was significantly higher in the BEV Arm. A tendency towards improved PFS, OS and 1-year survival was also observed in the BEV Arm, but the trial was not powered to detect statistical significance for these outcomes.TMZ+BEV is a feasible and effective option for unresectable GBM p. Clinical trial information: NCT01102595.

**2029 Poster Highlights Session (Board #20), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase 1/2 study of investigational hypoxia-targeted drug, TH-302, and bevacizumab (bev) in recurrent glioblastoma (GBM) following bev failure.** *Presenting Author: Andrew Jacob Brenner, Cancer Therapy and Research Center at UT Health Science Center, San Antonio, TX*

**Background:** Despite vascular dependence, GBM is resistant to antiangiogenic therapy. Co-targeting tumor angiogenesis and tumor hypoxia, a key driver of treatment resistance, is one approach to potentially prevent or reverse this mechanism of resistance. An ongoing Phase 1/2 study investigates TH-302 with bev in patients (pts) with recurrent GBM following bev failure. Median PFS and 3-mo PFS (PFS-3) in this pt population has been reported as 37.5 days and ~16% (Quant, Neuro-Onc 2009). **Methods:** Single center, dose-escalation, prospective study (NCT01403610) with 2:1 randomization to TH-302 single dose of 575 mg/m$^2$ or placebo administered pre-surgery (cohorts 1-3 only), followed by post-surgery combination therapy of bev at 10 mg/kg and TH-302 dose escalated 240-670 mg/m$^2$every 2 weeks (4 week cycle) until disease progression. Following the first 5 pts in cohort 3, pts were allowed to proceed directly to TH-302/bev combination therapy without surgery. Resected tumor tissue was evaluated for hypoxia induced pimonidazole (PIMO) adducts, endogenous CA-IX staining, γH2AX and TUNEL DNA damage biomarkers, and by metabolomic profiling. **Results:** 21 pts have been enrolled: 14 randomized in presurgery cohorts 1-3 with 9 proceeding to TH-302/bev after surgery and 7 pts proceeding directly to TH-302/bev. No Gr 4 AEs were observed. Two Gr 3 AEs were observed at 340 mg/m$^2$ (skin ulceration) and 670 mg/m$^2$ (thrombocytopenia). Primary TH-302 related toxicities were mucosal but not dose limiting: rectal mucositis in 2/4 pts at 480 mg/m$^2$ and 4/4 pts at 670 mg/m$^2$. Oral mucositis was limited. Co-localized PIMO and CA-IX staining showed extensive tumor hypoxia. MR-spectra showed significant differences in metabolites before treatment compared to at progression. Best tumor responses in 16 evaluable pts: 1 CR, 2 PRs, 9 SDs. Median PFS is 3.1 mos (95% CI: 2.1 to 4.0 mos) and PFS-3 is 52% (95% CI: 27% to 78%). **Conclusions:** Extensive tumor hypoxia was observed in GBM pts previously treated with bev. The recommended Phase 2 dose of TH-302 is 670 mg/m$^2$ when combined with bev. These preliminary data suggest potential activity of TH-302/bev in GBM pts with poor prognosis. Dose expansion at 670 mg/m$^2$ is ongoing. Clinical trial information: NCT01403610.

**2030 Poster Highlights Session (Board #21), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase II trial of vorinostat (VOR) combined with temozolomide (TMZ) and radiation therapy (RT) for newly diagnosed glioblastoma (GBM) (Alliance N0874/ABTC-0902).** *Presenting Author: Evanthia Galanis, Mayo Clinic, Rochester, MN*

**Background:** VOR is a histone deacetylase inhibitor that represents a rational targeted agent in GBM treatment. Given its single agent activity in recurrent disease (Galanis et al 2009) and radiosensitizing properties, this phase II trial was designed to test the addition of VOR to standard chemoradiation in newly diagnosed GBM patients (pts). **Methods:** Pts received vorinostat at 300 mg/day, days 1-5 weekly during RT in combination with temozolomide (75 mg/m$^2$/day). Following a 4-6 week rest period, pts received up to 12 cycles of standard adjuvant TMZ in combination with VOR at a dose of 400 mg/day on days 1-7 and 15-21 of each cycle (Lee et al, 2012). **Results:** A total of 107 patients were accrued to this single arm trial. This preliminary report is based on mature outcome data in 73 patients. Final data analysis will be presented at the meeting. With a median follow up of 11.3 months (range 0.8-21.6 months), OS 15, (survival status at 15 mo, primary trial endpoint) was 39.1% with a median OS of 14.3 months and PFS of 8.1 months. MGMT methylation status is available in 52 pts; OS 15 and PFS were 44.4% vs 11.1% and 8.1 vs 6.4 mo in methylated and unmethylated pts respectively. Most common grade 3/4 toxicities were lymphopenia (32%), thrombocytopenia (28%), neutropenia (22%), fatigue (12.1%), anemia (8.4%) and anorexia (6.5%). There were no treatment related deaths. **Conclusions:** The HDAC inhibitor VOR in combination with TMZ and RT has tolerable toxicity in newly diagnosed GBM patients. Initial analysis based on mature outcome data in 70% of the evaluable patients does not indicate an improvement in outcome; final data will be presented at the meeting. Ongoing RNA sequencing analysis of baseline tumor tissue in 80 pts will assess if a 43 gene VOR responsive signature, identified in preclinical models, can define subgroups of patients deriving benefit from treatment. Clinical trial information: NCT00731731.

**2031 Poster Highlights Session (Board #22), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase I study of plerixafor and bevacizumab in recurrent high-grade glioma.** *Presenting Author: Katrina H. Smith, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Although anti-angiogenic therapy for high-grade glioma (HGG) is promising, responses are not durable. The SDF-1/CXCR4 axis may help mediate resistance to VEGFR inhibition. SDF-1 is a known mediator of cancer cell invasion, vasculogenesis and vessel co-option. Plerixafor is a reversible CXCR4 inhibitor that has demonstrated growth inhibition in orthotopic glioblastoma xenografts. **Methods:** We conducted an open-label Phase I study to determine the safety and tolerability of plerixafor in combination with bevacizumab 10 mg/kg every two weeks in patients with recurrent HGG. In Part 1 of the study, plerixafor was dosed on Days 1-21 of each 28 day cycle. A 3 x 3 dose escalation design to a maximum planned dose level of plerixafor 320 $\mu$g/kg on Days 1-21 and bevacizumab 10 mg/kg on Days 1 and 15 of each 28 day cycle was used. Dose limiting toxicities (DLTs) were determined during the initial 4 weeks of therapy and included drug-related Grade ≥ 3 non-hematologic toxicities and Grade ≥ 4 hematologic toxicities. **Results:** 17 patients have been enrolled into Part 1 of the study to date: median age was 54 (23-67), median Karnofsky Performance Status was 90 (70-100), 9 were women (52.9%) , 9 had grade 4 glioma (52.9%), 8 had grade 3 glioma (47.1%), median number of prior therapies 1 (1-3). One DLT (grade 3 rectal fistula) was seen at a dose level of plerixafor 240 $\mu$g/kg + bevacizumab and the cohort was expanded to from 4 to 8 patients. Because no further DLTs were seen at the 240 $\mu$g/kg dose level, the maximum planned dose level of plerixafor 320 $\mu$g/kg + bevacizumb opened and 6 patients have been treated to date. Since no DLTs have been seen, the cohort has now been expanded to 12 patients. There are no other treatment-related grade 3 and no grade 4 toxicities. One grade 1 stroke (attributed to bevacizumab, unrelated to plerixafor) was found incidentally on imaging and the patient was removed from active treatment. **Conclusions:** Combination treatment with bevacizumab and plerixafor is well tolerated in HGG patients. No DLT has been seen in the first 6 patients treated at the maximum planned dose level (plerixafor 320 $\mu$g/kg on Days 1-21 and bevacizumab 10 mg/kg on Days 1 and 15 of each 28 day cycle) and the cohort has been expanded to 12 patients. Updated results will be presented. Clinical trial information: NCT01339039.

**2032 Poster Highlights Session (Board #23), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Predictive factors of bevacizumab efficacy in relapsed glioblastoma patients.** *Presenting Author: Patrizia Farina, Medical Oncology 1, Venetian Institute of Oncology-IRCCS, Padua, Italy*

**Background:** Bevacizumab is widely used in recurrent glioblastoma patients. Despite encouraging response rate, some patients do not respond to this schedule and many develop an early relapse. Predictive biomarkers of response or resistance are thus highly desirable to improve clinical benefit. **Methods:** Seventy patients with recurrent glioblastoma treated with bevacizumab (40 at first recurrence, 30 at > first recurrence) were included in the cohort and sequential plasma samples were collected before and during the treatment. The plasma of 23 healthy volunteers was also collected. Plasma concentrations of VEGF, PlGF, Ang2, TEK/Tie2 receptor (sTie2), BMP9, sFlt1, sRobo4 levels were assessed by ELISA based assays. Response to treatment was evaluated according to RANO criteria. **Results:** Median OS was 28.4 months for responders, 19.1 months for non responders patients ($p$=0.0009). Median PFS was 25.4 weeks for responder patients and 10.1 weeks for non responder patients ($p<$ 0.0001). A median of 10 cycles (range 2-32) per patient was administered. 36 patients were responders (4 complete responses and 32 partial responses) and 34 patients were considered as non responders (15 stable diseases and 19 progressive diseases). Baseline levels of VEGF-A, and PlGF were higher in patients than in healthy volunteers ($p<$0.0001) whereas BMP9 baseline median concentration was reduced in patients ($p=$ 0.003), and no difference was found for Ang2, sTie2, sFlt1 and sRobo4 between patients and healthy volunteers. No biomarker at baseline was associated with response, PFS or OS. During the first two months of bevacizumab treatment, VEGF-A, sTie2, Ang2 and sRobo4 decreased whereas PlGF level strongly increased. Bevacizumab treatment did not affect plasma levels of BMP9 and sFlt1. The evolution of plasma concentrations did not discriminated responder and non responder patients. Finally we found no significant variation for any biomarker at relapse. **Conclusions:** Our study identified plasmatic markers associated with gliomas and level variation associated with bevacizumab treatment but failed to identify any predictor of response, PFS or OS.

**2033 Poster Highlights Session (Board #24), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Venous thromboembolism (VTE) and glioblastoma.** *Presenting Author: Jacob Joseph Mandel, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The risk of VTE is very high for patients with brain tumors, with Glioblastoma (GB) considered one of the most at risk cancers. The aim of this study is to describe the occurrence and associated risk factors for the development of VTE among GB (patients) pts. **Methods:** In this IRB approved retrospective study, our neuro-oncology longitudinal database was screened for pts with GB, who were treated with concurrent radiation and Temozolomide (TMZ) followed by adjuvant TMZ from 2005-2011. 543 pts were identified. **Results:** 134 (24.6%) pts developed VTE, with 139 documented events. 56 pts (42%) were diagnosed with deep vein thrombosis (DVT) , 27 pts (20%) with pulmonary emboli (PE) with no evidence of DVT, and 51 pts (38%) had both DVT and PE. The majority were diagnosed after starting adjuvant TMZ (61%) with a median time of 6.5 months from starting adjuvant TMZ (range 0.03-120) with only 22 (16%) pts developing VTE before starting post surgery treatment and 32(23%) during chemoradiation. At time of VTE diagnosis, 44 (32%) patients had stable disease, 61 (43%) were clinically or radiographically progressing and the rest were newly diagnosed or during concurrent treatment. 56 (40%) patients were admitted secondary to their VTE. Treatment with anticoagulation alone was given to 68 (52%) pts, IVC filter only was inserted to 6 (5%) pts and 56 (43%)pts were treated with both modalities). 15 pts developed complications secondary to anticoagulation(5 brain haemorrhage , 6 bleeding in other locations and 4 thrombocytopenia). On univariate analysis risk factor associated with development of VTE after starting adjuvant TMZ treatment were: sex, prior history of venous thrombosis, poor KPS, requiring assistive device for ambulation, paresis, high BMI, pre chemotherapy WBC counts, and various medications (including anticoagulation, blood pressure drugs, anti-acid drugs and corticosteroids) ($p<0.05$). On multivariate analysis sex, poor KPS, high BMI, history of VTE and use of corticosteroids were significant risk factors for the development of VTE ($P<0.05$). **Conclusions:** VTE is a common complication of GB and can occur during the course of the disease. Factors associated with increased risk have been identified and will be useful in developing risk models in this patient population.

**2034 Poster Highlights Session (Board #25), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Joint modeling of longitudinal health-related quality of life (HRQoL) data and survival.** *Presenting Author: Divine Ewane Ediebah, European Organisation for Research and Treatment of Cancer Headquarters, Brussels, Belgium*

**Background:** In cancer clinical trials, several outcome measures may co-vary. Both treatment itself and treatment-related impairment of health-related quality of life (HRQoL) may affect survival. When these effects are analyzed separately, bias may arise. Therefore, our aim is to investigate the combined effect of treatment and longitudinally measured HRQoL on survival. **Methods:** We analyzed data from an EORTC randomized clinical trial (RCT) of 288 patients with anaplastic oligodendrogliomas who received radiotherapy (RT) alone or RT plus procarbazine, lomustine and vincristine (PCV) chemotherapy. HRQoL was assessed with the EORTC QLQ-C30 and Brain Cancer Module, at baseline, at the end of RT, and then every 3 to 6 months until progression. The appetite loss (AP) scale was pre-selected as the primary HRQoL endpoint, because this scale was previously found to be significantly different between the two treatment arms. Joint modeling was used to assess the combined effect of treatment and treatment-related AP on survival. The hazard ratios (HRs) for treatment effect were calculated using three different modeling strategies: Cox model with treatment only (model 1 [M1]), Cox model with treatment and time-dependent AP score (model 2 [M2]) and the joint model (model 3 [M3]). **Results:** In general, treatment with RT plus PCV chemotherapy resulted in decreased risk of death compared to RT alone. Estimated HR for treatment was 0.76 (95% CI 0.58–1.00) for M1, 0.72 (0.55–0.96) for M2 and 0.69 (0.52–0.92) for M3. This corresponds to a lower risk of death of 24% in M1, 28% in M2 and 31% in M3, for patients treated with RT plus PCV chemotherapy. Treatment-related AP resulted in increased risk of death, with estimated HR of 1.06 (1.01–1.12) for M2 and 1.13 (1.03–1.23) for M3. This translates to a 13% increased risk of death in M3 as compared to 6% increased risk of death in M2 for every 10-points increase of AP. **Conclusions:** Our findings suggest that part of the survival benefit of treatment with RT plus PCV chemotherapy can be masked by the negative effect that this treatment has on patients' HRQoL. In our study, up to 7% of the theoretical treatment efficacy was lost through increased AP affecting survival. Clinical trial information: NCT00002840.

**2035 Poster Highlights Session (Board #26), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Prospective assessment of neurocognitive outcomes in children and young adults with progressive/residual benign and low-grade brain tumors treated with high-precision conformal or conventional radiotherapy: Results of a randomized clinical trial.** *Presenting Author: Rakesh Jalali, Tata Memorial Hospital, Mumbai, India*

**Background:** Evidence for modern conformal partial brain radiotherapy is largely on retrospective or small case-series. We report longitudinal detailed neuropsychological outcomes from a prospective randomized trial comparing high-precision conformal radiotherapy (CRT) versus conventional radiotherapy (Conv RT) in children and young adults with progressive/residual benign and low-grade brain tumors (NCT00517959). **Methods:** Between 2001-10, 200 patients (132 males, 68 females; median age 13 years) were randomized to receive CRT (n=105; multiple non-coplanar fields using micromultileaf collimators under stereotactic guidance) or Conv RT (n=95; 2-4 open fields and beam modification) by 6 MV to dose of 54 Gy/30 fractions. Age-appropriate battery included full-scale IQ (FSIQ), verbal quotient (VQ), performance quotient (PQ), memory quotient (MQ>16 years of age) by Wechsler scores, LOTCA and anxiety-depression tests. Serial evaluations were done at pre-RT, 6-months and 2, 3 and 5 years and analyzed using generalized linear-mixed model (GLMM). **Results:** The most common histology was craniopharyngioma and low-grade astrocytoma. Baseline characteristics were well balanced between two arms. A substantial proportion of patients had low intelligence (FSIQ <69) in both arms (CRT-17%; Conv RT-16%) before RT. GLMM for repeated measures demonstrated significantly better preservation of FSIQ over time in patients treated with CRT compared to Conv RT at 3 year (p=0.003) and 5 year post-RT evaluation (p=0.012,Hyunh-Feldt test), as also in VQ (p=0.047) and MQ (p=0.049). Decline in LOTCA scores at 5-years (mainly in visuo-motor organization and attention-concentration) was significantly higher in Conv RT than CRT (p=0.019). Children <16 years had lesser depression in conformal arm (p=0.01) with no differences in anxiety between two arms. **Conclusions:** Our randomized trial provides high-quality evidence supporting use of high-precision conformal radiotherapy in children and young adults with progressive and residual benign and/or low-grade brain tumors. Clinical trial information: NCT00517959.

**2036 General Poster Session (Board #1), Sat, 1:15 PM-5:00 PM**

**Keeping GBM in check by targeting CHK1-CIP2A axis.** *Presenting Author: Anchit Khanna, Adult Cancer Program, Lowy Cancer Research Centre, UNSW Medicine, The University of New South Wales, Sydney, Australia*

**Background:** Checkpoint kinase1 (CHK1) is constitutively active in many human cancers including Glioblastoma (GBM). Unfortunately CHK1 inhibitors, currently in clinical trials, have shown deleterious effects on normal cells, thus limiting their clinical utility. Therefore, identification and targeting of cancer specific effectors of CHK1 signaling, emerges as an attractive therapeutic alternative. **Methods:** Analysis of 906 gliomapatient samples was done. GBM cell lines (including primary) were used for mechanistic and functional studies. *In vivo* models of GBM were used to verify the findings. **Results:** Meta-analysis of key datasets revealed a strong positive correlation for CHK1 and CIP2A expression. By contrast, a negligible correlation was seen in normal samples. Importantly, high mRNA expression of both proteins associated with reduced overall survival in glioma patients and marked for a more aggressive form of the disease. CIP2A amplification, found in 14.72% cases in the REMBRANDT study, was associated with worse overall survival in GBM patients. Inhibition of CHK1, by siRNA and chemicals, resulted in decreased CIP2A expression both *in vitro* and *in vivo*. Functionally, both CHK1 and CIP2A promoted viability, clonogenicity and anchorage-independent growth of GBM cells. Strikingly, the CHK1-mediated reduction in the clonogenic potential was partially rescued by exogenous CIP2A expression in GBM cells. Mechanistically, we identify STAT3 as the transcriptional mediator for CHK1-mediated CIP2A regulation. Depletion of STAT3 resulted in decreased CIP2A expression in both, U251MG and primary GBM cells. Further, CHK1 promoted STAT3 phosphorylation *in vitro* and *in vivo*. Accordingly, higher CIP2A, pCHK1 and pSTAT3 levels were observed in *de novo* and patient-derived GBM samples, relative to normal human astrocytes. Analogously, 10- to 15-fold higher CHK1 and CIP2A mRNA expression was seen in the genetically engineered mouse models of human GBM. Finally, using xenograft mouse models we show that both CHK1 inhibitor and CIP2A depletion inhibit GBM growth. **Conclusions:** These results highlight CHK1 and CIP2A expression as potential diagnostic and prognostic markers in human GBMs and identify CIP2A as a relevant cancer specific therapeutic target.

**2037 General Poster Session (Board #2), Sat, 1:15 PM-5:00 PM**

**Diagnostic value of plasma and urinary 2-hydroxyglutarate to identify patients with IDH-mutated glioma.** *Presenting Author: Giuseppe Lombardi, Medical Oncology 1, Venetian Institute of Oncology-IRCCS, Padua, Italy*

**Background:** Mutation of IDH1 gene is a prognostic factor and a diagnostic hallmark of gliomas. Mutant IDH1 enzyme can convert $\alpha$-KG into 2-Hydroxyglutarate(2HG); mutated gliomas have elevated amounts of intracellular 2HG. We analyzed 2HG concentration in plasma and urine in glioma patients(PTS) to identify a biomarker of IDH1 gene mutation **Methods:** All PTS had a prior histological confirmation of glioma, a recent brain MRI (within 2 weeks) showing the neoplastic lesions. The exclusion criteria were any chemotherapy performed within 28 days prior, other neoplastic and metabolic diseases. Plasma and urine samples were taken from all PTS and 2HG concentrations determined by liquid chromatography tandem mass spectrometry; Mann-Whitney test was used to test for differences in metabolite concentrations. ROC curve was used to evaluate the cut off value of 2HG biomarker. **Results:** 84 PTS were enrolled: 38 with IDH1 mutated and 46 IDH1 wild-type. Among PTS with mutant IDH1 we had 21 high-grade gliomas (HGG) and 17 low-grade gliomas (LGG); among PTS with IDH1 wild-type we had 35 HGG and 11 LGG. In all PTS we analyzed the mean 2HG concentration in plasma (P_2HG), in urine (U_2HG) and the ratio between P_2HG and U_2HG (R_2HG). The results are shown in Table. We found an important significant difference in R_2HG between PTS with and without IDH1 mutation. The optimal cut-off value of R_2HG to identify glioma PTS with and without IDH1 mutation was 19 with sensitivity (S) 63%, specificity (SP) 76% and accuracy (A) 70%.; in only PTS with HGG the optimal cut-off value was 20 (S 76%, SP 89%, A 84%, PPV 80%, NPV 86%). No association between the grade or size of tumor and R_2HG were found. In 7 out of 7 HGG PTS, we found a correlation between R_2HG value and response to treatment. **Conclusions:** By analyzing the R_2HG derived from individual plasma and urine 2HG levels is possible discriminate glioma PTS with and without IDH1 mutation. A larger samples need to be analyzed to investigate this method to monitor treatment efficacy.

**2038 General Poster Session (Board #3), Sat, 1:15 PM-5:00 PM**

**Features of adult clinical trial participants with glioblastoma (GB) at The University of Texas MD Anderson Cancer Center (MDACC).** *Presenting Author: Mark Daniel Anderson, University of Mississippi Medical Center, Jackson, MS*

**Background:** GB is the most common primary brain tumor in adults and has a poor prognosis. Less than 10% of pts are treated on clinical trials. **Methods:** In this IRB-approved retrospective study, our database was screened for GB pts from 2007-2012. 510 adult patients (pts) with primary GB were identified who participated on a clinical trial. 112 adult pts with primary GB were identified who were clinical trial eligible, but elected not to enroll in a clinical trial. **Results:** Median age was 54 years (18-83). 307 pts with a primary GB were consented for a newly diagnosed protocol (NDP) and their median OS was 25 months and their median PFS was 12.6 months. Median OS for pts who only enrolled on a recurrent GB protocol (RP) was 19 months from time of diagnosis. These 2 groups had differences in employment, education, symptoms, tumor location, performance status, extent of resection and location of therapy. Pts that were eligible for a clinical trial, but did not enroll, tended to be older, have a lower KPS, live farther away, but had no differences in outcome. Active smokers were less likely to participate in clinical trials. Many pts who enrolled on a clinical trial enrolled in more than one, but receiving dose dense TMZ reduced clinical trial enrollment at recurrence. Age, KPS at presentation, and extent of resection were confirmed as prognostic factors associated with OS. Also, location of radiation therapy (MDACC versus community facility; p=0.02) was associated with OS. 383 pts were identified who either did not follow up for enrollment (n=161, due to distance, evaluation as a second opinion, unknown) or were ineligible for clinical protocols (n=221, prior therapy, early progression or death, treatment toxicity/medical comorbidities, tumor location, insurance denial). **Conclusions:** Clinical trial eligible GB pts at MDACC have overall better prognoses than historical controls, consistent with other studies. Caution should be taken when interpreting efficacy from single institution, single arm clinical trials. Location of radiation therapy may represent an important variable associated with survival and requires additional investigation. Travel is a significant barrier to clinical trial enrollment.

**2039 General Poster Session (Board #4), Sat, 1:15 PM-5:00 PM**

**Recurrent glioblastoma: Does the timing of bevacizumab treatment impact survival?** *Presenting Author: Susmita Sakruti, Cleveland Clinic, Cleveland, OH*

**Background:** Bevacizumab (Bev) is FDA approved for use in recurrent glioblastoma (rGBM). There is limited literature on outcomes in rGBM depending on the time of initiation of Bev therapy. We examined the progression-free survival (PFS) and overall survival (OS) in rGBM patients treated with Bev at our center. **Methods:** With IRB approval, the Cleveland Clinic Brain Tumor database was used to examine 690 rGBM patient charts (2003 to 2013). The patients were stratified into three groups: 1) patients treated with Bev at first recurrence, 2) second recurrence, and 3) $\geq$ 3 recurrences. OS and PFS between the three cohorts were calculated using Kaplan-Meier analysis and compared using Renyi log-rank tests. **Results:** One hundred and fifty patients, median age 56 years (range: 24-83), were included in this analysis. Median KPS prior to Bev treatment was 80 (range: 40-100). Twenty-eight patients had multifocal and 122 had unifocal GBM at time of starting Bev therapy. The median number of comorbidities at diagnosis were 1 (range: 0-4). Seventy five patients (50%) received Bev at first recurrence, 50 patients (33%) started Bev at second recurrence, and 25 patients (17%) were treated with Bev at third or later recurrences. Median OS from start of Bev was 12.2 months (95% CI: 10.0, 14.3) and median PFS was 8.3 months (95% CI: 6.2, 10.2). Stratified by recurrence and initiation of Bev, median PFS was 7.1 months (95% CI: 5.9, 10.1) for the first recurrence, 9.9 months (95% CI: 6.3, 25.2) for second recurrence, and 9.4 months (95% CI: 3.8, 16.8) for the third recurrence (p=0.09). Median OS was 11.7 months (95% CI: 10.3, 14.3) for first recurrence, 10.0 months (95% CI: 8.1, 39.3) for second recurrence, and 13.9 months (95% CI: 8.2, 18.4) for the third recurrence (p=0.26). **Conclusions:** There was no significant difference in median OS or PFS in the three rGBM groups treated with Bev.

| GBM | N | OS [months] (p=0.26) | PFS [months] (p=0.09) |
|---|---|---|---|
| **1st recurrence** | 75 | 11.7 | 7.1 |
| **2nd recurrence** | 50 | 10.0 | 9.9 |
| **≥3rd recurrence** | 25 | 13.9 | 9.4 |

**2040 General Poster Session (Board #5), Sat, 1:15 PM-5:00 PM**

**A model to predict the feasibility of concurrent chemoradiotherapy with temozolomide in glioblastoma multiforme patients over age 65.** *Presenting Author: Florian Putz, Department of Radiation Oncology, University of Erlangen-Nuremberg, Erlangen, Germany*

**Background:** It is controversial whether concurrent chemoradiotherapy (CRT) with temozolomide is feasible and beneficial in elderly patients with glioblastoma (GBM). **Methods:** Retrospective analysis of 76 elderly GBM patients (≥ 65 years) treated with concurrent CRT with temozolomide. Factors influencing prognosis and feasibility of CRT were investigated. **Results:** Median overall survival (mOS) was 11.3 months. Univariate analysis showed a significant difference in mOS for cumulative dose of concurrent temozolomide (optimal cutoff, 2655 mg/m$^2$; 13.9 months for > 2655 mg/m$^2$ v 4.9 months for ≤ 2655 mg/m$^2$; P = .0103). Significant independent prognostic parameters in multivariate analysis were: a cumulative dose of concurrent temozolomide > 2655 mg/m$^2$ (hazard ratio [HR], 0.41; P = .008), thrombocytopenia grade III/IV (HR, 3.05; P = .034), and biopsy only (HR, 2.10; P = .022). Hematotoxicity was the most common cause of treatment interruption or discontinuation in patients with an insufficient cumulative temozolomide dose. Prognostic factors for successful performance of CRT with a cumulative dose of concurrent temozolomide > 2655 mg/m$^2$ were: female gender (odds ratio [OR], 0.208; P = .0103), age (OR, 0.849 per year; P = .0178), and pretreatment platelet count (OR, 1.010 per 1000 platelets/$\mu$l; P = .0057). **Conclusions:** The probability of successful performance of concurrent chemoradiotherapy with temozolomide can be estimated based on the patient's age, sex and pretreatment platelet count using the model developed in this study. Thus, a subgroup of elderly patients with GBM can be identified in whom concurrent chemoradiotherapy with temozolomide is feasible and who have a favorable prognosis.

**2041 General Poster Session (Board #6), Sat, 1:15 PM-5:00 PM**

**Predicting GBM response to targeted therapeutics using simulation with ex vivo validations.** *Presenting Author: Sandeep C. Pingle, University of California San Diego, La Jolla, CA*

**Background:** The unique signature of a patient's tumor implies that a one-size-fits-all treatment approach will likely fail. This necessitates a rationally designed personalized therapeutic approach employing N=1 segmentation. To predict clinical responses to targeted drugs, we (1) employed predictive modeling and validated this retrospectively (2) used patient tumor profiling data to create simulation avatars (3) screened drugs prospectively and predicted response for patient-derived cell lines (4) validated outcomes ex-vivo in patient lines. **Methods:** Human patient-derived glioblastoma (GBM) samples were cultured and characterized using histopathologic and integrated genomic analyses. Using these data, we created simulation avatars of patient lines. Responses of patient-derived GBM lines to erlotinib, sorafenib and dasatinib were used as alignment datasets. The predictive simulation-based approach from Cellworks provides a comprehensive representation of GBM disease physiology, incorporating signaling and metabolic networks with an integrated phenotype view. This model predicts clinical outcomes based on phenotype and biomarker assays. We prospectively screened ten drugs across eight patient profiles and validated their responses ex vivo. **Results:** We evaluated the ability of the simulation model to predict drug responses, using results from a recent study by Garnett et al. Of the gene mutation-drug response associations reported in this study, we predicted 22 of the 25 associations tested (>85% correlation). Importantly, we predicted the sensitivity of patient-derived GBM lines to various targeted therapeutic agents; more than 75% predictions matched our experimental ex vivo results. **Conclusions:** There is an unmet need for individualization of cancer treatment. Use of innovative simulation technology to predict responses to drugs may provide a way to stratify patients for clinical trials. This study validates our *in silico* model for predicting sensitivity of patient cells to targeted therapeutics. By accurately predicting responses *a priori*, the *in silico* model enables personalizing cancer therapy and promises to improve clinical management.

**2042^ General Poster Session (Board #7), Sat, 1:15 PM-5:00 PM**

**Survival and quality of life in the randomized, multicenter GLARIUS trial investigating bevacizumab/irinotecan versus standard temozolomide in newly diagnosed, MGMT-non-methylated glioblastoma patients.** *Presenting Author: Ulrich Herrlinger, Division of Clinical Neurooncology, Department of Neurology and Center of Integrated Oncology Cologne/Bonn, University of Bonn, Bonn, Germany*

**Background:** There is a need for more effective therapies in newly diagnosed glioblastoma (GBM) patients with an MGMT-non-methylated tumor. The GLARIUS trial explored the efficacy of bevacizumab (BEV) + Irinotecan (IRI) as compared to standard TMZ in the first-line therapy of MGMT-non-methylated GBM. The primary endpoint progression-free survival after 6 months (PFS-6) has already been reported as being markedly increased in the BEV/IRI arm (Herrlinger et al., ASCO 2013, LBA 2000). The present report focuses on progression-free survival, overall survival (OS) and quality of life (QoL). OS and QoL are particularly important parameters since previous randomized trials investigating BEV in primary therapy of GBM have not been able to demonstrate an OS benefit and have yielded conflicting results regarding QoL. **Methods:** Patients (n=170) with newly diagnosed, MGMT-non-methylated glioblastoma received local radiotherapy (RT, 30 x 2 Gy) and were randomized (2:1) for experimental therapy with BEV (10 mg/kg q2w) during RT followed by maintenance BEV (10 mg/kg q2w) + IRI (125 mg/m$^2$ q2w) or standard therapy with daily TMZ (75 mg/m$^2$) during RT followed by 6 courses of TMZ (150-200 mg/m$^2$/day for 5 days q4w). For 5 prespecified domaines of the EORTC-QLQ C30 and BN20 questionnaires (global health status, physical functioning, social functioning, motor dysfunction, communication deficit as prespecified domaines), the time to deterioration by at least 10 points was analyzed using Kaplan-Meier statistics. **Results:** With BEV/IRI, PFS was significantly prolonged from a median of 5.9 months (95%CI 2.7-6.2 months) to 9.7 months (95%CI 8.7-10.5 months, p=0.0004; hazard ratio 0.56, 95%CI 0.4-0.79). At progression, the crossover rate was similar in both arms (60.8 and 61.9%). Final OS results will be presented. In all prespecified dimensions of QoL, the time to deterioration was not significantly different between the treatment arms. Data of post-progression QoL will be presented. **Conclusions:** BEV/IRI therapy was superior to TMZ regarding PFS. BEV/IRI therapy did not alter QoL as compared to TMZ therapy. Clinical trial information: No.: 2009-010390-21.

**2043 General Poster Session (Board #8), Sat, 1:15 PM-5:00 PM**

**An update on high-dose chemotherapy with autologous stem cell transplantation in adults with recurrent embryonal tumors of the central nervous system.** *Presenting Author: Ryan Eldredge Wilcox, Mayo Clinic, Rochester, MN*

**Background:** Recurrent embryonal tumors of the central nervous system (CNS) in adults are rare and have a poor prognosis. High-dose chemotherapy followed by autologous stem cell transplant (HDC/ASCT) in our previous experience has shown to result in durable responses. (Gill; Cancer 2008; Apr 15;112(8):1805-11). We present an updated report of the Mayo Clinic experience. **Methods:** We performed a retrospective review of adults (age ≥18) with recurrent embryonal tumors at our institution treated with HDC/ASCT between 1998 and 2012. Kaplan-Meier method was used to calculate time to event and survival analysis. **Results:** 19 patients were identified: 14 medulloblastoma, 4 PNET/cerebral neuroblastoma, and 1 pineoblastoma. Median follow up was 120 mo. (95% CI: 74-157). At initial diagnosis, median age was 28 yrs. (18-64); 58% were male; 63%, 32% and 5% had gross total, subtotal, and no resection; 95 % had radiation therapy, and 53% had chemotherapy. Median time to first relapse was 58 mo. (12 - 146) and median time from relapse to transplant was 5 mo. (3 - 17). At first recurrence, median age was 35 yrs (21 - 65); M-stage was: M0 in 42%, M1 in 0%, M2 in 5%, M3 in 32%, and M4 in 21%, 11 pts had gross total, and 4 had subtotal resection; 2 had radiation, and 15 were treated with induction chemotherapy, with 87% receiving a platinum containing regimen. Prior treatment response status at transplant was CR in 37%, PR in 47%, and PROG in 16%. Most patients had tandem peripheral blood stem cell transplant following conditioning with ThioTEPA/BCNU then ThioTEPA/Carboplatin, (completed in 95% and 79% respectively). From first recurrence, mTTP was 23 mo. (95% CI: 15 - 49), and mOS was 35 mo. (95% CI: 24 - 50). 2-, 5-, and 10- year survival were 68%, 38%, and 14% respectively. There were no treatment related mortalities. **Conclusions:** These data in 19 adult patients confirm earlier observations in smaller patient cohorts, compare favorably with historic controls treated with standard dose chemotherapy in our institution, and support HDC/ASCT in adults with recurrent embryonal tumors of the CNS as a viable therapeutic option in appropriate patients.

**2044 General Poster Session (Board #9), Sat, 1:15 PM-5:00 PM**

**Primary central nervous system lymphoma: The influence of radiotherapy on patient outcome in an unselected population.** *Presenting Author: Scheryll Paula Alken, Departments of Neuro Oncology/Drug Development, Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

**Background:** Treatment strategies for newly diagnosed PCNSL typically combine high dose methotrexate with whole-brain radiotherapy (WBRT). However, although WBRT is associated with neurotoxicity, its omission may compromise disease control. To address these issues, we report a retrospective, population-based study of high dose methotrexate with or without WBRT. **Methods:** We included patients (pts) with newly diagnosed PCNSL treated in three major medical oncology centers in Ireland between 2001 and 2011, which included 57% of cases diagnosed in Ireland over the same period. Medical records were examined for clinicopathologic characteristics, administered treatment and survival. Progression-free survival (PFS) and overall survival (OS) were estimated with the Kaplan-Meier method. For the primary endpoint, PFS was compared by receipt of WBRT using the log-rank test and Cox proportional hazard test. **Results:** A total of 70 pts were included in the study, median age of 60 years (range 17–78); 39 (53%) were male. In total, 66 (94%) received high dose methotrexate and 25 (36%) received WBRT. Distribution of demographics and clinical features including MSKCC RPA were comparable by receipt of WBRT (table). At a median follow up of 25 months for survivors, 33% have no evidence of disease and 46% are alive. For the primary endpoint, PFS was similar for pts who received WBRT or not (HR 0.95, 95%CI 0.39–2.32) (Table). Similarly, there were no differences in OS by receipt of WBRT (HR 0.92, 95%CI 0.44 – 1.51). **Conclusions:** In this retrospective study of older patients with newly diagnosed PCNSL the omission of WBRT did not adversely affect patient outcomes though selection bias cannot be outruled. Randomized studies are ongoing to examine if WBRT can be omitted from first line treatment without compromising outcome.

**Pilot study of pulse high-dose lapatinib in combination with temozolomide (TMZ) and radiotherapy (RT) for upfront treatment of glioblastoma (GBM).** *Presenting Author: Phioanh Leia Nghiemphu, Department of Neurology, University of California, Los Angeles, Los Angeles, CA*

**Background:** The Epidermal Growth Factor Receptor (EGFR) is a potentially important therapeutic target for GBM since 45% of GBM tumors harbor either amplification, mutations, or both, of the EGFR gene (Cancer Genome Atlas Research Network, Nature, 2008).Lapatinibis a kinase inhibitor that potently targets the inactive conformation of EGFR. However, conventional, daily dosing of lapatinib is not sufficient to achieve a high intratumoral concentration for brain tumors and has proven ineffective in the treatment of recurrent GBM (Vivanco et al, Cancer Discov, 2012). High dosages of lapatinib given in pulses may be more effective at inhibiting brain tumor growth and enhancing the effect of chemotherapy and RT. We performed a pilot study of pulse high dose lapatinib to assess the safety of this novel dosage given in combination with TMZ and RT. **Methods:** After informed consent, adult patients with newly diagnosed GBM received lapatinib at 2500 mg twice a day, for 2 consecutive days per week, in combination with standard dosing of RT + TMZ. After RT, patients continued high dose lapatinib 2-day weekly pulses until progression and also received 12-24 cycles of adjuvant TMZ. **Results:** 10 patients were enrolled in this pilot study. At the time of this report, all patients had completed treatments in the Concurrent Period with RT + TMZ + pulse high dose lapatinib. Median follow-up was 16.6 weeks (range 8-59). The most common toxicities were lymphopenia (8 patients), diarrhea (7), fatigue (7), and skin rash (4), mostly at grade 1-2. The only grade 3 toxicity related to this combination was lymphopenia in 4 patients. There were no grade 4-5 toxicities. One patient withdrew from study after 10 weeks of treatment after a hospitalization for epigastric pain although no laboratory or imaging abnormalities were found, and patient improved on proton pump inhibitor. One patient had resection of an enhancing growth 6 months after completing RT and pathology was consistent with treatment-induced necrosis. **Conclusions:** High dose lapatinib given in 2-day weekly pulses with TMZ and RT was well tolerated, and this combination will be further evaluated in an expanded phase II trial for upfront treatment of GBM. Clinical trial information: NCT01591577.

**2046 General Poster Session (Board #11), Sat, 1:15 PM-5:00 PM**

**PC or PCV? That is the question: A retrospective review of primary anaplastic oligodendroglial tumors treated with procarbazine and CCNU without or with vincristine.** *Presenting Author: Courtney C. Webre, Texas A&M Health Science Center, Bryan, TX*

**Background:** While procarbazine, CCNU and vincristine (PCV) has been shown to be efficacious in the treatment of anaplastic oligodendroglial tumors (AOT), the question of whether procarbazine and CCNU (PC) alone is sufficient still exists, since vincristine has been argued to add toxicity with little if any clinical benefit. This retrospective study was designed to provide initial insight into the comparison of PC with and without vincristine. **Methods:** Using the Brain Tumor Center historical database, we queried patients diagnosed with (AOT) treated at MD Anderson Cancer Center from June 1, 1993 through October 13, 2009. Patients were eligible if they had been diagnosed with a primary AOT and were subsequently treated with either PC or PCV at some point in the treatment regimen. A total of 120 patients were included in the study population, with 97 patients included in the primary analysis of treatment before first progression. **Results:** Initial treatment included radiation and chemotherapy (80.4%), chemotherapy alone (18.6%), or radiation alone (1.0%). Overall survival did not differ with initial treatment. 21 patients (21.6%) received PC during primary treatment, while 76 patients (78.4%) received PCV. 11 patients reported neurotoxicity in the PCV arm (defined as dysautonomia, peripheral neuropathy and ataxia), compared with none in the PC arm. Of the 97 patients included in the analysis, 45 were alive at last contact with a median follow-up of 9.9 years. The median overall survival (OS) time was 6.5 years (95% CI: 4.8-16.7 years). OS was significantly associated with KPS within one month of diagnosis (p=0.002) but not with age (p=0.26). There were 63 patients with disease progression or death, and the median progression-free survival (PFS) was 2.9 years (95% CI: 2.0-6.3 years). There was no difference between the two groups in OS (p=0.61) or PFS (p=0.28). **Conclusions:** Initial therapy with PC vs. PCV achieved comparable results with a median follow-up of 9.9 years. There was no difference in dose reductions although neurotoxicity was more frequent with vincristine. Further studies with correlative codeletion status are needed.

**2047 General Poster Session (Board #12), Sat, 1:15 PM-5:00 PM**

**A meta-analysis of antiangiogenic therapy for glioblastoma (GBM).** *Presenting Author: Mustafa Khasraw, Andrew Love Cancer Centre, Geelong, Australia*

**Background:** Overall Survival (OS) and Progression Free Survival (PFS) results of randomized controlled trials (RCTs) are available of anti-angiogenic therapy (AAT) in GBM, especially Bevacizumab (Bev). **Methods:** Searches were conducted to identify published and unpublished RCTs starting in 2000 including The Cochrane Central Register of Controlled Trials (CENTRAL); MEDLINE and EMBASE. Proceedings of relevant oncology conferences from 2000 to 1/ 2014, were also searched. RCTs with random allocation of the use of AATs to treat GBM were included. Authors screened search results and reviewed abstracts of potentially relevant articles before retrieving the full text of eligible articles. **Results:** Seven eligible RCTs were identified including 3187 patients. There was significant heterogeneity in studies especially in response assessment criteria. Six studies were only available in abstract form. Trials included in this analysis did not show improvement in OS with a pooled hazard ratio (HR) of 0.95 (95% CI 0.87 to 1.04; P = 0.27). They did however demonstrate improvement in PFS with improvement in the HR for PFS at 0.74 (95% CI 0.68 to 081; P= 0.00001). The HRs of the studies containing Bev as the AAT were generally more likely to report favorable results than other AAT, the pooled HR for PFS for Bev studies (n = 1712 patients) was significant at 0.57 (95% CI 0.4 to 0.82; P = 0.002). In the adjuvant setting with 5 RCTs including 2441 patients (AVAGLIO, RTOG 0825, GLARIUS with Bev; CENTRIC and CORE with cilengitide), the HR for OS was 0.90 (P = 0.19). Pooled analysis for PFS in the adjuvant setting (4 studies, n= 2441) showed significant HR at 0.69 (95% CI 0.56, 0.85; P= 0.0006). In the recurrent setting pooling of 2 RCTs (n=576) namely the phase 3 with cediranib (REGAL) and the phase 2 study with Bev (BELOB) showed HR for OS was 1.02 (P = 93). The BELOB study did not report PFS i.e., there is no RCT data to assess PFS with Bev in recurrent GBM. **Conclusions:** Bev appears to prolong PFS in newly diagnosed GBM. Available data does not demonstrate a survival benefit in newly diagnosed patients. In the recurrent setting, there is no adequately powered RCT to address if there is a PFS or survival benefit with Bev. A more detailed analysis is prepared as a Cochrane systematic review.

**2048 General Poster Session (Board #13), Sat, 1:15 PM-5:00 PM**

**Association of high volume center with survival for glioblastoma patients: Results from a prospective population-based registry (PERNO).** *Presenting Author: Alba Ariela Brandes, Bellaria-Maggiore Hospital, Azienda USL of Bologna - IRCCS Institute of Neurological Sciences, Bologna, Italy*

**Background**: The Project of Emilia Romagna in Neuro-Oncology (PERNO) is a prospective registry and it was created to evaluate the incidence and treatment of primary brain tumors (PBTs) in this italian region. In this network, as a subproject, a population-based prospective study was conducted to assess the survival outcome of glioblastoma (GBM) patients, and correlations with potential prognostic factors. **Methods**: Based on the data from this registry, from January 1st 2009 to December 31st 2010, a prospective study was made of the treatment efficacy and outcome in newly diagnosed GBM patients £70 years treated with the worldwide accepted standard treatment according to the EORTC 22981/26981) /NCIC CE.3 trial (temozolomide concomitant with and adjuvant to radiotherapy - RT/TMZ). **Results**: 267 GBM patients were enrolled, 139 patients were £70 years and received RT/TMZ, achieving a median overall survival (OS) of 16.4 months (95%CI: 14.0–18.5). At multivariate analysis, OS was significantly correlated with KPS (HR=0.458, 95%CI: 0.248-0.847, p=0.0127), *MGMT* methylation status (HR=0.612, 95%CI: 0.388-0.966, p=0.0350) and if treatment was received in the high volume center (HR=0.569, 95%CI: 0.328-0.986, p=0.0446). Median overall survival was 24.1 months for patients treated in the referral high volume center and 15.9 months in other centers (HR: 0.533, 95% CI: 0.328 – 0.866, p=0.0110), with no significant differences in KPS and *MGMT* methylation status among the centers. **Conclusions**: For the first time in the field of neuro-oncology, we have investigated the impact of center volume and expertise in post-surgical treatment, as a variable that may influence the outcome of GBM patients < 70 years and treated with RT/TMZ. Our findings may have depended on several factors, such as expertise in neuroradiology interpretation as well as the management of adverse events, and the use of third line treatments or the best supportive care. The amount of OS improvement supports further investigation of center volume and expertise as a prognostic factor.

**2049 General Poster Session (Board #14), Sat, 1:15 PM-5:00 PM**

**Changing trend of HIV-associated PCNSL over 15 years: A single-center experience.** *Presenting Author: Andrew Bayat, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Primary central nervous system lymphoma (PCNSL) is a rare form of extra nodal non Hodgkin lymphoma, accounting for approximately 3-4% of primary brain tumors and approximately 1% of all NHL. HIV is one of the leading risk factors for PCNSL. Though whole brain radiation is used often, there is no standard of care available for HIV associated PCNL. In this single center retrospective study we report the survival data of patients with biopsy-proven PCNSL with and without HIV between 1998-2013. **Methods:** We identified patients with PCNSL between 1998 and 2013 through our institution's tumor registry. After patient identification, the medical records were reviewed for the following patient data: age at diagnosis, ethnicity, sex, HIV status, CD4 cell count, HIV viral load, neuroimaging, treatment (radiation therapy and/or chemotherapy), date of death and date of last contact. Survival data and date of death were obtained from our tumor registry, chart reviews, and social security death index searches. **Results:** A total of 128 patient were identified as having biopsy-proven PCNSL: 41 HIV-positive and 87 HIV-negative. Average age at diagnosis was 60.8 for HIV-negative patients and 38.9 HIV-positive. The HIV-positive cohort was 80% males while only 54% in HIV-negative. Median survival for the two groups was 4.6 and 15.9 months respectively. Amongst HIV-negative patients: those who received MTX + WBRT had median survival of 25.7 months whereas those who received MTX alone had a median survival of 10.9 months although this difference did not meet statistical significance. HIV-positive patients who were diagnosed between 2009 and 2013 had significantly longer median survival than those diagnosed between 2004-2008 as well as 1998-2003 timeframes. **Conclusions:** Our current data confirm that there remains a marked gap in median survival among HIV-negative and HIV-positive patients diagnosed with PCNSL. It would also suggest that there is no significant difference in median survival among HIV-negative patients who receive WBRT versus those who receive MTX alone. We also confirm that median survival for HIV-positive patients has improved over the last decade coinciding with improvements in antiretroviral therapy.

**2050^ General Poster Session (Board #15), Sat, 1:15 PM-5:00 PM**

**Radiotherapy (RT), temozolomide (TMZ), procarbazine (PCB), and the integrin inhibitor cilengitide in patients (pts) with glioblastoma (GBM) without methylation of the MGMT gene promoter (ExCentric): Results of an Australian phase II clinical trial.** *Presenting Author: Mustafa Khasraw, Andrew Love Cancer Centre, Geelong, Australia*

**Background:** Building on our preclinical data, we proposed that combination of low dose TMZ and PCB may overcome TMZ chemoresistance in MGMT unmethylated GBM. We proposed adding Cilengitide, a selective $\alpha v\beta 3$ and $\alpha v\beta 5$ integrin inhibitor, to PCB, TMZ and RT. **Methods:** Newly diagnosed GBM pts with unmethylated MGMT received cilengitide 2000 mg twice weekly over 18 months. On week 2 of cilengitide, RT (60 Gy, 2 Gy per fraction) was started for 6 weeks with daily TMZ (60 mg/m2) and PCB (50 mg if BSA < 1.7; 100 mg if BSA ≥ 1.7) followed by 6 cycles of adjuvant TMZ (50mg/m2 in first cycle, 60 mg/m2in subsequent cycles) and PCB (50 mg if BSA < 1.7; 100 mg if BSA ≥ 1.7) given D1 to 20 every 28 days. The primary endpoint was 12m Overall Survival (12 mOS). The probability of accepting insufficiently active treatment was set to 10% and the probability of rejecting an active treatment was set to 20%. If 16 of 29 pts (55%) or less were alive at one year, the treatment was to be declared inactive. Secondary endpoints include 6-month progression-free survival (6mPFS) and toxicity. **Results:** MGMT was tested in 60 pts to enrol 29 evaluable GBM pts with unmethylated MGMT status (median age: 55 y, range 24-74 y; 11 women and 18 men). ECOG status was 0, 1 and 2 in 16, 11 and 2 pts, respectively. The last pt was enrolled in June 2013 and at time of submission of this abstract 18 of 29 included pts (62%) were alive, 11 (38%) who have been followed-up for a year or more and 7 (24%) less than a year. Current median OS and PFS are 58 (95% CI 44-72) and 30 (95% CI 20-39) weeks respectively. Grade (G) 3 and 4 toxicities included thromboembolism (1 G 4 and 2 G3), seizures (1 G4 and 2 G3), neutropenia without fever (5 G3) and asymptomatic elevated transaminases (1 G4 and 6 G3). **Conclusions:** The safety profile of the combination was confirmed. As of Jan 2014, the 12mOS has not yet been reached. Of the 7 pts still alive, 5 will need to survive 12 months or more after enrolment for the primary endpoint of 12 mOS to be met. Updated endpoints, including 12 mOS, will be available and presented at the ASCO annual meeting. Clinical trial information: NCT01124240.

**2051^ General Poster Session (Board #16), Sat, 1:15 PM-5:00 PM**

**Patterns of tumor progression in a phase 3 study of bevacizumab (Bv) plus radiotherapy (RT) plus temozolomide (T) for newly diagnosed glioblastoma (GB).** *Presenting Author: Wolfgang Wick, Neurooncology, University of Heidelberg Medical Center, Heidelberg, Germany*

**Background:** In the AVAglio study, Bv+RT/T prolonged PFS (co-primary endpoint) in pts with newly diagnosed GB v placebo (P)+RT/T. It has been suggested that antiangiogenic therapy may promote infiltrative tumors at PD, so patterns of tumor progression were prospectively assessed in AVAglio (exploratory endpoint). **Methods:** Randomizedpts (n=921) received: RT/T+Bv or P, 6 wks; 28-day break; maintenance T+Bv or P (x6); Bv or P until PD/unacceptable toxicity. PD was investigator (INV) assessed (adapted Macdonald criteria). Lesion patterns were retrospectively assessed by an independent review facility for each disease assessment (baseline [BL]/during treatment/at INV-assessed PD). Diffuse/infiltrative patterns were defined as extended hypersignal on T2/fluid-attenuated inversion recovery (FLAIR) sequences, and are reported in pts with pattern derived at BL and INV-assessed PD. **Results:** Most pts had similar tumor invasiveness at BL and PD (Table). Among pts with non-diffuse disease at BL (n=100 and 138), numerically more Bv- v P-treated pts changed to diffuse disease at PD; median OS for these pts was similar (17.4 v 15.0 mo for Bv+RT/T v P+RT/T, respectively; HR 0.85, 95% CI 0.51–1.42, p=0.5355), and comparable with the OS of the ITT population. In all pts who had BL non-diffuse tumors, median OS was 20.1 v 18.4 months (Bv+RT/T v P+RT/T, respectively; HR 0.76, 95% CI 0.59–0.98, p=0.0303). In all pts with BL diffuse tumors, median OS was 15.6 v 16.2 months (Bv+RT/T v P+RT/T, respectively; HR 0.99, 95% CI 0.82–1.19, p=0.8882). **Conclusions:** In this exploratory analysis, a change from BL non-diffuse disease to diffuse disease at PD did not affect OS; BL pattern of disease did, suggesting that tumor infiltration at diagnosis is an important prognostic factor. Also, in the subset of pts with newly diagnosed non-diffuse GB, there was an OS benefit from adding Bv to standard of care. Clinical trial information: NCT00943826.

| Tumor pattern, $n_{PD}/n_{BL}$ | | Bv+RT/T | P+RT/T |
|---|---|---|---|
| **BL** | **PD** | n=299 | n=333 |
| **Pts with no changes** | | | |
| **Nondiffuse** | Nondiffuse | 64/100 (64.0%) | 104/138 (75.4%) |
| **Diffuse** | Diffuse | 197/199 (99.0%) | 194/195 (99.5%) |
| **Pts with changes from BL** | | | |
| **Nondiffuse** | Diffuse | 36/100 (36.0%) | 34/138 (24.6%) |
| **Diffuse** | Nondiffuse | 2/199 (1.0%) | 1/195 (0.5%) |

**2052 General Poster Session (Board #17), Sat, 1:15 PM-5:00 PM**

**A randomized clinical trial for the treatment of glioblastoma multiforme with the individualized dendritic cell-based cancer immunotherapy AV0113.** *Presenting Author: Thomas Felzmann, Activartis Biotech GmbH, Vienna, Austria*

**Background:** We recruited 78 patients aged 18-70 years suffering from newly diagnosed glioblastoma multiforme (GBM) into a randomized clinical trial designed for demonstrating the efficacy of the individualized dendritic cell-based cancer immunotherapy concept AV0113 (GBM-Vax, EudraCT 2009-015979-27). DC are charged with autologous tumor antigens and contacted with lipopolysaccharide (LPS) in the presence of Interferon (IFN) -$\gamma$ enabling IL-12 secretion for 1 day thus priming cytolytic anti-tumor immune responses. Exposure to LPS/IFN-$\gamma$ is limited to 6 hours in order to permit DC/T-lymphocyte interaction in the presence of IL-12. **Methods:** Patients underwent first line GBM therapy (surgery, radiotherapy, chemotherapy) according to the standard of care; patients randomized into the treatment group received AV0113 as add-on therapy. Primary and secondary objectives were PFS and OS. After progression, patients were treated with Bevacizumab, which was not part of the protocol. The study still collects follow up information. **Results:** AV0113 DC-CIT was well tolerated. Reactions at the injection site were mild and included redness and swelling; some patients developed fever. There are some imbalances of severe adverse events between control and treatment groups, which, however, didn't appear to be linked to CIT. No signs of autoimmunity were observed. A trend analysis of one-year survival revealed that 45% of control group patients died during the first year; in the AV0113 treatment group only 16% died during the first year of their disease. A similar trend is observed in overall survival. DC-CIT didn't improve progression free survival, but increased the number of surviving patients. Accompanying immunological assays demonstrated a correlation of longer survival with signs of polarization of the immune system towards cytotoxicity. **Conclusions:** Randomization for the GBM-Vax study was completed in May 2013; hence we expect a complete data set for the one-year survival in May 2014 and will present this outcome. If the current trend is confirmed, we expect a first demonstration of efficacy for IL-12 secreting DC in the treatment of GBM. Clinical trial information: 2009-015979-27.

**2053 General Poster Session (Board #18), Sat, 1:15 PM-5:00 PM**

**Phase II trial of triple tyrosine kinase receptor inhibitor nintedanib in recurrent high-grade gliomas: Final results.** *Presenting Author: Andrew David Norden, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Bevacizumab is FDA-approved for patients with recurrent GBM. However, the median duration of response is only 4 months. Potential mechanisms of resistance include upregulated FGF signaling and increased PDGF-mediated pericyte coverage. Nintedanibis an oral, small-molecule tyrosine kinase inhibitor of PDGFR $\alpha/\beta$, FGFR 1-3, and VEGFR 1-3 that may overcome resistance to prior anti-VEGF therapy. **Methods:** This was an open-label, phase II trial in adults with first or second recurrence of GBM, stratified by prior bevacizumab. The primary endpoint was PFS6 in the bevacizumab-naive arm (arm A) and PFS3 in the post-bevacizumab arm (arm B). A Simon two-stage design was employed. Up to 10 anaplastic glioma (AG) patients were accrued to each arm in exploratory cohorts. **Results:** Twenty-two patients enrolled in Arm A and 14 in Arm B. Accrual to both arms was stopped after the first stage due to futility. Arm A included 12 GBMs (55%), 13 patients with one prior regimen (59%), and median age 54 years (range 28-75). Arm B included 10 GBMs (71%), one patient with one prior regimen (7%), and median age 52 years (range 32-70). Median KPS overall was 90 (range 60-100). There were no responses. In Arm A (GBM only), PFS6 was 0%, median PFS 28 days (95% CI: 27-83), and median OS 6.9 months (3.7-8.1). In Arm B (GBM only), PFS3 was 0%, median PFS 28 days (22-28), and median OS 2.6 months (1.0-6.9). In Arm A (AG only), PFS6 was 0% and median PFS 28 days (27-68). In Arm B (AG only), PFS3 was 0% and median PFS 28 days (7-56). Rare grade $>3$ toxicities included transaminase elevation, hypophosphatemia, hypertension, intracranial hemorrhage, and abdominal pain. Two participants died during therapy, one from thromboembolism and one from colon perforation. **Conclusions:** Nintedanib is not active against recurrent high-grade glioma, regardless of prior bevacizumab therapy. Clinical trial information: NCT01380782.

**2054 General Poster Session (Board #19), Sat, 1:15 PM-5:00 PM**

**REBECA: A phase I study of bevacizumab (BEV) and whole-brain radiation therapy (WBRT) for treatment of solid tumors brain metastases (BM), EudraCT: 2009-015977-11.** *Presenting Author: Christelle Levy, Centre François Baclesse, Caen, France*

**Background:** BM, the most frequent malignancy in the central nervous system, remains of poor prognosis. Standard treatment is WBRT. Neoangiogenesis plays an important role in BM growth. Angiogenesis inhibitors, particularly agents targeting the VEGF/VEGFR pathway like BEV, could be optimal partners of radiotherapy (RT) for treating BM. Adding BEV to standard RT-based treatment of newly diagnosed glioblastoma improves progression free survival. REBECA aims at assessing the recommended phase II dose (RP2D) of BEV plus WBRT for BM and delivering preliminary efficacy data. **Methods:** A multicentric phase I trial assessed BEV combined to conventional WBRT for unresectable BM of solid tumors with a 3+3 dose-escalation design. BEV was administered every 2 weeks (wks) for a total of 3 injections at day 1, 15 and 29 (5, 10 or 15 mg/kg for dose levels (DL) 0, 1 and 2) with WBRT starting at day 15, for a total dose of 30 Gy in 15 fractions/3 wks. DL3 consisted in BEV 15 mg/kg with WBRT delivered from day 15 in 30 Gy/10 fractions/2 wks. Safety was evaluated using NCI-CTCAE v3. BM response was assessed 6 wks and 3 months after the end of treatment by MRI using RECIST 1.1 criteria. **Results:** Among 21 patients (pts) enrolled (including 14 breast cancers), 19 were treated: 3 in DL0, 4 in DL1, 3 in DL2 and 9 in DL3, including 3, 3, 3 and 7 pts assessable for dose limiting toxicity (DLT), respectively. No DLT occurred: DL3 could be defined as RP2D. Among the 19 pts, treatment-related toxicity (excluding alopecia) included a grade(gr) 2 asthenia at DL1 and 7 gr2 (2 HTA, 1 asthenia, 1 digestive disorders, 1 mouth dryness, 1 lymphopenia and 1 liver injuries) occurring in 4 out of 9 pts at DL3. Gr1 events were noted for 7 pts in all DLs: HTA, headache, asthenia, nausea/vomiting, pain and appetite loss. No BM progression was observed during treatment but 2 pts at DL1 and 1 pt at DL3 died of disease progression during the 3 months post-treatment period. *Per Protocol* efficacy analysis concerned 16 pts: 8 had a BM partial response (1/3 at DL0, 1/3 at DL1, 2/3 at DL2, 4/7 at DL3). **Conclusions:** In absence of DLT, BEV+WBRT appears safe for the treatment of BM. DL3 seems optimal for further efficacy evaluation in phase II trials. Clinical trial information: NCT01332929.

**2055 General Poster Session (Board #20), Sat, 1:15 PM-5:00 PM**

**GEINOFOTE: Safety and activity analysis of the use of fotemustine (FT) in different schedules in progressive high-grade glioma (HGG) in Spain.** *Presenting Author: Pedro Pérez-Segura, Medical Oncology Department, Hospital Universitario Clínico San Carlos, Madrid, Spain*

**Background:** Previous studies showed that FT may be useful as treatment in recurrent high-grade glioma (HGG). The present study evaluate the activity and toxicity of FT in recurrent malignant glioma patients in the clinical setting in Spain. **Methods:** Patients (age $>18$ years) with HGG that was progressive (first or second recurrence) after prior standard radiotherapy plus TMZ chemotherapy were eligible for the study. Patients were scheduled to receive FT in different schedules (Addeo vs others). Tumor response was assessed by MRI every 8-12 weeks. The primary end point was safety; secondary points included progression free survival (PFS), overall survival (OS). We analyze the differences between Addeo schedule (A) vs others (O) and 1º recurrence (1ºR) vs 2º recurrence (2ºR) in terms of safety and activity. **Results:** 114 patients were assessed (84 glioblastoma and 30 grade III glioma); all of them began FT previously Nov 31, 2012. There were 60 males, and the median age was 52.5 years (ranged from 19 to 73). The median KPS was 70 (30-100). Addeo schedule was used in 85 pts (74.6%). FT in first recurrence was used in 51 pts (44.7%) and 58 pts (50.9%) in second recurrence. The median PFS was (A 1ºR / O1ºR/ A 2ºR / O 2ºR) 3.37/2.41/3.04/2.68 months, the median OS was (A 1ºR / O1ºR/ A 2º R / O 2ºR) 5.62/5.59/5.09/3.97 months. The most common toxicities include neutropenia and thrombocytopenia. There were no statistical differences in Grade III or IV toxicities in relation with the type of schedule (A vs O) nor the 1º or 2º R (20%-32.6%). The patients in 1ºR received more frequent A schedule than in 2ºR (86.3% vs 62.1%, p=0.004). No differences between A vs O in terms of clinical benefit, PS improve or less dexametasone use. Time to response: patients in A schedule spent less time to get the better response than patients with O schedules, whenever we use FT (no significant differences). **Conclusions:** FT has modest activity for recurrent high grade glioma with acceptable toxicity, regardeless the type of schedule. Probably, A get better response in less time than O schedules.

**2056 General Poster Session (Board #21), Sat, 1:15 PM-5:00 PM**

**Management of primary intraocular lymphoma (PIOL): Results from the prospective German PIOL registry (PIOL-R).** *Presenting Author: Kristoph Jahnke, Department of Hematology and Oncology, Charité Campus Benjamin Franklin, Berlin, Germany*

**Background:** The optimal management of primary intraocular lymphoma (PIOL) is yet to be defined. We report on clinical characteristics, treatment and outcome of newly diagnosed, immunocompetent PIOL patients enrolled in the prospective German PIOL registry (PIOL-R). **Methods:** Patient data in this prospective, non-interventional multicenter study were compiled by standardized questionnaires sent to Ophthalmology and Hematology/Oncology centers in Germany. **Results:** Twenty-seven patients (17 female, median age 67 years, median Karnofsky performance status 90%) were included between August 2008 and December 2013. Median time from onset of symptoms to PIOL diagnosis was 5 (range, 1-36) months. Diffuse large B-cell histology was found in all patients. First-line treatment included high-dose methotrexate (MTX)- or ifosfamide-based systemic chemotherapy with or without rituximab in 21 (including high-dose chemotherapy [HDCT] with autologous stem cell transplantation [ASCT] in 4), intraocular (i.o.) chemotherapy with MTX (n=1) and/or rituximab (n=10) in 11, ocular radiation in 2, and vitrectomy only in one patient(s). Two patients received prophylactic intrathecal treatment with MTX but none had whole-brain radiotherapy (RT). The PIOL remission rate was 100% with complete remission in 19/23 evaluable patients and partial remission in 4 patients. Median progression-free survival of patients without prior brain involvement (n=23) was 21 (95% CI, 1.2-39.9) months. Overall survival has not yet been reached. Relapses were located in the brain (n=9), eye (n=3), eye/brain (n=3) and eye/meninges (n=1) and were treated with systemic chemotherapy in 12 (including HDCT with ASCT in 3), systemic and i.o. chemotherapy in one, whole brain/spine RT in 2 and best supportive care in one patient(s). **Conclusions:** Although the awareness of PIOL and diagnostic possibilities have improved, time from symptom presentation to diagnosis seems to remain at previously reported levels. There appears to be a shift from local ocular treatments and RT to systemic therapy as compared to anecdotal data with promising response and survival rates. However, relapse rates remain high with the brain frequently being involved.

**2057 General Poster Session (Board #22), Sat, 1:15 PM-5:00 PM**

**Therapeutic implications of perivascular invasion in the context of high-density brain microvascular networks: A study on recursive pattern formation in malignant glioma.** *Presenting Author: Gregory Joseph Baker, University of Michigan, Ann Arbor, MI*

**Background**: Malignant glioma cells use distinct brain structures for tumor growth and invasion. However, the cellular mechanisms and biological consequences of malignant glioma growth patterning remain poorly understood. **Methods**: We utilized multiple experimental imaging modalities (i.e. confocal-, multi-photon-, epifluorescence-, and electron- microscopy) to examine the routes of intracranial malignant glioma invasion using implantable and genetically-induced glioma models; we also examined brain tissue specimens from patients affected by primary human glioblastoma and brain metastasis. The clinical implications of our findings are discussed. **Results**: Mouse, rat, and human experimental malignant glioma cells commonly utilized the dense brain microvascular network as a scaffold for tumor invasion. Perivascularly invading brain tumors became vascularized as they engulfed brain microvessels at the invasive margin over the entire course of tumor progression. Macroscopic tumor formation occurred as a consequence of recursive inter-vessel displacement of normal brain tissue by mitotic glioma cells localized within the perivascular space. Based on these observations, we implemented a computational model that recapitulates this pattern of brain tumor growth. Notably, a parameter for neoangiogenesis was not required to obtain continued *in-silico* perivascular growth and recursive space filling. Treatment of perivascularly invading brain tumors with anti-VEGF (bevacizumab) or anti-VEGFR-2 antibodies (DC101) did not prolong animal survival, yet potentiated long distance glioma cell invasion, especially in a model of human glioma stem cells. **Conclusions**: Perivascular invasion, high brain microvascular network density, and recursive inter-vascular space filling is a common pattern of malignant brain tumor growth that supports tumor progression independently of VEGF-A signaling.

**2058 General Poster Session (Board #23), Sat, 1:15 PM-5:00 PM**

**Histogram analysis of apparent diffusion coefficient within enhancing and nonenhancing tumor volumes in recurrent glioblastoma patients treated with bevacizumab.** *Presenting Author: Rifaquat Rahman, Harvard Medical School, Boston, MA*

**Background:** While patients with recurrent glioblastoma receiving anti-angiogenic therapy demonstrate significant response rates, the benefit on patient survival is less clear. We assessed whether histogram analysis of diffusion weighted MRI can stratify for progression-free and overall survival. **Methods:** Baseline and 3-6 week post-treatment MRI exams of 91 patients with recurrent glioblastoma treated with bevacizumab were retrospectively evaluated. Histograms of apparent diffusion coefficient (ADC) within the volume of contrast enhancing and nonenhancing T2/FLAIR lesions were analyzed using curve-fit analysis. Overall survival (OS) and progression-free survival (PFS) were assessed using ADC parameters in a Cox proportional hazards model adjusted for clinical variables. **Results:** Baseline $ADC_L/ADC_M$ within nonenhancing T2/FLAIR volume ($>$ or $\leq 0.64$) can stratify OS (HR=2.24, p=0.002) and PFS (HR=1.90, p=0.005). $\%ADC_H$ within enhancing T1+C volume ($>$ or $\leq 25\%$) can also stratify OS (HR=0.59, p=0.034) and PFS (HR=0.56, p=0.01). Stratification of patient survival can be improved by merging these two ADC parameters into a single combined ADC factor (HR= 0.17, p<0.0001). The median OS ratio of patient groups stratified by this combined factor was 2.03, larger than median OS ratio when stratifying by either $\%ADC_H$ within T1+C volume alone (1.3) or $ADC_L/ADC_M$within T2/FLAIR alone (1.86). **Conclusions:** ADC histogram analysis within both enhancing and nonenhancing components of tumor can be used to stratify for PFS and OS in patients with recurrent glioblastoma.

**2060 General Poster Session (Board #25), Sat, 1:15 PM-5:00 PM**

**Expression profile of angiogenic factors in paired initial and recurrent glioblastoma.** *Presenting Author: Emeline Tabouret, Aix-Marseille University, AP-HM, Service de Neuro-Oncologie, CHU Timone, Marseille, France*

**Background:** Angiogenesis is one of the key features of Glioblastoma (GB). Our objective was to identify the changes in the expression of angiogenic factors in GB after radio-chemotherapy. **Methods:** Analysis of all patients with available frozen tumor material from initial and recurrent surgery for GB treated with chemo-radiotherapy (CTRT) in first line setting in our institution between 2003 and 2009. Molecular screening was realized using two types of $RT^2$Profiler PCR arrays (Qiagen). The RNA expression profile of selected genes was validated using quantitative RT PCR. Protein expression was analyzed by immunohistochemistry (IHC). Explants of newly GB were treated with temozolomide, radiotherapy and anti-CXCR4 (AMD3100). **Results**: Twenty nine patients were included with median age of 57.1 years (37.2-74.1). The $RT^2$Profiler PCR arrays results allowed a selection of seven genes: VEGFA, VEGFR2, VEGFR1, Adrenomedullin, SDF1, CXCR4, and HIF1$\alpha$. The steady state levels of CXCR4 RNA at recurrence was significantly increased (p=0.029) while HIF1$\alpha$ RNA was significantly decreased (p=0.009). A trend for a decrease of VEGFR2 RNA (p=0.081) and an increase of SDF1 RNA (p=0.107) was observed. Changes of SDF1 RNA tended to be correlated to changes of CXCR4 RNA (p=0.077) and inversely correlated to changes of HIF1 $\alpha$ RNA (p=0.064). By IHC, VEGFR2 staining was significantly decreased at recurrence (p=0.004) while SDF1 expression tended to increased (p=.096). Medians initial and at recurrence overall survival (OSI and OSR) of this selected population were 25.5 (95% confidence interval (CI) 17-34) and 11.4 (95%CI 9-13.9) months respectively. By multivariate analysis, VEGFR2 RNA initial and at recurrence levels were significantly correlated to OSI (p=0.019, Hazard ratio (HR) =3.650) and OSR (p=0.024, HR=2.536) while HIF1 $\alpha$ RNA level at baseline was correlated to OSI (p=0.012, HR=0.300). In newly GB explants, a higher anti-tumoral effect was observed with the combination of AMD3100 and CTRT versus CTRT alone. **Conclusions**: Acquired resistance of GB to chemo-radiation could be associated with a switch of angiogenic pattern from VEGFR2-HIF1$\alpha$ to SDF1-CXCR4 pathway, leading to new perspectives in angiogenic modulation and GB treatment.

**2061 General Poster Session (Board #26), Sat, 1:15 PM-5:00 PM**

**Targetable signaling pathway mutations and progression of *IDH*-mutant glioma.** *Presenting Author: Hiroaki Wakimoto, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

**Background:** Isocitrate dehydrogenase (*IDH*) gene mutations occur in low-grade and high-grade gliomas. We sought to identify the genetic basis of malignant phenotype heterogeneity in *IDH*-mutant gliomas. **Methods:** We prospectively implanted tumor specimens from 20 consecutive *IDH1*-mutant glioma resections into mouse brains and genotyped all resection specimens using a CLIA-certified molecular panel. Gliomas with cancer driver mutations were tested for sensitivity to targeted inhibitors *in vitro*. Associations between genomic alterations and outcomes were analyzed in patients. **Results:** By 10 months, 8 of 20 *IDH1*-mutant gliomas developed intracerebral xenografts. All xenografts maintained mutant *IDH1* and high levels of 2-hydroxyglutarate on serial transplantation. All xenograft-producing gliomas harbored "lineage-defining" mutations in *CIC* (oligodendroglioma) or *TP53* (astrocytoma), and 6 of 8 additionally had activating mutations in *PIK3CA* or amplification of *PDGFRA*, *MET,* or *N-MYC*. Only *IDH1* and *CIC*/*TP53* mutations were detected in non-xenograft-forming gliomas ($P = 0.0007$). Targeted inhibition of the additional alterations decreased proliferation *in vitro*. Moreover, we detected alterations in known cancer driver genes in 13.4% of *IDH*-mutant glioma patients, including *PIK3CA*, *KRAS*, *AKT* or *PTEN* mutation or *PDGFRA*, *MET* or *N-MYC* amplification. *IDH*/*CIC* mutant tumors were associated with *PIK3CA*/*KRAS* mutations while *IDH*/*TP53* tumors correlated with *PDGFRA*/*MET* amplification. Presence of driver alterations at progression was associated with shorter subsequent progression-free survival (median 9.0 vs. 36.1 months, $P=0.0011$). **Conclusions:** A subset of *IDH*-mutant gliomas with mutations in driver oncogenes has a more malignant phenotype in patients. Identification of these alterations may provide an opportunity for use of targeted therapies in these patients.

**2062 General Poster Session (Board #27), Sat, 1:15 PM-5:00 PM**

**QOL and neurocognitive functions in patients with GBM.** *Presenting Author: Christine Marosi, Medical University Vienna, Vienna, Austria*

**Background:** The importance of QOL and neurocognitive functions in patients with GBM is meanwhile beyond controversy. We followed newly diagnosed patients with GBM during first and second line therapy by evaluating their QOL and cognitive functions **Methods:** Consecutive newly diagnosed patients with GBM were included in this study. To assess QOL we used the EORTC QLQ C30 and BN20 questionnaire and the computer based NeuroCog FX for neurocognitive assessments. The first assessment was done at the beginning of radiotherapy and was followed by further 5 evaluations every three months **Results:** 42 patients underwent radiation therapy with concomitant and adjuvant temozolomide. Non enzyme enhancing antiepileptic drugs (NEIAED) was prescribed for the majority of the patients (71%). Median progression free survival was 9.6 months (2.5-30.9 months). Second line therapies applied were bevacizumab in 11 patients (26%), dose-dense temozolomide in 10 patients (24%) and imatinib in 8 patients. (19%). Neither QOL nor cognitive scales differed considering prescription of antiepileptic drugs and type of second line therapy, whereas limited data was available after progression of disease (19/42 patients) **Conclusions:** QOL and cognition of patients with GBM under NEIAEDs did not differ from patients without NEIAED. Similarly, no difference was found between patients receiving different drugs in second line therapy, however, just a minority of the patients is able to do QOL and cognitive assessments after progression of disease. Clinical trial information: EK 976/2009.

**2063 General Poster Session (Board #28), Sat, 1:15 PM-5:00 PM**

**Delayed contrast MRI: A new paradigm in neuro-oncology.** *Presenting Author: Yael Mardor, Sheba Medical Center, Ramat Gan, Israel*

**Background:** Conventional MRI is unable to differentiate tumor progression from treatment-induced effects (pseudoprogression/radiation-necrosis) in brain tumor patients, thus significantly impacting patients' management with no current solution. **Methods:** We have applied a novel MRI-based methodology for high resolution depiction of tumor/non-tumor tissues. This unique model-independent technique is based on robust MRI sequences acquired with a delay, enabling complete separation between tumor (contrast clearance at the delayed time point) and treatment effects (contrast accumulation) with no overlap. 498 treatment response assessment maps were calculated for 149 patients with primary/metastatic brain tumors and 9 with AVM recruited/followed on study. **Results:** The maps were validated by comparing pre-surgical maps of 51 patients with primary/metastatic brain tumors who underwent surgery with histology, resulting in 100% sensitivity and 94% specificity to active tumor. This validation confirms that contrast clearance in the maps represent morphologically active tumor while contrast accumulation represents non-tumor tissues. Following initial validation, the maps were used for making 231 clinical decisions. In 67 cases the decision was to continue follow-up (no treatment change) and in 164 cases to change treatment (including surgery, chemoradiation, radiation treatments, switch to Avastin, etc). Our data demonstrates the application for management of patients with various types of tumors after various treatments, for depiction of residual tumor post surgery, detection of tumor within hemorrhages and differentiating malignant transformation from treatment effects. **Conclusions:** Our high resolution, easy to interpret, model-independent maps provide complete/clear differentiation between tumor/non-tumor tissues in patients with brain tumors. The increasing rate in which the maps are being used for clinical decisions making in Israel reflects their added value as an efficient/friendly tool for decision making in neuro-oncology. Excellent agreement between pre-surgical maps and histology suggests that the maps may be further applied for planning high precision procedures such as biopsies, resections, SRS and iMRT.

**2064 General Poster Session (Board #29), Sat, 1:15 PM-5:00 PM**

**Surgery for central nervous system tumors in the Brazilian National Health Care System: A review of 57,361 cases in DATASUS.** *Presenting Author: Julio Leonardo Barbosa Pereira, Instituto de Ensino e Pesquisa da Santa Casa de Belo Horizonte, Belo Horizonte, Brazil*

**Background:** In low- and middle-income countries, resource limitations make the management of central nervous system (CNS) tumors challenging, particularly in Brazil, a country with major socioeconomic and health access disparities. We aimed to evaluate cancer-related neurosurgical procedures in the public health care system. **Methods:** Based on Brazilian's public health system database (DATASUS), we collected data for neurosurgical procedures related to CNS tumors performed between January 2008 and November 2013. Information about number of procedures, costs, length of stay and number of inpatient deaths were analyzed for each State and then correlated to State specific population, gross domestic product (GDP) per capita and number of procedures. **Results:** 57,361 procedures were performed, the majority (45.9%) in the Southeast region. Total cost was $108,363,829.00; average cost per admission was $1,889.00. Average cost in each State, for a fixed number of procedures and population, tended to decrease as GDP per capita increased (OR -0.14; 95% CI -0.4 to -0.1; $p=0.001$). The mean length of hospital stay was 14.4 days, longer for patients treated at the North of the country (19.9 days). On multivariate analysis, number of procedures, GDP per capita, and population had an independent association with days of hospitalization. A total of 4,079 patients died, translating into an inpatient mortality rate of 7.11%, higher than expected based on US and European data. Northern States had the highest rates (12.76% for the region and 17.6% for the State with the highest mortality). Mortality rates decreased as number of procedures ($p<0.001$), GDP per capita ($p<0.001$) or State population increased ($p<0.001$). On multivariate analysis, only number of procedures (OR 0.93; 95% CI 0.91 to 0.96; $p<0.001$) and State population (OR 1.25; 95% CI 1.13 to 1.38; $p<0.001$) had an independent association with mortality. **Conclusions:** This is the first study to evaluate disparities in CNS tumor surgery in a middle income country, confirming that regional disparities exist and that clinical and economic outcomes correlate with income level, number of procedures and state population.

**2065 General Poster Session (Board #30), Sat, 1:15 PM-5:00 PM**

**Hypofractionated (HRT) versus standard (SRT) radiotherapy with or without temozolomide (T) for elderly patients with glioblastoma (GBM).** *Presenting Author: Shyam Kumar Tanguturi, Harvard Radiation Oncology Program, Boston, MA*

**Background**: No randomized trials among elderly GBM patients using HRT have compared efficacy to the Stupp regimen of SRT+T, and many elderly patients in the United States receive SRT+T. **Methods**: We evaluated 88 consecutive patients ≥ 65 years old with GBM diagnosed from 1994-2010 who received HRT or SRT with or without concurrent T. Overall survival (OS) was calculated by the Kaplan-Meier method. Prognostic factors were evaluated using the Cox proportional hazards model and Fisher exact test. HRT consisted of 40 Gy/15 fractions, and SRT consisted of 59.4-60 Gy/30-33 fractions. **Results**: Patients received SRT+T (n = 26), SRT (n = 35), HRT+T (n = 21), or HRT (n = 6). Median age was 70 among SRT±T patients and 80 among HRT±T patients ($P < 0.001$), KPS was lower among HRT±T patients ($P < 0.001$), and SRT-alone patients were more likely to be treated prior to the year 2000 ($P < 0.001$); there were no significant differences between groups with regard to gender, tumor size or multifocality, extent of resection, or MGMT methylation status. With a median follow up of 9.7 mo, median OS was 10.1 mo (SRT+T), 9.5 mo (SRT), 10.8 mo (HRT+T), and 3.0 mo (HRT). On multivariate analysis, compared to SRT+T, mortality was significantly lower for HRT+T (AHR = 0.39; 95% CI, 0.16-0.91; $P = 0.030$) and higher for HRT (AHR = 3.94; 95% CI, 1.16-13.42; $P = 0.028$). Increasing age (AHR = 1.08; 95% CI, 1.01-1.15; $P = 0.018$), lower KPS (AHR = 1.03; 95% CI, 1.01-1.04, $P = 0.002$), and multifocal tumors (AHR = 3.18; 95% CI, 1.57-6.46; $P = 0.001$) were also associated with higher mortality. **Conclusions**: Among elderly GBM patients, HRT+T was associated with improved survival compared to SRT+T, despite older age and lower KPS at baseline. These data suggest that with the addition of T, the number of radiotherapy treatments may be reduced by half with no decrement in survival, and should be explored in a randomized setting.

**2066 General Poster Session (Board #31), Sat, 1:15 PM-5:00 PM**

**A phase 1 study of repeat radiation, minocycline, and bevacizumab in patients with recurrent glioma (RAMBO).** *Presenting Author: Adam Louis Cohen, Huntsman Cancer Institute, Salt Lake City, UT*

**Background:** There are no proven therapies for glioblastoma after progression on bevacizumab. Mesenchymal shift mediated by microglia-mediated NF-kappaB activation is one mechanism of treatment resistance in recurrent glioblastoma. Minocycline inhibits NF-kappaB activation and can restore radiation sensitivity to glioblastoma in vitro and in vivo. **Methods:** RAMBO is a phase 1 study of reirradiation, bevacizumab, and minocycline in people with glioblastoma that has progressed on bevacizumab who are at least one year away from prior radiation. The minocycline is dose escalated in a 3+3 design with planned cohorts of 100mg PO BID (cohort 1), 200mg (cohort 2), and 400mg PO BID (cohort 3). **Results:** Cohorts 1 and 2 have been completed. Completion of cohort 3 is expected by the meeting. No dose limiting toxicities have been encountered. Two people dropped out because of clinical progression and decision to go to hospice, and one person dropped out after 1 week due to unwillingness to take antiemetics for grade 1 nausea. No grade 3 toxicities unrelated to tumor progression have been seen other than one case of grade 3 asymptomatic hypertension attributed to bevacizumab and one case of grade 3 hypokalemia. Grade 2 toxicities have included 3 cases of fatigue, one case of anemia, one case of hiccups, three cases of hypertension, one case of intracranial hemorrhage, one case of nausea, one case of thrush, and one case of vertigo. Of these, only the nausea, fatigue, and thrush were thought possibly related to the minocycline. **Conclusions:** Minocycline can be safely combined with radiation and bevaciuzmab in glioblastoma patients who have progressed on bevacizumab. Clinical trial information: NCT01580969.

**2067 General Poster Session (Board #32), Sat, 1:15 PM-5:00 PM**

**Prognostic value of pretreatment MRI in breast cancer related leptomeningeal metastases.** *Presenting Author: Emilie Le Rhun, Centre Oscar Lambret, Lille, France*

**Background:** The National Comprehensive Cancer Network (NCCN) guidelines considers radiographic bulky disease as assesed by MRI as a negative prognostic factor in leptomeningeal metastases (LM). Our aim was to determine the prognostic value of pre-treatment MRI in patients with breast cancer (BC) related LM. **Methods:** We retrospectively evaluated pretreatment MRI in a cohort of 60 women with BC and LM to determine the correlation between CNS MRI abnormalities and survival. All images were reviewed by a neuroradiologist and a neuro-oncologist. Statistical analyses were performed using SAS software V9.3. **Results:** At LM diagnosis, patient median age was 56 (range, 35-81) and ECOG performance status was 0-2 in 64.5%. Breast cancers were invasive ductal carcinoma in 70.5%. Estrogen receptor and progesterone receptor were present in 71.5% and 56.5% respectively. 25% of tumors were HER2 positive and 16.5% were triple negative. Malignant cells were observed in the CSF in 64%. Brain MRI showed abnormalities consistent with LM in 73% including ; hydrocephalus (10% of all patients), focal (29%) or a diffuse (35.5%) linear leptomeningeal contrast enhancement (CE), subependymal CE (27%), sulci (35.5%), folia (46%) and cranial nerve (30.5%) CE and intracranial nodules (12.5%). Spine MRI revealed the following : linear focal (8.5%) or diffuse (54%) CE (71%) and subarachnoid nodules (16.5%). The cauda equina showed enhancement in 71% of patients. 91.5% of patients received intra-CSF chemotherapy, 59.5% systemic therapy and 18% radiotherapy. All but one patient died. Survival was less than 2 months in 33.5% and greater than 6 months in 36%. Median progression free survival (PFS) was 2.5 months (range, 0.03-3.3). Median overall survival was 4 months (0.03 – 34.88). Patients with linear focal leptomeningeal CE had a significantly better PFS (p=0.02) however no other MRI characteristic was associated with survival. **Conclusions:** In this retrospective cohort of patients with BC and LM, linear focal leptomeningeal CE by pre-treatment MRI was the only significant radiographic abnormality that correlated with survival. These data will be confirmed in a larger cohort of patients.

**2068 General Poster Session (Board #33), Sat, 1:15 PM-5:00 PM**

**Venous thromboembolism in patients with glioblastoma multiforme.** *Presenting Author: Natasha Edwin, Cleveland Clinic Foundation, Cleveland, OH*

**Background:** Patients with glioblastoma (GBM) are at increased risk of venous thromboembolism (VTE) as well as intracranial bleeding and clinicians are reluctant to use anticoagulants. The natural history of VTE in GBM in the post-bevacizumab era is not well understood. We conducted a cohort study to evaluate the risk of recurrent VTE and bleeding **Methods:** We studied consecutive Cleveland Clinic patients with GBM presenting with objectively diagnosed deep vein thrombosis (DVT) or pulmonary embolism (PE) from 2008 to 2013 with at least 6-month follow-up. We collected information on patient demographics, VTE, treatment, recurrence and bleeding. **Results:** The study population comprised 450 patients of whom 129 (28.7%) developed 229 VTE events. Of these, 24 (10.4%) were PE and 205 (89.5%) were DVT. Sixty (46.5%) VTE occurred in the first 30 days post-operatively, 45 (34.9%) on chemotherapy and 70 (54.3%) in the outpatient setting. Inpatient thromboprophylaxis rates were low in eligible patients (N=10/59, 16.9%). Treatment of VTE included enoxaparin monotherapy (N=32, 24.8%), warfarin (N=11, 8.5%) or vena caval filters either alone (N=39, 30.2%) or in combination with anticoagulation (N=18, 13.9%)Recurrent VTE occurred in 24% (N=31)at a median of 39 days (range, 2-375 days). Forty percent occurred in the immediate postoperative period (N=13, 41.9%). There were 20(15.5%) episodes of major bleeding after index VTE; a majority were intracranial (N=15, 75%).Two(10%) bleeds occurred in the absence of anticoagulation, 10 (50%) on enoxaparin and 4(5%) on warfarin. **Conclusions:** GBM patients with VTE are at high risk for both recurrent VTE (24%) and major bleeding (15.5%), seemingly confirming clinicians' concerns regarding anticoagulation. However, bleeding is common both with and without anticoagulation. Both primary and recurrent VTE are common in the post-operative period and improved adherence to thromboprophylaxis in this setting could reduce the risk. A prediction tool to individualize risk of VTE and bleeding could optimize use of anticoagulation in prophylaxis and treatment.

**2069 General Poster Session (Board #34), Sat, 1:15 PM-5:00 PM**

**Outcomes in patients with unresected glioblastoma including assessment of treatment with bevacizumab as a component of initial therapy.** *Presenting Author: Stuart Burri, Levine Cancer Institute-Radiation Oncology, Charlotte, NC*

**Background:** Radiation therapy (RT) and concurrent temozolomide (CRT) is the accepted standard for newly diagnosed glioblastoma (GBM). Despite promising results in recurrent settings, addition of bevacizumab (BEV) to CRT did not improve survival in prospective trials where the majority of patients underwent surgery with gross total resection. The biologic mechanism of BEV, however, suggests increased efficacy in tumors with intact blood supply, such as unresected GBM (UGB). Given the dismal prognosis of UGB, we have incorporated use of BEV into the management of select patients with UGB. We performed a retrospective analysis of our UGB patient population to assess outcomes and evaluate effectiveness of BEV in addition to CRT. **Methods:** Retrospective review for all UGB patients (stereotactic biopsy only) treated 2005-2012 was performed. 67 patients were identified. Treatment was categorized by treatment intent : hospice referral (group 1)-24%, palliative RT (group 2)-7%, definitive CRT (group 3)-55%, and CRT+BEV (group 4)-12%. Median age was 65; median ECOG PS 2. **Results:** Median overall survival (OS) was 4.8 months. Survival was similar for PS 1 and 2 and inferior for PS 3-4. Patient's <65 OS was superior at 8.3 months vs. 3.7 months (p=.005) versus >65. OS for patients <75 was 6.0 versus 2.3 months (p=.002). Median OS for groups 1-4 were 1.0, 1.7, 7.9 and 15.9 months, respectively. In Cox multivariate analysis adjusted for age and PS CRT+BEV patients survival was superior to group 1 (p<.001) and group 2 (p=.002) with a trend compared to CRT (p=.108). 7 patients survived > 24 mos. 3 (43%) were in the CRT+BEV group (representing only 12% of all treated patients). 4.5% of the patients suffered hemorrhage at biopsy and expired in < 1 month. **Conclusions:** Patients treated with CRT+BEV had median OS > three times the group median and twice that of patients treated with CRT. The median survival of 15.9 months in UGB treated with CRT+BEV is numerically similar to patients treated with resection followed by CRT in other series. Adjusting for age and PS there remained a statistical trend to superior OS for CRT+BEV versus standard CRT. Further study regarding the benefit of BEV in patients with UGB is warranted.

**2070 General Poster Session (Board #35), Sat, 1:15 PM-5:00 PM**

**Intratumoral heterogeneity of 1p/19q codeletion in brain tumors.** *Presenting Author: Maria Martinez-Garcia, Medical Oncology, Hospital del Mar, Barcelona, Spain*

**Background:** Evaluation of 1p and 19q is a relevant diagnostic, prognostic and predictive test for oligodendroglial tumors. The aims of this study were to determine the reliability of core specimens to assess 1p/19q codeletion in brain tumors, as well as to provide additional data on its potential role in glioblastoma (GB). **Methods:** We evaluated 1p/19q codeletion by FISH using 1p/1q and 19p/19q probes (Vysis) in a tissue microarray (TMA) from brain tumor specimens, mostly GB. Four 1mm-diameter cores were punched from selected areas of each donor block. We used a cutoff value of 50%. In order to compare the percentage of deletion between the four cores the intraclass correlation coefficient (ICC) was calculated. In 23 cases Pearson correlation coefficient was used to compare results from TMA with those from tumor sections. Also, for each sample we extracted DNA for *MGMT* methylation (MSP-PCR) and *IDH1*mutation (Real time allele-specific PCR) analysis. Clinical outcome for GB patients was correlated with these biomarkers. **Results:** We selected 45 grade IV gliomas (42 GB and 3 gliosarcoma). Mean age was 59 years and 29 were men. Fifteen tumors were *MGMT* methylated (33%) and 7(16%) *IDH1* mutated. There were 38 patients (84%) with 1p deletion (at least one of the cores) and 17 (38%) with 1p/19q codeletion. In tumor sections 2/23 (8.6%) had 1p/19q codeletion. There was a low rate of correlation between cores of the same patient. The ICC for 1p and 19q were 0.324 and 0.743, respectively. We observed a high correlation between the mean percentage of deletion in cores and sections. The correlation between the mean of the cores and the sections for 1p was 0.819 and for 19q was 0.810. With a median follow-up of 11 months the OS was 10.5 months. 1p/19q codeletion had no impact on survival and neither did isolated loss of 1p or 19q or *MGMT* methylation. *IDH1*mutation was significantly correlated with survival (P= 0.046). **Conclusions:** Our data show substantial intratumoral heterogeneity of 1p/19q codeletion in grade IV glioma and establishes the need to test for this biomarker in whole sections or in several cores if only TMA is available. The outcome supports the lack of correlation between 1p/19q codeletion and OS in GB.

**2071 General Poster Session (Board #36), Sat, 1:15 PM-5:00 PM**

**Phase IB trial of carboxyamidotriazole orotate (CTO) and temozolomide for recurrent malignant glioma (MG): A novel mechanism for modulation of multiple oncogenic pathways.** *Presenting Author: Antonio Marcilio Padula Omuro, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** A possible mechanism of resistance to targeted therapeutics is the existence of redundant signaling pathways. CTO is an oral inhibitor of non-voltage-dependent calcium signaling resulting in simultaneous modulation of several receptor-mediated, calcium-dependent signal transduction pathways, including EGFR, MEK, RAS, HDAC, HSP90, WNT/$\beta$-catenin and VEGF. A phase I single-agent study in solid tumors found a safe toxicity profile and predictable pharmacokinetics at doses of 75-427 mg/m$^2$/day, with responses seen in refractory tumors with different mutations. CTO crosses the blood-brain barrier, and pre-clinical studies have shown single-agent activity in glioblastoma xenografts and robust synergism with temozolomide (TMZ), prompting this phase IB study. **Methods:** Patients with recurrent glioblastoma or MG were eligible regardless of number of recurrences and previous bevacizumab exposure. The primary objective was to establish the maximum tolerated dose (MTD) of daily oral CTO combined with TMZ 150 mg/m$^2$x5 every 28 days, using a standard 3+3 design. **Results:** The combination was well tolerated, with no dose-limiting toxicities observed at the 4 dose levels examined (N=15), ranging from 219mg to 481mg/m$^2$/day. The most frequent adverse events were fatigue, nausea, vomiting, and dizziness, all of which grades 1 or 2; no QTc prolongation was seen. PK data demonstrated therapeutically relevant metabolite (CAI) levels starting at 219mg/m$^2$doses, with no significant interactions with TMZ. Preliminary evidence of activity was observed: three radiographic responses among 11 evaluable patients; 7 patients continuing treatment beyond 2 cycles; stable disease as durable as 9+ cycles. Tissue correlates and analysis of DCE-perfusion MRI are ongoing. **Conclusions:** CTO at doses as high as 481mg/m$^2$/day is safe and well tolerated in combination with TMZ, with no MTD defined after examination of all pre-established dose-escalation levels; further escalation to increase CNS exposure may be warranted. The early signals of activity in this heavily pre-treated population are encouraging and deserve further investigation. Clinical trial information: NCT01107522.

**2072 General Poster Session (Board #37), Sat, 1:15 PM-5:00 PM**

**Phase II study of arsenic trioxide and temozolomide in combination with radiation therapy in patients with malignant gliomas.** *Presenting Author: Priya Kumthekar, Northwestern University Health System, Chicago, IL*

**Background:** Current standard treatment for GBM is radiation (RT) and temozolomide (TMZ). We published phase I data of the addition of arsenic trioxide (ATO) to RT and TMZ. We now present the phase II data. **Methods:** Patients with newly diagnosed malignant gliomas were eligible for treatment in this single arm phase II. Patients were treated with RT (60GY), TMZ (75 mg/m2 daily x 42 days) and ATO 0.20 mg/kg daily in week 1 then twice a week x 5 weeks. **Results:** Twenty-five patients (14 M and 11 W) were enrolled with a median age of 56 (28-73). Histology was GBM 18, AA 6 and AO 1. All patients completed RT/TMZ/ATO. Median number of post RT cycles of TMZ was 3 (0-12); 9 patients completed 6 or more cycles. Median PFS was 6 m for GBM and 15 m for AG and median OS was 15 m for GBM and NR for AA. Response was SD in 20, PR in 1 and PD in 4. **Conclusions:** Adding ATO to RT and TMZ is feasible and tolerable but does not appear to improve outcome compared to RTOG 0525 data where OS is 16.6 months in newly diagnosed GBM. Tissue MGMT status is being analyzed. Clinical trial information: NCT00275067.

**2073 General Poster Session (Board #38), Sat, 1:15 PM-5:00 PM**

**Application of a validated predictive model for venous thrombo-embolism in cancer to patients with glioblastoma.** *Presenting Author: Ajay P Abad, Wilmot Cancer Center, University of Rochester Medical Center, Rochester, NY*

**Background:** Venous thromboembolism (VTE) is a major cause of morbidity and mortality in patients with Glioblastoma (GBM). Despite a 7-28% incidence of VTE in GBM, there is no data to initiate thromboprophylaxis. A risk score developed by Khorana et al. for non-CNS malignancies incorporates histology, BMI, and pre-chemotherapy blood counts, reliably predicting those patients at highest risk of VTE. We sought to determine if this risk score could identify those GBM patients at highest risk and therefore, potential candidates for thromboprophylaxis. **Methods:** We performed an IRB-approved retrospective study of all GBM patients at the Wilmot Cancer Center from January 2005 to May 2011. Baseline blood counts and BMI were obtained and charts were reviewed to determine occurrence of VTE. We assigned 1 point each for PLT≥350,000/$\mu$l, Hgb<10 g/dl, WBC >11,000/$\mu$l, and BMI≥35 kg/m$^2$; all patients received 2 points for having a high-risk histology. We assessed whether patients with a risk score ≥3 had a higher occurrence of VTE compared to patients with a risk score of 2. **Results:** 167 GBM patients (median age=64) were identified and 20% developed VTE. VTE was characterized as DVT only in 15 patients, PE only in 13 patients, and concomitant DVT/PE in 6 patients. 46% (n=77) had a risk score of 2 (intermediate risk), and 64% (n=90) had a risk score ≥3 (high risk). 15.6% of patients with a score of 2 developed VTE compared to 18.9% with risk score ≥3 (p=0.575). **Conclusions:** VTE is common in GBM and our rate of 20% is consistent with previous reports. All GBM patients were intermediate or high risk, and the percentage of patients developing VTE (18.9%, score ≥3, 15.6%, score=2) far exceeds that reported in non-CNS cancers (6.7%, score ≥3, 2.0%, score=2). Although there was no statistical difference in this relatively small cohort of patients, our findings suggest that this risk model can discriminate higher risk patients. Future risk models specific to GBM may benefit from incorporating post-operative ambulation status, extent of resection and biomarkers such as tissue factor.

**2074 General Poster Session (Board #39), Sat, 1:15 PM-5:00 PM**

**Plasma levels and tumor tissue RNA of MMP2 and MMP9 exhibit similar distribution in newly diagnosed and recurrent glioblastoma (GB).** *Presenting Author: Emeline Tabouret, Aix-Marseille University, AP-HM, Service de Neuro-Oncologie, CHU Timone, Marseille, France*

**Background:** We have previously showed that a high MMP2, and to a lesser extend a low MMP9 plasma levels were associated to a high response rate, a prolonged PFS and OS in recurrent GB treated with bevacizumab (BEV), but not with cytotoxic agents, (Tabouret and col. Neuro-Oncol 2013). In order to further explore the optimal timing of bevacizumab administration, we analyzed potential differences of MMP2/MMP9 plasma levels and tumor RNA in patients with newly diagnosed and recurrent GB. **Methods:** Plasma was collected before radiotherapy in newly diagnosed GB patients (pts) (Pop ND) and in a distinct population of pts at the time of recurrence (Pop RD). MMP2 and MMP9 plasma levels were assessed using ELISA. In a third population with paired initial and recurrent GB tumors (Pop NDT and RDT respectively), MMP2 and MMP9 RNA were analyzed using quantitative RT PCR. Correlations were analyzed using the Mann Whitney U test, the Spearman corelation and the T-test. **Results:** MMP plasma levels were tested in 44 ND and 76 RD pts. Mean levels of ND and RD MMP2 levels were 196.4 pg/ml (± 9.6) and 218.2 pg/ml (± 9.6). Mean levels of ND and RD MMP9 levels were 365.4 pg/ml (± 50.7) and 302.0 pg/ml (± 34.9). No significant difference was observed between ND and RD plasma levels of MMP9 and MMP2. In ND pts, no correlation was found between MMP2 and MMP9 plasma levels, neither between these plasma markers and KPS or age. In NR pts, MMP2 and MMP9 plasma levels were inversely correlated (p<0.001). Paired MMP9 and MMP2 RNA were available in NDT and RDT for 29 pts. No difference was observed between NDT and RDT expressions of MMP9 and MMP2. At initial diagnosis, MMP9 and MMP2 were 95.7-fold and 15.9-fold over-expressed compared with normal brain. At recurrence, MMP9 and MMP2 were 80.6-fold and 25.9-fold over-expressed. MMP2 and MMP9 RNA were correlated in NDT (p=0.001) but not in RDT. **Conclusions:** In this retrospective study, the prebiomarkers of BEV activity, MMP2 and MMP9, did not show significant change between GB initial presentation and recurrence both for plasma levels and tumor RNA. These results may suggest that BEV could be similarly active for pts with newly diagnosed and recurrent GB. Adequate prospective studies are warranted.

**2075 General Poster Session (Board #40), Sat, 1:15 PM-5:00 PM**

**Impact of adverse effects of bevacizumab on survival outcomes of patients with recurrent glioblastoma.** *Presenting Author: Mohamed Ali Hamza, OhioHealth, Columbus, OH*

**Background:** Bevacizumab (bev) is widely used for treatment of patients with recurrent glioblastoma (GB). Adverse effects (AEs) to bev or bev-containing regimens can cause discontinuation of treatment. The effects of these adverse effects on survival outcomes are not well defined. **Methods:** In this retrospective chart review, we identified patients with recurrent GB, who were treated with BEV alone or BEV-containing regimens between 2006 and 2011, and who discontinued bev treatment either because of AEs (bleeding, stroke, hypertension, renal disease or low blood counts) or because of physician's decision. We excluded those who had disease progression before discontinuation. Data was analyzed to determine overall survival (OS) and progression free survival (PFS). **Results:** A total of 65 patients were identified, of whom 39 patients who discontinued bev because of AEs and 26 patients who discontinued bev because of physician's decision. There were no significant differences in age, performance status, extent of resection, number of lesions, time from diagnosis to first recurrence, time from diagnosis to start of bev, number of recurrences before bev start, and duration of bev treatment between the two groups. Patients who discontinued bev because of AEs progressed earlier after bev discontinuation (3.9 months vs 5.7 months, $P$= 0.02), had significantly lower PFS (10.4 months vs 14.2 months, $p$ = 0.01) and had significantly lower OS from bev start (13.9 months vs 32.5 months, $P$ = 0.009) and lower OS from diagnosis (20 months vs 49.3 months, $p$=0.007) when compared to patients who discontinued bev because of physician's decision. **Conclusions:** In patients with recurrent GB who were treated with bev, discontinuation of bev because of AEs is associated with earlier progression and shorter OS when compared with patients who discontinued bev because of physician's decision. These results indicate that AEs to bev or bev-containing regimens are associated with unfavorable glioma-related outcomes in patients with recurrent GB.

**2076 General Poster Session (Board #41), Sat, 1:15 PM-5:00 PM**

**Molecular profiling of low-grade gliomas (LGG) in Colombia (ONCOL-Group).** *Presenting Author: Andres F. Cardona, Clinical and Traslational Oncology Group, Fundacion Santa Fe de Bogota, Bogotá, Colombia*

**Background:** LGG are classified according to the WHO as being astrocytoma (DA), oligodendroglioma (OD) or mixed glioma (OA). TP53 mutation and 1p19q codeletion have been the main molecular abnormalities recorded to date. Although IDH1/2 mutations have been described in up to 85% of LGG, IDH negative gliomas do occur. It has recently been found that ATRX plays a significant role in glioma oncogenesis. **Methods:** We searched for P53 and Olig2 protein expression, MGMT methylation status (pMGMT), 1p19q codeletion and IDH/ATRX status in 63 Colombian LGG patients (pts). Overall survival (OS) rate was estimated and compared between groups and according to genotype. **Results:** Mean age was 40.1-yo (±12.3), 50% of the pts were male, mean lesion diameter was 41.7 mm (±17.2 mm) and histological distribution was 61.9%, 25.4% and 12.7% for AD, OD and OA, respectively. Surgical resection was total in 47.6%, subtotal in 31.7% and biopsy was performed in 20.6% of the cases. Alterations in IDH1/2 were found in 57.1%, pMGMT+ in 65.1%, overexpression of p53 and Olig2 in 30.2% and 44.4%, and 1p19q codeletion in 34.9%. The presence of alterations in ATRX was analysed in 25 patients, being positive in 16% (all IDH1+/1p19q-). Median follow-up was 15.8 months (95%CI 7.6-42.0), OS was 39.2 months (95%CI 2.5-274) and the variables positively modifying OS were pMGMT+ (p=0.004), 1p19q codeletion (p=0.015), the extension of surgical intervention (p=0.011) and the number of lobes involved (p=0.021). Multivariate analysis showed that pMGMT and 1p19q codeletion modified the OS in our population (p=0.039 and 0.047, respectively). **Conclusions:** This is the first study which has evaluated the molecular profile in LGG pts from Latin-America. Our findings confirmed the prognostic relevance of pMGMT and 1p19q codeletion, without finding a positive relation for IDH1/2 mutations. This finding could have been explained by sample size and selection bias. Mutations in ATRX are limited to the population of pts having AD/OA and IDH1+/1p19q-.

**2077 General Poster Session (Board #42), Sat, 1:15 PM-5:00 PM**

**Cost utility analysis of a randomized radiation therapy trial among patients with one to three brain metastases.** *Presenting Author: Anna Likhacheva, Banner MD Anderson Cancer Center, Gilbert, AZ*

**Background:** Two common options for the treatment of 1-3 brain metastases (BM) are whole brain radiotherapy with stereotactic radiosurgery boost (WBRT+SRS) and stereotactic radiosurgery alone (SRS). These two approaches entail differences in efficacy, neurocognitive toxicity and cost. Currently, there is an absence of evidence contrasting these two strategies both in terms of effectiveness and cost in a randomized setting. **Methods:** A randomized single institution trial tested the difference between outcomes and utilities among patients with 1-3 BM receiving WBRT+SRS or SRS alone. Patients receiving SRS alone could undergo salvage SRS or WBRT. Between 2001 and 2007, 58 patients were randomized to one of two arms. Another 42 patients refused the assigned treatment at randomization but were still followed prospectively. Institutional costs were utilized and adjusted using the Consumer Price Index. Overall survival (OS) was estimated by the Kaplan-Meier method. Utility score was derived using a time trade-off method. Cost per life-years saved and cost per quality-adjusted life-year (QALY) saved were calculated. **Results:** OS and utility scores in the SRS alone group were significantly higher than SRS+WBRT group among randomized patients ($p=0.005$ and $p=0.05$) while neither metric was statistically different in the non-randomized cohort ($p=0.72$ and $p=0.5$). The incremental cost effectiveness ratios (ICER) of SRS alone over WBRT+SRS were $47201, $74,560, and $56,455 per QALY for randomized patients, non-randomized patients and all patients, respectively. Sensitivity analysis demonstrated that the likelihood of having 1 versus 2-3 BM had the highest impact on ICER. **Conclusions:** The degree of cost effectiveness for SRS alone, as estimated by patient level costs in a prospective study, varied with whether the patients were randomized or chose their own treatment. Nonetheless, SRS alone for 1-3 brain metastases is a reasonable option from the payor perspective in all populations.

**2078 General Poster Session (Board #43), Sat, 1:15 PM-5:00 PM**

**A phase II study of whole brain radiotherapy with simultaneous integrated boost using volumetric modulated arc therapy for 1 to 10 brain metastases.** *Presenting Author: Alan Nichol, BC Cancer Agency, Vancouver, BC, Canada*

**Background:** Local control of brain metastases reduces risk of death from intracranial progression and improves survival in selected patients. Volumetric modulated arc therapy can deliver a fraction of whole brain radiotherapy (WBRT) and a simultaneous integrated boost (SIB) to multiple brain metastases in about 5 minutes. This is the first registered clinical trial (NCT01046123) to report WBRT and SIB for up to 10 brain metastases. **Methods:** Sixty subjects with 1-10 brain metastases were accrued to a single-institution phase II study of a 5-fraction course of 20 Gy WBRT and 50 Gy SIB. Eligible subjects had Karnofsky Performance Status (KPS) 70 - 100, maximum diameter of the largest metastasis $\leq$ 3 cm, and estimated $\geq$ 6-month median life expectancy. The phase II primary endpoint was a comparison of 3-month local control with that of the WBRT (37.5 Gy/15) and stereotactic radiosurgery (SRS: 15-24 Gy/1) arm of the RTOG 95-08 study (90%). Overall survival for subgroups with 1-3 and 4-10 metastases were compared. **Results:** The median number of brain metastases was 3 (range: 1-10). Known prognostic factors for overall survival in the 1-3 subgroup ($n = 33$) and the 4-10 subgroup ($n = 27$) were not significantly different. The cancers were: 53% lung, 32% breast and 15% other. The minimum follow-up was 5 months and the median follow-up was 9 months. The 3-month radiographic responses were: 10% complete, 48% partial, 33% stable (90% local control) and 10% progressive disease. Grade 3-4 radionecrosis occurred in 7% (4/60) of subjects at a median of 9 months. The median survival was 10 months in the 1-3 subgroup and 12 months in the 4-10 subgroup ($p = 0.8$). Multivariable analysis of overall survival showed that KPS 70-80 ($HR = 3.2$, $p < 0.004$), extracranial disease ($HR = 2.9$, $p = 0.04$) and no use of targeted systemic therapy ($HR = 7.5$, $p = 0.0003$) were associated with worse survival, but age ($HR = 0.98$, $p = 0.1$) and number of metastases 1-3 vs. 4-10 ($HR = 1.1$, $P = 0.8$) were not. **Conclusions:** WBRT and SIB had similar 3-month local control to the WBRT and SRS arm of RTOG 95-08. Equivalent survival of the 1-3 and 4-10 subgroups justifies including selected patients with 4-10 brain metastases in phase III trials for brain metastases. Clinical trial information: NCT01046123.

**2079 General Poster Session (Board #44), Sat, 1:15 PM-5:00 PM**

**Lenalidomide in the treatment of relapsed primary central nervous system lymphoma (PCNSL).** *Presenting Author: Caroline Houillier, APHP-CHU Pitié-Salpêtrière, Paris, France*

**Background:** Lenalidomide is an immunomodulator agent that exhibits efficacy in multiple myeloma and haematological malignancies including refractory/relapsed diffuse large B-cell (DLBC) systemic lymphoma (Witzig et al, Ann Oncol 2011). **Methods:** Retrospective review of PCNSL patients treated with lenalidomide at the Pitié-Salpêtrière hospital. Inclusion criteria were: (1) immunocompetent status (2) pathologically proven diagnosis of DLBC-PCNSL, (3) recurrent or refractory disease after at least two prior chemotherapy treatments, including intravenous high-dose methotrexate and cytarabine based regimens, (4) lenalidomide administered orally, at a dose of 25 mg/day on days 1-21 of a 28-days cycle. MRI scans were performed monthly. Response was evaluated according to the IPCG criteria. **Results:** Between June 2011 and March 2013, 6 patients (4 women and 2 men) met the inclusion criteria. Lenalidomide was given as 3rd line in 4 patients, as 4th line in 1 and 5th line in 1. Median age was 73.5 years (range 64-78) and median Karnofsky Performance Status was 60 (range 40-70). Two patients achieved complete response (CR). Patient 1 received a total of 9 monthly cycles of lenalidomide without any steroids and is still in remission after a follow-up of 18 months from the start of the treatment. Patient 2 achieved a CR and was off-steroids at the time of CR, but relapsed during the third cycle and died after 14 weeks. Patient 3 achieved a partial response after one cycle but died suddenly during the second cycle. Patients 4, 5, and 6 progressed and died 2, 5, and 6 months respectively after the start of lenalidomide. One of them who suffered from an oculo-cerebral relapse demonstrated a partial ocular response while progressing in the brain. Apart from the sudden death of unknown cause, the treatment was well tolerated. None of the patients experienced any grade III or IV toxicity. **Conclusions:** These results suggest that lenalidomide exhibits activity in heavily pre-treated PCNSL and is well tolerated in elderly patients. Lenalidomide efficacy on PCNSL needs to be evaluated prospectively, alone or in association with other cytotoxic agents. A phase II trial combining rituximab and lenalidomide for recurrent PCNSL is ongoing in France (NCT01956695).

**2080 General Poster Session (Board #45), Sat, 1:15 PM-5:00 PM**

**Preoperative chemotherapy as a new strategy of treatment for low-grade gliomas in eloquent areas: A phase II study.** *Presenting Author: Roberta Ruda, Department of Neuro-Oncology, University and City of Health and Science Hospital of Turin, Turin, Italy*

**Background:** Total/near total resection has been associated with increased survival and reduced risk of malignant transformation in low grade gliomas (LGGs). This study is aimed to evaluate whether preoperative chemotherapy with temozolomide can reduce tumor infiltration and improve the surgical resectability of LGGs in eloquent areas. **Methods:** Patients with LGG after biopsy or partial resection at a previous surgery, who progressed with increasing seizures and/or radiologically, received 1 week on/1 week off temozolomide to a maximum of 12 cycles. Response on MRI-FLAIR images was evaluated every 3 months based on RANO and volumetric criteria. Changes on diffusion tensor imaging (DTI) were assessed by histogram analysis and Functional Diffusion Maps and compared with RANO and volumetric criteria, and response of seizures. **Results:** 24 patients with an histological diagnosis of LGG according to WHO 2007 were enrolled from 2008 to 2013. Reasons for chemotherapy were either a large residual tumor in 15/24 (seizures in 13/15) or tumor progression in 9/24 (seizures in 3/9). Nineteen of 24 patients are evaluable for response so far. Best response according to RANO was: MR in 3/19 (16%), SD in 14/19 (74%) and PD in 2/19 (10%). Among patients with response or stable disease according to RANO, tumor volume reduction on FLAIR images ranged between 4.3% and 42.7% (median: 26.6%). In all patients significant changes in diffusion patterns, suggestive of a reduced tumor infiltration, were observed after 3 cycles ($p<0.05$) and became more significant ($p<0.01$) after 6 cycles. Twelve out of 15 patients had a significant reduction of seizure frequency concurrent with significant changes on DTI despite a volumetric stability. Seventeen out of 19 patients underwent reoperation: overall, a near-total resection ($\geq$ 95%) was achieved in 9/19 (47%) patients of the whole series. In 4 patients total resection was confirmed by the absence of IDH1 mutated cells in tumor margins. **Conclusions:** Preoperative chemotherapy in patients with LGG in "eloquent" areas can allow a total near-total resection at reoperation in a significant subset of patients. DTI could improve the evaluation of feasibility and timing of reoperation.

**2081 General Poster Session (Board #46), Sat, 1:15 PM-5:00 PM**

**Preliminary evaluation of the tolerability and feasibility of combining 5-amino-levulinic acid (5-ALA) with carmustine wafers (Gliadel) in the surgical management of primary glioblastoma.** *Presenting Author: Colin Watts, University of Cambridge, Cambridge, United Kingdom*

**Background:** Fluorescence-guided resection of glioblastoma improves surgical cytoreduction, which may improve therapeutic benefit from intra-operative carmustine wafers. The objective of this study was to establish the safety and tolerability of combining fluorescence-guided surgical resection (5-ALA) with intra-operative chemotherapy (carmustine wafers) in patients with primary glioblastoma (GBM) prior to standard treatment with radiotherapy and temozolomide. **Methods:** A single arm design with the following inclusion criteria: Age 18+ years; patient reviewed at a specialist neuro-oncology MDT; imaging evaluated by a neuro-radiologist and judged to be a GBM; radical resection judged to be realistic by the neurosurgeons (i.e. NICE criteria for the use of Carmustine wafers can be met); and WHO performance status 0 or 1 on clinical review **Results:** Seventy-two patients were recruited from 8 UK sites between July 2011 and May 2013; 64 patients received carmustine wafer implants and 59 patients were found to be eligible after surgery. Thirteen patients were ineligible due to wafers not inserted ($n$=8); GBM not diagnosed post-operatively ($n$=4); simultaneous diagnosis of cutaneous sebaceous carcinoma ($n$=1). There were 8 surgical complications reported in 6 patients: wound infections in 5 patients (8%) and cerebrospinal fluid leakage in 3 patients (5%). One patient was unable to begin chemoRT (1/33, 3%), and 4 patients (4/33, 12%) were not able to begin chemoRT within 6 weeks of surgery, due to surgical complications. After a median follow-up of 10.8 months, 25 patients (42%) are alive without progression, 16 patients (27%) are alive having progressed and 18 patients (31%) have died. Thirty-three patients (56%) have reported 68 adverse events of grade 3 or higher, 5 of these were reported as being 'possibly' related to the combination of 5-ALA and carmustine wafers: sepsis ($n$=2), wound infection ($n$=2), seizure ($n$=1). **Conclusions:** The combination of 5-ALA and carmustine wafers is safe and tolerable in the surgical management of primary glioblastoma. A phase III randomised controlled trial is being designed to confirm efficacy Clinical trial information: 77105850.

**2082 General Poster Session (Board #47), Sat, 1:15 PM-5:00 PM**

**Single-institution retrospective review of newly diagnosed glioblastoma (GBM) patients (pts) treated on bevacizumab (BEV) in clinical practice.** *Presenting Author: Henry S. Friedman, Duke University Medical Center, Durham, NC*

**Background:** Following the FDA approval of BEV for recurrent GBM pts, two multicenter phase III trials, RTOG0825 and AVAglio, evaluated the addition of BEV to radiation and temozolomide in newly diagnosed GBM. These trials failed to show statistically significant increased survival [median overall survival (OS) of 15.7 and 16.8 months for the BEV groups, respectively]. We performed a retrospective chart review of newly diagnosed GBM pts treated with BEV at Duke, with the goal to identify subgroups of pts who might benefit from BEV in the community. **Methods:** Newly diagnosed adult GBM pts treated at Duke were identified through our "Primary and Recurrent Glioblastoma Registry". We conducted a retrospective chart review of pts who initiated BEV off clinical trial between January 1, 2009 and May 14, 2012. Pts who participated in a clinical trial prior to receiving BEV were excluded from analysis. Pts alive on May 15, 2012 consented to the prospective collection of their data. Demographic, clinical, and outcome data were analyzed. **Results:** Thus far, a total of 181 pts have been identified. Median age at start of BEV was 57 years (range 20-80) and 66% were male. Gross total resection was obtained in 46%, biopsy in 20%, and subtotal resection in 34% of pts. At a median follow-up of 31.2 months, median OS from the time of GBM diagnosis was 26.2 months (95% Confidence Interval [CI], 23.3-32 months) and median progression-free survival (PFS) was 17.8 months (95%CI, 14.9-19.8 months). Grade 3 or higher proteinuria occurred in 6% of pts; grade 3 or higher thromboembolic events occurred in 9% of pts. Two grade 2 intracranial hemorrhages were observed. **Conclusions:** This retrospective review suggests a median OS of 26.2 months and median PFS of 17.8 months in newly diagnosed GBM pts treated on BEV in clinical practice. One possible explanation for the long-term survival could be our practice of continuing BEV at progression. Further prospective and retrospective analyses to identify subgroups of pts who can benefit from the addition of BEV to the standard of care will be performed.

**2083 General Poster Session (Board #48), Sat, 1:15 PM-5:00 PM**

**"Salvage" neoadjuvant bevacizumab in newly diagnosed glioblastoma multiforme (GBM).** *Presenting Author: Ciprian Barlog, APHP Service de Neuro-Oncologie, Paris, France*

**Background**: Some patients (pts) with GBM are in such a poor condition at the onset of radiotherapy (RT), particularly because of severe steroid-resistant intracranial hypertension (ICH), that RT is cancelled. Our objective was to evaluate if upfront bevacizumab (BEV) could be of help in this rare setting, allowing some patients to resume standard radio-chemotherapy treatment. **Methods**: We retrospectively analyzed all pts with newly diagnosed GBM who could not start RT because of severe ICH or altered neurological status incompatible with the requirements for administering RT and who received BEV as neo-adjuvant therapy. Clinical, radiological characteristics and response to BEV were recorded. It was also noted if radio-chemotherapy could be secondarily delivered. **Results**: Twelve pts received neo-adjuvant BEV because of larger tumor volume (N=8) or altered neurological status (N=4). All but one were diagnosed by biopsy. Median age was 60 years (range 19-72). All pts were under high dose steroids. Seven pts (58%) could receive standard RT after BEV administration. After BEV and before RT, neurological status was improved in 6 pts, and 8 had stable or partial response on MRI. Completion of RT was correlated to age ($p<0.001$), but not to initial tumor volume ($p=0.886$) nor KPS ($p=0.381$). Median progression free survival (PFS) and overall survival (OS) were 3.7 (95% confidence interval (CI):1.4-6.0) and 10.1 (95%CI: 0-20.4) months, respectively. Median PFS for patients with or without RT were 8.2 (95%CI: 0.1-16.4) and 2.5 (95%CI: 2.2-2.9) months ($p=0.150$), respectively. **Conclusions**: "Salvage" neo-adjuvant BEV may be of help in some GBM patients whose very poor clinical condition, often with impeding herniation, does not allow the safe onset of RT. Prospective evaluation is warranted.

**2084 General Poster Session (Board #49), Sat, 1:15 PM-5:00 PM**

**Immune checkpoint blockade for glioblastoma: Preclinical activity of single agent and combinatorial therapy.** *Presenting Author: David A. Reardon, Dana-Farber Cancer Center Institute, Boston, MA*

**Background:** Outcome for glioblastoma (GBM) remains dismal and innovative treatment strategies are desperately needed. Growing data support the contribution of local and systemic immune checkpoint molecules mediating immunosuppression by GBM tumors. **Methods:** Luciferized GL261 cells (GL261-Luc) were stereotactically implanted intracranially in albino C57BL/6 mice. Cohorts of mice with growing tumors (increasing bioluminescence) were treated with murine monoclonal antibodies (MAb) against PD-1, PD-L1, PD-L2, and CTLA-4 (single agent and combinations) every 3 days X 8 beginning 6 days following tumor implantation and were followed for overall survival. Subsets of mice underwent MRI as well as analysis of tumor infiltrating immune cells, and systemic immune cells and immunocytokines. Tumor re-challenge experiments were performed among long-term surviving mice. **Results:** Immune checkpoint blockade was well tolerated with no apparent morbidity or mortality among treated animals. Improved survival was noted among mice treated with immune checkpoint blockade compared to appropriate controls. The most robust survival benefit was noted among mice treated with combinatorial therapy including 12/18 (75%) mice treated with anti-PD-1 + anti-CTLA-4 MAbs alive at 140 days with no evidence of residual tumor. MRI imaging among long-term surviving animals demonstrated clear evidence of initial tumor growth followed by regression and eradication of tumors. Long-term surviving mice appeared fully intact neurologically and exhibited no evidence of tumor growth following re-challenge of GL261-Luc cells injected subcutaneously. Characterization of tumor infiltrating immune cells as well as systemic immune cells and immunocytokines is ongoing. **Conclusions:** Immune checkpoint blockade provides significant survival benefit and appears safe in this immunocompetent, orthotopic syngeneic GBM model. Re-challenge experiments demonstrate evidence of long-term immunologic memory and further elucidation of underlying mechanisms of immune-mediated anti-tumor activity is ongoing. These data strongly support the evaluation of immune checkpoint inhibitors among patients with GBM.

**2085 General Poster Session (Board #50), Sat, 1:15 PM-5:00 PM**

**Angiogenic and procoagulant factors in plasma of brain tumor patients treated with bevacizumab.** *Presenting Author: Andrea Pace, Neurology, Regina Elena National Cancer Institute, Rome, Italy*

**Background:** Glioblastoma (GBM) is one of the most vascularized human tumors and GBM cells produce proangiogenic factors, including vascular endothelial growth factor (VEGF). Bevacizumab (BV), a monoclonal antibody against VEGF, has shown antitumor activity, but so far no biomarkers have been identified to predict outcome. The purpose of the present study was to investigate the possible predictive value of circulating VEGF, von Willebrand factor (vWF) and procoagulant factors in patients with recurrent GBM. **Methods:** We conducted a prospective analysis of recurrent malignant gliomas (MG) patients treated with BV alone or in combination with chemotherapy performing serial evaluations of plasma VEGF levels, vWF antigen and procoagulant factors such as thrombin-antithrombin complex (TAT), prothrombin fragment F1+2 (F1+2), Factor VIII and D-Dimer. Baseline, and post-treatment samples were collected at each administration of BV. **Results:** Forty-nine recurrent MGs (glioblastoma=26, astrocytoma=17, oligodendroglioma=6) who received BV at 10 mg/kg intravenously every 3 weeks, of whom 26 in association with chemotherapy were included in the study. Median age was 45 years (22-73), median Karnofsky performance status was 80 (60-100). Out of the 48 evaluable, 17 partial responses (35%), 7 stable disease (15%) and 24 disease progressions (50%) were observed. At baseline all patients presented with laboratory signs of coagulation activation (i.e. high TAT and FVIII levels). Circulating plasma levels of VEGF and vWF antigen significantly increased in all patients post-treatment of BV ($p=0.0001$ and 0.009 respectively). No responder patients showed significantly higher vWF antigen levels than responders ($p=0.01$) after second administration of BV. **Conclusions:** These preliminary data suggest that low vWF antigen levels might help predict response in recurrent MG patients treated with BV. This marker should help clinicians to decide the right therapy, advise them of the generation of mechanisms of drug resistance during antiangiogenic treatment.

**2086 General Poster Session (Board #51), Sat, 1:15 PM-5:00 PM**

**Effect of inhibition of $\alpha$-secretase activity on cleavage of p75 neurotrophin receptor (p75NTR) and proliferation of brain tumor initiating cells (BTICs) and malignant gliomas (MGs).** *Presenting Author: Rajappa Kenchappa, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** MGs are highly invasive, proliferative, and are resistant to treatment. The identification of Glioma Stem Cells (GSCs a.k.a. BTICs) suggests MGs may arise from these cells. By using an unbiased strategy of serial *in vivo* selection, we identified p75NTR as a novel mediator of invasion of MGs/BTICs, and p75NTR proteolysis by $\gamma$-Secretase was required for glioma invasion (Johnston et al., 2007; Wang et al., 2008). However, p75NTR's role in glioma proliferation is unknown. We hypothesized that p75NTR also mediates BTICs proliferation via proteolysis by $\gamma$-Secretase. **Methods:** We used frozen human MG tissues and BTICs isolated from fresh human MGs, examined the expression of neurotrophin receptors and their ligands, and studied their role in proliferation. Gene expression data from TCGA and a validation set from the Moffitt Cancer Center MG datasets were also used. **Results:** We show that BTICs express neurotrophin receptors (p75NTR, TrkA, TrkB and TrkC), their ligands (NGF, BDNF and NT3), and predominantly secrete NGF. Down regulation of p75NTR significantly decreased BTICs proliferation. Conversely, exogenouous NGF, stimulated BTIC proliferation through $\gamma$-secretase mediated p75NTR cleavage and release of its intracellular domain (ICD). In contrast, overexpression of the p75NTR-ICD induced proliferation. Interestingly, inhibition of Trk signaling blocked NGF stimulated p75NTR cleavage and BTIC proliferation; suggesting the Trk receptors role in p75NTR signaling and BTIC proliferation. Further, knockdown of p75NTR or pharmacologic inhibition of cleavage attenuated Akt activation in BTICs, suggesting role of Akt in p75NTR mediated proliferation. We also found that p75NTR, Trk receptors, $\alpha$-secretase and the $\gamma$-secretase enzymes were elevated in GBM patients. Importantly, the ICD of p75NTR was commonly found in MG patient specimens suggesting that the receptor is activated and cleaved in patient tumors. **Conclusions:** These results show that p75NTR proteolysis is required for BTIC proliferation and is a novel clinical target.

**2087 General Poster Session (Board #52), Sat, 1:15 PM-5:00 PM**

**Association of increased progression-free survival in primary glioblastomas with lymphopenia at baseline and activation of NK and NKT cells after dendritic cell immunotherapy.** *Presenting Author: Marica Eoli, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy*

**Background:** DENDR1 is a phase I-II phase study aimed at evaluating dendritic cell (DC) immunotherapy in patients with first diagnosis of glioblastoma multiforme (GBM). Here we provide results of the interim analysis on 22 patients **Methods:** Patients with post-surgery volume $\leq$10 cc underwent leukapheresis before radiotherapy and chemotherapy with temozolomide (TMZ) (Stupp et al, 2005). DC prepared under GMP procedures were loaded with whole tumor lysate (Nava et al, 2012). Three intradermal injections of mature DC were done before adjuvant chemotherapy. The subsequent 4 injections were performed 17 $\pm$3 days after adjuvant TMZ. MRI, clinical and immunological follow-up were performed every 2 months **Results:** Median age at surgery was 54.5 years (28-69). After a median follow up of 14 months (6-27), the median progression-free survival (PFS) was 9 mo, with PFS6 90% (C. I. 0.78-1.029%) and PFS12 42% (C. I: 0.20-0.64) at Kaplan Meier analysis. Median overall survival (OS) was 22 mo with OS 12 70%. (C. I. 0.50-0.9). RT-TMZ induced significant lymphopenia (<1000 lymphocytes/microl) in 17/22 patients (77.2%). Patients with >1000 lymphocytes/microl (5/22) before first vaccination had shorter PFS than others ($p<0.005$). Peripheral Blood Lymphocytes (PBLs) were analyzed by flow cytometry to identify CD8+ T cells, NK and NKT cells before and after DC vaccines. The ratio of vaccination/baseline cell frequencies (V/B ratio) was calculated for each patient and the median of all values used as the cut off value to separate patients. Increased V/B ratio for NK cells and NKT cells, but not for CD8 T lymphocytes, was significantly associated with prolonged PFS (median PFS 14 vs 8.0 mo, $p=0.01$; 15.0 vs 8.0 mo). 2/4 patients with MGMT methylation were in the group of high V/B ratio. Interferon-gamma in peripheral blood was significantly higher in patients with PFS12 ($p<0.02$). **Conclusions:** The results show significant positive association between PFS and increased peripheral levels of NK and NKT cells, encouraging the expansion of this study to a larger number of primary GBM. Clinical trial information: 2008-005035-15.

**2088 General Poster Session (Board #53), Sat, 1:15 PM-5:00 PM**

**Gene expression analysis of B-cell receptors (BCR) pathway for identification of PDE4B gene as potential therapeutic target to overcome glucocorticoid resistance in primary CNS lymphoma.** *Presenting Author: Ariz Akhter, University of Calgary, Calgary, AB, Canada*

**Background:** Gene expression profile (GEP) and supervised learning has identified effective targeted therapies and B-cell receptors (BCR) pathway inhibitors have improved outcomes in refractory Diffuse Large B-cell lymphoma (DLBCL) patients (pts). Primary lymphoma of the central nervous system (PCNSL) is a specific DLBCL entity arising in and confined to the CNS. BCR pathway is frequently dysregulated in PCNSL due to mutations affecting CD79B, *CARD11*, and *MYD88* genes. Studies focusing on GEP in PCNSL; thus providing clinical tool for selection of novel targeted therapies is lacking. **Methods:** Here, we report GEP data on BCR related genes and associated downstream pathways (154 gene-probeset) in a cohort (n=21) of PCNSL pts, utilizing mRNA from diagnostic tissue, assessed by Nano string technology. **Results:** Hierarchical clustering (based on BCR genes) revealed two distinct clusters (A, n=15 and B, n=6) with differential expression of *CD79a, CD79b, Bcl10* and *CARD-11* ($p<0.002$). Cell of origin signatures were not distinct between two clusters ($p=0.825$). However, MAP kinase pathway (*MEK1/ERK2*) ($p<0.018$); *TAB2/TAB3* ($p<0.05$); *CCDN1* ($p<0.05$); *TLRs* ($p<0.02$) genes were differentially expressed. *PDE4B* gene, that regulates responses to BCR signaling and apoptosis, exhibited higher (1.5 x) expression in cluster A vs. cluster B (0.004). *PDE4B* expression correlated well with mTOR expression ($p=0.018$). **Conclusions:** BCR activity defines two distinct sub-groups within PCNSL with distinct signatures including expression of *PDE4B*. PCNSL pts may benefit from *PDE4B* inhibitors, through improving glucocorticoid sensitivity. It also demonstrates that insights into disease pathogenesis can be exploited to rationally overcome drug resistance.

**2089 General Poster Session (Board #54), Sat, 1:15 PM-5:00 PM**

**Comparison of hypofractionated radiation with temozolomide to the current standard of care in the treatment of glioblastoma: Results from a single institution.** *Presenting Author: Melissa Azoulay, McGill University Health Centre, Montreal, QC, Canada*

**Background:** The multimodality treatment of patients with glioblastoma (GBM) includes adjuvant radiation with concomitant chemotherapy. At this time the optimal radiation fractionation is yet to be determined. In this retrospective study, we compared different fractionation regimens and identified independent prognostic variables associated with outcome. **Methods:** 457 underwent surgery for GBM between January 2005 and December 2012. Data related to clinical information, extent of surgery and adjuvant treatment was collected using electronic records and patient charts. Patients excluded were those who did not receive or complete adjuvant radiation and patients with infra-tentorial lesions. Univariate and multivariate analysis was performed using Cox model in order to identify variables associated with the primary endpoint, overall survival (OS). **Results:** 276 patients with a median follow-up of 13.4 months were included in this analysis. There were 147 patients in the conventional fractionation (CF) group of 60 Gy/30 fractions, 86 patients in the hypofractionation group of 60 G/20 fractions (HF60), and 43 patients in the 40 Gy/15 fractions group (HF40). Ninety-five percent of patients in both the CF and HF60 group received concomitant temozolomide, while 49% in HF40 group of patients received it. The median survival (MS) was 15.7 months for the CF group with a 2 year OS of 30.6%. MS was 13.8 months and 7 months in the HF60 and HF40 groups with a 2-year OS of 26.2% and 5.3%, respectively. Cox analysis showed no significant difference in terms of OS between the CF and HF60 group (HR1.22, $P$=0.20) but worse outcome in the HF40 group (HR 2.09, $P$=0.004). Multivariate analysis showed age, performance status, extent of surgery, repeat surgery, concomitant chemotherapy and methylation status to be significant factors associated with survival. **Conclusions:** HF60 shows OS comparable to CF while allowing for a shorter treatment time and potential radiobiological benefit without added toxicity. Our data also confirms that HF40 should be reserved for the palliative setting. There is a need for a prospective trial comparing the HF60 regimen to the current standard of care.

**2090 General Poster Session (Board #55), Sat, 1:15 PM-5:00 PM**

**Revised graded prognostic assessment (GPA) index for small cell lung cancer (SCLC) patients (pts) with brain metastases (BM).** *Presenting Author: Lingling Du, Cleveland Clinic Foundation, Cleveland, OH*

**Background:** Pts with SCLC commonly develop BM and the GPA is frequently used as a prognostic index for overall survival (OS). GPA includes 4 groups (GPA scores 0-1.0 (worst), 1.5-2.0, 2.5-3.0, and 3.5-4.0 (best)). The purpose of this study is to develop a revised GPA in this population using a contemporary pt cohort. **Methods:** With IRB approval, the Cleveland Clinic Brain Tumor and Neuro-Oncology Center's database was used to identify SCLC BM pts treated between 2000 and 2013. OS from the diagnosis (dx) of SCLC BM was the primary endpoint. Cox proportional hazards models with stepwise variable selection were used to identify independent prognostic factors. **Results:** 197 pts (52% male) with BM from SCLC were included for analysis. Median age at dx of BM was 64 yrs (range 36-85). 41% had BM at the initial dx of SCLC. Median number (No.) of BM was 2 (Range 1-25). 6% had leptomeningeal disease. Median OS after the dx of BM was 9.5 months (m) (95%C.I. 7.8-10.1 m). Conventional GPA for lung cancer is derived from KPS, No. of BM, presence of extracranial mets, and age. Overall GPA was prognostic of OS ($p<.0001$) but the categorizations of the factors comprising it were not optimal. A revised set of factors was identified (Table): the 4 original factors, but with different characterizations and weights, and control of the primary tumor. The revised GPA index categorizes pts into 3 groups - unfavorable (total score $<8$; 27% of pts), intermediate (8-13; 43% of pts), and favorable ($>13$; 30% of pts); with OS of 3.0m (vs 6.4m for pts with GPA $<1.0$; 36% of pts), 9.6m, and 15.8m (vs 13.3 for pts with GPA$>2.5$; 29% of pts) respectively ($p<.0001$). **Conclusions:** A revised prognostic index consisting of modified versions of the factors comprising the GPA and primary controlled/uncontrolled in pts with BM from SCLC is proposed.

| Factor | No. of points | Hazard ratio | p |
|---|---|---|---|
| **No. of extracranial mets (based on liver, bone, and soft tissue mets).** | | | |
| **0** | 6 | 1.62 (1.26-2.06) | .0001 |
| **1** | 2 | | |
| **≥2** | 0 | | |
| **No. of BM** | | | |
| **0, 1, or 2** | 4 | 1.88 (1.30-2.70) | .0007 |
| **≥3** | 0 | | |
| **KPS** | | | |
| **≥80** | 4 | 1.71 (1.20-2.43) | .003 |
| **<80** | 0 | | |
| **Age** | | | |
| **<65** | 3 | 1.65 (1.16-2.35) | .005 |

**The potential role of $^{18}$F-FDOPA PET imaging in low-grade gliomas.** *Presenting Author: Carmine Maria Carapella, Neurosurgery, Regina Elena National Cancer Institute, Rome, Italy*

**Background**: Brain tumors have been widely evaluated with 3,4-dihydroxy-6-$^{18}$F-fluoro-L-phenylalanine ($^{18}$F-FDOPA) PET examination, that demonstrated higher sensitivity and specificity for gliomas than $^{18}$F-FDG PET imaging. The aim of the present study is to evaluate the potential role of $^{18}$F-FDOPA PET in low grade glioma (LGG). **Methods**: We enrolled 56 patients (35 males and 21 females) affected by LGG; 23% were newly diagnosed, 45% were studied during chemotherapy, and 32% were observed out of treatment during a periodic follow-up. The mean age at diagnosis was 44.5 years. All patients underwent $^{18}$F-FDOPA PET and MRI examinations. Both FLAIR and contrast-enhanced T1 sequences were considered for the assessment of therapeutic response according to RANO criteria. PET images were considered as positive when the lesion definitely presented $^{18}$F-FDOPA accumulation taking into account background and controlateral site. The slices with a maximal $^{18}$F-FDOPA uptake in the ROI were chosen for quantitative measurement of metabolic activity of the tracer [standardized uptake value (SUV)]. In order to evaluate the concordance between diagnostic test 1 (MRI) and diagnostic test 2 ($^{18}$F-FDOPA) we calculated the unweighted kappa statistic and its relative 95% Confidence Interval (CI). This value was interpreted in a qualitative manner on the basis of Landis and Koch criteria. **Results**: The Kappa statistic for the whole sample was equal to 0.301 (95% CIs from 0.21 to 0.40) showing a fair concordance between the two tests in terms of diagnostic ability. We found a good correlation between residual volume and SUV max ($r=0.435$, $p=0.002$ by Spearman Rank Correlation Coefficient), indicating that greater the residual volume, higher is the SUV max. Also multivariate analysis showed that a SUV max greater than 1.65 was the only independent predictor of tumor progression (HR=4.59, 95% CIs from 0.99 to 21.31, $p=0.054$). This implies that a patient with a SUV max higher than 1.65 had an almost 5-fold increased risk of progressive disease, regardless of its clinical and MRI characteristics. **Conclusions**: Our results confirm that $^{18}$F-FDOPA PET imaging could assume a relevant role mainly in the prognostic assessment of patients affected with primary and recurrent LGG.

**2092 General Poster Session (Board #57), Sat, 1:15 PM-5:00 PM**

**A phase I study of niraparib in combination with temozolomide (TMZ) in patients with advanced cancer.** *Presenting Author: Razelle Kurzrock, University of California, San Diego, La Jolla, CA*

**Background:** Niraparib (Np) is an oral, highly potent and selective PARP1/2 inhibitor. The hypothesis for this study is 1) PARP inhibition of DNA repair damage is potentiated with TMZ. 2) PARP inhibition restores sensitivity to TMZ mismatch repair-deficient tumors. **Methods:** This was a multi-center (3), open-label, non-randomized two-part study in patients with advanced cancers. Patients were treated with Np (once daily continuously) + TMZ (once daily for first five days) in 28-day treatment cycles. In Part A, the objective was to determine the preliminary MTD of the two drugs in combination. Part B was to explore the efficacy and tolerability of this combination in two cohorts (recurrent GBM and melanoma). The study was closed after defining MTD in Part A. **Results:** There were 19 patients treated in Part A with Np at 3 dose levels 30 mg (6 subjects), 40 mg (10 subjects), and 70 mg (3 subjects) and 150 mg/m2 TMZ once daily. The MTD and RP2D was determined to be 40 mg Np and 150 mg/m2 TMZ. The DLT of Grade 4 Thrombocytopenia occurred in 2/10 patients at the 40 mg dose level for Np. The DLT of Grade 4 neutropenia occurred in 1/3 patients at the 70 mg dose level for Np. At this dose level all 3 patients enrolled experienced Grade 4 thrombocytopenia with only one patient meeting protocol-specified DLT criteria. The most frequently reported AEs were thrombocytopenia (78.9%), anemia (68.4%), and leukopenia (57.9%). The most common ≥ grade 3 AEs were thrombocytopenia (52.6%), neutropenia (31.6%), and neoplasm progression (15.8%). Based on the in vitro metabolism data, the likelihood of a drug interaction between Np and TMZ is highly unlikely. Out of 16 evaluable subjects, 1 subject reported a PR (Glioblastoma), 2 subjects experienced SD (Malignant melonama and Serous ovarian carcinoma) and 13 subjects had PD. **Conclusions:** Niraparib, dosed at 40 mg continuously in combination with 150mg/m2 TMZ was tolerable and demonstrated antitumor activity. 40 mg Np and150 mg/m2 TMZ was considered an MTD and RP2D. A future study will evaluate full dose, 300 mg daily Np in combination with escalating TMZ dose levels. Clinical trial information: NCT01294735.

**2093 General Poster Session (Board #58), Sat, 1:15 PM-5:00 PM**

**The frequency and impact of ROS1 rearrangement on clinical outcomes in GBM.** *Presenting Author: Miriam Dorta, Fundación Jiménez Díaz University Hospital, Madrid, Spain*

**Background:** The tirosine kinase (TK) receptor ROS1 is described in several preclinical analysis of glioblastoma (GBM) cells and its role in gliomagenesis has been reported as well. Since TK inhibitors has changed clinical response of ROS1 rearranged lung cancer, new therapeutic approach has emerged for GBM. However its rearrangement in GBM human tissue still has not been explored and it should be defined to check if those are relevant to assess ROS1 inhibitors in these neoplasms. We performed ROS1 FISH in human GBM tissue and correlates molecular alterations with overall survival (OS) and progression free survival (PFS) in a cohort of uniformly treated GBMs. **Methods:** Clinical history of 54 patients treated from GBM at Doce de Octubre Spanish Hospital, between 2008 and 2010, were reviewed. Only 33 patients had accessible data, tumor specimen, received treatment out of any other clinical trial and had an adequate follow-up. To better analyze the series of 33 cases, a tissue array paraffin platform was performed, and we disposed probes for ROS1 split. 30 samples from 33 from tissue array keeped enough quality to ROS1 microscope analysis. Results were sorted and pooled in non-mutated and mutated, including deletions and rearrangements in mutated group. **Results:** Mutations were found in 51,5% of samples. Deletion was the most common mutation (48,5%). Only 1 sample showed rearrangement (3%). 39,4% was not mutated, and 3 patients were not evaluable for ROS1 (9.1%). The median overall survival (OS) and progression-free survival (PFS) of the whole series (33 samples) was 19 months (CI 95 %: 13.66-24.34) and 8 months (95 % CI: 6.47 to 9.53), respectively. For ROS1 subgroup, median OS resulted in 19 versus 11 months for non-mutated and mutated cases, respectively, with statistical signification ($p = 0.005$). ROS1 median PFS was 9 versus 6 months for non-mutated and mutated respectively, also with statistical significance ($p = 0.044$). **Conclusions:** In our series of human GBM tissues treated uniformly, a high frequency of genetic splits is estimated, with just 3% of rearrangements. These findings have prognostic relevance by the relation resulted between ROS1 status and patients survival, being significantly worse for those with ROS1 rearrangements or deletions.

**2094 General Poster Session (Board #59), Sat, 1:15 PM-5:00 PM**

**Feasibility of lymphocyte harvesting and reinfusion in patients with newly diagnosed high-grade gliomas.** *Presenting Author: Jian Li Campian, Washington University in St. Louis, St. Louis, MO*

**Background:** Standard radiation (RT), temozolomide (TMZ), and dexamethasone cause severe treatment-related lymphopenia (TRL) (total lymphocyte counts (TLC) $<500$ cells/mm$^3$) two months after initiating therapy in patients with newly diagnosed high grade gliomas (HGG). Published studies suggest that severe TRL is related to radiation of circulating lymphocytes and is associated with shorter survival due to tumor progression. This study was designed to evaluate the feasibility of harvesting lymphocytes before radiation and reinfusing them after radiation is completed. **Methods:** Ten patients with newly diagnosed HGGs and baseline TLC $>1000$ cells/mm$^3$ were enrolled. Lymphocytes were harvested with a single 120 minute apheresis procedure via peripheral veins, cryopreserved, and reinfused immediately after RT was complete. Weekly blood counts were followed for 20 weeks. A post-reinfusion TLC rise of $>300$ cells/mm$^3$was desired. **Results:** 10 patients were harvested and 8 received lymphocyte reinfusion. Median age was 55.5 years (range 40-67); median dexamethasone dose was 3 mg/day (range 0-4mg/day), and 70% was glioblastoma multiforme. Their baseline median TLC was 1980 cells/mm$^3$ (range: 1060-2290) and a median of $8.9x10^7$ lymphocytes/Kg (range $3.4\text{-}11.1x10^7$) were harvested. After 6 weeks of therapy, the TLC fell 63% (median 605 cells/mm$^3$, $p<0.0001$). A median of $7.0x10^7$ lymphocytes/Kg (range: $2.7\text{–}9.5x10^7$) were reinfused. Four weeks after reinfusion the average increase in TLC was 274 cells/mm$^3$ (STD: $\pm$ 298, $p=0.045$). Overall, 7 of 8 patients (88%; 90%CI: 53-99%) had an absolute increase in TLC $>300$ cell/mm$^3$in the 14 weeks following reinfusion and this persisted in 4 of 7 (57%) patients. No adverse events occurred related to harvest or reinfusion. **Conclusions:** Lymphocyte harvest and reinfusion is feasible in HGG patients on dexamethasone and no toxicities were noted. An increase in TLC $>300$ cells/mm$^3$ was seen in 88% of reinfused patients during the 14-week observation period post reinfusion. Future studies are being designed to document the role of lymphocyte reinfusion in the increase in TLC. Clinical trial information: NCT01653834.

**2095 General Poster Session (Board #60), Sat, 1:15 PM-5:00 PM**

**Cognitive function and depressive symptoms in patients with newly diagnosed primary brain tumors: A potential interactive relationship.** *Presenting Author: John E. Schmidt, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** Primary Brain Tumor (PBT) and its treatment result in reduced cognitive function which significantly interferes with work, personal, and social activities. Depression is also a clinically significant problem in patients with PBT at diagnosis, during and post-treatment. Recent research in non-cancer patients with mild-cognitive impairment has found strong associations between reduced cognitive function and depression; however this association has been little researched in PBT patients. The goal of the present study was to explore the potential interactive relationship between cognitive function (psychometrically assessed) and depression in patients undergoing primary adjuvant treatment for newly diagnosed PBT. **Methods:** Participants included 49 patients (51% male, mean age 48.0) with glioblastoma (n=18), oligodendroglioma (n=17), and astrocytoma (n=14). All completed a pre-treatment psychological and cognitive assessment. The assessment was repeated twelve months later. Assessments included depression (CES-D), physical symptoms and interference (MDASI-BT), and cognitive function (STROOP, Digit Symbol Coding). **Results:** At both assessments, mean scores on Digit Symbol Coding were in the low-average to borderline range compared to WAIS-IV norms. Mean STROOP T-scores fell in the average to low-average range. No significant differences were found in physical symptom severity or interference between assessments (p's>.05). Performance on the STROOP and Digit Symbol Coding declined significantly (rANOVA, p's<.05). Depression scores did not change (p's>.05). When pretreatment depression scores were included as a covariate, changes in cognitive function were no longer significant. The majority of the participants were working or in school at baseline (n=34, 70%), but were on disability or unemployed at second assessment (n=33, 67%). **Conclusions:** The results suggest that depressive symptoms may contribute to declines in cognitive function over time in PBT patients. It is tempting to speculate that interventions focused on improving cognitive function in these patients might be enhanced by early intervention to reduce depressive symptoms.

**2096 General Poster Session (Board #61), Sat, 1:15 PM-5:00 PM**

**Etirinotecan pegol (EP, NKTR-102) in the treatment of high-grade glioma (HGG): A phase 2 trial.** *Presenting Author: Seema Nagpal, Stanford Cancer Institute, Stanford, CA*

**Background:** Patients with recurrence of HGG after bevacizumab (BEV) have an extremely poor prognosis and generally do not respond to further treatment. EP is the first long-acting topoisomerase-I inhibitor designed to concentrate in and provide continuous tumor exposure throughout the entire chemotherapy cycle. Becasue irinotecan has demonstrated activity against HGG, we conducted a Phase 2, single arm, open label trial to evaluate EP in HGG patients who progressed after BEV. **Methods:** Patients age $>18$ with histologically proven anaplastic astrocytoma (AA) or glioblastoma (GB) who previously received standard chemo-radiation and recurred after BEV were eligible. A predicted life expectancy $> 6$ weeks, KPS $\geq 50$ and adequate organ and bone marrow functions were required for entry. Primary endpoint was PFS at 6-week, secondary endpoints were survival from first EP infusion, overall survival from date of pathologic diagnosis of HGG, and safety profile of EP. Response was assessed by RANO criteria. EP as a single agent is administered IV every 3 weeks at 145mg/m2. Patients did not receive BEV while on EP. **Results:** Between August 2012-May 2013, 20 patients were enrolled. Median age was 50 years, median KPS was 70%. 90% of patients had GB with a median time of 1 year from a diagnosis of HGG to study entry with a median of 3 prior lines of therapy. Patients received a median of 3 cycles (1-19) of EP. All patients were evaluable for PFS and toxicity. 2 patients (both with GB) had partial MRI responses. 10 patients had stable disease. 2 patients are still on treatment after receiving 19 and 9 treatment cycles. 6-week PFS was 55%. Median and 6-month PFS were 1.9 mos and 10%, respectively. Median overall survival from first EP infusion was 4.1 months. Only one patient (5%) had a Grade 3 toxicity (diarrhea with dehydration) attributable to EP. Hematologic toxicity was mild. **Conclusions:** Despite discontinuing BEV prior to starting EP, 2 patients had confirmed partial responses (10%) according to RANO criteria and an additional six patients had stable disease at their 1$^{st}$ and 2$^{nd}$ imaging assessment. These encouraging clinical data combined with a favorable safety profile warrant further clinical investigation of this agent in GB. Clinical trial information: NCT01663012.

**2097 General Poster Session (Board #62), Sat, 1:15 PM-5:00 PM**

**Neurocognitive functions in adults treated with radiation for primary brain tumors: A longitudinal study.** *Presenting Author: Kim Edelstein, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** Cranial radiation is associated with progressive declines in processing speed, attention, memory and executive functions, presumably due to deleterious effects on white matter growth in children and accelerated cognitive aging in older adults. However, little is known about the longitudinal effects of radiation in the adult brain tumor population. **Methods:** In this retrospective cohort study, we conducted neurocognitive assessments in 21 adults diagnosed with a primary brain tumor (12 male; mean age 44 years, range 21-66) within a year of radiation (baseline mean ± SD: 0.17 ± 0.36 years, range -0.15 to 1.1 years), and 3.05 ± 1.83 years later (range 0.51 to 6.77 years). Patients who required additional surgery, or developed tumor progression prior to neurocognitive follow up were excluded from analyses. Neurocognitive test scores were converted to scaled scores according to published criteria, and transformed to z-scores (mean 0, SD 15). Tests measuring the same construct were averaged to provide 4 cognitive domains: Speed, Attention, Memory, and Executive Functions. **Results:** At baseline, Memory, Attention, and Executive Function were below population norms, and Speed was within normal limits (one-sample t-tests, respective means ±SD: -0.66±0.84;-0.40±0.74; -0.70±1.12; -0.30±0.94; all $p<0.05$). At follow-up, only Attention was below average (-0.40±0.81). Moreover, there was no difference in performance at baseline compared to follow-up across domains, nor was there an interaction between time and domain (time x domain repeated measures ANOVA, all $p>0.1$). There was also no difference in the number of tests that were impaired (defined as one standard deviation below the population mean) at baseline compared to follow up. **Conclusions:** Adult brain tumor patients showed deficits in cognitive functions that did not appear to decline over time after radiation in the absence of tumor progression. Longitudinal assessments of neurocognitive functions following radiation treatment in a larger sample is warranted to identify factors contributing to neurocognitive decline across the lifespan in this population.

**2098 General Poster Session (Board #63), Sat, 1:15 PM-5:00 PM**

**The utility of MR enhancement as a noninvasive predictor for high-grade histology in patients with progressive low-grade gliomas: Is histology needed to guide therapy?** *Presenting Author: Amol Narang, The Johns Hopkins Department of Radiation Oncology, Baltimore, MD*

**Background:** In patients with low-grade gliomas, pathologic grade at time of progression has important therapeutic and prognostic implications. Whether surrogate radiographic variables such as new MR contrast enhancement can be used with high accuracy to predict malignant degeneration is uncertain. **Methods:** Patients with a pathologic diagnosis of low-grade glioma (WHO grade I or II) who underwent biopsy or resection at time of progression from 1995-2010 were retrospectively reviewed. Radiologic studies were examined to determine the presence of new MR contrast enhancement, which was analyzed as a predictor of high-grade transformation. **Results:** One hundred and eight patients underwent biopsy or resection for progressive low-grade gliomas, with 19 patients undergoing multiple repeat resections, allowing a total of 127 evaluable records. Median age at initial diagnosis was 36.2 years, while 10% of patients were under the age of 18. Initial pathology consisted of astrocytoma (43%), oligodendroglioma (39%), oligoastrocytoma (11%), and pilocytic astrocytoma (11%). Of the 127 instances of progression, malignant degeneration was present in 74 specimens (58%). Sensitivity (sens) and specificity (spec) of MR contrast enhancement for high-grade transformation were 89% and 57% respectively, while positive (PPV) and negative predictive values (NPV) were 74% and 79%. Values were similar when patients under 18 or with pilocytic astrocytoma were excluded (sens 89%, spec 57%, PPV 71%, NPV 81%), or when patients who only underwent biopsy at time of progression were excluded (sens 91%, spec 64%, PPV 79%, NPV 83%). **Conclusions:** Radiographic enhancement and pathologic grade were discordant in greater than 20% of cases, largely due to the lack of specificity of new MR enhancement for predicting malignant degeneration. As such, additional radiographic or clinical predictors are needed to better non-invasively identify tumors that have undergone malignant degeneration. Meanwhile, pathologic confirmation of grade at time of progression should be considered when safe.

**2099 General Poster Session (Board #64), Sat, 1:15 PM-5:00 PM**

**Primary and secondary malignant meningiomas: A clinical and histological comparison.** *Presenting Author: Tareq A. Juratli, Carl Gustav Carus University Hospital Dresden - Department of Neurosurgery, Dresden, Germany*

**Background:** Malignant meningiomas WHO Grade III (MM °III) represent the most rare but aggressive subtype of all meningioma. They may progress from low- grade meningiomas °I or °II (secondary MM) or develop as de novo primary MM. In this study, we compared clinical and histological factors influencing outcome and survival of primary and secondary MM. **Methods:** The dataset of over 1200 patients with intracranial meningiomas was used toidentify patients with histological proven MM. Of those patients clinical, histological, radiological, tumor- and treatment-related data were evaluated and analyzed. **Results:** We identified 22 MM patients (median follow-up of 8 years); 12 patients with a secondary MM and 10 patients with a primary MM. Histologically, primary and secondary MM were largely indistinguishable. Even the immunohistochemistry including proliferation index (MIB-1), vascular density as well as PDGFR-/ EGFR- and VEGFR-expression failed to show significant differences between either groups or a significant influence on the overall survival. A typical feature of secondary MM were that they are preferentially located at the skull base, whereas primary MM aroused at the convexity ($p=0.049$). Patients with secondary MM underwent in average 4 surgeries, in opposite to patients with primary MM who had in average a single operation ($p=0.002$). 8 patients with secondary MM and all patients with primary MM received radiotherapy; whereas only 3 patients in each group underwent adjuvant chemotherapy. Repeated operations demonstrated a marked survival benefit in both groups in respect to the extent of resection ($p=0.025$). The median overall survival rate for secondary MM following the confirmation of malignant histology was 2.2 years; whereas this wasn't reached yet in the patients group with primary MM at follow-up after 10 years ($p<0.05$). **Conclusions:** Secondary MM seem to be of more aggressive nature than primary ones with a higher risk toward recurrence and with a significantly reduced survival time. Surgery is an effective treatment for secondary and primary MM WHO °III at initial presentation and recurrence. In addition, repeated surgery was the only identified significant prognostic factor for improved PFS and OS in both groups.

**2100 General Poster Session (Board #65), Sat, 1:15 PM-5:00 PM**

**Comprehensive analysis of demographics and survival of pediatric medulloblastoma.** *Presenting Author: Therese A. Dolecek, University of Illinois at Chicago, Chicago, IL*

**Background:** We evaluated the American College of Surgeon's National Cancer Data Base (NCDB) to describe current hospital-based epidemiologic frequency and survival patterns of pediatric medulloblastoma. **Methods:** We analyzed NCDB 1998-2010 data on medulloblastoma defined as ICD-0-3 histology codes 9470, 9471, 9474 diagnosed in primary site brain codes C71.0-C71.9 for children ages 0-19 years. Demographic variables analyzed were age, gender, race and Hispanic origin. Comparisons were also made among histologic subtypes and primary site. Frequencies and Kaplan-Meier relative survival estimates were generated using SEER*Stat software version 8.1.2. **Results:** A total of 3,067 cases of medulloblastoma were identified. Among pediatric age groups, frequency was highest for 5-9 years and lowest in infants. Males were observed to have higher incidence than females. Whites had highest counts among race groups and non-Hispanics were observed to have more frequent diagnoses than Hispanics. The most common histologic subtype was classic medulloblastoma (9470), accounting for 88.2% cases. More than 75% of cases occurred in infratentorial sites C71.6 (cerebellum) or C71.7 (brain stem). Better relative survival was observed as age at diagnosis increased. Females were observed to have better survival than males. No significant differences in survival were observed among race or origin groups. Statistically significantly better 5-year relative survival was observed for cases diagnosed with histologic subtypes 9470 (75.5%) and 9471 (desmoplastic, 79.6%) than 9474 (anaplastic/large cell, 50.6%). Site at diagnosis did not appear to influence survival time for medulloblastoma. **Conclusions:** We report an extensive demographic and survival analysis of pediatric medulloblastoma. Observed differences likely reflect biology across age, gender, race and origin groups.

**TPS2101 General Poster Session (Board #66A), Sat, 1:15 PM-5:00 PM**

**Randomized phase IIb study of nivolumab (anti-PD-1; BMS-936558, ONO-4538) alone or in combination with ipilimumab versus bevacizumab in patients (pts) with recurrent glioblastoma (GBM).** *Presenting Author: John Howard Sampson, The Preston Robert Tisch Brain Tumor Center at Duke University Medical Center, Durham, NC*

**Background**: GBM, the most common primary brain tumor in adults, has an aggressive clinical course and a median survival of 12–15 months post first-line therapy with maximal surgical resection, radiation, and temozolomide. Bevacizumab is approved in the US for pts with progressive disease following therapy; no data has shown durable improvement of disease-related symptoms or overall survival (OS). With limited efficacy of current therapy, more effective treatments to extend survival and preserve quality of life are needed. Ipilimumab, a cytotoxic T-lymphocyte antigen-4 receptor blocking antibody, has shown clinical activity in advanced melanoma pts with brain metastases; preclinical studies demonstrate a benefit from combining a programmed death-1 (PD-1) pathway inhibitor with radiation in a mouse glioma model. We present a phase IIb, randomized, open-label study to evaluate the efficacy and safety of nivolumab, a fully human IgG4 PD-1 immune checkpoint inhibitor antibody, alone or with ipilimumab, vs bevacizumab in pts with recurrent GBM. **Methods**: Pts with Karnofsky performance status ≥70, grade IV malignant glioma treated with radiotherapy and temozolomide, and documented first GBM recurrence within 28 days of randomization are eligible. Pts with >1 recurrence of GBM, extracranial disease, autoimmune conditions, or previous VEGF inhibitor or anti-angiogenic treatment are ineligible. Safety cohort 1; nivolumab 3 mg/kg [n=10; Q2W x 4] and nivolumab 1 mg/kg + ipilimumab 3 mg/kg [n=10; Q3W x 4 followed by nivolumab 3 mg/kg Q2W]) will establish safety and tolerability in GBM pts. Upon successful completion of cohort 1, efficacy cohort 2 will enroll up to 240 pts with recurrent GBM, randomized 1:1:1 to receive nivolumab, nivolumab + ipilimumab (dosed as cohort 1), or bevacizumab (10 mg/kg Q2W). The primary objectives are to evaluate safety in cohort 1 and OS in cohort 2, vs bevacizumab, with secondary objectives of PFS and ORR. Responses will be assessed (Response Assessment Neuro-Oncology criteria) at the end of wks 6 and 12, and Q8W until progression or treatment discontinuation. Clinical trial information: NCT02017717.

**TPS2102 General Poster Session (Board #66B), Sat, 1:15 PM-5:00 PM**

**Phase II study of atorvastatin in combination with radiotherapy and temozolomide in patients with glioblastoma.** *Presenting Author: Abdullah Khalaf Altwairgi, Comprehensive Cancer Center, King Fahad Medical City, Riyadh, Saudi Arabia*

**Background:** Glioblastoma multiforme (GBM) is the most common primary brain tumor in adults. Despite recent advances in the understanding of the molecular mechanism of tumorigenesis, the outcome remains poor. Atorvastatin is an inhibitor of HMG-CoA reductase, a rate-limiting enzyme in the mevalonate pathway. Preclinical studies have demonstrated pro-apoptotic, anti-proliferative, anti-invasive, and radiosensitizing properties of statins. To date, no prospective studies have addressed the anti-tumor effects of statins in GBM. This trial was designed to determine the efficacy and safety of atorvastatin in combination with radiotherapy and temozolomide (TMZ) in patients with newly diagnosed GBM. **Methods:** In this open-label, prospective, single-arm, phase II study, eligible patients will receive oral atorvastatin (40 mg/d for 3 weeks and 80 mg/d thereafter) until disease progression or significant toxicity, in combination with standard therapy comprising radiotherapy (60 Gy/30 fractions) and TMZ (75 mg/m$^2$/d) in the 6-wk concurrent phase, then with TMZ (150-200 mg/m$^2$/d on days 1-5 for 6 cycles). The key eligibility criteria includes: adults (≥18 years) with newly diagnosed GBM, who have undergone surgical resection or biopsy, ECOG performance status ≤ 2, adequate organ function, no prior chemotherapy or radiotherapy, stable dose of steroids for ≥14 days prior to registration, and written informed consent. The primary endpoint is progression free survival (PFS) at 6 months (RANO criteria). Secondary endpoints include overall survival (OS), and safety. A minimum of 80% power required at least 32 eligible patients to be enrolled starting January 2014 with a planned interim analysis after the first 15 evaluable patients. Statistical analysis plan includes Kaplan Meir techniques and Cox proportional hazard modeling. Clinical trial information: NCT02029573.

**TPS2103 General Poster Session (Board #67A), Sat, 1:15 PM-5:00 PM**

**A phase I trial of sorafenib with whole brain radiotherapy (WBRT) in breast cancer patients with brain metastases and a correlative study of FLT-PET brain imaging to evaluate treatment response after WBRT sorafenib.** *Presenting Author: Aki Morikawa, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** WBRT is a standard therapy for metastatic breast cancer (MBC) patients with brain metastases (BM). Despite WBRT, disease progression in the brain is common, and survival is poor. One approach to improve outcome is the use of radiosensitizers. Sorafenib, a multi-kinase TKI with anti-VEGF activity, has demonstrated anti-tumor efficacy in MBC and radiosensitizing activity in preclinical studies. Concurrent use of anti-VEGF drug with radiotherapy (RT) has a potential to confound response assessments due to pseudo-progression and pseudo-response using brain magnetic resonance imaging (MRI). FDG PET is not ideal for brain imaging due to high background glucose uptake. Thus, a newer imaging modality is warranted for accurate response assessment. [18F] 3'deoxy-3'-fluorothymidine (FLT) is a new PET tracer which has shown to correlate with cellular proliferation and may be useful in improving response assessment. **Methods:** We are conducting a phase I trial of sorafenib with WBRT in MBC patients with BM using a 3+3 design. Sorafenib is given orally daily and continuously with the start of WBRT for a total of 21 days. Dose limiting toxicities are assessed weekly for 4 weeks. There are 3 doses levels: 200mg, 400mg, and 600mg daily. The primary endpoints are to determine a maximum tolerated dose (MTD) and to evaluate safety and toxicity. The secondary endpoint is central nervous system progression-free survival. An additional 6 patients will be enrolled as a safety-expansion cohort at the MTD. Key eligibility criteria include MBC with new or progressive ≥ 1cm BM, age≥18 , ECOG PS 0-2, planned WBRT, non-escalating dose of corticosteroid for ≥5 days, and no other concurrent anti-tumor therapy other than trastuzumab.In addition, as an imaging correlative study, we are evaluating FLT-PET to assess radiographic changes after WBRT sorafenib with planned sample size of 20 patients (10 patients in the sorafenib + WBRT cohort and 10 patients in the WBRT only cohort). A total of 3 FLT scans are done: baseline, 7-10 days and 10-12 weeks after the WBRT. Accrual is currently ongoing. Clinical trial information: NCT01724606 and NCT01621906.

**TPS2104 General Poster Session (Board #67B), Sat, 1:15 PM-5:00 PM**

**Salvage therapy with bendamustine for temozolomide-refractory recurrent anaplastic gliomas: A prospective phase II trial.** *Presenting Author: Marc C. Chamberlain, Fred Hutchinson Cancer Research Center, Seattle Cancer Care Alliance, Seattle, WA*

**Background:** There is no standard therapy for recurrent anaplastic glioma (AG). Salvage therapies include alkylator-based chemotherapy (temozolomide [TMZ] or lomustine [CCNU]), re-resection with or without carmustine implants, re-irradiation and bevacizumab. Bendamustine is a novel bifunctional alkylator with CNS penetration but never previously evaluated in AG. Objective: Assess response and toxicity of bendamustine in recurrent AG following prior surgery, radiotherapy and TMZ in a prospective Phase II trial. **Methods:** 26 adults (11 males; 15 females: median age 38 years {range 30-65}) with TMZ refractory recurrent AG (8 anaplastic astrocytoma, 10 anaplastic oligodendroglioma, and 8 anaplastic oligoastrocytoma) were treated with bendamustine. 14 patients were treated at first recurrence and 12 patients were treated at second recurrence. Prior salvage therapy included re-resection in 14 (carmustine implant in 1), TMZ re-challenge in 13 and bevacizumab in 3. A cycle of bendamustine was defined as 2 consecutive days of treatment (100mg/m2/day) administered once every 4 weeks (maximum number of cycles 6). Success of treatment was defined as progression free survival at 6 months of 40% or better. **Results**: Grade 3 toxicities included lymphopenia (14 patients), myalgia, diarrhea, leukopenia, allergic reaction and thrombocytopenia in 1 patient each. No grade 4 or 5 toxicities were seen. The median number of cycles of therapy was 2 (range 1-7). Best radiographic response was progressive disease in 13 (50%) and stable disease in 13 (50%). Response did not differ by histology. Median progression free survival (PFS) was 3.5 months (range 1-14 months), 6-month PFS was 30.8% and 12 month PFS was 15%. **Conclusions**: In this small prospective series of patients with recurrent AG refractory to TMZ, bendamustine appears to have modest single agent activity though not meeting pre-specified criteria (40% 6-month PFS) with manageable toxicity. Confirmation in a larger series of similar patients is required. The study was supported in part through research funds provided by TEVA Pharmaceuticals and the National Comprehensive Cancer Network. Clinical trial information: NCT00823797.

**TPS2105^ General Poster Session (Board #68A), Sat, 1:15 PM-5:00 PM**

**An Internet-based registry for the documentation of neoplastic meningitis.** *Presenting Author: Herwig Matthias Strik, University of Marburg, Marburg, Germany*

**Background:** Cerebrospinal fluid (CSF) and meningeal neoplastic involvement is rare, but severe and often limits patient survival. Only few randomized studies investigated different treatment strategies and achieved no conclusive results. New prospective studies with homogeneous entities are difficult to establish and some initiatives failed recently. An open, multicentric registry may be an adequate alternative for a prospective documentation of a large number of cases of neoplastic meningitis from different primary neoplasms. **Methods:** To enable an easy multicentric access, an internet-based database was chosen. Secutrial is a professional database which enables pseudonymized registration of clinical courses and meets all requirements for the protection of personal data. Predefined routines allow for a immediate calculation of parameters like survival or toxicity also with newly documented data. The configuration of the database allows for a separate documentation of treatment responses of primary neoplasm, systemic and solid central nervous system metastases as well as of neoplastic meningitis. Also, complications of the disease and toxicity of treatment can be documented. By such, the database is able to discriminate between different causes of clinical deterioration and death.

**TPS2106 General Poster Session (Board #68B), Sat, 1:15 PM-5:00 PM**

**Phase I study of the intratumoral administration of an oncolytic polio/rhinovirus recombinant (PVSRIPO) in recurrent glioblastoma (GBM).** *Presenting Author: Annick Desjardins, Duke University Medical Center, Durham, NC*

**Background:** PVSRIPO is the live attenuated, oral (SABIN) serotype 1 poliovirus vaccine containing a heterologous internal ribosomal entry site stemming from human rhinovirus type 2. PVSRIPO recognizes nectin-like molecule-5, an oncofetal cell adhesion molecule and tumor antigen widely expressed ectopically in malignancy. We report a phase I study evaluating the intratumoral convection-enhanced delivery (CED) of PVSRIPO. **Methods:** Eligibility criteria for adult patients (pts) with recurrent supratentorial GBM included: 1-5 cm in diameter; ≥1cm away from the ventricles; ≥4 weeks after chemotherapy, bevacizumab (BEV) or study drug; adequate organ function; KPS >70%; and positive anti-poliovirus titer. Dose was rapidly escalated using a two-step continual reassessment method with anticipated accrual of 1 pt each on dose levels 1-4, and up to 21 pts at dose level 5. **Results:** Thus far, 10 pts have been treated (1 each at levels 1 and 3, 2 at level 2, 2 at level 4, 4 at level 5). One dose limiting toxicity (pt #8) was observed at level 5, a grade 4 intracranial hemorrhage at the time of catheter removal, which required de-escalation to level 4. Adverse events possibly related to study include: hemiparesis (grade 3, n=1; grade 2, n=1; grade 1, n=1); lymphopenia (grade 3, n=1); seizure (grade 2, n=1; grade 1, n=2); lethargy (grade 1, n=4); headache (grade 1, n=2); one each of grade 2 diarrhea, paresthesia, dysphasia and hyperbilirubinemia; and one each of grade 1 fever, cough, nasal congestion, memory impairment, thrombocytopenia, anemia, nausea and vomiting. Eight pts remain alive, with pts #1 and #2 now 20 and 19 months post PVSRIPO, respectively. Two BEV failure pts died six months post-infusion after initiating hospice care due to persistence of baseline neurologic limitations. After observing prolonged steroid use in 5 of 7 pts treated on dose levels 3 to 5 and considering the clinical effects of the complex host inflammatory response to viral tumor infection, it was agreed upon that dose level 2 is probably the optimal dose level. The study has been amended to treat a total of 6 pts at dose level 2. **Conclusion:** Infusion of PVSRIPO via CED is safe thus far and observed efficacy outcomes are intriguing. Clinical trial information: 01491893.

**TPS2107 General Poster Session (Board #69A), Sat, 1:15 PM-5:00 PM**

**A phase I/II study of the combination of indoximod and temozolomide for adult patients with temozolomide-refractory primary malignant brain tumors.** *Presenting Author: Yousef Zakharia, Georgia Regents University Cancer Center, Augusta, GA*

**Background:** Indoleamine 2, 3-dioxygenase (IDO) is a key immune-modulatory endogenous enzyme that inhibits CD8+ T cells and enhances the suppressor activity of Tregs. IDO is expressed in a large proportion of solid tumors, including 50% to 90% of glioblastomas (GBMs). High IDO expression is correlated with poor prognosis in GBM. IDO inhibitors such as indoximod (1-Methyl-D-tryptophan / D-1MT) can improve anti-tumor T cell responses which slows tumor growth *in vivo*. We have demonstrated a synergistic effect of indoximod when combined with temozolomide (TMZ) and radiation in a syngeneic orthotopic brain tumor model. The purpose of this ongoing phase I study is to determine maximal tolerated dose (MTD) of indoximod in combination with TMZ in GBM. This will be followed by an expansion phase II cohort, testing the activity of the indoximod-TMZ combination in several relevant situations, including the addition of bevacizumab or stereotactic radiosurgery in clinically-indicated cases. **Methods:** After progression to standard front line-therapy, patients with GBM are currently being enrolled in a phase I dose escalation study of indoximod (600, 1000 or 1200 mg twice daily given orally) with a standard fixed dose of TMZ. Then, in the phase II portion, patients will be separated into 3 cohorts: Cohort 2a: indoximod with TMZ, cohort 2b: indoximod with TMZ and bevacizumab (for patients who are currently on bevacizumab), cohort 2c: indoximod with TMZ and stereotactic radiosurgery. **Statistical analysis:** The study uses a 3+3 dose escalation design, until reaching the MTD or the maximal absorbed dose. Sample size in phase II is based on the primary endpoint of 6 months progression free survival (PFS). **Correlative studies:** This study will assess primary tumor samples for methylguanine-DNA methyltransferase, IDO expression, intra-tumoral T cells (CD4:CD8 ratio); patient serum for biomarkers of IDO activity (kynurenine and tryptophan) and indoximod pharmacokinetics. Clinical trial information: NCT02052648.

**TPS2108 General Poster Session (Board #69B), Sat, 1:15 PM-5:00 PM**

**Successful treatment of multiple intracranial meningiomas with mifepristone (RU486).** *Presenting Author: Patrizia Farina, Medical Oncology 1, Venetian Institute of Oncology-IRCCS, Padua, Italy*

**Background:** Meningiomas, the most frequent primary brain tumors in adults, are twice more frequent in females compared to males. Several evidence suggest a role for female sex hormones, and particularly progesterone, whose receptor (PR) is highly expressed in the majority of grade I meningiomas. Mifepristone (RU 486) is a synthetic steroid with high affinity for both the progesterone and glucocorticoid receptors. In vitro and in vivo studies suggest an antitumor effects of mifepristone on meningiomas. A phase III randomized trial failed to demonstrated its efficacy in meningioma patients. However a subgroup of patients may still benefit from RU486, particularly multiple meningiomas (diffuse meningiomatosis) which are less frequent, but have a higher female predominance and a higher PR expression. **Methods:** Three female patients with multiple meningiomas inaccessible to either surgical or radiosurgical treatment were treated with mifepristone at 200 mg per day. Results. The treatment was well tolerated (one patient reported hypothyroidism, one patient reported benign ovarian cystadenoma). MRI brain follow-up revealed a partial response (>50% reduction) in two patients and a complete stabilization in the other. All the three patients are now stable after 5 to 9 years of treatment. Conclusion. These encouraging results strongly support a prospective clinical trial in this pre-selected population of multiple meningioma female patients.

**TPS2109 General Poster Session (Board #70A), Sat, 1:15 PM-5:00 PM**

**Phase I/II study of dianhydrogalactitol in patients with recurrent malignant glioblastoma multiforme (GBM).** *Presenting Author: Kent C. Shih, Tennessee Oncology, Nashville, TN*

**Background:** Median survival for patients with recurrent GBM is < 6 months. Front-line systemic therapy is temozolomide but resistance due to $O^6$-methylguanine-DNA-methyltransferase (MGMT) activity is implicated in poor outcomes. Dianhydrogalactitol (VAL-083) is a structurally unique bi-functional DNA alkylating agent that accumulates in brain tumor tissue. Previous clinical studies suggest that VAL-083 has anti-tumor activity against a range of cancers including GBM. In *in vitro* studies VAL-083 demonstrated activity in pediatric and adult GBM cell lines, as well as GBM cancer stem cells. Notably, VAL-083 overcomes resistance to MGMT *in vitro*. In light of extensive safety data from clinical trials and promising efficacy in CNS tumors, DelMar initiated a new clinical studyto establish the maximum tolerated dose (MTD) and identify a dose and dosing regimen for future efficacy trials in GBM. Dose limiting toxicity is expected to be myelosuppression, the management of which has improved in recent years. Early in the development of VAL-083, a cumulative IV dose of 125 mg/m$^2$ delivered in a 35 day cycle in combination with radiation was shown superior to radiation alone in brain cancer (Eagan, et al. 1979). In the present study, the cumulative dose in a 33 day cycle ranges from 9 mg/m$^2$ (cohort 1) to 240 mg/m$^2$ (cohort 7). Five dose cohorts, with the highest 33 day cycle cumulative dose of 120 mg/m$^2$, have completed the trial with no drug-related serious adverse events: MTD was not yet reached. Enrollment for cohort 6 (33 day cumulative dose: 180 mg/m$^2$) has been initiated. The final cohort of this study, cohort 7 (33 day cumulative dose: 240 mg/m$^2$), will be initiated subject to no DLT in cohort 6; the results will determine the design of the safety and efficacy registration trial. **Methods:** Open-label, single-arm Phase I/II dose-escalation study in patients with histologically-confirmed initial diagnosis of malignant GBM. The study utilizes a 3+3 dose-escalation design. Patients receive VAL-083 IV on days 1, 2, and 3 of a 21 day cycle. GBM patients previously been treated with surgery and/or radiation, if appropriate, must have failed both bevacizumab and temozolomide, unless contraindicated. Clinical trial information: NCT01478178.

**TPS2110 General Poster Session (Board #70B), Sat, 1:15 PM-5:00 PM**

**GEINO-11: A prospective multicenter, open label, phase II pilot clinical trial to evaluate safety and efficacy of PF-299804 (dacomitinib), a pan-HER irreversible inhibitor, in patients with recurrent glioblastoma with EGFR amplification or presence of EGFRvIII mutation.** *Presenting Author: Juan Manuel Sepúlveda, 12 de Octubre Universitary Hospital, Madrid, Spain*

**Background:** Recurrent GBM has a very poor prognosis and there is an unmet need for new treatment options. EGFR is an attractive therapeutic target for GBM, due to high rates of amplifcation and the growing evidence linking the activation of the EGFR and tumor proliferation, survival, angiogenesis and invasion. Amplification of *EGFR* is reported in approximately 50% of GBM and approximately 50% of these cases are associated with deletion of the extracellular ligand binding domain, the constitutively active mutant protein EGFRvIII. Dacomitinib (DA) is a second-generation, oral, irreversible, pan-HER tyrosine kinase inhibitor active in erlotinib and gefitinib-resistant nonclinical models of lung cancer. **Methods:** This multicenter, 2-stage, open-label, phase II trial aims to assess the efficacy and safety of DA in pts with recurrent GBM with EGFR gene amplification with or without EGFRvIII mutation. DA will be administered orally at a dose of 45 mg/day, until disease progression, unacceptable adverse side effects or study end. Pts at first recurrence will be enrolled onto 1 of 2 cohorts that will be recruited and analysed independently. *Cohort A* will include patients who have EGFR gene amplification and EGFRvIII mutations. *Cohort B* will include patients who have EGFR gene amplification but no EGFRvIII mutations. The primary endpoint is progression-free survival at six months (PFS6m) according to RANO criteria and each cohort will follow a Simon´s 2-stage optimal design (P0 = 15% PFS6m; P1=35% PFS6m; a, b error = 0.1, 0.1). For each cohort, 17 patients will be accrued in the stage 1. Additional 15 patients per cohort will be enrolled in stage 2 if the predetermined PFS6m of at least 3 patients is met in that cohort in stage 1. Secondary endpoints include safety, response rate, OS, duration of response and changes in steroid use. In December 2011 the study protocol received institutional review board approval and in April 2012 the trial commenced enrolment in 12 Spanish institutions members of GEINO.

**TPS2111 General Poster Session (Board #71A), Sat, 1:15 PM-5:00 PM**

**First combined intravenous and intracerebral application of an oncolytic virus, parvovirus h-1, in a phase I/IIa clinical trial in patients with recurrent glioblastoma multiforme (ParvOryx01).** *Presenting Author: Karsten Geletneky, University of Heidelberg, Heidelberg, Germany*

**Background:** The management of glioblastoma multiforme (GBM) is an unsolved problem and medium survival has remained at dismal 15 months. Among alternative treatments is the use of oncolytic viruses which preferentially kill tumor cells. Preclinical work using rat glioma models showed that the oncolytic rodent parvovirus H-1PV was able to cure gliomas after single intratumoral or multiple intravenous injections (K. Geletneky et al. *Neuro-Oncology* 2010), forming the basis for a clinical trial with H-1PV. **Methods:** ParvOryx01 (NCT01301430) is a dose-escalation phase I/IIa clinical trial treating patients with recurrent GBM with H-1PV. The trial has two arms of 9 patients each, subdivided in 3 dose groups of 1E6, 5E7 and 1E9 pfu H-1PV. In arm A patients first receive an intratumoral injection of H-1PV followed by tumor resection and virus injection in the tumor-surrounding infiltration zone 10 days after the first treatment. In arm B patients receive for the first time in a clinical trial a combined intravenous/intracerebral virus injection. At days 1 to 5 half of the designated dose is injected intravenously followed by tumor resection and virus injection in the peritumoral brain as in arm A. Main inclusion criteria are a single and completely resectable recurrent GBM, 18+ years of age, confirmed diagnosis of GBM (WHO IV), failed previous radio- and/or chemotherapy, Karnofsky Performance Score ≥60, commitment to omit exposure to infants < 18 months of age. Patients have to be isolated during treatment (K. Geletneky et al. *BMC Cancer* 2012). Arm A has been completed without DLT. As intratumoral injection in arm A led to asymptomatic systemic exposure to H-1PV, arm B can be conducted at the two higher dose levels only. Due to the lack of DLT the trial was amended with 3 additional patients in arm A receiving a high dose of 5E9 pfu. At the moment patients are recruited for Arm B and high-dose arm A. The trial design allows for the in depth analysis of infected tumor tissue and H-1PV penetration into the tumor after systemic injection. Clinical trial information: NCT01301430.

**TPS2112 General Poster Session (Board #71B), Sat, 1:15 PM-5:00 PM**

**Multidose oxygen therapeutic for radiation sensitization treatment of glioblastoma multiforme.** *Presenting Author: David Brown Wilson, NuvOx Pharma, Tucson, AZ*

**Background:** NuvOx is running a Phase 1b/2 evaluation of dodecafluoropentane emulsion (2% DDFPe) as a radiation sensitizer administered intravenously prior to radiation treatment (RT) in Glioblastoma (GBM) patients. Pre-clinically, DDFPe has been shown to increase tumor pO2 concentration of hypoxic solid tumors with an increase in survival. An NDA for DDFPe was previously to the FDA and considered safe and effective as an imaging agent in over 2200 patients. Subsequently DDFP was found to have 200 times the oxygen carrying capacity relative to hemoglobin, which led to the hypothesis that relatively low doses of DDFPe would be safe and effective at reversing hypoxic conditions and improve the effectiveness of the standard fractionated RT in post-resected GBM patients. **Methods:** This study is intended to determine the safe and effective therapeutic dose for fractionated radiation treatment of GBM. The dosing schedule begins at 0.05cc/kg and escalates to 0.35 cc/kg. The study is in two parts; the first part being dose optimization and the second will be expansion at the optimal dose to include enough patients to establish progression free survival statistics at 6 months post-treatment. Tumor hypoxia will be measured using Tissue Oxygen Level Dependent MRI at proscribed points during the course of therapy along with other molecular, hematologic and biochemical markers indicative of hypoxia. The FDA has granted the right of reference to the NDA submission as an imaging agent and provided guidance for the development strategy for DDFPe as an oxygen therapeutic. Elevated tumor pO2 provides a background for more efficient RT in solid tumors. Data will be presented regarding the status of enrollment, residual tumor size and relative oxygenation during treatment, changes in tumor size, as well as hematologic, and other indicators of safety and efficacy as a consequence of DDFPe administration. Ethics Committee approval was granted as of the preparation of this abstract and dosing will begin very soon. The intent of this presentation is to delve further into the study design as well as present data regarding the pharmacokinetic parameters and biomarker determination reflecting tumor oxygenation data collected thus far.

**2500** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**A phase I/IIa study evaluating the safety, efficacy, pharmacokinetics, and pharmacodynamics of lucitanib in advanced solid tumors.** *Presenting Author: Jean-Charles Soria, Gustave Roussy, Villejuif, France*

**Background:** Lucitanib is a potent, oral inhibitor of the tyrosine kinase activity of FGFR1/2, VEGFR1-3 and PDGFRA/B. These well-described signaling pathways are essential for tumor growth, survival, migration, and angiogenesis. Further, several tumor types, including carcinoma of the breast, demonstrate amplification of FGF-related genes. Currently, there are no approved drugs for patients (pts) with molecularly defined FGF-aberrant (*FGFR1* or *FGF3/4/19* amplified) tumors. **Methods:** The first in human 3-part study is evaluating oral lucitanib monotherapy. Part 1 employed a 3+3 ascending cohort design in pts with advanced solid tumors to establish a recommended dose for further study. Parts 2 and 3 evaluated safety and efficacy of lucitanib in pts with FGF aberrant or angiogenesis sensitive tumors using continuous (part 2) or intermittent schedules (part 3) of administration. **Results:** 109 (part 1 n=17; part 2 n=59; part 3 n=33) pts were treated. Median age was 55 yrs [range 34-80]; 59 female; 105 stage IV; 29 breast cancer, 16 colon, 13 thyroid and 51 other tumor. Doses from 5 mg to 30 mg were evaluated with dose limiting toxicities (DLTs) dominated by VEGF-inhibition related toxicity at the 30 mg dose level. The most common adverse events (all grades, all cohorts, continuous and intermittent dosing schedules) were hypertension (86%), asthenia (73%) and proteinuria (69%). Exposure increased with dose and a $t_{1/2}$ of 25-40 hours, deemed suitable for once daily administration. Clinical activity was observed at all doses tested with durable RECIST PRs in a variety of tumor types. In evaluable FGF-aberrant breast cancer pts, 50% (6 of 12) achieved RECIST PR with a median PFS of 9.4 months for all treated patients. Additionally, 1 of 3 pts with advanced squamous NSCLC experienced SD for 8 months with lucitanib therapy. **Conclusions:** Lucitanib demonstrated promising clinical activity and a tolerable side-effect profile in pts with advanced solid tumors, including those with FGF pathway aberrations. A phase 2 program in FGF aberrant breast and squamous NSCLC is underway in US and Europe. Clinical trial information: NCT01283945.

**2501** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Phase 1 study of JNJ-42756493, a pan-fibroblast growth factor receptor (FGFR) inhibitor, in patients with advanced solid tumors.** *Presenting Author: Rastislav Bahleda, Drug Development Department (DITEP), Gustave Roussy Institute, Villejuif, France*

**Background:** JNJ-42756493 is an orally bioavailable FGFR 1, 2, 3 and 4 inhibitor with nanomolar antitumor activity in cell lines and in vivo models with FGFR pathway aberration. **Methods:** This first in human study consists of 3 parts: dose escalation part 1to determine the recommended phase 2 dose (RP2D), dose confirmation part 2 with focus on pharmacodynamic effects, and dose expansion part 3 to evaluate the antitumor activity in selected solid tumors with FGFR gene amplification, mutation or translocation at the RP2D. Biomarkers include tumor tissue genomic profiling, skin/tumor biopsies and soluble serum markers. Toxicity is graded with CTCAE-4 and antitumor activity is assessed using RECIST 1.1. **Results:** As of 27 January 2014, 37 patients have been treated at 6 dose levels (0.5, 2, 4, 6, 9 and 12 mg daily continuously) in part 1. Most common (≥ 20% of patients) adverse events (AEs) were hyperphosphatemia (60%), asthenia (46%), dry mouth (30%), constipation (27%), abdominal pain (22%), stomatitis (22%), and vomiting (22%); all were ≤ Grade 2 in toxicity. Ten (27%) patients had ≥ Grade 3 AEs, and one dose limiting toxicity of Grade 3 AST/ALT elevation was noted at 12 mg dose. Daily 9 mg continuous dosing was declared the RP2D. Seven (19%) patients had serious AEs, including 1 death, but none were drug-related. Six (16%) patients had dose reductions due to drug-related hyperphosphatemia at 9 and 12 mg. Pharmacokinetics were linear, dose proportional and predictable with a half-life of 50 to 60 hours. Exposure dependent increases in phosphate blood levels were observed at doses up to 9 mg, thereafter reaching a plateau. Also a trend was seen for increase in FGF23 and decrease in PTH. Out of 8 patients enrolled to date with FGFR pathway aberration, we observed 1 partial response in a bladder cancer patient with FGFR3-TACC3 translocation and 1 near complete response in an urothelial cancer of renal pelvis harboring FGFR2 truncation at the RP2D. Four patients (2 lung cancer, 1 chondrosarcoma and 1 breast cancer patients with FGFR1 amplification) had stable disease. **Conclusions:** JNJ-42756493 has favorable pharmaceutical properties, with manageable side effects at the RP2D and evidence of antitumor activity. Clinical trial information: NCT01703481.

**2502** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Phase 1 open label, dose escalation study of RXDX101, an oral pan-trk, ROS1, and ALK inhibitor, in patients with advanced solid tumors with relevant molecular alterations.** *Presenting Author: Filippo G. De Braud, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

**Background:** RXDX-101 is an oral small molecule inhibitor of TrkA, TrkB and TrkC, as well as ROS1 and ALK, with high potency and selectivity. RXDX-101 has demonstrated potent pharmacological activity in preclinical studies and has the potential to be first-in-class against the Trk family of kinases. This study aims to determine the MTD, PD, PK, and anti-tumor activity in patients with advanced cancer with applicable molecular alterations. **Methods:** Phase 1 dose escalation in patients with advanced solid tumors. Patients were treated with RXDX-101, dosed orally once each day in a 4 day on, 3 day off schedule for 3 weeks, followed by a 7 day rest period, in continuous 28-day cycles. A minimum of 3 patients were enrolled at each dose level. Endpoints include safety, PK, and tumor response by RECIST. **Results:** 17 patients have been treated at 5 dose levels (100, 200, 400, 800, and 1200 mg/m2). RXDX-101 has been well tolerated to date; the MTD has not been reached in this trial. The most common AEs (all grade 1-2), considered possibly treatment-related, included paresthesias, nausea, dysgeusia, and diarrhea. No treatment related grade 3/4 AEs or SAEs were observed; one patient had grade 3 dyspnea considered to be disease-related. No DLTs seen to date. A patient with neuroblastoma (ALK+) has a PR and is in cycle 13. Two patients have prolonged stabilization of their disease and remain on treatment; a patient with NSCLC (ALK+) in cycle 11, and a patient with pancreatic cancer (ROS1+) in cycle 8. PK analysis shows maximum concentrations of RXDX-101 were generally achieved within 2 to 4 hours following dosing. Despite a degree of variability, RXDX-101 exposure (Cmax and AUC) increased with dose, with minimal accumulation following multiple doses. Average terminal half-life was ~21 hours across the dose range of 100 to 400 mg/m2/day, but increased to 32 hours in patients treated with 800 mg/m2/day; steady state was reached within 4-days. **Conclusions:** RXDX-101 has been well tolerated in patients with advanced solid tumors. Continued clinical development is supported by the tolerability and early evidence of antitumor activity in patients with relevant molecular alterations.

**2503** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Phase I trial of AZD1775 (MK1775), a wee1 kinase inhibitor, in patients with refractory solid tumors.** *Presenting Author: Khanh Tu Do, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

**Background:** Wee1 tyrosine kinase phosphorylates and inactivates Cdk1, causing G2 cell cycle arrest in response to DNA damage. AZD1775 is a novel inhibitor of Wee1 kinase with single-agent anti-tumor activity in preclinical models. Objectives of this study were to establish the safety, toxicity, maximum tolerated dose (MTD) of single agent AZD1775; determine the pharmacokinetics (PK) of AZD1775; evaluate for target modulation in paired tumor biopsies. **Methods:** Eligible adult patients (pts) had refractory cancers that had progressed on standard therapy; ECOG PS 0-2; adequate organ function. Dose level (DL) 1 was 225 mg BID x 5 doses, q 21d cycles. Dose escalation: 225 mg (DL 2) or 300 mg (DL 3) BID x 5 doses for 2 wks, q21d cycles; 3 + 3 design. Blood sampling for PK and circulating tumor cells (CTCs) occurred on C1D1 and C1D3. Tumor biopsies at MTD were performed at baseline and C1D3 (2-5 hrs post-drug) and were evaluated for pTyr15-Cdk to assess target modulation. **Results:** 18 pts treated; median age 54; median # of prior therapies 4; cancer dx (#pts): sarcoma (8); NSCLC (2); head and neck (3); fallopian tube (1); cervical (1); granulosa cell tumor (1); breast (1); appendiceal cancer (1). One pt with BRCA mutated head and neck cancer had a confirmed PR. Common toxicities were myelosuppression and diarrhea. Two DLTs occurred at DL 3: 1 pt had Gr 4 myelosuppression, developed pneumonia, and died; a second pt had SVT. At the MTD of DL 2, average Cmax was 1650 nM on D3; total exposure on D3 was 2-3 fold higher than on D1. Reduction in phosphorylated Tyr15-Cdk levels was shown in 3 of 5 paired tumor biopsies; quantitation of γH2AX, a DNA damage marker, is ongoing in CTCs and tumor biopsies. **Conclusions:** This is the first single-agent trial of AZD1775 in pts with refractory solid tumors. MTD was established at 225mg BID x 5 doses/week, 2 of 3 wks, with evidence of antitumor activity in a pt with BRCA mutated head and neck cancer. Accrual is ongoing for BRCA+ pts. The accumulation of drug on the BID regimen is consistent with a $t_{1/2}$ of ~ 24 hrs, which supports a QD schedule for future trials. Target modulation was demonstrated in paired tumor biopsies. CTCs were isolated from 2 pts with non-epithelial cancers. Analysis of tumor biopsies and CTCs for γH2AX is ongoing. Clinical trial information: NCT01748825.

**2504** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**A phase I study of DNIB0600A, an antibody-drug conjugate (ADC) targeting NaPi2b, in patients (pts) with non-small cell lung cancer (NSCLC) or platinum-resistant ovarian cancer (OC).** *Presenting Author: Howard A. Burris, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** NaPi2b (*SLC34A2*) is a multi-transmembrane, sodium-dependent phosphate transporter expressed in ~70% non-squamous NSCLC and ~90% OC. DNIB0600A is an ADC consisting of a humanized IgG1 anti-NaPi2b monoclonal antibody conjugated to an anti-mitotic agent MMAE that shows anti-proliferative activity in xenograft models . **Methods:** This study evaluated safety and activity of DNIB0600A (0.2-2.8 mg/kg) given by intravenous infusion every 3 weeks (q3w) to pts with NSCLC or platinum-resistant OC. A traditional 3+3 design was used for dose escalation followed by expansion at the recommended Phase 2 dose (RP2D) of 2.4 mg/kg in patients with NSCLC and OC. Tumor NaPi2b expression was evaluated by immunohistochemistry (IHC) in archival tissue. **Results:** As of 10 Dec 2013, 73 pts have enrolled (43 NSCLC; 30 OC), median age 62 (range 39-85), PS 0-1, median number of prior regimens 3 (1-10) in NSCLC, and 5 (1-12) in OC. Pts received a median of 4 (range 1-28) cycles of DNIB0600A. One pt experienced a DLT (Grade 3 dyspnea) at 1.8 mg/kg; no additional DLTs occurred through the maximally administered dose of 2.8 mg/kg. The most common related AEs (all grades) were fatigue (55%), nausea (40%), peripheral neuropathy (36%), decreased appetite (34%), vomiting (26%), and alopecia (19%). Related Grade 3/4 adverse events included neutropenia (8%), anemia, peripheral neuropathy, and pneumonia (each 3%), dehydration, dyspnea, fatigue, hyperglycemia, hyperkalemia, hypertensions, transaminitis, and URI (each 1%)— only dyspnea led to study treatment discontinuation. At the RP2D of 2.4 mg/kg q3w, 7/17 (41%) of IHC 2/3+ pts with OC had confirmed PRs (DoR range 1.4+ to 9.4+ months). In NSCLC, 2/21 (10%) of IHC 2/3+ pts had confirmed PRs (DoR 4.3 and 4.8 months), and 5/21 (24%) had unconfirmed PRs for best response. No pt with an IHC Score of 0 showed clinical response by RECIST criteria. + : censored. **Conclusions:** DNIB0600A administered q3w has an encouraging safety profile and evidence of anti-tumor activity in both OC and NSCLC. These data support Phase 2 development in OC with further clinical evaluation of DNIB0600A in NSCLC. Clinical trial information: NCT01375842.

**2505** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**A first-in-human phase 1 study of anticancer stem cell agent OMP-54F28 (FZD8-Fc), decoy receptor for WNT ligands, in patients with advanced solid tumors.** *Presenting Author: Antonio Jimeno, University of Colorado Denver, Aurora, CO*

**Background:** The WNT/FZD signaling pathway is implicated in tumor cell de-differentiation and cancer stem cell (CSC) function in numerous cancer types. As a first-in-class recombinant fusion protein, OMP-54F28 binds WNT ligands and blocks WNT signaling through its domain of an extracellular part of human Frizzled 8 receptor (fused to a human IgG1 Fc fragment). In patient-derived xenograft models, OMP-54F28 inhibits growth and CSC frequency, promotes differentiation of tumor cells, and synergizes with chemotherapy in a broad spectrum of malignancies. **Methods:** A 3+3 design was used; OMP-54F28 was given intravenously every 3 weeks. Objectives were determination of maximum tolerated dose (MTD), safety, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy. **Results:** 25 patients were treated in 7 dose-escalation cohorts (0.5, 1, 2.5, 5, 10, 15 and 20 mg/kg). No further dose escalation was pursued as animal data and PK modeling indicated 10 mg/kg as the target efficacious dose. Most common related Grade 1 and 2 adverse events (AEs; ≥20% of patients) were dysgeusia, decreased appetite, fatigue, muscle spasms, nausea, and vomiting. No related Grade ≥3 AEs were reported. OMP-54F28 had a half-life of ~4 days at ≥10 mg/kg. Consistent with WNT pathway inhibition in bone, 5 patients had doubling from baseline of bone turnover marker β-C-terminal telopeptide (β-CTX), an event that was reversible (β-CTX return to baseline) upon treatment with a single dose of zoledronic acid. PD modulation of WNT pathway genes was shown in hair follicles at ≥2.5 mg/kg. Two desmoid tumor patients have experienced stable disease (SD) for >6 months. 4 of 4 patients at 20 mg/kg with ≥1 on-study tumor assessment continue on study with SD. **Conclusions:** OMP-54F28 is well tolerated up to 20 mg/kg, double the target efficacious dose. PD modulation in bone and hair follicles was observed. Several patients experienced prolonged SD. Dose escalation is completed, and 3 Phase 1b studies are ongoing (pancreas cancer with nab-paclitaxel and gemcitabine, ovarian cancer with carboplatin and paclitaxel, and hepatocellular cancer with sorafenib). Detailed efficacy, safety, PK and PD results will be presented. Clinical trial information: NCT01608867.

**2506** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**A first-in-human (FIH) phase I study of SAR125844, a novel selective MET kinase inhibitor, in patients (pts) with advanced solid tumors: Dose escalation results.** *Presenting Author: Eric Angevin, Institut Gustave Roussy, Villejuif, France*

**Background:** SAR125844 (SAR) is a potent and highly selective MET kinase inhibitor ($IC_{50}$= 4.2 nM; Ki = 2.8 nM) demonstrated to be effective in MET-driven tumors with a good safety and pharmacokinetics (PK) profiles in preclinical models. This FIH phase I study was designed to determine the maximum tolerated dose (MTD), assess tolerance, PK and pharmacodynamics of SAR. **Methods:** Escalating doses of SAR, using a standard 3+3 escalation scheme, were administered intravenously (IV) every week in solid tumor pts with either high membrane total-MET protein expression or *cMET*-gene amplification. **Results:** 33 heavily pre-treated pts were enrolled: 17M/16F, median age 56 [range 27-75], ECOG-PS 0/1: 10/23 with a variety of solid tumors including 9 colorectal and 9 lung adenocarcinomas. A total of 434 infusions (median 10 [range 1-57]) of SAR was administered across 9 Dose Levels (DLs) ranging from 50 to 740 mg/m$^2$. DLTs were observed in 2 pts during the first 4 weeks consisting in grade (Gr) 3 transaminase increase (TI): 1 pt at 740mg/m$^2$ and 1 pt at 570mg/m$^2$. Recovery was obtained with dose omission and dose reduction. A Gr2 creatinine increase in 1 pt at 740mg/m$^2$ was also taken into account for dose selection. No dose-dependent adverse events (AE) were observed. No Gr≥3 related clinical toxicity was observed. Main drug-related Gr1-2 toxicities included: nausea/vomiting (33.3%), fatigue (18.2%), diarrhoea (15.2%), headache (12.1%), infusion site phlebitis (12.1%), pyrexia (9.1%). Blood exposure PK parameters (AUC and Cmax) increased in proportion with the dose, with a mean clearance of 32.2 L/h associated with a large volume of distribution (528L). Preliminary anti-tumor activity was observed at 570mg/m$^2$ with one partial response among a c*MET-gene* amplification lung adenocarcinoma pt. Seven pts with tumors not harbouring c*MET*-gene amplification experienced a long lasting stabilization over 3 months. **Conclusions:** SAR is well tolerated with early evidence of activity. SAR 570 mg/m$^2$is currently being confirmed in 2 extension cohorts. Clinical trial information: NCT01391533.

**2507** **Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**Phase 1, open-label, dose-escalation, and expansion study of ABT-700, an anti-C-met antibody, in patients (pts) with advanced solid tumors.** *Presenting Author: John H. Strickler, Duke University Medical Center, Durham, NC*

**Background:** *MET* amplification (MA) is an oncogenic driver in multiple malignancies. MA is relatively rare in primary tumors (~1-5%), but may increase after treatment with inhibitors of the EGFR pathway or cytotoxic chemotherapy. We are developing ABT-700 (hz224G11), an antagonistic antibody directed against c-Met, as monotherapy in MA tumors. **Methods:** In a 3+3 dose escalation design, ABT-700 was administered at doses of 5, 10, 15 and 25 mg/kg once every 21 days. ABT-700 was then studied at the recommended single-agent dose of 15 mg/kg (chosen based on safety, pharmacokinetic (PK), and biomarker analyses) in 26 pts with advanced solid tumors (10 colorectal, 5 non-small cell lung, 4 ovarian, 3 gastric, 2 esophageal, 1 renal, 1 uterine). MA was assessed by fluorescence in situ hybridization (FISH). **Results:** As of Dec 17, 2013, 41 pts received between 1-12 doses of ABT-700. The PK demonstrated target-mediated disposition with a mean $T_{1/2}$ of 13.9 days at 15 mg/kg. (n=10, cycle 1 of expansion cohort). There were no acute infusion reactions. Common toxicities at the 15 mg/kg dose occurring in ≥15% of pts included constipation (24%), fatigue (24%), decreased appetite (21%), peripheral edema (21%), hypoalbuminemia (17%), hypokalemia (17%) and vomiting (17%). There was no dose limiting toxicity and no maximum tolerated dose identified. By RECIST, 3/5 (60%) of pts with MA tumors had a partial response (1 each ovarian, gastric and esophageal). Among these 3 pts, the duration of response was 19, 23, and 24 weeks, respectively. Two other pts with MA did not respond: 1 pt with papillary renal cancer treated at 5 mg/kg (considered to be sub-therapeutic based on preclinical studies) and 1 pt with gastric cancer treated at 15 mg/kg. Among pts with non-amplified tumors (n=36), no objective responses were observed, however 5 pts had stable disease at the 12 week assessment. **Conclusions:** ABT-700 is well tolerated at the recommended single-agent dose of 15mg/kg. ABT-700 monotherapy has demonstrated promising anti-tumor activity in pts with MA solid tumors. The study has been expanded to identify and enroll pts with MA tumors to better define predictive biomarkers of clinical benefit. Clinical trial information: NCT01472016.

**2508 Oral Abstract Session, Sat, 1:15 PM-4:15 PM**

**First-in-human study of AMG 337, a highly selective oral inhibitor of MET, in adult patients (pts) with advanced solid tumors.** *Presenting Author: David S. Hong, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Dysregulation of the MET pathway can promote tumor growth and metastasis, making MET an attractive target for cancer therapy. AMG 337 is an investigational, oral inhibitor of MET kinase activity. This study evaluated the safety, tolerability, pharmacokinetics, and efficacy of AMG 337. **Methods:** Key eligibility: age ≥ 18 years, advanced solid tumors, measurable disease, ECOG ≤ 2, adequate organ function. AMG 337 was administered orally QD or BID on D1 and D3–28. After 1 week without AMG 337 in the absence of dose-limiting toxicity (DLT) or progression, pts resumed AMG 337 until progression. The starting dose of AMG 337 was 25 mg with planned dose escalation of 50-500 mg QD and 100-200 mg BID (3-9 pts/cohort) until the maximum tolerated dose (MTD, highest dose at which < 33% of pts/cohort had a DLT) was reached or the highest dose was tested. Pts with MET overexpression/amplification/mutation could enroll to the highest dose deemed safe at any time. **Results:** As of OCT 2013, 66 pts (QD escalation: 3 at 25 mg, 4 at 50 mg, 14 at 100 mg, 9 at 150 mg, 15 at 200 mg, 8 at 300 mg, 6 at 400 mg; BID escalation: 5 at 100mg, 1 at 150mg; expansion: 1 at 300 mg) received ≥ 1 dose of AMG 337. Median age, 59 (19-79) years; men, 56%; ECOG ≤1, 96%. See Table for treatment-related AEs in >10% pts. 8 pts had DLTs: grade (G) 3 headache (150 mg QD, n=1; 200 mg QD, n=2; 300 mg QD, n=1; 400 mg QD, n=2); G3 hypertension (200 mg QD, n=1); G3 increased amylase (400 mg QD, n=1). QD MTD is 300 mg; BID MTD not yet reached. AMG 337 exposures increased with dose, with minimal accumulation after 28 days; half-life, 4.6-7.4 h. Tumor-response data (central read) were available for 45 pts: 1 complete response (CR), 4 partial response (PR), 28 stable disease (SD), 12 progressive disease (PD). Of these, 8 pts had known MET amplification, 7 with gastroesophageal cancer (1 CR [duration of response, 100 weeks], 4 PR, 1 SD, 1 PD) and one with renal cell carcinoma (PD). **Conclusions:** Responses were observed in a subset of pts with MET-amplified tumors. A dose-expansion phase will enroll up to 50 pts at the MTD (300 mg QD). Clinical trial information: NCT01253707.

**2509 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Safety/efficacy of MK-8669 (ridaforolimus) plus MK-2206 (AKT inhibitor) in patients with advanced breast cancer with low RAS signature and PTEN deficient prostate cancer.** *Presenting Author: Shilpa Gupta, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** The PI3K/AKT/mTOR signaling pathway is aberrantly activated in a variety of cancers. The combination of ridaforolimus (mTOR inhibitor) and MK-2206 may lead to blockade of the PI3K pathway. Methods**:** We conducted a phase 1 study with ridaforolimus + MK-2206 in advanced solid tumors (n=35). Part A defined the maximum-tolerated dose (MTD); part B evaluated preliminary clinical efficacy in enriched breast cancer (BCa) and prostate cancer (PCa) patients. BCa patients had low RAS gene signature; ER+ BCa patients required a high Ki67 index. PCa patients had evidence of PTEN deficiency. Results**:** Eleven patients were in part A and 24 patients were in part B (16 BCa/8 PCa patients). In addition, 1 BCa patient from part A was found to be biomarker-eligible when tested after a clinical response. Total of 124 BCa patients were prescreened: 98 tissues were evaluable; 51were biomarker-eligible. Sixty-eight PCa patients were prescreened: 40 tissues were evaluable; 24 had loss of PTEN. The MTD was 10 mg qd ridaforolimus 5 days/wk + 90 mg weekly MK-2206; 1/17 patients had a dose limiting toxicity of G3 rash. For BCa patients, investigator-assessed objective responses were seen in 2/16 (2 partial responses [PR], 12.5%), centrally read objective responses were seen in 2/14 (2 complete responses [CR], 14.3%), and objective responses using volumetric 3-D assessment were seen in 4/14 (2 PR + 2 CR, 28.6%). In addition, stable disease (SD) ≥6 months was seen in 1 patient by the investigator assessment and 1 patient by central read. For PCa patients, 1/8 patient had SD for > 6 months. No responses were seen in other non-biomarker-tested tumors in part A (although one subject with colorectal cancer had SD for 7 months). At the MTD, the following drug-related AEs were seen: rash (44.4%); stomatitis (38.9%); diarrhea and decreased appetite (27.8%); asthenia, nausea and fatigue (22.2%). Conclusions**:** The combination of ridaforolimus and MK-2206 shows promising activity in BCa patients with low RAS. This combination was overall well tolerated with rash, stomatitis, diarrhea and asthenia being among the most common drug-related AEs. Clinical trial information: NCT01295632.

**2510 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Phase I study of oral BKM120 and oral olaparib for high-grade serous ovarian cancer (HGSC) or triple-negative breast cancer (TNBC).** *Presenting Author: Ursula Matulonis, Department of Medical Oncology, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

**Background:** In vivo synergy of the PI3-kinase inhibitor BKM120 and the PARP inhibitor olaparib is seen using a mouse model of BRCA1-related breast cancer (BrCa) and sporadic TNBC (Juvekar et al and Ibrahim et al, *Cancer Discovery* 2012). The PI3kinase pathway is activated in both TNBC and HGSC (www.cancergenome.nih.gov). Olaparib is active in HGSC and germlineBRCA mutation (gBRCAm) ovarian cancer (OvCa) and gBRCAm BrCa. These data were the rationale for this phase I, multi-center study (NCT01623349) combining BKM120 and olaparib in patients (pts) with recurrent HGSC or TNBC. **Methods:** This study has a 3 + 3 design, escalating dose levels (DL) if 0/3 or 1/6 pts have a dose limiting toxicity (DLT) during the first cycle (1st 28 days). Objectives are to determine the MTD and RP2D of daily oral olaparib (tablet formulation) and BKM120, assess toxicities, preliminary activity of this combination, and PK profiles of both drugs. Planned translational endpts include PI3kinase pathway effects, BRCA1 immunostaining/methylation, IL-8/circulating DNA levels, and somatic mutations in BRCA1/2 using FFPE tissue. Eligibility included: recurrent TNBC or HGSC *or* any histology of OvCa or BrCa with presence of a gBRCAmut, PS 0-1, and measurable/evaluable cancer. Prior PARP inhibitor use was allowed. **Results:** 34 pts to date have received study drugs; 9 pts w/TNBC and 25 pts wHGSC. 26 have known gBRCAm. Dosing started at DL1 (BKM120 60 mg and olaparib 100 mg BID); 2 DLTs were observed (1 gr 3 LFTs and 1 gr 3 hyperglycemia). A lower dose (-1) was pursued followed by re-escalation as below. DL 6 was not feasible because of of grade 3 LFTs and grade 3 depression early in cycle 2. Evidence of clinical benefit by RECIST 1.1 was observed on all DL's, and AEs seen were compatible with AE profile of BKM120 and olaparib. Expansion cohorts are accruing. **Conclusions:** Combined BKM120 and olaparib is feasible with evidence of clinical benefit seen at all DL's. Further studies combining PARP and PI3kinase inhibitors are warranted. Clinical trial information: NCT01623349.

**2511 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Phase 1 study of the BRAF inhibitor dabrafenib (D) with or without the MEK inhibitor trametinib (T) in combination with ipilimumab (Ipi) for V600E/K mutation–positive unresectable or metastatic melanoma (MM).** *Presenting Author: Igor Puzanov, Vanderbilt-Ingram Cancer Center, Vanderbilt University, School of Medicine, Nashville, TN*

**Background:** D, T, and Ipi are each indicated for treatment of patients (pts) with MM (D+T in *BRAF* V600 mutation–positive MM). D and T can be safely combined and prolong progression-free survival compared with monotherapy. Combining D+T with the CTLA-4 antibody Ipi has the potential to improve treatment outcomes, but the safety profile is unknown. A recent report suggested caution in combining the BRAF inhibitor vemurafenib (V) with Ipi; V+Ipi resulted in G3 elevations of ALT in 6/10 pts leading to study discontinuation (NEJM2013 368; 14). The present study will characterize the safety of D±T+Ipi, select recommended phase 2 doses (RP2Ds), and report efficacy. **Methods:** Pts with stage IIIc/IV *BRAF* V600E /K mutation–positive MM and ≤1 prior treatments are eligible. Dose escalation occurs in cohorts of 3-6 pts followed by expansion (≤30 pts) at the RP2D. At data cutoff (Nov 8, 2013), 10 pts were enrolled: 4 received D+Ipi (doublet), 2 received D only (withdrawn before Ipi treatment), and 4 received D+T+Ipi (triplet). **Results:** Median age of the10 pts was 59.5 y (range, 32-75 y). Doublet: D 150 mg bid + Ipi 3 mg/kg q3w × 4 doses was well tolerated and selected as RP2D. No G3/4 ALT elevations or dose-limiting toxicities (DLTs) were observed. The most frequent adverse events (AEs; ≥2) were chills, fatigue, hand-foot syndrome, pyrexia, and maculopapular rash. Of 4 pts, 2 are ongoing and 2 stopped treatment (disease progression). Pts are currently being enrolled at this dose level in the expansion. Triplet: At current doses (D 100 mg bid/T 1 mg qd+Ipi 3 mg/kg q3w × 4), no G3/4 ALT elevations and 1 DLT (G3 colitis; associated with Ipi) occurred. The most frequent AEs (≥2) were pyrexia, chills, arthralgia, insomnia, and maculopapular rash. One pt had G4 renal insufficiency that reversed rapidly. Of 4 pts treated, 1 stopped treatment (DLT), and 3 are ongoing. Updated safety data and preliminary efficacy data will be presented for both cohorts. **Conclusions:** To date the combinations of D+Ipi and D+T+Ipi appear to be tolerable and have not been associated with significant hepatotoxicity in MM, suggesting differences between BRAF inhibitors when combined with Ipi. Clinical trial information: NCT01767454.

**2512 Clinical Science Symposium, Sat, 8:00 AM-9:30 AM**

**Combinatorial effect of dabrafenib, trametinib, and adoptive cell transfer (ACT) in an immune-competent murine model of $BRAF^{V600E}$ mutant melanoma.** *Presenting Author: Siwen Hu-Lieskovan, UCLA Johnsson Comprehensive Cancer Center, Los Angeles, CA*

**Background:** The first clinical trial testing the combination of BRAF targeted therapy with vemurafenib and immunotherapy with ipilimumab was terminated early due to significant liver toxicities, possibly due to paradoxical activation of cells with wild type BRAF. MEK inhibitors can potentiate the MAPK inhibition in tumor, while alleviating the unwanted paradoxical MAPK activation. We hypothesized that addition of a MEK inhibitor would enhance the immunosensitization effects of BRAF inhibition, with decreased toxicity. **Methods:** A mouse model of syngeneic $BRAF^{V600E}$ driven melanoma (SM1) was developed. C57BL/6 mice treated with myeloid-depleting total body irradiation and bone marrow transplantation, were implanted SM1 tumors subcutaneously, followed by iv injection of $3x10^6$gp100 peptide-activated pmel-1 splenocytes when tumors reach 4-5mm. For bioluminescent imaging (BLI), splenocytes were transduced with luciferase-transfected retrovirus. Activated splenocytes from wild type C57 BL/6 mice were controls. BRAF inhibitor dabrafenib (D), MEK inhibitor trametinib (T), vehicle (V), or D+T, were given daily by oral gavage from the day of ACT. **Results:** Combination of D+T with pmel-1 ACT showed complete tumor regression, not observed in any other groups, including D+T with control ACT (mean volume of 0 mm2 pmel+D+T, vs 30 C57+D+T, 118 pmel +D on day 20, $P<0.0001$ by one way ANOVA). BLI showed increased T cell infiltration to tumors with the triple combination, compared to ACT with D, or V. Intracellular IFNr staining of the tumor infiltrating T cells did not show significant difference among groups, indicating trametinib is not detrimental to the effector functions. No significant toxicity observed with the triple combination by weight. **Conclusions:** The MEK inhibitor trametinib, when combined with the BRAF inhibitor dabrafenib and ACT immunotherapy, enhances the antitumor effect, with increased infiltration and preserved function of effectors. Our findings support the testing of this combination in patients with $BRAF^{V600E}$ mutant metastatic melanoma.

**2513 Poster Highlights Session (Board #27), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Activity of TGR-1202, a novel once-daily PI3K$\delta$ inhibitor, in patients with relapsed or refractory hematologic malignancies.** *Presenting Author: Howard A. Burris, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** TGR-1202 is a novel, next generation PI3K$\delta$ inhibitor. Preliminary data from an ongoing Ph I study of TGR-1202 demonstrated clinical activity in patients (pts) with advanced hematologic malignancies. Herein we present updated results from this Phase I, first in human study of TGR-1202. **Methods:** TGR-1202 is administered orally daily following a 3+3 dose escalation design. Previously treated pts with an ECOG PS $< 2$ and confirmed diagnosis of B-cell non-Hodgkin lymphoma (NHL), chronic lymphocytic leukemia (CLL), or other lymphoproliferative disorders are eligible. Endpoints include safety, PK/PD, and efficacy. **Results:** 27 pts have been enrolled to date across 7 dose levels: 50, 100, 200, 400, 800, 1200, and 1800 mg QD. 74% male, ECOG 0/1: 33%/67%, median age of 59 yrs (range: 28-82), median 3 (range: 1-14) prior treatment regimens, and 40% were refractory to prior treatment. Evaluable pts include 7 indolent NHL (iNHL), 11 CLL/SLL, 4 Hodgkin's lymphoma (HL), 2 mantle cell lymphoma (MCL), 1 each of lymphoplasmacytic lymphoma, DLBCL, and atypical hairy cell leukemia. TGR-1202 was well tolerated. Gr$\geq$3 AE's in $>$5% of patients were limited to: dyspnea (7%), neutropenia (15%), rash (7%), and thrombocytopenia (7%). Two DLTs were observed: 1 Gr. 3 rash at 800 mg (pt rechallenged with no recurrence), and 1 Gr. 3 hypokalemia at 1800 mg (pt discontinued due to non-compliance). Notably, no hepatotoxicity has been observed to date. Of the 27 enrolled, 23 were evaluable for efficacy. A significant dose-response relationship was observed. Of the 13 pts treated at $<$ 800 mg QD who completed 2 cycles of treatment, 7 achieved SD. Of 10 pts treated at $\geq$ 800 mg QD: 4/6 CLL pts (67%) achieved a nodal PR, 1/3 Hodgkin's pts (33%) achieved a PR. Nodal reductions occurred rapidly in patients with CLL and were accompanied by marked lymphocytosis. **Conclusions:** TGR-1202 is well tolerated in pts with rel/ref hematologic malignancies with no reported hepatic toxicity and signs of clinical activity at doses $\geq$ 800 mg QD. Enrollment continues in expansion cohorts and at higher dose cohorts. Updated safety, efficacy, PK, and PD data will be presented. Clinical trial information: NCT01767766.

**2514^ Poster Highlights Session (Board #28), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase I/II, first-in-human dose-escalation study of GSK2636771 in patients (pts) with PTEN-deficient advanced tumors.** *Presenting Author: Hendrik-Tobias Arkenau, Sarah Cannon Research Institute UK, London, United Kingdom*

**Background:** GSK2636771 is a potent, orally bioavailable and selective inhibitor of PI3K$\beta$ (0.89 nM), with $>$900-fold selectivity over PI3K$\alpha$/PI3K$\gamma$ and $>$10-fold over PI3K$\delta$. It inhibits AKT phosphorylation and downstream signalling measured as decrease of PRAS40-, GSK3$\beta$-, and RPS6-phosphorylation in PTEN mutant cell lines. **Methods:** An ongoing phase-I/IIa FTIH, open label dose escalation study of GSK2636771, once daily (QD), is being conducted to evaluate safety, pharmacokinetics (PK), pharmacodynamics (PD) and efficacy in pts with advanced tumors deficient in PTEN. The study comprised 3 parts: starting-dose selection, 3+3 dose escalation and phase-2 expansion. Backfill cohorts with mandatory, paired biopsies were opened to evaluate PD. The DLT period was 28 days. **Results:** As of 01/2014, 53 pts (35 m: 18 f, mean 60 yrs) were enrolled into 7 dose escalation (25 -500 mg) and 4 PD cohorts (50-350 mg). In total 5 DLTs (3x hypophosphatemia/ 2x hypocalcemia G3) were observed in 3 pts at 500 mg, defining MTD. AEs $>$20% (all grades) included diarrhoea, nausea, vomiting, fatigue, abdominal pain, anemia and decreased appetite - hyperglycemia was infrequent (4%). $C_{max}$ was reached 4-6 h after single and repeat dosing, with a $t_{1/2}$ of 17-38.6 h across cohorts. Increases in $C_{max}$and AUC(0-24 h) were dose-proportional up to 350 mg, but less than proportional at 400 and 500 mg. Phosphorylated AKT analysis in surrogate tissue among 20 pts across cohorts revealed a $>$50% (18 pts) and $>$80% (12 pts) decrease, 1-10 h post dosing, suggesting target engagement. One pt (prostate) had a RECIST PR and 13 pts had SD, 6 of whom were on study for $\geq$6 months. **Conclusions:** MTD and recommended phase-2 dose of GSK2636771 was 400 mg QD. PD effects on AKT and downstream proteins were observed and early efficacy signals suggest anti-tumor activity in pts with PTEN deficient tumors. Recruitment into the phase-2 part is ongoing. Clinical trial information: NCT01458067.

**2515 Poster Highlights Session (Board #29), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Glyco-optimized trastuzumab-GEX, a novel anti-HER2 monoclonal antibody with ADCC activity: A phase I clinical study in patients with HER2-positive tumors.** *Presenting Author: Hellmut Samonigg, Division of Clinical Oncology, Department of Internal Medicine, Medical University of Graz, Graz, Austria*

**Background:** TrasGEX is a glyco-optimized anti-HER2 antibody. It is designed to fully retain the antigen-binding properties of trastuzumab. It is manifold improved by fully human glycosylation and optimized for its antibody dependent cellular cytotoxicity (ADCC)-mediated anti-tumor efficacy for all FcγRIIIa genotypes as well as for lower HER2 expressing tumors. In vitro studies showed an approximate 10 to 140 fold improvement of ADCC-mediated anti-tumor activity for TrasGEX depending on the level of HER2 expression and of the FcγRIIIa receptor status. **Methods:** This is a phase I, dose-escalation trial of TrasGEX 12 to 720 mg IV flat-dose q3w in patients progressive with advanced or metastatic cancer for whom no effective standard treatment is available and ErbB2 (HER2) positivity (at least 1+). The primary objective of this first-in-human study was to determine the optimal dose and regimen of TrasGEX in the study population. **Results:** A total of 37 patients were treated with up to 720 mg TrasGEX IV flat-dose q3w in 5 cohorts of 3 to 6 patients each and an extension group of 16 patients who received 720 mg. No DLT was observed, the MTD was not reached. Infusion-related reactions (IRR) were the most frequently observed drug-related AEs (51.4%) all but two of grade 1 or 2. Premedication with paracetamol and steroids reduced the frequency and intensity of IRRs. The pharmacokinetic properties were dose-dependent with a maximal half-life of 263 h ± 99 h at 720 mg. One patient with HER2+++ salivary duct tumor developed a CR, two HER2+++ patients reached strong PR (breast: 240 mg, FcγRIIIa allotype: FF, prior trastuzumab non-responder; colon: 480 mg, FV allotype) and 12 (32.4%) showed SD (HER2+ = 4; HER2++ = 3; HER2+++ = 5), of which 40% had been exposed to trastuzumab at earlier therapies. **Conclusions:** TrasGEX at doses of up to 720mg IV q3w was well tolerated. No DLT was observed. The pharmacokinetic properties support a q3w infusion scheme. Evidence of activity was seen in 40.6% of patients, including one CR and 2 PRs in patients with progressive disease at study entry. Clinical trial information: NCT01409343.

**2516 Poster Highlights Session (Board #30), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase 1 study of REGN1400 (anti-ErbB3) combined with erlotinib or cetuximab in patients (pts) with advanced non-small cell lung cancer (NSCLC), colorectal cancer (CRC), or head and neck cancer (SCCHN).** *Presenting Author: Kyriakos P. Papadopoulos, START Center for Cancer Care, San Antonio, TX*

**Background:** REGN1400 (R) is a fully human mAb targeting ErbB3. Preclinically, dual inhibition of ErbB3 and EGFR confers augmented antitumor potency. This first-in-human dose escalation trial evaluates safety, tolerability, recommended phase 2 dose (RP2D), pharmacokinetics (PK) and anti-tumor activity of R alone or combined with erlotinib (E) or cetuximab (C) in NSCLC, CRC or SCCHN pts who progressed on prior E or C. **Methods:** This study used a 2-stage 3+3 design. R is administered IV Q2W at doses of 3, 10, or 20 mg/kg. Once safety of a monotherapy R dose level was established, subsequent pts enrolled directly into combination cohorts. Pts tolerating R monotherapy in cycle 1 (2 doses) could receive combination therapy thereafter. E and C are given per label, po QD or IV QW, respectively. **Results:** 22 pts [median age of 61 (range 38-78 yrs); M/F (15/7); ECOG PS 0/1 (5/17)] have been treated with R at 3 (n=8), 10 (n=8), and 20 mg/kg (n=6). Twelve pts received R monotherapy, and 20 pts received R combined with E or C. No protocol defined DLTs were observed. Ten treatment-related AEs (TRAEs) in 4 pts occurred with R monotherapy; 2 pts each had fatigue and vomiting. There were 64 TRAEs in 15 pts during combination therapy including rash (11) diarrhea (8), nausea (4), hypomagnesemia (3), increased AST, dry skin, fatigue and stomatitis (2 each). Four TRAE in 3 pts were grade ≥ 3; stomatitis, increased alk phos and pyrexia. There were 14 SAEs in 8 pts: pneumonia (3) and disease progression (3); and single events including dehydration, fatigue, nausea, pyrexia, respiratory failure, sepsis and vomiting. One pt required E dose reduction after addition of R. A pt with advanced tongue cancer who had progressed on C achieved a PR of 17 weeks duration with R + C. The PK profile of R showed linear and dose proportional kinetics; combination with E or C had no impact on R kinetics. **Conclusions:** R alone or combined with E or C was generally tolerated at the RP2D of 20 mg/kg Q2W. Combination therapy did not appear to potentiate any anti-EGFR related AEs. Enrollment into combination expansion cohorts is ongoing in SCCHN and CRC and will include pts who are naïve to EGFR inhibitors. Clinical trial information: NCT01727869.

**2517 Poster Highlights Session (Board #31), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 1 study of LJM716 in patients with esophageal squamous cell carcinoma, head and neck cancer, or HER2-overexpressing metastatic breast or gastric cancer.** *Presenting Author: Kerry Lynn Reynolds, Massachusetts General Hospital, Boston, MA*

**Background:** The HER3 receptor is important for maintenance of EGFR- and HER2-driven cancers and targeted therapy resistance. LJM716 is a fully human HER3 monoclonal antibody active in ligand-dependent and -independent preclinical models. **Methods:** This phase 1, first-in-human study is evaluating LJM716 in patients (pts) with squamous cell carcinoma of the head and neck (SCCHN) or esophagus (ESCC) and HER2-overexpressing metastatic breast cancer (MBC) or gastric/gastroesophageal junction cancer (MGC) for which no effective treatment exists. The objective for the dose-escalation part of the study, guided by a Bayesian model with overdose control, was to identify the maximum tolerated dose (MTD), recommended dose for expansion (RDE), and preferred dosing schedule. MTD was based on cycle 1 dose-limiting toxicity (DLT). **Results:** As of October 4, 2013, 54 pts (escalation, n = 24; expansion, n = 30) were enrolled (SCCHN, n = 21; ESCC, n = 15; MBC, n = 10; MGC, n = 8) and treated intravenously for 2 hr at dose levels (DLs) 3, 10, 20, or 40 mg/kg once weekly (QW, n = 48) or 20 mg/kg every 2 wk (n = 6) in 28-day cycles. Twenty-nine pts (54%) had ≥ 3 prior anticancer regimens. LJM716 exposure was approximately dose proportional, with an effective half-life of 10 ± 2 days in 5 evaluable pts, supporting QW dosing. Treatment-related toxicities (≥ 20%, all grades) were diarrhea (39%), chills (24%), infusion-related reactions (24%), and reduced appetite (22%). At ≥ 20 mg/kg QW (n = 48), grade 3/4 events occurred (gastrointestinal disorders [n = 3], hypokalaemia [n =2], asthenia [n = 1], and elevated lipase [n = 1]). One DLT was reported (grade 3 diarrhea and hypokalemia), which resolved after discontinuing LJM716. The MTD/RDE of LJM716 was 40 mg/kg QW. One pt with HER2+ MGC achieved an unconfirmed partial response. pHER3 reduction was seen in 4 of 5 paired tumor biopsies. Minor responses were observed in pts with SCCHN, ESCC, and MBC. Stable disease (SD) was observed in 17 pts (31%), including 1 SCCHN pt with SD > 40 wk. Five pts were on the study > 16 wk. **Conclusions:** LJM716 was well tolerated at DLs up to the RDE of 40 mg/kg QW and demonstrated preliminary evidence of antitumor activity. The study is ongoing. Clinical trial information: NCT01598077.

**2518 Poster Highlights Session (Board #32), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase 1 trial of MM-151, a novel oligoclonal anti-EGFR antibody combination in patients with refractory solid tumors.** *Presenting Author: Christopher Hanyoung Lieu, University of Colorado Denver, Denver, CO*

**Background:** MM-151 is a novel oligoclonal anti-EGFR antibody combination designed to overcome key challenges of the EGFR network: ligand redundancy and signal amplification. Preclinical studies confirm MM-151's potent ligand antagonism and signal inhibition. A Phase 1, first-in-human study was initiated to assess the safety, tolerability, pharmacokinetics (PK), immunogenicity and preliminary clinical activity of MM-151 in patients with refractory solid tumors. **Methods:** 57 patients were enrolled on 3 schedules (QW, Q2W, or Q3W) at escalating doses using a standard 3+3 design. Response was assessed per RECIST criteria every 8 weeks. Patients continued on study until disease progression or unacceptable toxicity. **Results:** Results presented are based on preliminary data collected as of Dec. 4, 2013. 57 patients (median age 63 years, 30 male, 27 female) have been enrolled (27 QW, 16 Q2W and 14 Q3W) at escalating dose levels, with 56 evaluable for safety and 31 evaluable for efficacy. The most common tumor types were colorectal cancer (CRC) (26 [46%]), pancreatic cancer (5 [9%]), and NSCLC (6 [11%]). An MTD has not been reached and dose escalation continues. Most adverse events (86%) were CTCAE grades 1 and 2. Infusion related reaction (IRR) was the most common AE (43 [76.8%]); however, this was managed to good effect with premedication and an optimized infusion schedule. The most common non-IRR AEs were comprised of EGFR-pathway toxicities, including rash (45 [80%]), hypomagnesemia (12 [21%]), mucositis (6 [11%]) and diarrhea (13 [23%]). Partial responses were observed in 2 CRC patients and a total of 8 (30% of mCRC) patients had SD for > 4 months (2 of the 8 had SD for 20.1 and 19.8 months, respectively). **Conclusions:** Results to date show that MM-151 has an acceptable safety profile and objective clinical activity in CRC. Clinical trial information: NCT01520389.

**2519 Poster Highlights Session (Board #33), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 1 dose-escalation study of anti-HER3 monoclonal antibody LJM716 in combination with trastuzumab in patients with HER2-overexpressing metastatic breast or gastric cancer.** *Presenting Author: Seock-Ah Im, Department of Internal Medicine and Cancer Research Institute, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea*

**Background:** TheHER2-HER3 heterodimer, a key driver in HER2-positive tumors, is not completely blocked by available therapies. LJM716 is a fully human anti-HER3 monoclonal antibody (mAb) shown to enhance trastuzumab activity in HER2+ preclinical breast and gastric cancer models. **Methods:** This phase 1, open-label study is currently evaluating LJM716 in combination with trastuzumab in patients (pts) with HER2+ metastatic breast (MBC) or gastric (MGC) cancer who failed previous HER2-directed therapy. The objective for the dose-escalation part of the study was to estimate the maximum tolerated dose (MTD) and/or recommended dose for expansion (RDE). **Results:** As of October 4, 2013, 35 pts (escalation, n = 17; expansion, n = 18) were enrolled (MBC, n = 29; MGC, n = 6) and treated intravenously with LJM716 at dose levels (DLs) 3, 10, 20, or 40 mg/kg once weekly (QW) in combination with trastuzumab 2 mg/kg QW. All pts had prior antineoplastic therapy, including 19 (54%) with ≥ 3 regimens. Common treatment-related adverse events (≥ 20%, all grades) were diarrhea (91%), nausea (29%), fatigue (23%), and chills (20%). Grade 3/4 events were observed in 7 pts (20%) at all DLs except 20 mg/kg QW. One dose-limiting toxicity (grade 3 diarrhea) was reported. The MTD/RDE of LJM716 in combination with trastuzumab was 40 mg/kg QW. The pharmacokinetics of LJM716 and trastuzumab was consistent with that of single agents. A reduction in pHER3 was demonstrated in 3 of 4 paired tumor biopsies. Of 30 evaluable pts, 2 partial responses (PRs) were observed: 1 each at 3 mg/kg and 10 mg/kg QW (18 and 40 weeks of exposure, respectively). Both pts with PRs had MBC and documented progression with the most recent prior regimen, which contained trastuzumab. Six additional pts (17%) with MBC demonstrated minor responses (8-27% tumor shrinkage). Twelve pts (40%) with MBC or MGC had stable disease as the best response (> 16 weeks of exposure in 3 MBC pts). **Conclusions:** LJM716 is the first anti-HER3 mAb to demonstrate clinical activity in combination with trastuzumab in trastuzumab-resistant pts. The safety profile of the combination was acceptable up to the highest LJM716 DL tested, 40 mg/kg QW. Clinical trial information: NCT01602406.

**2520^ Poster Highlights Session (Board #34), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Phase I study of the safety and efficacy of INC280 in patients with advanced MET-dependent solid tumors.** *Presenting Author: Yung-Jue Bang, Seoul National University Hospital, Seoul, South Korea*

**Background:** Aberrations in the MET receptor tyrosine kinase pathway occur in various human malignancies (via *MET* amplification, mutation, or overexpression) driving cell proliferation, survival and metastasis. INC280 is a highly selective, oral small molecule MET inhibitor with preclinical activity in human tumor models. This dose escalation study evaluated INC280 in patients (pts) with MET dependent advanced solid tumors. **Methods:** In this Phase (Ph) I study, the primary objective was to determine the MTD or recommended Ph II dose (RP2D), safety and tolerability of INC280; secondary objectives included preliminary antitumor activity and PK. Eligible pts (aged ≥18 years, ECOG PS ≤2) had tumors that were refractory to current therapy or for which no effective therapy exists, and confirmed MET dysregulation (by FISH or IHC). An adaptive Bayesian logistic regression model guided dose escalation in establishing the MTD/RP2D. **Results:** As of December 2, 2013, 33 pts were enrolled in the dose-escalation part of the study (79% male, median age 57 years, 61% PS 0). The most common tumors were hepatocellular carcinoma (HCC; 45%) and colon cancer (21%). Pts were treated in 6 dose cohorts of 100–600 mg BID. DLTs occurred at 200 mg BID, 250 mg BID and 450 mg BID (1 pt each). DLTs were Gr 3 fatigue (2 pts), and Gr 3 serum bilirubin increased. The most frequent drug-related AEs (any grade [Gr]) were decreased appetite (33%), nausea (30%), vomiting (27%), and fatigue (27%). The most common drug-related Gr 3/4 AEs were fatigue (9%), and decreased appetite (6%). INC280 plasma concentration generally increased with dose; mean steady state $AUC_{last}$ and $C_{max}$ following 600 mg BID were 6630 ng/mL and 29800 ng*h/mL, respectively, with a median $T_{max}$of 1.9 h and a mean apparent terminal half-life 3.1 h. Stable disease was reported in 8/33 (24%) heavily pretreated pts. Paired biopsy data showed near-complete phospho-MET shutdown in a colorectal cancer pt at 450 mg BID. **Conclusions:** Oral INC280 BID is well tolerated, and the RP2D is 600 mg BID. Dose expansion is ongoing in pts with NSCLC, HCC, and other tumors. These results suggest INC280 should be further evaluated, and Ph II studies in various solid tumors are ongoing. Clinical trial information: NCT01324479.

**2521^ Poster Highlights Session (Board #35), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Results of the first-in-human phase I trial assessing MSC2156119J (EMD 1214063), an oral selective c-Met inhibitor, in patients (pts) with advanced solid tumors.** *Presenting Author: Gerald Steven Falchook, MD Anderson Cancer Center, Department of Investigational Cancer Therapeutics (Phase I Clinical Trials Program), Houston, TX*

**Background:** MSC2156119J, a selective c-Met inhibitor, suppresses tumor growth in preclinical models. **Methods:** Primary endpoint of this dose-escalation study (3+3 design; NCT01014936): to assess an MTD; secondary endpoints: antitumor activity, safety, pharmacokinetics (PK), and pharmacodynamics (Pd). Pts received 1x/d oral MSC2156119J (21-d cycles; 3 regimens [R]): d1–14 followed by 7-d rest (R1); 3x/wk (R2); or d1–21 (R3). An optimized formulation (OF) was introduced in Aug 2011. **Results:** Up to Nov 25, 2013,126 pts were analyzed (R1=42; R2=45; R3=39). On the initial formulation, doses were escalated from 30–230 mg/d in R1 and 30–115 mg/d in R2; on the OF (R1–3): 30–400 mg/d, 60–315 mg/d, and 300–1400 mg/d. AUC and $C_{max}$ increased with dose; bioavailability was higher with OF. An MTD was not reached. Six pts reported dose-limiting toxicities: asymptomatic G4 lipase and G3 amylase increase (R1; 115 mg/d), G3 nausea and vomiting (R2; 130 mg/d; OF), asymptomatic G3 lipase increase (R2; 60 + 100 mg/d; OF), G3 fatigue (R3; 1400 mg/d; OF), and G3 ALT elevation (R3; 1000 mg/d; OF). Other ≥G3 treatment-related adverse events (trAEs) were G3 peripheral edema (1 pt; R3; 300 mg/d; OF) and G3 AST elevation (1 pt; R3; 1000 mg/d; OF). Most frequent G2 trAEs (R1–3): fatigue (n=8), peripheral edema (n=3), vomiting (n=3), nausea (n=2), asymptomatic lipase increase (n=2), and neutropenia (n=2). 79% of pts had no trAE >G1. Pre- and on-therapy tumor biopsies showed phospho-c-Met inhibition in 19/21 evaluable pts. One pt (esophageal adenocarcinoma) had confirmed partial response (PR); 2 pts (nasopharyngeal and colorectal carcinoma) had unconfirmed PRs. Stable disease (SD) ≥4 mo was seen in 18 pts, incl. 1 pt with SD >32 mo. Based on preclinical PK/Pd models and clinical Pd data, 500 mg was considered biologically active and sufficient to reach ≥95% target inhibition. **Conclusions:** MSC2156119J was well tolerated and showed antitumor activity. Recommended phase II dose (RP2D) is 500 mg 1x/d. Dose escalation was stopped at 2.8xRP2D (1400 mg/d). An MTD was not reached. Additional Pd and biomarker data (c-Met status by immunohistochemistry [IHC] and in situ hybridization) will be presented. Clinical trial information: NCT01014936.

**2522 Poster Highlights Session (Board #36), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 1b study of combined angiogenesis blockade with nesvacumab, a selective monoclonal antibody (MAb) to angiopoietin-2 (Ang2) and ziv-aflibercept in patients with advanced solid malignancies.** *Presenting Author: Kyriakos P. Papadopoulos, START Center for Cancer Care, San Antonio, TX*

**Background:** Nesvacumab (N) is a selective, human Ang-2 MAb, that potently blocks Ang2 signaling through the Tie2 receptor. Ziv-aflibercept (Z) is a recombinant human fusion protein and a decoy receptor for VEGF-A, VEGF-B, and placental growth factor. In mouse xenograft models, N+Z significantly inhibited tumor growth and angiogenesis compared to either agent alone. **Methods:** This phase 1b dose escalation study seeks to evaluate safety, pharmacokinetic (PK), and pharmacodynamics (PD), to find a recommended phase 2 dose (RD), and to explore antitumor activity of N+Z administered IV Q2W in patients (pts) with advanced solid tumors. Pts were treated at 1 of 5 dose levels of combination treatment [6mg/kg N + 2mg/kg Z (6N/2Z), 12N/2Z, 20N/2Z, 12N/4Z, 20N/4Z]. **Results:** 30 pts [11M/19F; median age 60.5 (range 25-89); ECOG PS 0(5)/1(25)] were enrolled. Two pts experienced DLT: esophageal variceal bleeding (12N/4Z) and prolonged proteinuria (20N/4Z). MTD was not defined. Most common treatment-related AEs (TRAEs) were HTN (19), fatigue (13), proteinuria (8), diarrhea (6), stomatitis (6), and decreased appetite (5). Grade ≥ 3 TRAEs were hypertension (11), proteinuria (2) and fatigue (1). Proteinuria was dose related, but resolved with dose modification. Four pts discontinued treatment due to AE: rectal obstruction, skin ulcers, esophageal variceal bleeding, and fatigue. Two pts achieved PR: 1 pt with CRC previously treated with bevacizumab (32+ wk) and 1 pt with OvCa (19 wks);15 patients achieved disease control with median duration of 29 wks; 7 pts experienced SD ≥16 wks. Across all dose levels, the PK and resulting systemic exposures of both N and Z were not affected by co-administration of the 2 agents. Each agent appeared linear and dose-proportional over the Q2W dosing interval. Total circulating serum Ang2 and VEGF appeared saturated following treatment at all dose levels. **Conclusions:** Co-administration of N+Z in patients with advanced cancer is generally well tolerated. TRAEs were as expected for anti-VEGF therapy. Enrollment into expansion cohorts with a planned dose of 20N/4Z with and without chemotherapy is ongoing. Clinical trial information: NCT01688960.

**2523 Poster Highlights Session (Board #37), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Evaluation of CNS and peripheral antitumor activity of ANG1005 in patients with brain metastases from breast tumors and other advanced solid tumors.** *Presenting Author: Nancy U. Lin, Dana-Farber Cancer Institute, Boston, MA*

**Background:** ANG1005 consists of 3 paclitaxel molecules covalently linked to a proprietary 19 AA peptide that targets the LRP1 receptor. This receptor is highly expressed on endothelial cells of the blood-brain barrier, where it mediates transcytosis, and on multiple tumor cells, where it mediates endocytosis. Thus, ANG1005 is both brain-penetrant and tumor-penetrant due to the LRP1-targeting peptide moiety. **Methods:** Ph I: Patients with advanced solid tumors and brain metastases received ANG1005 by IV infusion q3w at escalating doses of 30-700 mg/m$^2$ (n=56), including 20 patients at 650 mg/m$^2$ (MTD). Study objectives included safety/tolerability and overall tumor response (CNS and peripheral). Ph II: Patients with breast cancer brain metastases received ANG1005 by IV infusion q3w at a starting dose of 650 mg/m$^2$ (n=13) or 550 mg/m$^2$ (n=67). Study objectives included independent CNS and peripheral tumor response evaluations as per RECIST 1.1. **Results:** Safety and tolerability of ANG1005 were consistent with a taxane profile. In the Ph I study, 5/27 (18.5%) patients were observed with an overall PR and 11/27 (41%) with SD at doses ≥420 mg/m$^2$. Eighteen of these patients were evaluated for CNS response and 16 for peripheral response, based on unidimensional measurements. In the Ph II study, 80 patients were dosed, with 61 and 33 patients evaluable for CNS and peripheral tumor response, respectively (Table). Peripheral tumor reductions were observed in various metastatic tumor locations, such as liver, lung, bone and lymph nodes. In the Ph I study, 3 patients showed complete lesion disappearance in some of these organs. **Conclusions:** ANG1005 has shown antitumor activity in both CNS and peripheral metastases. Clinical trial information: NCT00539383.

**2524 Poster Highlights Session (Board #38), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A first-in-human phase I study of VGX-100, a selective anti-VEGF-C antibody, alone and in combination with bevacizumab in patients with advanced solid tumors.** *Presenting Author: Gerald Steven Falchook, Department of Investigational Cancer Therapeutics (Phase I Program), University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Tumoral escape following VEGF-A inhibition may be due to increased VEGF-C.VGX-100 is a novel fully human IgG1λ neutralizing monoclonal antibody targeting VEGF-C, inhibiting its activation of VEGFR-2 & VEGFR-3 receptors. Combination of VGX-100 with bevacizumab may result in synergistic effects by targeting multiple VEGF signalling pathways that mediate angiogenesis and lymphangiogenesis. **Methods:** An open label phase 1 study(NCT01514123) using a 3+3 design was initiated in patients (pts) with advanced solid tumors, ECOG PS 0-1, and adequate organ function. Pts were treated with escalating doses of intravenous VGX-100 monotherapy or combination VGX-100 + bevacizumab in sequential cohorts of 3-6 pts for assessment of safety, maximum tolerated dose (MTD), PK, anti-VGX-100 antibodies, angiogenic biomarkers, and tumor response. **Results:** 43 pts were enrolled and treated; 19 pts with single agent VGX-100 (1-30 mg/kg, QW) and 24 pts with combination VGX-100 (2.5-20 mg/kg, QW) and bevacizumab (5 or 10 mg/kg, Q2W). Overall, the most common grade 1-2 toxicities were fatigue, rash, nausea, anorexia and hypertension. One dose-limiting toxicity of grade 3 hypertension occurred during cycle 1 in a pt at the lowest combination dose level VGX-100 (2.5 mg/kg) and bevacizumab (5 mg/kg); a grade 3 worsening congestive heart failure in another pt was also reported in cycle 3 at dose level VGX-100 2.5 (mg/kg) and bevacizumab (10 mg/kg). At steady state, weekly doses ≥20 mg/kg of VGX-100 exceeded predicted human circulating VEGF-C levels and efficacy exposures in xenograft models. No binding antibodies to VGX-100 were seen. Infusion related reactions grade 1-2 at VGX-100 doses ≥10 mg/kg were controlled by routine premedication allowing escalation to the maximum planned dose of 30 mg/kg weekly; thus a MTD was not reached. A total of 5 of 42 evaluable pts (12%), achieved a best response of durable stable disease ≥4 months. **Conclusions:** VGX-100 alone and in combination with bevacizumab was well tolerated. PK data support weekly dosing. Further clinical evaluation of VGX-100 in combination with chemotherapy and other targeted agents is warranted. Clinical trial information: NCT01514123.

**2525 Poster Highlights Session (Board #40), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Results from the first-in-human (FIH) phase I study of RO5520985 (RG7221), a novel bispecific human anti-ANG-2/anti-VEGF-A antibody, administered as an intravenous infusion to patients with advanced solid tumors.** *Presenting Author: Manuel Hidalgo, START Madrid, Centro Integral Oncológico Clara Campal, Hospital Universitario Norte Sanchinarro, Madrid, Spain*

**Background:** RO5520985 is a novel bi-specific human IgG1 antibody, acting as a dual- targeting inhibitor of the two key angiogenic factors VEGF-A and Ang-2. RO5520985 led to strong inhibition of angiogenesis with enhanced vessel maturation and demonstrated potent tumor growth inhibition, superior to single pathway inhibitors in a panel of preclinical models. **Methods:** This is a 3-part FIH phase I study: Part 1 explores the safety/ tolerability, PK, PD and anti-tumor activity, to establish the recommended phase 2 dose (RP2D) and schedule, part 2 will assess PD effects in tumor tissues and part 3 the efficacy and safety in patients (pts) with rec. ovarian cancer. Results of part I are presented here, where pts were treated on a bi-weekly (Q2W) or weekly (QW) schedule at escalated dose levels (DLs). A Bayesian logistic regression model with overdose control guided the dose escalation. **Results:** 42 pts (18m/24f) were treated on 7 DLs: Q2W 3mg/kg (1pt), 6 (3), 12 (4), 19 (8), 30 (6); QW 10mg/kg (4), 20 (4), 30 (12). Median age: 63 years (range 25-76). Plasma concentrations (Cmax and AUC) increased proportionally, with low inter-individual variability for both schedules. The elimination $t_{1/2}$ was 7-9 days, based on Q2W. DCE-MRI of tumor lesions demonstrated moderate to significant reduction of vascular characteristics in 22/34 pts; within Q2W sustained effects were associated with 30 mg/kg. DW-MRI showed signs of on treatment necrosis and decreased cell density in 7 pts, particularly at 30 mg/kg. Depletion of circulating targets Ang-2 and VEGF-A was evident and apparently independent of dose and schedule. The most frequent AE of any grade (G) were hypertension (50%), asthenia (36%), headache (29%) and fatigue (19%). Most common AE ≥ G3 was hypertension (19%), predominantly associated with the weekly regimen (QW 30% vs. 9% Q2W). One DLT of pulmonary hemorrhage G5 occurred at 19mg/kg Q2W; a MTD was not reached. The progression-free rate at 8 weeks was 67% (Q2W) and 53% (QW). **Conclusions:** The RP2D and schedule was determined at 30mg/kg Q2W, where RO5520985 demonstrated an acceptable safety profile with favorable PK and PD effects. Clinical trial information: NCT01688206.

**2526 Poster Highlights Session (Board #41), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 1 first-in-human study of XMT-1107, a polymer-conjugated fumagillol derivative, in patients (pts) with advanced solid tumors.** *Presenting Author: Johanna C. Bendell, Sarah Cannon Research Institute/ Tennessee Oncology, Nashville, TN*

**Background:** Fumagillol derivatives are novel anti-angiogenic agents that inhibit methionine aminopeptidase 2 (MetAP2) rather than directly inhibiting VEGF signaling. Clinical development of fumagillol derivatives (e.g. TNP-470) has been limited by CNS toxicities and short-half life. XMT-1107 is a small molecule fumagillol derivative (XMT-1191) conjugated to PHF (Fleximer), a 70 kDa biodegradable, hydrophilic polymer that does not cross the blood-brain barrier. XMT-1107 is hypothesized to decrease CNS exposure to XMT-1191 and lead to prolonged pharmacokinetic (PK) and pharmacodynamic (PD) effect. **Methods:** This study (NCT01011972) explored the maximum tolerated dose (MTD), recommended phase II dose (RP2D), safety, PK, PD and antitumor activity of XMT-1107 as a single agent in pts with advanced solid tumors. XMT-1107 was given IV every 3 weeks at escalating doses using a 3+3 design. **Results:** 52 pts were enrolled in 14 dose cohorts ranging from 6-770 mg XMT-1191 equivalents/ $m^2$. MTD was not reached. Infusion volume limited the maximum administered dose to 770 mg/$m^2$. One DLT of grade 4 thrombocytopenia was seen at 245 mg/$m^2$; Grade 3 (n=4) and Grade 4 (n=3) thrombocytopenia were seen after Cycle 1 at 105 mg/$m^2$ and above. Grade 3 anemia was reported in 3 pts. 2 pts had Grade 3 transaminase elevation. There were 2 cases of ataxia: Grade 3 at 40 mg/$m^2$ in a pt with multiple CNS metastases evaluated as probably not related to study drug; and Grade 2 at 580 mg/$m^2$ evaluated as possibly related to study drug. Otherwise there were no CNS AEs. Free and conjugated XMT-1191 concentrations increased linearly with XMT-1107 dose. Evidence of MetAP2 inhibition was detectable in leukocytes at all dose levels, with complete inhibition throughout the 21 day cycle in 6/7 pts evaluated for PD at doses above 325 mg/$m^2$. 26 pts had a best response of stable disease with 12 pts stable for at least 4 cycles. **Conclusions:** XMT-1107 is well tolerated without significant CNS toxicity. The PK and PD profile supports once every 3 week intravenous dosing. The safety profile and preliminary antitumor effect supports further development in combination with chemotherapy and/or other anti-angiogenic agents. Clinical trial information: NCT01011972.

**2527 Poster Highlights Session (Board #42), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 1 dose-escalation study of BBI503, a first-in-class cancer stemness kinase inhibitor in adult patients with advanced solid tumors.** *Presenting Author: Scott Andrew Laurie, Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

**Background:** Targeting cancer stem cells (CSC) may hold significant therapeutic promise. BBI503 is an orally-administered first-in-class multi-kinase inhibitor with potent activity against CSC. Preclinically, potent anti-CSC and broad-spectrum anti-tumor and anti-metastatic activity was seen *in vitro* and *in vivo*. **Methods:** A first-in-man phase 1 dose escalation studyin patients with advanced cancer was conducted to determine safety, tolerability, RP2D, pharmacokinetics and preliminary anti-tumor activity of BBI503. BBI503 was given orally, continuously, in 28-day cycles until disease progression, unacceptable toxicity, or other discontinuation criteria were met. **Results:** Escalating doses from 10 mg to 450 mg once daily were administered to 26 patients. MTD was not reached. BBI503 was well tolerated, with mild GI adverse events, including grade 1, 2 diarrhea, abdominal cramping, nausea, anorexia. Grade 3 diarrhea was observed in 2 subjects at 450 mg once daily. BBI503 exhibited favorable pharmacokinetics with dose-dependent increases in plasma concentration up to 300 mg once daily. Inhibition of cancer stem cell markers was observed in biopsied tumor tissues. Of 20 evaluable patients, 11 (55%) had stable disease (SD) with a median time to progression of 16 wks. Of those patients with SD, tumor regression and/or prolonged stable disease (≥ 16 weeks) were observed in 10 (50% of all enrolled patients) (see Table). Clinical trial information: NCT01781455.

| Diagnosis | Number of patients evaluable | Number of patients with minor regression or SD ≥ 16 wks. |
|---|---|---|
| Colorectal cancer | 5 | 3 |
| Head and neck cancer | 2 | 2 |
| Hepatocellular carcinoma | 2 | 1 |
| Renal cell carcinoma | 1 | 1 |
| Gastric/GEJ adenocarcinoma | 1 | 1 |
| Pancreatic neuroendocrine | 1 | 1 |
| Non-small cell lung cancer | 1 | 1 |

**2528^ Poster Highlights Session (Board #43), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase I study of the single-agent CDK4/6 inhibitor LEE011 in pts with advanced solid tumors and lymphomas.** *Presenting Author: Jeffrey R. Infante, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

**Background:** LEE011, an orally bioavailable, highly specific CDK4/6 inhibitor, causes cell cycle arrest and tumor growth inhibition in multiple preclinical models with intact retinoblastoma protein (pRb+). **Methods:** Pts withpRb+ advanced solid tumors and lymphomas were treated with escalating doses of LEE011 on a 21-of-28-d or continuous schedule. Dose escalation was guided by a Bayesian Logistic Regression Model with overdose control principle. Primary objective: to establish the MTD and/or RP2D of LEE011. Secondary objectives: safety, efficacy, PK, and PD. **Results:** As of Jan 17, 2014, 132 pts were treated; 85 during escalation (50–1200 mg/d) and 47 during RP2D expansion. The following results are from dose escalation (data cut-off: July 2, 2013). Ten DLTs were observed in 10 pts: neutropenia (3 pts); asymptomatic thrombocytopenia (2 pts); mucositis, pulmonary embolism, hyponatremia, QTcF prolongation (>500 ms), and increased creatinine (1 pt each). The MTD and RP2D were declared as 900 and 600 mg/d on 21-of-28-d schedules, respectively. The most common study drug-related AEs (all grades) were neutropenia (40%), leukopenia (36%), nausea (35%), and fatigue (27%). G3/4 AEs included neutropenia (19%), lymphopenia (14%), and leukopenia (12%). Asymptomatic QTcF prolongation (>450 ms) was seen at doses ≥600 mg/d: in 10% of pts at 600 mg/d and in 27% of pts at doses >600 mg/d. Plasma exposure increases were slightly higher than dose proportional; mean $T_{1/2}$ at RP2D was 36.2 h. Paired skin biopsies from 40 pts showed reductions of ≥50% from baseline in Ki67 and phospho-pRb in 55% and 42% of samples, respectively. Among 70 evaluable pts, 2 (2.9%; 600 mg/d) had confirmed PRs: 1 pt with *PIK3CA*-mut, *CCND1*-amp, ER+ breast cancer; 1 pt with *BRAF*/*NRAS*-WT, *CCND1*-amp melanoma. SD for ≥4 and ≥6 cycles was seen in 26% and 14% of pts, respectively. **Conclusions:** LEE011 showed an acceptable safety profile, dose dependent plasma exposure, evidence of target inhibition and preliminary signs of clinical activity. The study expansion is confirming safety and efficacy. Further studies are investigating LEE011 as a single agent (neuroblastoma and malignant rhabdoid tumors) and in combination with other agents (breast cancer and melanoma). Clinical trial information: NCT01237236.

**2529 Poster Highlights Session (Board #44), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase I study of DMOT4039A, an antibody-drug conjugate (ADC) targeting mesothelin (MSLN), in patients (pts) with unresectable pancreatic (PC) or platinum-resistant ovarian cancer (OC).** *Presenting Author: Colin D. Weekes, University of Colorado Cancer Center, Aurora, CO*

**Background:** MSLN is a tumor antigen over-expressed in PC and OC. The ADC DMOT4039A is a humanized IgG1 anti-MSLN monoclonal antibody and anti-mitotic agent, MMAE, that shows anti-proliferative activity in xenograft models. **Methods:** This study evaluated safety, PK, and activity of DMOT4039A (0.2-2.8 mg/kg) given every 3 weeks (q3w) to pts with PC or OC. A traditional 3+3 design was used for dose escalation followed by expansion by disease ($2^{nd}$ line in PC) at the recommended Phase 2 dose (RP2D). Anti-tumor response was evaluated per RECIST 1.1, and serum CA19-9 or CA125. Tumor MSLN expression was determined in archival tissue by immunohistochemistry (IHC). **Results:** As of 5 Dec 2013, 49 pts have enrolled (30 PC; 19 OC), median age 63 (range 39-75), PS 0-1, median number of prior regimens 2 (1-7) in PC, and 5 (1-16) in OC. Pts received a median of 3 (range 1-14) cycles of DMOT4039A. The MTD was 2.4 mg/kg, with 2 DLTs at the maximum dose level of 2.8 mg/kg: hyperglycemia (G3) and hypophosphatemia (G3). The most common related AEs (all grades) were fatigue (49%), nausea (37%), diarrhea (29%), vomiting (27%), decreased appetite (22%), abdominal pain, and constipation (both 20%). The majority of AEs were G1-2. Seven related SAEs (fatigue, hyperglycemia, hypophosphatemia, infection, pyrexia, tachycardia, and vomiting) were observed in 2 pts. ADC exposure was dose-proportional over all dose levels. Four pts (8%) had a confirmed partial response (PR), including 1/19 PC (no IHC sample) and 3/10 OC pts (IHC 2+/3+) treated at the RP2D of 2.4 mg/kg q3w. One PC pt without RECIST response showed > 50% decrease from baseline in CA19-9 levels; 7 OC pts showed > 50% decrease in CA125. MSLN expression was IHC 2+/3+ in 64% of in the PC cohort (25 pts), and 91% in the OC cohort (23 pts), in part due to diagnostic selection for enrollment in expansion cohorts. IHC assessment was unavailable for 2 pts with PC with RECIST / CA19-9 response; all patients with OC with RECIST/CA125 responses were IHC 2/3+. **Conclusions:** DMOT4039A administered at 2.4 mg/kg q3w has a tolerable safety profile and encouraging anti-tumor activity in both PC and OC, supporting further evaluation in these diseases. Clinical trial information: NCT01469793.

**2530 Poster Highlights Session (Board #45), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A phase 1b study of the cancer stem cell inhibitor BBI608 administered with paclitaxel in patients with advanced malignancies.** *Presenting Author: Matthew Hitron, Boston Biomedical, Inc., Cambridge, MA*

**Background:** BBI608 is an oral first-in-class cancer stemness inhibitor which inhibits the Stat3, β-catenin and Nanog pathways. Preclinically, potent, broad-spectrum anti-tumor and anti-metastatic activity was observed *in vitro* and *in vivo,* alone and in combination with other agents. BBI608 with paclitaxel showed marked synergy *in vivo*. In a phase I study, BBI608 monotherapy was well tolerated with encouraging signs of anti-tumor activity and a RP2D of 500 mg BID. **Methods:** A phase Ib dose-escalation study in patients with advanced cancer was undertaken to determine safety, tolerability, RP2D, and preliminary anti-cancer activity of BBI608 plus weekly paclitaxel. BBI608 was administered in 3 escalating dose cohorts (200 mg BID, 400 mg BID, 500 mg BID) in combination with paclitaxel (80 mg/m$^2$ weekly; 3 of every 4 weeks) until progression of disease, unacceptable toxicity, or other discontinuation criteria was met. **Results:** 24 patients were enrolled. The BBI608 monotherapy RP2D could be given in combination with paclitaxel in full dose. MTD was not determined. No new adverse events were observed, and the safety profile was similar to that of each agent as monotherapy. The most common adverse events included grade 1 and 2 diarrhea, abdominal cramps, nausea, vomiting. Grade 3 events related to protocol therapy occurred in 4 patients and included diarrhea, dehydration, and weakness. No significant pharmacokinetic interactions were observed. Disease control (CR+PR+SD) was observed in 10 of 15 (67%) evaluable patients. Of 5 patients with refractory gastric/GEJ adenocarcinoma enrolled, 2 had PR (48% and 45% regressions), 1 had SD with 25% regression, and 2 (who failed prior taxane) had prolonged SD ≥ 24 wks. Tumor regression or SD ≥ 16 wks was also seen in patients with platinum-resistant ovarian cancer (1 of 2), melanoma (2 of 3), bladder CA (1 of 3) and NSCLC (1 of 1). **Conclusions:** This phase Ib study demonstrated that BBI608 and weekly paclitaxel can be safely combined at full dose. Encouraging anti-tumor activity was observed across several tumor types, particularly in patients with gastric and GEJ adenocarcinoma. Clinical trial information: NCT01325441.

**2531 Poster Highlights Session (Board #46), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**ProGem1: A phase I/II study of a first-in-class nucleotide, Acelarin, in patients with advanced solid tumors.** *Presenting Author: Essam Ahmed Ghazaly, Centre for Haemato-Oncology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

**Background:** Acelarin (NUC-1031) is a first-in-class nucleotide designed to overcome key cancer cell resistance by having nucleoside transporter-independent cellular uptake, activity independent of deoxycytidine kinase and being resistant to cytidine deaminase inactivation. **Methods:** The ProGem1 study objectives were to establish the MTD, PK, safety profile and clinical activity of Acelarin in patients with advanced, rapidly progressing treatment-resistant or refractory solid tumours. Acelarin was administered by 10 minute IV injection on a weekly (D1, 8 and 15 of a Q28 schedule), or twice weekly schedule, for 6 cycles. Acelarin doses ranged from 375 to 1000 mg/m$^2$. Compassionate use was allowed after 6 cycles for those benefiting from treatment. **Results:** To date, 29 patients (pts), with a mean age of 57 yrs (range 35-73 yrs), have been enrolled with: ovarian (5), breast (3), colorectal (3), mesothelioma (3), CUP (3), uterine (3), pancreatic (3), cholangiocarcinoma (2), lung (2), and other (2) primary disease. 26 pts had metastatic disease. Pts had received a mean of 2.6 prior lines of therapy (range 1-7). DLTs were: G3 raised AST in 1/6 at 725mg/m$^2$; G4 thrombocytopenia in 1/6 at 750mg/m$^2$; G4 injection site pain in 1 at 1000mg/m$^2$; and G4 thrombocytopenia in 1/6 at 375mg/m$^2$ twice weekly. The most common (>20%) adverse events (AEs) were grade 1-2, and reversible: thrombocytopenia (22%), fatigue (22%), and hypoalbuminaemia (21%). High intracellular levels of the active anti-cancer agent dFdCTP were rapidly achieved and maintained for 24 hours, confirming Acelarin's ability to bypass the key resistance pathways. Responses evaluated by RECIST were: 5 PR (17%); 13 SD (45%); with an ITT Disease Control Rate (DCR) of 62%; and, an OTA DCR of 90% in patients refractory or resistant to standard chemotherapy. All 6 pts who received ≥2 cycles of Acelarin, and were refractory / relapsed on prior gemcitabine, achieved disease control. Disease control in all patients has been durable (range 3 to >12 months; mean 5.8 months). **Conclusions:** Acelarin is a well tolerated, first-in-class nucleotide that has achieved a high, durable Disease Control Rate (ITT 62%; OTA 90%) in a wide range of advanced refractory / resistant cancers. Clinical trial information: NCT01621854.

**2532 Poster Highlights Session (Board #47), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**First-in-human, pharmacokinetic (PK), and pharmacodynamics (PD) phase I study of Debio1143 (AT-406) in patients with advanced cancer: Final results.** *Presenting Author: Herbert Hurwitz, Duke University Medical Center, Durham, NC*

**Background:** Inhibitors of apoptosis proteins (IAPs) modulate multiple processes, including caspases activation and NF-κB signalling. Expression and/or overexpression of IAPs have been reported for a variety of tumour types and are correlated with tumour growth and resistance to apoptosis induced by standard chemo and radiation therapies. The small molecule Debio 1143 (formerly AT-406) is a potent orally-active IAP antagonist able to promote apoptosis in tumour cells by restoring caspase activity, and modulating NF-κB signalling and TNFα effects in various preclinical models. **Methods:** This first-in-human study in patients with advanced cancer used an adaptive design for dose titration. Debio 1143 was given orally once daily on days 1-5 every 2 or 3 weeks. The starting dose of 5 mg was escalated by 100% in consecutively enrolled single patients until related grade 2 toxicity occurred. This triggered expansion to cohorts of 3 and subsequently 6 patients as well as reduction of dose increments to 50%. The MTD was exceeded when any two patients within the same cohort experienced dose-limiting toxicity (DLT). On days 1 and 5, PK and PD samples were taken. **Results:** Thirty-one patients received doses from 5 to 900 mg. Only one DLT (G3 reversible ALT elevation) was reported at 180 mg. Most common adverse events of any grade deemed related to study drug were fatigue (26%), nausea (23%), and vomiting (13%). Average $t_{max}$ and $t_{½}$ were about 1 and 6 h, respectively. Exposure showed inter-individual variability but increased generally proportionally with dose for doses ranging between 80 mg and 900 mg, without accumulation over 5 days. Degradation of cIAP-1 in surrogate tissue was observed at all doses >80 mg. Plasma MCP-1 increased at 3-6 h post-dose and caspase-cleaved fragment of cytokeratin 18 (M30) significantly increased on day 5. Five patients (17%) had stable disease as best response and 1 patient with metastatic melanoma had an 11% reduction in target lesion dimensions. **Conclusions:** The MTD was not reached and 900 mg was the highest tested dose. Debio 1143 was safely administered, with confirmed on-target PD effects at dose level >80 mg and signs of antitumor efficacy. Clinical trial information: NCT01078649.

**2533^ Poster Highlights Session (Board #48), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**VE-BASKET, a first-in-kind, phase II, histology-independent "basket" study of vemurafenib (VEM) in nonmelanoma solid tumors harboring BRAF V600 mutations (V600m).** *Presenting Author: David Michael Hyman, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Low prevalence of V600m in non-melanoma cancers requires a novel trial design to assess the activity of BRAF inhibitors. We undertook a histology-independent, "basket" study of VEM in BRAFV600m-positive cancers (NCT01524978). Six disease cohorts were prespecified, remaining tumors were enrolled to a 7th "all-comers" cohort. Here we present preliminary efficacy and safety data for the non-small cell lung cancer (NSCLC), cholangiocarcinoma (CLC), and Erdheim-Chester disease (ECD)/Langerhans cell histiocytosis (LCH) cohorts. **Methods:** Multicenter Simon 2-stage adaptive design in adult patients (pts; majority pretreated) with metastatic V600m-positive cancers receiving VEM (960 mg bid) until investigator (INV)-assessed disease progression (PD) or unacceptable toxicity. Primary endpoint is INV-assessed response rate (RR) at week 8 (RECIST v1.1). Secondary objectives include overall RR, clinical benefit rate, duration of response, progression-free survival, overall survival, and safety. **Results:** 95 pts have been enrolled (04/2012-12/2013). Median treatment duration (days, range) was 121 (32-449) in NSCLC, 61 (29-451) in CLC, 168 (39-435) in ECD/LCH. In NSCLC, 8/19 pts had unconfirmed partial responses (uPRs) (wk 8, stage II) and 8/19 pts stable disease (SD). 6 uPRs were subsequently confirmed. At stage I CLC analysis, 4/7 pts had SD, 3/7 pts had PD (wk 8). By wk 24, 2 pts converted to PR. At stage I ECD/LCH analysis, 7 pts were enrolled (1 pt not evaluable for response). A confirmed CR was observed in 1/6 pts and SD in 5/6 pts. By wk 16, 2 pts converted to PR. Moving to stage II, 3 further pts have been enrolled, showing 1 SD and 2 PR at wk 8. All 9 evaluable ECD/LCH pts had shrinkage of target lesions, median change (%, range) from baseline was -18% (5-100) at wk 8 and -30% (7-100) at wk 16. Safety data were consistent with prior pivotal VEM studies. **Conclusions:** Histology-independent trials of rare molecularly defined populations are feasible and yield important signals of activity. VEM has promising activity in pts with V600m-positive NSCLC, CLC, and ECD/LCH. Updated efficacy results from all patients will be provided at the time of ASCO. Clinical trial information: NCT01524978.

**2534 Poster Highlights Session (Board #49), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Next-generation sequencing (NGS) in 936 patients (pts) with advanced cancers to prospectively guide clinical trial selection: The Sarah Cannon Research Institute (SCRI) experience.** *Presenting Author: Todd Michael Bauer, Sarah Cannon Research Institute/Tennessee Oncology, PLLC, Nashville, TN*

**Background:** With an increasing number of clinical trials testing new molecularly targeted drugs in pts with specific molecular alterations, there is a growing need for comprehensive molecular profiling in community-based practices where nearly 80% of pts in the United States are treated. In October 2012, SCRI launched an initiative to identify molecular alterations with proven or potential therapeutic significance to match pts to mutation-selective clinical trials. **Methods:** Samples from consenting pts were analyzed using NGS (CLIA/CAP laboratory) to detect hotspot mutations in 35 cancer-related genes (1000x average coverage). Results were reported to the treating physician within 12 calendar days, used to inform treatment decisions, and captured in a database to enable correlation with clinical outcomes. **Results:** As of December 31, 2013, 1040 pts consented; 936 (90%) had sufficient material for NGS. At least one mutation was identified in 420 pts (45%). To date, 206 of the 936 pts (22%) have been prospectively enrolled on clinical trials; 91 of these (44%) had no mutations identified, and 12 pts (6%) had non-actionable mutations. One hundred three pts (50%) had actionable mutations. A total of 50 pts (24%) were enrolled to at least one treatment trial of agent(s) matched to their mutation (table, most common genes shown). The remaining 53 pts were enrolled onto trials not matched to genetic alterations (including immunotherapy, 17; antibody-drug conjugate, 8). Response rates and durations will be presented. **Conclusions:** This first effort to prospectively identify and match pts to clinical trials by NGS in a community practice setting establishes a model to facilitate development of therapies targeting actionable mutations. Nearly half of the pts tested had at least one mutation, and depending on the mutation identified, 10-25% enrolled on a matched trial.

| Actionable mutation | Total pts identified (n) | Pts enrolled on any trial | Pts enrolled on a trial matched to mutation |

**Phase 1 dose escalation, food effect, and biomarker study of RG7388, a more potent second-generation MDM2 antagonist, in patients (pts) with solid tumors.** *Presenting Author: Lillian L. Siu, Princess Margaret Cancer Centre, Toronto, ON, Canada*

**Background:** RG7388 is an oral pyrrolidine designed as a potent antagonist of MDM2. Preclinical studies demonstrate p53 activation, tumor growth inhibition, & increased life span in xenograft models. **Methods:** A phase 1 study in solid tumor pts was conducted to determine the maximum tolerated dose (MTD), safety, pharmacokinetics (PK), food-effect (FE) & biomarker (BM) activity of RG7388. Administration schedules of once weekly (qwk) x 3, & daily (3 or 5d) every 28d were evaluated. Following initial accelerated titration, a modified continual reassessment method-escalation with overdose control (EWOC) requiring at least 2 DLT evaluable pts per cohort, was used to guide escalation. Enrolment in BM cohorts was initiated at the prior dose level once EWOC was triggered. PK, baseline p53 & MDM2 status, & serum MIC-1 (a marker for p53 activation) were measured for all pts. The FE cohort consisted of 10 pts in a randomized, 3-way crossover, partial-replicate design. In BM cohorts, tumor biopsies were collected pre-dose & during cycle 1 for analysis of p53 activation, anti-proliferative & pro-apoptotic effects of RG7388. Correlative changes in FLT-PET imaging were also assessed. **Results:** Accrual to dose escalation, FE & core BM cohorts is complete: 46 pts enrolled on the qwk schedule (7 dose levels from 100 - 3200 mg qwk x 3); 49 pts enrolled on the daily schedule: 34 pts treated for 5d at 8 dose levels (100 - 1200 mg daily) & 15 pts treated for 3d at 2 dose levels (1000 & 1600 mg daily). Nausea/vomiting & myelosuppression (more frequent in the daily dosing schedule & associated with PK exposure) were the DLTs. MTD per schedule was: 1600 mg bid qwk x 3; 500 mg bid x 3d & 500 mg qd x 5d. Dose-PK exposure was proportional up to 2,400 mg/d; $t_{½}$: ~ 1 d. No major effect of high-fat food on PK exposure was seen. MIC-1 activation was seen at the lowest dose evaluated. Preliminary BM results suggest that p53 activation is greater with 5d dosing than with other schedules at respective MTDs. Stable disease for 17, 22 & 23+ months has been seen in sarcoma pts. **Conclusions:** RG7388 demonstrates p53 activation which may be dose & schedule dependent and warrants further evaluation. Safety, PK, FE, PD & BM results will be presented. Clinical trial information: NCT01462175.

**2536 Poster Highlights Session (Board #51), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**Risks and benefits of phase I liver dysfunction studies: Should patients with severe liver dysfunction be included in these trials?** *Presenting Author: Selena Juarez Stuart, The University of Texas Health Science Center at San Antonio, San Antonio, TX*

**Background:** Liver dysfunction studies on novel oncologic agents are necessary to evaluate effects of metabolism and pharmacokinetics, but data regarding risks and benefits of these trials in cancer patients with liver dysfunction is lacking. Our objective was to evaluate clinical benefit rates (CBR), death on study (DOS) rates, and rates of G3/4 toxicity for patients enrolled on liver dysfunction Phase I studies. **Methods:** We performed a retrospective review of non-pediatric Phase I hepatic dysfunction studies in patients with solid tumors from 2003-2013 at a single institution. We report the CBR, defined as response rate (RR) plus rate of stable disease (SD), rates of DOS from all causes, and rates of drug related G3/4 toxicity. **Results:** We analyzed 10 trials involving a total of 126 patients. In 9 of the 10 studies, patients were stratified based on degree of hepatic dysfunction according to the NCI Organ Dysfunction Working Group (NCI-ODWG) criteria. The most common tumor types were colorectal cancer (37%), hepatocellular carcinoma (18%), pancreatic adenocarcinoma (7%), and lung cancer (5%). Median age was 58 years (23-81). Liver dysfunction was from liver metastases in 61% and underlying cirrhosis in 19%. Therapeutic classes included targeted therapies in 7 trials and cytotoxics in 3 studies. The ORR among all patients was 2% (CR 0%/PR 2%). An additional 21% of patients had SD. The overall DOS rate was 15%. Overall G3/4 toxicity rate was 34% with hematologic toxicity being most common (21%). The CBR, DOS rates, and G3/4 toxicity rates were calculated for each group of patients by degree of liver dysfunction (see Table). **Conclusions:** In patients with severe liver dysfunction, CBR from Phase I studies was <1% while risk of death on study was 25%. Therefore, patients with severe liver dysfunction may not be ideal candidates for these types of trials. Further analysis of the data is needed to identify prognostic factors that further predict risk of death on study.

| Degree of liver dysfunction | # of patients (%) | CBR (%) | DOS rate (%) | #cycles completed median (range) | G3/4 toxicity (%) |
|---|---|---|---|---|---|
| **Normal** | 17 (13) | 53 | 12 | 4 (1-62) | 24 |

**2537 Poster Highlights Session (Board #52), Fri, 1:00 PM-4:00 PM and 4:30 PM-5:45 PM**

**A first-in-class, first-in-human phase I trial of KPT-330 (selinexor), a selective inhibitor of nuclear export (SINE) in patients (pts) with advanced solid tumors.** *Presenting Author: Morten Mau-Soerensen, Department of Oncology, Rigshospitalet, Copenhagen, Denmark*

**Background:** KPT-330 is an inhibitor of Exportin 1 (XPO1) that forces the nuclear retention and activation of over 10 Tumor Suppressor Proteins (TSPs) resulting in tumor cell death in preclinical models. **Methods:** KPT-330 was administered orally for 8-10 doses in a 28-day cycles. Cycle 1 was the DLT period. Pharmacokinetic (PK) analyses were performed. XPO1 mRNA, a pharmacodynamic (PDn) marker of XPO1 inhibition, was assessed in blood. Tumor biopsies were performed. Response was evaluated every 2 cycles (RECIST 1.1). All pts had to have documented progressive disease on study entry. **Results:** 103 pts (59/44 M/F; median age 61 yrs; median treatment regimens: 3; ECOG PS 0/1: 24/79) received KPT-330 across 12 dose levels (3 to 65 mg/m$^2$) in dose escalation and expansion cohorts. 2 DLTs (fatigue, dehydration) at 40mg/m$^2$ on the 10-doses/cycle regimen; 1 DLT (nausea) at 35mg/m$^2$ on the 8-doses/cycle (twice weekly, BIW) regimen were noted. Dosing at 65mg/m$^2$ BIW is ongoing (MTD not reached). Grade 3/4 non-DLT, drug related, adverse events (AEs) in cycle 1 in >2 pts: hyponatremia (9%), fatigue (6%), thrombocytopenia (5%), vomiting (4%), anemia (3%), nausea (3%). The most common grade 1/2 AEs in cycle 1: nausea (63%), fatigue (52%), anorexia (42%) and vomiting (37%). The PK and PDn showed dose-dependent increases in $C_{max}$ / $AUC_{0\text{-}inf}$ and XPO1 mRNA increases. Tumor biopsies showed nuclear localization of TSPs (p53, FOXO3A, IkB) and apoptosis induction. Of 87 response evaluable pts, 3 partial responses were observed in colorectal cancer (KRAS mutant), melanoma (BRAFwt) and ovarian adenocarcinoma (OvCa) pts. Stable disease (SD) was noted in 39 pts, with 12 pts for ≥6 months. Five of 5 evaluable pts with hormone and chemotherapy refractory prostate cancer (HRPC) achieved SD; all pts still on study 70-240+ days. Nine of 13 evaluable pts with squamous head and neck cancer (HNCa) achieved SD with 7 on study 75-290+ days. **Conclusions:** Oral KPT-330 has a manageable toxicity profile and prolonged dosing is feasible. Preliminary signals of durable antitumor activity were observed. The recommended dose for phase 2 is ≥50mg/m$^2$ BIW. Phase 2 studies in HNCa, OvCa, and HRPC are planned. Clinical trial information: NCT01607905.

**2538 General Poster Session (Board #1), Sun, 8:00 AM-11:45 AM**

**Relationships between occurrence of chills and clinical outcome during NGR-hTNF therapy.** *Presenting Author: Alessandra Bulotta, Department of Oncology, Istituto Scientifico San Raffaele, Milan, Italy*

**Background:** NGR-hTNF, a selective antivascular agent, quickly and transiently modulates the release of systemic cytokines/chemokines. Intravenous infusion of NGR-hTNF is characterized by onset of an early on-target adverse effect consisting of short-lived chills **Methods:** The impact of the onset of chills over treatment on the clinical outcome was assessed by a pooled analysis of individual patient data from 7 phase II trials. Dataset included 336 patients who had received NGR-hTNF 0.8 $\mu$g/m$^2$ every 3 weeks (q3w) or weekly (q1w) as single agent (mesothelioma, colon and liver cancer) or combined with doxorubicin (ovarian cancer, sarcomas and SCLC) or with platinum-based regimen (NSCLC). In all trials, tumor response by RECIST criteria was assessed q6w until disease progression. To mitigate guarantee-time bias, onset of chills was treated as a time dependent covariate in Cox models fitted to estimate unadjusted and adjusted hazard ratios (HR). Endpoints of interest were progression free survival (PFS) and overall survival (OS). Median follow-up time was 26.9 months **Results:** 204 patients (61%) experienced chills on treatment, while 132 (39%) did not, with rates of all-grade events ranging from 40% to 76% among different trials (p=0.008). According to severity, 64% of patients had grade 1, 34% grade 2 and 2% grade 3. By timing of chills appearance, 88% occurred over the first six weeks and 12% later. Incidence was higher with q1w than with q3w dosing schedule (70% vs 56%; odds ratio, 1.78; p=0.02). Baseline characteristics (chills vs no-chills groups): median age, 63 vs 61; male, 58% vs 42%; PS ≥ 1, 67% vs 33%; prior lines ≥ 1, 66% vs 34%. Among baseline factors, logistic regression analysis retained only previous treatment associated with higher incidence of chills (odds ratio, 2.0; p=0.003). Onset of chills, used as a time-varying covariate, significantly correlated with improved PFS (HR=0.79; 95% CI, 0.69-0.91; p=0.001) in multivariable analysis adjusted for baseline factors and stratified on trial. Occurrence of chills remained also independently associated with better OS (HR=0.88; 95% CI, 0.79-0.99; p=0.03) **Conclusions:** Early onset of chills on treatment with NGR-hTNF may be associated with more prolonged clinical benefit Clinical trial information: NCT00994097 and others.

**2539 General Poster Session (Board #2), Sun, 8:00 AM-11:45 AM**

**Phase I trial of FOLFIRI in combination with sorafenib and bevacizumab in patients with advanced gastrointestinal malignancies.** *Presenting Author: Joleen Marie Hubbard, Mayo Clinic, Rochester, MN*

**Background:** Sorafenib inhibits various pro-angiogenesis pathways including PDGFR-B, a factor associated with resistance to anti-VEGF therapy. A previous phase II trial in patients with chemorefractory metastatic CRC demonstrated a 63% disease control rate with a combination of bevacizumab (BEV) and sorafenib. This phase I trial sought to determine the MTD of BEV and sorafenib combined with standard cytotoxic therapy for advanced gastrointestinal (GI) cancers. **Methods:** Patients with advanced GI malignancies appropriate for irinotecan-based therapy were enrolled (14 with CRC, 3 gastroesophageal). A standard 3 + 3 design was used with 3 escalating sorafenib dose levels (DL): (1) 200 mg po daily, days 3-7, 10-14; (2) 200 mg po twice daily, days 3-6, 10-13; and (3) 200 mg po twice daily, days 3-7, 10-14. FOLFIRI: irinotecan 180 mg/m$^2$ d1, leucovorin 400 mg/m2 d1, 5-fluorouracil (FU) bolus 400 mg/m$^2$ d1, 5-FU infusion 2400 mg/m$^2$d1-2 and BEV 5 mg/kg d1. 1 cycle = 14 days. **Results:** Seventeen pts were enrolled, median age of 56 (range 32 and 81). Two pts were replaced, as they did not complete DLT evaluation, leaving 15 evaluable pts. Four evaluable pts at DL1 and 6 pts at DL2 had no DLTs. At DL 3, the first cohort of 3 pts did not experience any DLTs. In the second cohort of 3 pts, 2 pts experienced DLTs (asymptomatic G3 hypophosphatemia, G3 dehydration and diarrhea). MTD was determined to be DL2: sorafenib 200 mg PO twice daily, days 3-6, 10-13 combined with FOLFIRI and BEV at standard doses. Of the 15 evaluable pts, 4 pts had PR, 8 pts had SD as best response, 1 pt had PD, and 2 pts discontinued treatment prior to first tumor assessment. The median number of cycles was 12 (range 1 - 46). Three pts with CRC had disease control > 12 months. **Conclusions:** The MTD of this regimen is sorafenib 200 mg PO twice daily, Days 3-6,10-13 combined with standard doses of FOLFIRI and BEV. Dual VEGF inhibition combined with cytotoxic therapy may provide prolonged disease stabilization for select patients with advanced GI malignancies. Clinical trial information: NCT01383343.

**2540 General Poster Session (Board #3), Sun, 8:00 AM-11:45 AM**

**Phase 1 first-in-human (FIH) study of nesvacumab (REGN910) a fully human and selective angiopoietin-2 (Ang2) monoclonal antibody (MAb): Results from hepatocellular carcinoma (HCC) cohort.** *Presenting Author: Robin Kate Kelley, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

**Background:** Nesvacumab (N) is an Ang2 selective, human MAb that potently blocks signaling through the Tie2 receptor, inhibiting tumor angiogenesis and growth. In mouse xenograft models of human solid tumors, N inhibits tumor growth. In the dose-escalation (DE) portion of this trial [JCO 31, 2013 (suppl; abstr 2517)] anti-tumor activity (significant decline AFP) was observed in a patient (pt) with HCC, prompting expansion in this indication. **Methods:** Safety and anti-tumor activity are reported from all pts with HCC treated in the FIH trial in DE and expansion phases combined. In DE, single agent N was administered IV Q2W at 1 of 5 dose levels starting at 1 mg/kg; HCC expansion at 2 doses, 12, and 20 mg/kg Q2W, were studied. **Results:** 15 pts with HCC were enrolled: [11M/4F; median age 69 (range 24-82); ECOG PS 0=6/1=9; prior sorafenib 60%]. Dose levels were: 1 (n=1), 12 (n=6) and 20 mg/kg (n=8). Median number of doses administered was 8 (range 1-23). No pts experienced protocol defined DLTs. Most common adverse events (AEs) (all/related) were fatigue (8/5), diarrhea (5/0), decreased appetite (4/2), dizziness (4/0), nausea (4/2), abdominal pain (3/1), vomiting (3/1), back pain (3/0) and dyspnea (3/0); 9 grade ≥3 events reported in 7 pts, of which 3 events were assessed as treatment related: abdominal pain, infusion-related reaction, and retinal detachment, each reported in a single pt. One pt treated with 20 mg/kg experienced a non-severe lower GI bleed, assessed as not treatment related. No objective responses were observed. Two pts experienced a ≥ 50% decline in AFP (1 pt >90%). Nine of 15 pts achieved best response of SD (median duration 24 wks); 6 pts achieved SD for ≥ 20 wks. Notably, 5 of 8 pts treated at 20 mg/kg achieved best response of SD; median duration of 40 wks. **Conclusions:** Single-agent N up to 20mg/kg Q2W was generally tolerated in pts with HCC, with primarily mild and moderate AEs, independent of dose. SD occurred in 60% of pts across doses, with prolonged SD at highest dose. The safety profile supports combination with chemotherapy and/or other anti-angiogenic agents. Expansion in pts with HCC receiving N in addition to sorafenib is ongoing. Clinical trial information: NCT01271972.

**2541 General Poster Session (Board #4), Sun, 8:00 AM-11:45 AM**

**Pharmacodynamic activity of the AKT inhibitor AZD5363 in patients with advanced solid tumors.** *Presenting Author: Paul Elvin, AstraZeneca Oncology Innovative Medicines, Macclesfield, United Kingdom*

**Background:** AZD5363 is an ATP competitive small molecule inhibitor of AKT1, AKT2 and AKT3 and is currently in phase 1 and 2 clinical trials in breast, gynaecological and prostate cancer. In pre-clinical tumour xenograft models, AZD5363 inhibited the phosphorylation of AKT substrates PRAS40 and GSK3$\beta$ in tumour tissue. **Methods:** Tumour biopsies were obtained from patients with advanced solid tumours in Western and Japanese phase 1 studies. Pharmacodynamic activity of AZD5363 in formalin fixed paraffin embedded tumour tissue was measured by immunohistochemistry (IHC) for total and phospho-AKT, phospho-PRAS40 and phospho-GSK3$\beta$ using commercially available antibodies. IHC was quantified by H-score (sum of % tumour cells with 0=negative; 1=weak; 2=moderate; 3=strong staining) based on the results from 3 sections for each antibody. Inhibition of PRAS40 phosphorylation in hair follicles obtained 4 hours after dosing was measured by immunofluorescence and quantified by image analysis. **Results:** Paired tumour biopsies at baseline and after approximately 2 weeks dosing were obtained from patients on continuous and intermittent dosing schedules. Inhibition of GSK3$\beta$ and PRAS40 phosphorylation of >30% or >50% respectively was seen in 4/7 (GSK3$\beta$) and 2/8 (PRAS40) tumours at tolerated doses of AZD5363. Phospho-AKT was increased in 4/7 (AKT-Thr308) and 4/5 (AKT-Ser473) tumours commensurate with the mechanism of action of AZD5363. Hair follicle PRAS40 phosphorylation was reduced by >50% in 22/71 patients and showed evidence of an exposure related response with an IC50 of 2$\mu$M total plasma concentration. Blood glucose also demonstrated an exposure response relationship with maximum glucose concentration correlating with drug plasma $C_{max}$. **Conclusions:** Inhibition of AKT substrate phosphorylation in tumour biopsies from advanced cancer patients with a range of solid tumours was qualitatively comparable to that observed in preclinical models showing tumour growth inhibition at clinically achievable exposures. Clinical trial information: NCT01226316; NCT01353781.

**2542 General Poster Session (Board #5), Sun, 8:00 AM-11:45 AM**

**A first-in-human study of AMG 780, an angiopoietin-1 and -2 (ANG1/2) inhibitor, in patients (pts) with advanced solid tumors.** *Presenting Author: Afshin Dowlati, Case Western Reserve University and University Hospitals Seidman Cancer Center, Cleveland, OH*

**Background:** AMG 780 is a fully human monoclonal antibody binding Ang1/2, thereby inhibiting their interaction with Tie2. This first-in-human study evaluated AMG 780 in advanced solid tumors. **Methods:** Pts (≥ 18 yrs) received open-label AMG 780 IV Q2W until pts progressed, developed intolerable toxicities, or withdrew consent. Doses (0.1, 0.3, 0.6, 1.2, 2.5, 5, 10, 20, 30 mg/kg) were escalated in a 3 + 3 design. Primary endpoints were dose-limiting toxicities (DLTs), treatment-emergent adverse events (AEs), and pharmacokinetics (PK). Secondary endpoints included tumor response per RECIST and tumor vascularity ($K^{trans}$, IAUC) measured with DCE-MRI. The profile of circulating angiogenic factors was an exploratory endpoint. **Results:** 44 pts were enrolled (n = 3 – 9 per cohort; 25 males; mean age [SD] = 61 [9] yrs). Three DLTs occurred (0.6 mg/kg, gr 3 thrombocytopenia; 10 mg/kg, gr 3 proteinuria; 30 mg/kg, gr 3 pericardial effusion; all n = 1). The most frequent AEs were hypoalbuminemia (n = 16; gr ≥ 3, n = 1), peripheral edema (n = 13; gr ≥ 3, n = 0), fatigue (n = 12; gr ≥ 3, n = 1), and decreased appetite (n = 12; gr ≥ 3, n = 0). The most common gr ≥ 3 AEs were blood alkaline phosphotase increase (n = 4) and hyponatremia (n = 3). No treatment-related deaths occurred. At 30 mg/kg, a maximally tolerated dose was not identified. PK was nearly dose-linear. Mean terminal half-life was 8 – 12 days. Steady state was reached after three doses. Of 31 evaluable pts, six pts had stable disease (SD); one pt had SD lasting > 6 months. Twenty pts had progressive disease. Of 16 pts with DCE-MRI data, $K^{trans}$ for 6 pts and IAUC for 5 pts decreased > 20% at week 5 postdose relative to baseline. No $K^{trans}$or IAUC responses occurred prior to reaching the 0.6 mg/kg cohort. Levels of soluble vascular cell adhesion molecule-1 (sVCAM-1) and placental growth factor (PLGF) levels increased and soluble kinase insert domain receptor (sKDR) decreased with higher AMG 780 doses. Circulating angiogenic factors did not correlate with tumor response. **Conclusions:** Results suggest that AMG 780 IV Q2W is tolerable up to 30 mg/kg. Based on safety and PK, additional trials of AMG 780 at 20 – 30 mg/kg monotherapy or combined with targeted agents or chemotherapy are warranted. Clinical trial information: NCT01137552.

**2543 General Poster Session (Board #6), Sun, 8:00 AM-11:45 AM**

**A comparative study of circulating biomarkers of anti-VEGF therapy in phase II trials in advanced hepatocellular carcinoma (HCC) patients (pts).** *Presenting Author: Lipika Goyal, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background:** Sorafenib, a multikinase inhibitor of VEGFR, remains the only approved systemic therapy in HCC. Several other anti-VEGFR agents have either failed or continued in phase III trials. Despite the extensive efforts in developing antiangiogenic agents in HCC, no biomarker currently exists for appropriately selecting patients with HCC for antiangiogenic therapy. We performed a comparative study of circulating biomarkers in single arm, phase II studies of sunitinib, cediranib and ramucirumab in pts with advanced HCC. **Methods:** Clinical trial design and outcomes have been previously reported (PMID 19470923, 23362324, 24088738). Peripheral blood was obtained prior to and at various time points after treatment and was analyzed for circulating biomarkers using multiplex ELISA. **Results:** A total of 54 pts were analyzed in this study: sunitinib (S) (n=33), cediranib (C) (n=12), and ramucirumab (R) (n=9). Compared to baseline, monotherapy with all three agents increased the Day 14 circulating levels (Day 14 level/baseline level) of PlGF (S, 3.1; C, 3.4; R, 3.5) and VEGF (S, 2.1; C, 1.3; R, 2.0) and decreased those of soluble VEGFR2 (S, 0.7; C, 0.8; R, 0.7). In exploratory correlative studies, high baseline and on-treatment levels of soluble VEGFR1 – an endogenous inhibitor of VEGF and PlGF – were associated with poor outcomes for all three treatments. Other biomarkers, including angiogenic molecules and inflammatory cytokines, showed differential kinetics and no significant associations with clinical outcomes. **Conclusions:** Exploratory studies from phase II trials of pts with advanced HCC who received sunitinib, cediranib, or ramucirumab suggest that circulating PlGF, VEGF, and sVEGFR2 are potential pharmacodynamic and response biomarkers of anti-VEGF therapy. They also show that soluble VEGFR1 may be a useful biomarker of resistance to anti-VEGF therapy. These biomarker candidates need to be validated in large prospective studies.

**2544 General Poster Session (Board #7), Sun, 8:00 AM-11:45 AM**

**A phase 1b study of the anticancer stem cell agent demcizumab (DEM), pemetrexed (PEM), and carboplatin (CARBO) in pts with first-line nonsquamous NSCLC.** *Presenting Author: Mark James McKeage, University of Auckland, Auckland, New Zealand*

**Background:** Delta-like ligand 4 (DLL4) activates the Notch pathway and is important for cancer stem cell (CSC) survival. DEM is a humanized $IgG_2$ anti-DLL4 antibody that has been shown to inhibit tumor growth, decrease CSC frequency & cause dysfunctional sprouting of new vessels resulting in an antiangiogenic effect in human tumor xenograft models. **Methods:** Pts received DEM (2.5, 5 or 7.5 mg/kg), PEM 500 mg/m$^2$ & CARBO (AUC = 6) every 3 weeks followed by maintenance DEM or PEM (7.5 mg/kg cohort) every 3 weeks until progression. The objectives were to determine the MTD, safety, efficacy, immunogenicity, pharmacokinetics & biomarkers of Notch signaling. **Results:** Thirty-two pts were enrolled; 6 received 2.5 mg/kg, 20 received 5 mg/kg & 6 received 7.5 mg/kg of DEM. Related AEs in > 20% of pts were: nausea (53%), fatigue (47%), hypertension (41%), vomiting (34%), edema (28%), neutropenia (25%), & increased B-type natriuretic peptide (BNP) (22%). Increased BNP values are an early indicator of the cardiac effects of DEM & mildly elevated values are being used to initiate cardioprotective therapy with an ACE inhibitor or carvedilol. Two pts receiving 5 mg/kg developed reversible pulmonary hypertension & heart failure on days 167 and 183, respectively. As a result, DEM treatment was limited to 63 days in subsequent cohorts. One of 28 (4%) evaluable pts had a RECIST CR, 12 (43%) had a PR and 11 had SD. The Kaplan Meier estimated median progression free survivals for the 2.5, 5 and 7.5 mg/kg pts were 4.8, 6.3 and 4.4 months, respectively. Five pts who discontinued the study for a reason other than progression (3 continued to receive CARBO & PEM off-study) were progression-free through Day 223+, 243+, 457+, 497+, 680+ and a sixth pt (who continued to receive CARBO & PEM off-study) progressed at Day 850. **Conclusions:** DEM, CARBO & PEM was generally well tolerated with nausea, fatigue & hypertension being the most common drug related toxicities. The duration of DEM therapy is being limited to 63 days due to cardiopulmonary toxicity which was observed following more prolonged administration. Encouraging early clinical activity has been observed. Enrollment is ongoing and updated results will be presented. Clinical trial information: NCT01189968.

**2545 General Poster Session (Board #8), Sun, 8:00 AM-11:45 AM**

**Effect of sulfasalazine (SSZ) on cancer stem-like cells (CSCs) via inhibiting xCT signal pathway: Phase 1 study in patients with gastric cancer (EPOC 1205).** *Presenting Author: Kohei Shitara, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** CD44 is an adhesion molecule expressed in cancer stem-like cells (CSCs). Our group recently reported that CD44 splice variant (CD44v) is expressed in CSCs and interacts with xCT, a glutamate-cystine transporter, keeping high levels of the intracellular reduced glutathione (GSH). Thus, CSCs with a high expression of CD44v have an enhanced capacity for GSH synthesis and defense against reactive oxygen species (ROS), resulting in resistance to various therapeutic stresses. Sulfasalazine (SSZ) as an xCT inhibitor suppressed CD44v-dependent tumor growth and increased sensitivity to cytotoxic drugs in vivo study. **Methods:** A phase 1 dose escalation study in patients with advanced gastric cancer was conducted to determine the optimal dose. SSZ was given fourth-daily oral administration with 2 weeks as one cycle. A 3+3 escalation was used to evaluate a MTD. Tumor tissues were obtained pre- and post SSZ administration to evaluate expression of CD44v and intra-tumor level of GSH by immunohistochemistry and boron doped diamond microelectrode, respectively. **Results:** Eleven patients were dosed from 8 g to 12 g/day; median age: 71 years (61-78); median number of prior chemotherapies: 3 (1-4). There was two DLT of grade 3 anorexia and nausea among patients who were treated with 12 g/day. One additional patients required frequent dose interruption with grade 2 anorexia and nausea. Therefore 12g/day was judged as MTD. No DLT was observed among patients with 8g/day. Patients with high CD44v expression patientss achieved reduced expression of CD44v after the administration of SSZ for 2 weeks as well as decreased level of GSH. The individual variability of SSZ exposure was explainable in terms of the genotypes of ABCG2 and NAT2 which influence SSZ pharmacokinetics. **Conclusions:** Optimal dose of SSZ was considered as 8g/day. Down regulation of CD44v expression and decreased level of GSH migh be a pharmacodynamic marker of drug-on-target effect and mode of action of SSZ for CSCs, which warrants further investigation for combination with chemotherapy or other targeting agents. Clinical trial information: UMIN000010254.

**2546 General Poster Session (Board #9), Sun, 8:00 AM-11:45 AM**

**A phase I extension study of BBI608, a first-in-class cancer stem cell (CSC) inhibitor, in patients with advanced solid tumors.** *Presenting Author: Derek J. Jonker, The Ottawa Hospital Research Institute, Ottawa, ON, Canada*

**Background:** BBI608, an orally-administered first-in-class cancer stemness inhibitor, blocks CSC self-renewal and induces cell death in CSC as well as non-stem cancer cells by inhibiting Stat3, $\beta$-catenin, and Nanog pathways, and has shown potent anti-tumor and anti-metastatic activities preclinically. In a phase 1 study, BBI608 demonstrated tolerability as well as signs of anti-cancer activity in patients with solid tumors. This phase 1 extension study evaluated a formulation designed for pivotal trials to determine pharmacokinetics (PK) in patients with advanced cancer. **Methods:** Day 1, patients received a single 500mg dose of the original BBI608 formulation (DP1). Day 4 and 8, a higher strength capsule designed for pivotal trials (DP2A) was given with fasting then fed conditions. DP2A was then administered daily until disease progression or unacceptable toxicity. Endpoints were safety, PK and preliminary anticancer activity. **Results:** DP2A was evaluated in 24 patients. No significant difference in plasma exposure between DP1 and DP2A, and no significant food effect were observed. Nine patients received BBI608 DP2A 4 h apart (DP2A-4h) only, and 15 patients received BBI608 DP2A 500 mg bid 12 h apart (DP2A-12h). Despite PK equivalence to DP1, DP2A-4 h was associated with higher frequency of gastrointestinal (GI) adverse events (AE) than observed in the prior study, including diarrhea, abdominal cramps, nausea/vomiting, anorexia, and fatigue. In contrast, DP2A-12 h had fewer GI AE and was selected for the extension study. Among 15 patients receiving DP2A-12h, prolonged stable disease was observed in 2 of 7 non-CRC patients (ovarian cancer-16 wk and anal squamous cancer-32 wk) and among 8 CRC patients enrolled, disease control was observed in 67% evaluable for response (4/6), with progression free survival and overall survival at 17 weeks and 39 weeks, respectively. **Conclusions:** The recommended dosing regimen for BBI608 in pivotal trials was determined to be about 500 mg bid q12 h. Signs of anticancer activity were observed in patients with CRC, anal squamous carcinoma, and ovarian cancer. Clinical trial information: NCT01775423.

**2547 General Poster Session (Board #10), Sun, 8:00 AM-11:45 AM**

**Characterization of isolated, uncomplicated neutropenia–related to the CDK4/6 inhibitor palbociclib.** *Presenting Author: Angela DeMichele, Abramson Cancer Center of the University of Pennsylvania, Philadelphia, PA*

**Background:** Palbociclib (P), an oral, selective, reversible CDK4/6 inhibitor induces transient G1 arrest in hematopoietic stem/progenitor cells (HSPC), without DNA damage or apoptosis in preclinical studies. In patients (pts) with advanced malignancy, P had activity in several tumor types, but neutropenia was dose-limiting. We sought to characterize the incidence and patterns of myelosuppression to determine if the mechanisms observed preclinically were reflected in the clinical experience. **Methods:** Data from 2 phase 2 studies of single agent P in pts with advanced RB+ tumors (UPenn, NCT01037790) and liposarcoma (MSKCC, NCT01209598) were analyzed. Dose (125 mg P), schedule (3 wks on/1 wk off) and safety assessments (baseline, weekly cycle 1 and d 1 of subsequent cycle) were identical. Both trials required P be held for > grade (Gr) 3 myelosuppression until resolved to < Gr 2. **Results:** 140 patients with breast (36%), sarcoma (21%), germ cell (21%), colon (13%), gastric (7%) tumors were enrolled. Neutropenia, anemia and thrombocytopenia rates in cycle 1 by Gr are shown. Mean absolute neutrophil count was 4.98, 4.24, 2.15, 1.62 and 1.86 at weeks 1, 2, 3, 4 and 5, respectively, reflecting time to nadir. Time to Gr3 neutropenia was 3 wks in 11%, 4 wks in 30%, 5 wks in 14%. Recovery occurred after brief dose delay. Neutropenia led to dose interruption in 19% of pts in cycle 1 and 8% had Gr3 neutropenia on day 1/cycle 2. Despite the high rate of Gr 3/4 neutropenia (39%), only 1 episode of neutropenic fever occurred (in setting of disease progression), with no infections or use of G-CSF. Mucositis was rare and <Gr2. Concurrent Gr3 anemia or thrombocytopenia were rare (6% and 15% respectively). **Conclusions:** Frequent, isolated and uncomplicated neutropenia in patients receiving P is consistent with preclinically observed quiescence but not death of HSPC and little effect on differentiated myeloid cells. The lack of clinical morbidity or pancytopenia suggests that P-induced neutropenia is short lasting, reversible and may be managed conservatively. PK data will be reported to confirm the relationship between ANC and drug exposure. Clinical trial information: NCT01037790, NCT01209589.

| Grade | Neutropenia | Anemia | Thrombocytopenia |
|---|---|---|---|
| 2 | 31% | 28% | 14% |
| 3 | 36% | 4% | 9% |
| 4 | 3% | 0 | <1% |

**2548 General Poster Session (Board #11), Sun, 8:00 AM-11:45 AM**

**Association of hypertension and proteinuria with overall survival in solid-tumor patients treated with anti-VEGF drugs in the MARS study.** *Presenting Author: Vincent Launay-Vacher, Service ICAR - Pitie-Salpetriere Hospital, Paris, France*

**Background:** MARS is a multicentric, noninterventional, prospective study which first reported the high prevalence of both baseline and de novo hypertension (HTN) and proteinuria (Pu) in patients receiving bevacizumab (Bev) or sunitinib (Su) (Gligorov J et al. SABCS 2013; Ray-Coquard I et al. ASCO GI 2014; Ray-Coquard I et al. ASCO GU 2014; Goldwasser F et al. ECC 2013; Launay-Vacher V et al. ASCO 2013). **Methods:** It included 1,124 patients, all naive of any previous anti-VEGF treatment. A First Renal Assessment was performed before the anti-VEGF was started with periodic follow-up for 1 year (Renal Follow-up Plan). Univariate (UA) and multivariate analyses (MA) tested the associations of HTN and Pu, at baseline or de novo, with overall survival (OS) (pre-planned). **Results:** De novo Pu was not associated with reduced OS, in any group. De novo Pu was a statistically significant prognostic factor for better OS in Bev-treated CRC, both in UA and MA. Baseline Pu was prognostic of reduced OS in Bev-treated LC, in UA but not in MA. HTN, either at baseline or de novo, was not found to be associated with OS, in any group. **Conclusions:** HTN was not associated with OS in our study, even in RCC Su-treated patients. De novo Pu, determined with a urinary dipstick, which is neither invasive nor costly, could be an easily accessible prognostic factor of better OS in Bev-treated CRC. Bev treatment in LC patients experiencing de novo Pu should be discussed since it can be prognostic of poorer OS.

**2549 General Poster Session (Board #12), Sun, 8:00 AM-11:45 AM**

**Correlation between phase 2 clinical trial design and subsequent phase 3 outcome.** *Presenting Author: Annette E. Hay, NCIC Clinical Trials Group, Kingston, ON, Canada*

**Background:** Randomized phase 2 (RP2) trials have been postulated to better predict phase 3 (P3) outcome than single arm trials. The aim of this study was to determine which characteristics of P2 trials that led to the conduct of P3 trials are associated with a positive P3 outcome. **Methods:** Randomized P3 trials testing systemic therapy in patients with malignancy, published in English from 2007 to 2012, were identified through a Medline search. Those of superiority design which cited P2 trials contributing to development of the experimental arm were included. Detailed information regarding design and outcome of P2 and P3 trials was extracted in duplicate. Discrepancies were adjudicated by a third investigator. Positivity was defined as statistical difference between arms for primary endpoint in P3. P2 trials reporting that a pre-stated numeric or statistical target had been met were deemed positive. Statistical analysis was performed using the Generalized Estimating Equation model correlating P2 features with P3 outcome, accounting for any P3 duplication. **Results:** Of 189 eligible P3 trials 19% were in hematologic malignancies and 81% in solid tumors. The primary outcome was positive in 79 (42%). These were supported by 336 P2 trials (range 1 - 9 per P3 trial); 66 of which were RP2s (29 selection, 21 control, 3 discontinuation, 7 phase 2/3 and a combination of these in 6). RP2 trials were not associated with P3 positivity (see Table, p = 0.44). Positive P2 outcome correlated with positive P3 outcome (p = 0.031). P2 trial features found not to be predictive of P3 outcome included primary endpoint, sponsorship, sample size, similarity in patient population and therapy. **Conclusions:** We did not find RP2 more predictive than single arm trials. When designing P2 trials consideration should be given to the increased resources required to conduct RP2 studies and anticipated gain for a given disease.

**2550^ General Poster Session (Board #13), Sun, 8:00 AM-11:45 AM**

**Final results from the phase I study expansion cohort of Debio0932, an oral HSP90 inhibitor, in patients with solid tumors.** *Presenting Author: Pierre Fumoleau, Centre Georges François Leclerc, Dijon, France*

**Background:** Debio 0932 is an oral second-generation heat shock protein 90 (HSP90) inhibitor that has shown promising anti-tumor activity against a broad range of tumors in pre-clinical models. Here we report the results of the expansion part of a phase I study in patients with advanced solid tumor or lymphoma. **Methods:** 30 patients with solid tumor comprising 15 NSCLC patients were enrolled. Patients received the treatment schedule derived from results of the dose-escalation phase, i.e. 1000 mg Debio 0932 QD. PK samples were taken on day 1 and 29. CYP 450 and transporter polymorphism was explored through Affymetrix DMET chip. **Results:** The safety population analysis considered 39 patients of which 30 enrolled into the expansion phase and additional 9 patients treated at 1000 mg QD during the dose-escalation phase of the study. Adverse events (AEs) and the frequencies are reported in the Table. The main reason for treatment withdrawal was progressive disease. Although no objective tumor responses were seen, 25% of patients evaluable for response achieved disease stabilization including long lasting episode. Moreover, one partial metabolic response (PMR) and 5 (41.7%) stable metabolic response (SMR), were observed in the 12 NSCLC evaluable patients. Debio 0932 was rapidly absorbed and subjected to first-pass metabolism. Large inter-individual variability in PK was observed but without evidence of food effect. No obvious relationship between PGx and PK was evidenced. **Conclusions:** Debio 0932 mono-therapy at recommended dose of 1000mg was generally well tolerated and showed signs of activity in patients with advanced NSCLC and can be administered in fed state. A phase I-II study of Debio 0932 in combination with standard of care in NSCLC is ongoing. Clinical trial information: NCT01168752.

**Pharmacodynamic assay for evaluation of first-in-class pyruvate kinase-M2 activators in tumors.** *Presenting Author: Payal Khanna, Leidos Biomedical Research Inc., Fredrick National Laboratory for Cancer Research, Frederick, MD*

**Background:** A new class of compounds targets conversion of enzymatically inactive dimeric pyruvate kinase-M2 (PKM2) to an active tetramer complex as a mechanism to tilt the balance between glycolysis and oxidative phosphorylation and reverse the metabolic advantage acquired by tumor cells. The dimer PKM2, which is also a transcription factor, diverts glucose to macromolecular biosynthesis. We developed a pharmacodynamic (PD) assay for PKM2 modulation and evaluated in vivo target engagement using an allosteric PKM2 activator (PKM2a). **Methods:** An experimental PKM2a [N-(4-(4-(2-methoxyphenyl)piperazine-1-carbonyl)phenyl)quinoline-8-sulfonamide] (Kung et. Al., Chem & Biol 2012) was synthesized at NCI. The PD response was determined in H1299 xenografts (n=3/group) dosed daily at 6, 20, and 60 mg/kg for 10 days; tissue samples were collected 2, 6, 24, and 48 hrs post dose 1, 3, and 10. Tumor volumes were recorded biweekly until 27 days after treatment was stopped. A sandwich immunoassay was developed that detects monomer/dimer but not tetrameric PKM2. The assay showed >80% lower PKM2 levels in tumor cell lines treated in vitro with the PKM2a. **Results:** PD analysis showed that the majority of PKM2 (60-80%) was detected in the nuclear fraction of tumor lysates. Compared to controls, nuclear accumulation was decreased by 30-60% between 24 and 48 hrs post dose 10 in the 60 mg/kg treatment group. Changes observed at lower doses or at earlier time points were not significant. Marginal decreases in mean tumor volume (<18%, p=NS) was observed in the 60 mg/kg dose group on 4 and 8 days after treatment. **Conclusions:** Our results show that PKM2 monomers/dimers accumulated in the nuclear fraction suggesting that they may play a role as transcription factors in the model we tested. PKM2 modulation was evident only at the highest dose tested after multiple administrations, and a delayed PD response was consistent with the marginal efficacy observed in this study. Together, these results suggest that sustained modulation of PKM2 with higher doses may be required to reverse the metabolic fate of cancer cells. Importantly, our PD assay provides a critical tool to guide translational studies of PKM2a.

**2552 General Poster Session (Board #15), Sun, 8:00 AM-11:45 AM**

**Risks and benefits of phase 1 oncology trials, 2001 through 2012.** *Presenting Author: Yoko Korenaga Fukuda, MedStar Washington Hospital Center, Washington, DC*

**Background:** The primary objective of phase I clinical trials is to evaluate the tolerability and pharmacokinetics of a new agent. Phase I trials in oncology remain ethically controversial. Our previous analysis from year 1991 through 2002 reported a response rate of 10.6 percent and a toxicity-related death rate of 0.49 percent. An increasing number of molecular targeted agents are under investigation and these results may not reflect current phase I oncology trials. **Methods:** We reviewed all non-pediatric phase 1 oncology trials sponsored by the Cancer Therapy Evaluation Program at the National Cancer Institute between January 1, 2001 and December 31, 2012. We report the rates of response to treatment, of stable disease, of grade 4 toxic events, and of treatment-related deaths. **Results:** We analyzed 286 trials, comprising 8314 participants. All 8314 participants were evaluated for toxic events, whereas 6604 participants were evaluated for response. The overall response rate (complete and partial response) and disease control rate (complete and partial response and stable disease) were higher than in the previous analysis. (13.2 percent vs 10.6 percent, p-value $<$ 0.0001, 52.6 percent vs 34.1 percent, p-value $<$ 0.0001, respectively.) 1651 participants (19.86 percent) experienced at least one grade 4 toxic event that was at least possibly related to the treatment. The overall rate of death at least possibly related to the treatment was 0.99 percent. The overall rates of death due to toxic events and grade 4 toxic events were both higher than in the previous analysis. (1.02 percent vs 0.49 percent, p –value $<$ 0.0001, 19.86 percent vs 14.3 percent, p-value $<$ 0.0001, respectively.) All p-values reported are 2-sided. **Conclusions:** The rates of response and toxicity in non-pediatric phase 1 oncology trials were higher than in the previous analysis and more than 50 percent of patients achieved at least stable disease. The higher disease control rate may be due to greater use of cytostatic molecularly targeted agents. More toxic-related deaths were reported, but this may be because of the change in serious adverse events reporting requirements by the FDA. Rate of death that was probably or definitely related to the treatment remained stable at about 0.2 percent.

**2553 General Poster Session (Board #16), Sun, 8:00 AM-11:45 AM**

**Integrated nonclinical and clinical risk assessment to obviate the need for a dedicated QTc study of ixazomib citrate (MLN9708) in cancer patients (pts).** *Presenting Author: Neeraj Gupta, Takeda Pharmaceuticals International Co., Cambridge, MA*

**Background:** Ixazomib citrate is an investigational oral proteasome inhibitor in phase 3 (P3) clinical development. It is expected to have a favorable cardiac safety profile based on weak in vitro inhibition of the hERG channel ($IC_{50}$ 59.6 $\mu$M) and in vivo nonclinical data. To confirm, serial PK-matched triplicate electrocardiograms (ECGs) were collected in phase 1 (P1) dose-escalation studies to characterize the effect of the active moiety ixazomib (Ix; MLN2238) on QTc intervals and potentially obviate the need for a dedicated QTc study. **Methods:** Data from 245 pts in 2 IV (0.125–3.11 mg/m$^2$, N=125, solid tumor and lymphoma pts) and 2 oral (0.24–3.95 mg/m$^2$, N=120, multiple myeloma pts) P1 studies were included. Mean (range) age was 56.5 (23–86) years; 43% were female. Centrally read 12-lead digital ECGs were used to derive heart rate (HR)-corrected QT intervals using Fridericia's method (QTcF). Relationship between Ix plasma concentration (C) and QTcF was analyzed using linear mixed effects models with fixed effects for day and time to account for circadian variation. **Results:** A safety margin of $>$1700-fold was calculated between the hERG $K_i$ (24.9 $\mu$M) and unbound day 15 $C_{max}$ (14.6 nM) at the fixed P3 dose of 4 mg. Non-clinical dog telemetry studies showed no QT prolongation, or changes in ECGs, HR, or waveform intervals at doses up to 4.2 mg/m$^2$. Linear models relating Ix C to QTcF and RR were developed from clinical data acquired over a wide C range (26% of data $>$mean $C_{max}$ at P3 dose). Ix has no clinically meaningful effect on cardiac repolarization based on the model-predicted mean change in QTcF from baseline, consistent with outlier analyses (Table). There was no relationship between C and RR interval suggesting Ix has no effect on HR. **Conclusions:** Ixazomib citrate has no clinically meaningful impact on QTc or HR. Integrating preclinical cardiac electrophysiology data and clinical C-QTc modeling of P1 data represents an efficient approach in oncology drug development that may obviate the need for a dedicated QTc study.

**2554 General Poster Session (Board #17), Sun, 8:00 AM-11:45 AM**

**First-in-human, first-in-class phase 1 study of a novel oral multi-AGC kinase inhibitor AT13148 in patients (pts) with advanced solid tumors.** *Presenting Author: Rajiv Kumar, Drug Development Unit at The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, UK, London, United Kingdom*

**Background:** Aberrant signaling through the AGC kinases is implicated as a critical driver of multiple cancers. AT13148 is a novel multi-AGC kinase inhibitor, which potently inhibits AKT, P70S6K, PKA and ROCKI/II. Following promising in vivoantitumor activity through mechanisms distinct from specific AKT inhibitors, a phase I trial was initiated. **Methods:** Pts with advanced solid tumors were enrolled onto study using a standard 3+3 dose escalation strategy. AT13148 was given orally on days (D) 1, 3 and 5 of every week, in 28-day cycles. The starting dose was 5mg, with a 4-week dose limiting toxicity (DLT) period. Pharmacokinetic (PK) parameters were assessed after a run-in dose (D1-7) and at cycle (C)2 D1. Pharmacodynamic (PD) biomarkers for AKT signaling were analyzed in tumor, platelet rich plasma (PRP) and hair follicles at multiple timepoints. **Results:** 14 pts were treated with AT13148 (7M: 7F; 4 ECOG 0, 10 ECOG 1). Median age 57y. Median duration of treatment was 40 days (range 25-76). AT13148 was well tolerated with no drug-related toxicities observed. No DLTs have been observed in 9 evaluable pts in 3 completed dose levels (5, 10 and 20mg). PK analysis in 3 pts at 20mg AT13148 demonstrated $C_{max}$ between 18-50nmol/L , with $T_{max}$ of 4h. The average $T_{1/2}$was 24h resulting in a 2 fold increase in exposure on cycle 2. Preliminary PD data in PRP showed no modulation of pAKT, pGSK3$\beta$ or pP70S6K at the first 2 dose levels i.e. 5 and 10mg cohorts. 2 pts currently remain on study in the 20mg cohort. **Conclusions:** AT13148 was well tolerated and showed no drug-related toxicities at 5, 10 and 20mg doses. Preliminary PK and PD data are in keeping with early phases of dose escalation. Dose escalation will continue until a MTD is established. Clinical trial information: NCT01585701.

**2555 General Poster Session (Board #18), Sun, 8:00 AM-11:45 AM**

**A phase I study of ARQ 197 in combination with temsirolimus in patients (Pts) with advanced solid tumors.** *Presenting Author: Amy M. Braden, University of Wisconsin, Madison, WI*

**Background:** Disregulated c-Met activity is implicated in tumor progression and metastasis. Phosporylation of c-Met leads to activation of the PI3K/AKT/mTOR pathway. Preclinical studies demonstrate that combined inhibition of c-Met and mTOR is effective. ARQ 197 (tivantinib) is an inhibitor of c-Met and Temsirolimus selectively inhibits mTOR. This study is designed to determine the maximum tolerated dose (MTD), dose-limiting toxicities (DLTs), adverse events (AEs), clinical activity, and pharmacokinetic (PK) parameters of this combination. **Methods:** This open label phase I study utilizes a 3+3 dose escalation of ARQ 197 (120mg-480mg bid) and Temsirolimus (20-25mg IV weekly) followed by dose expansion at MTD. ARQ 197 is primarily metabolized by CYP2C19. Separate cohorts for dose escalation are incorporated for poor and extensive metabolizers. Cycles are 28 days, except cycle 1 which is 35 days, to evaluate PK interactions. **Results:** 14 pts (median age 60.5 [range 29-71]; 8 male:6 female) were enrolled. The most common malignancies were colorectal (4 pts), ovarian (2 pts) and renal cell carcinoma (2 pts). 3 pts were unevaluable per protocol. 11 evaluable patients were on study a median of 55.5 days (range 15-296). After 3 evaluable subjects there was no DLT at dose level (DL) 1. At DL2, there were 2 DLTs. 1 pt received $<$75% of drug due to grade (gr) 3 hypophosphatemia and gr 3 diarrhea but had baseline diarrhea. A 2$^{nd}$pt had gr 4 neutropenia and gr 3 mucositis. DL 1 was expanded with 3 additional pts without DLT. An amendment with stricter eligibility criteria was approved by CTEP and dose was re-escalated to DL2. 2 additional pts have been treated without DLT. Dose escalation will continue if 1 additional pt at DL2 does not have DLT. The most common AEs at least possibly related to therapy included: fatigue (gr 1-2 in 9 pts), anemia (gr 2 in 7 pts, gr 3 in 1 pt), nausea (grade 1-2 in 8 pts) and diarrhea (gr 1-2 in 6 pts, and gr 3 in 1 pt). 1 pt with ovarian cancer had a confirmed partial response, a decline in CA 125 and remained on study for $>$ 9 months. **Conclusions:** ARQ 197 in combination with Temsirolimus appears to be well-tolerated at biologically active doses. Dose escalation and PK analysis is ongoing. MTD expansion is planned. Clinical trial information: 9145.

**2556 General Poster Session (Board #19), Sun, 8:00 AM-11:45 AM**

**Predicting success in regulatory approval from phase I results.** *Presenting Author: Laeeq Malik, Institute for Drug Development at Cancer Therapy and Research Center, University of Texas Health Science Center, San Antonio, TX*

**Background:** Drug development in oncology is resource intensive and has a high failure rate. In this exploratory analysis, we aimed to identify the characteristics and outcomes of Phase I studies associated with future Food and Drug Administration (FDA) approval or non-approval. **Methods:** Published Phase I studies of anticancer agents between 2000 and 2013 were retrospectively identified by searching PubMed, relevant oncology journals, and the oncologic drugs advisory committee website. Phase I trials of supportive drugs, radiopharmaceuticals, endocrine agents, vaccines, Ib combination studies and agents without Phase III evaluation were excluded. We then examined trial characteristics and outcomes associated with future FDA-approval or non-approval. Fisher's Exact and Chi-square tests were used to compare the potential predictive measures. Responses were classified according to the description in the published study (RECIST or WHO criteria). **Results:** Phase I results of 88 new agents treating a total of 4423 subjects met the eligibility criteria (54 approved and 34 non-approved by the FDA). The median number of patients in Phase I trials of approved and non-approved agents were 44.5 and 32 respectively. A total of 423 subjects had complete responses (CR) and 342 had partial responses (PR). Higher number of PRs ($P<0.001$), PR rate ($P=0.003$) and longer PR duration ($P=0.001$) were predictive of regulatory success. A positive trend toward higher regulatory success was observed for studies with larger study size ($P=0.053$), higher CR rate ($P=0.049$), and number of patients with stable disease ($P=0.047$). **Conclusions:** Approved anticancer agents in hematological and solid organ malignancies demonstrated a higher number, rate and duration of PRs in Phase I trials than non-approved agents. This information might be useful as part of the decision process regarding which agents proceed to later stages of drug development.

**2557 General Poster Session (Board #20), Sun, 8:00 AM-11:45 AM**

**A phase 1 study of phospholipid ether [$^{131}$I]-CLR1404 in patients with advanced solid tumors.** *Presenting Author: Sam Joseph Lubner, University Wisconsin Carbone Cancer Center, Madison, WI*

**Background:** Preclinical data suggest that tumor cells of many types selectively accumulate and retain phospholipid ethers. To capitalize on this, a radiolabeled phospholipid ether [$^{131}$I]-CLR1404 was developed with the goal of improving tumor imaging specificity and as a novel approach to therapy. Experiments with [$^{131}$I]-CLR1404 in mouse models demonstrated safety and efficacy. We conducted a phase 1 study of escalating doses of [$^{131}$I]-CLR1404 in patients with advanced solid tumors. The primary objective of this study was to determine a recommended dose of [$^{131}$I]-CLR1404 for treating advanced solid malignancies. The secondary objectives were to expand the safety and pharmacokinetic profile, determine anti-tumor activity, and obtain tumor imaging with [$^{131}$I]-CLR1404. **Methods:** Patients were first given a dosimetric dose followed by a treatment dose 1-2 weeks later in an algorithmic escalation design. Toxicity follow up included q 7 day lab and clinical assessment. Patients had single photon emission computed tomography (SPECT) scans to assess [$^{131}$I]-CLR1404 biodistribution. **Results:** Twelve patients were enrolled (7 male, 5 female, age range 40-70) at 3 open centers. Two patients withdrew from study before receiving drug; 10 patients (3 colon, 2 breast, 2 prostate, 2 esophagus, 1 ovarian) received protocol therapy. The per-protocol dose-limiting toxicities (DLT) were grade 4 thrombocytopenia (PLT) and grade 4 neutropenia (ANC) at 37.5mCi/m$^2$. For further safety analysis, an intermediate dose level was opened at 31.25 mCi/m$^2$; 2 DLTs (grade 4 PLT, grade 3 ANC with fever) were encountered. Clinical activity was shown with 4 patients with stable disease (SD) up to 6 months. SPECT imaging confirmed selective [$^{131}$I]-CLR1404 accumulation in known tumors. **Conclusions:** At a dose of 31.25 mCi/m$^2$, DLTs were low PLT and ANC. Studies exploring the mechanism(s) of action of [$^{131}$I]-CLR1404 toxicity are ongoing to minimize myelosuppression. Disease-specific studies are also underway to identify patients most likely to benefit from [$^{131}$I]-CLR1404 monotherapy. In this study, there was evidence of [$^{131}$I]-CLR1404 anti-tumor activity (4 pts with SD) and sustained uptake in tumors by SPECT imaging. Clinical trial information: NCT01495663.

**2558 General Poster Session (Board #21), Sun, 8:00 AM-11:45 AM**

**A phase 1 multicenter open-label dose-escalation study of BMS-936561 (MDX-1203) in clear cell renal cell carcinoma (ccRCC) and B-cell non Hodgkin lymphoma (B-NHL).** *Presenting Author: Taofeek Kunle Owonikoko, The Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** BMS936561 is a fully human monoclonal anti-body conjugate targeting the CD70 transmembrane cell-surface protein highly expressed in ccRCC and B-NHL. The study was designed to determine the safety profile and maximum tolerated dose (MTD) of BMS-936561 in this patient population. **Methods:** This phase 1 study employed an accelerated titration design followed by a 3+3 dose escalation to evaluate the safety, maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of BMS-936561. Patients with advanced ccRCC or B-NHL, $\leq$ 3 prior chemotherapy regimens, ECOG performance status 0-2 were treated with escalating doses of BMS-936561 (0.5mg/kg, 1mg/kg, 2mg/kg, 4mg/kg, 8mg/kg, 15mg/kg) by IV infusion every 21 days in a 42 day cycle up to 17 cycles. Dose limiting toxicity (DLT) was defined as any of the following adverse events (AEs): $\geq$ Grade 4 anemia, leukopenia, thrombocytopenia, neutropenia or any other $\geq$ Grade 3 events according to NCI CTCAE 3.0 during the first cycle. **Results:** There were 26 patients enrolled into the escalation (16) and expansion cohorts (10): median age: 63 y, range 48-74; gender: 18M/8F; race: 25W/1AA. BMS-936561 was tested at doses ranging from 0.1 to 15 mg/kg without a defined MTD. There was DLT of grade 3 hypersensitivity in 2/16 (13%) subjects treated at the 15 mg/kg dose cohort. The most commonly reported AEs included fatigue (85%), nausea (54%), decreased appetite (39%), anemia, dyspnea (35% each), constipation, peripheral edema (31% each), vomiting (27%), cough, skin hyperpigmentation, thrombocytopenia (23% each). Delayed toxicities characterized by facial edema and/or pleural or pericardial effusions were observed in 6/16 (38%) subjects treated at the 15mg/kg dose. All treatment emergent grades 3-4 serious AEs occurred in subjects treated at the 15 mg/kg dose. No deaths were attributed to BMS-936561. Exploratory efficacy analysis by investigator assessment showed a best response of stable disease in 18 of 26 patients (69%) without any apparent correlation with the administered dose. **Conclusions:** BMS936561 is well tolerated over a wide range of doses in patients with advanced ccRCC and B-NHL. Clinical trial information: NCT00944905.

**2559 General Poster Session (Board #22), Sun, 8:00 AM-11:45 AM**

**Population pharmacokinetics (PK) and exposure–neutropenia relationship of *nab*-paclitaxel (*nab*-P) in patients (pts) with solid tumors.** *Presenting Author: Nianhang Chen, Celgene Corporation, Summit, NJ*

**Background:** *nab*-P is a solvent-free, human albumin–stabilized formulation of paclitaxel (P) with a distinct clinical efficacy and safety profile in several indications (lung, breast, and pancreatic cancers) compared with solvent-based paclitaxel (sb-P). This study characterized the population PK and the exposure–neutropenia relationship with *nab*-P in pts with solid tumors. **Methods:** Plasma and blood concentrations of paclitaxel and neutrophil data were collected from 150 pts with various solid tumors over the *nab*-P dose range of 80 to 375 mg/m$^2$. Data were analyzed using nonlinear mixed-effect modeling or logistic regression. **Results:** Population PK of *nab*-P was described by a 3-compartment model with saturable distribution and elimination. The rapid disappearance of circulating P was driven by its fast distribution to peripheral compartments; maximum rate for saturable distribution (325,000 mg/h) was 40-fold greater than that for saturable elimination (8070 mg/h). Albumin was a significant covariate of P elimination ($P < 0.001$), while total bilirubin, creatinine clearance, body weight, body surface area, age, sex, and tumor type had no significant or clinically relevant effect. Neutropenia development was driven by systemic P exposure. The probability of experiencing a $\geq$ 50% reduction in neutrophils was best correlated to the duration of time above the drug concentration of 720 ng/mL. At a given exposure level, neutropenia development was positively correlated with increasing age but not significantly influenced by hepatic function, tumor type, sex, or dosing schedule. **Conclusions:** *nab*-P causes more rapid and deeper tissue penetration and slower elimination of paclitaxel compared with sb-paclitaxel. Rapid decline of paclitaxel concentration below the threshold of 720 ng/mL is associated with less-frequent neutropenia. The covariate analysis supports exposure-matched dose adjustments in patients with moderate to severe hepatic impairment and suggests that no dose adjustments are needed in patients with mild to moderate renal impairment.

**2560 General Poster Session (Board #23), Sun, 8:00 AM-11:45 AM**

**A phase I study of metformin and chemotherapy in solid tumors.** *Presenting Author: Athena Kritharis, Tufts Medical Center, Boston, MA*

**Background:** Metformin has recently received increased attention because of its potential antitumorigenic effects on a number of cancers. It activates AMP-related pathways leading to inactivation of mTOR and suppression of its downstream effectors, crucial for cancer growth. Data also suggests reduced incidence of cancer and better response to chemotherapy with metformin. We conducted a prospective phase I study to assess safety of metformin + chemotherapy in pts with solid tumors. **Methods:** We conducted delayed start randomized trial of non-diabetic pts in 2 stages. In stage 1, we randomized pts to 2 arms: concurrent arm (metformin + chemo) vs. delayed arm (chemo alone). In stage 2, pts in delayed arm were crossed over to receive metformin. Pts received metformin 500mg twice daily + chemotherapy to define DLTs in both stages. Secondary endpoints assessed AEs (CTCAE v.3.0) and response rates (RECIST). Translational correlates included effects of metformin on expression and phosphorylation of AMPK by western blot in PBMCs. **Results:** A total of 100 pts were enrolled (51 in delayed arm vs. 49 concurrent arm). There were 17 tumor types (CRC = 14, breast = 11). 26 chemoregimens were combined with metformin. Rate of DLTs in pts receiving metformin + chemotherapy was 6.1% vs. 7.8% in pts receiving chemotherapy alone (Table). DLTs seen with addition of metformin included those associated with established chemo AEs. No lactic acidosis or hypoglycemia occurred. Restaging showed stable disease in 46% at cessation of metformin. 28% of pts with measurable tumor markers showed improvement. AMPK phosphorylation showed a 4 to 6 fold increase in AMPK phosphorylation after metformin. **Conclusions:** This large phase I study suggests that metformin can be given safely with chemotherapy and offers a platform for future studies. Post-metformin increase in AMPK phosphorylation may potentially explain lack of disease progression in nearly half of our pts. Clinical trial information: NCT01442870.

**2561 General Poster Session (Board #24), Sun, 8:00 AM-11:45 AM**

**Pilot study of sorafenib and biweekly capecitabine in patients with advanced breast and gastrointestinal tumors.** *Presenting Author: Ami P. Jhaveri, Yale Cancer Center, New Haven, CT*

**Background:** Combination of sorafenib (S) and capecitabine (C) has shown clinical activity in single arm and randomized phase II trials of patients (pts) with metastatic breast (B) or GI (G) tumors. We sought an alternative schedule for C and S to reduce toxicity based on studies using the bi-weekly schedule for C and flat-dose administration. Study objectives are to assess safety, dose limiting toxicity (DLT), and maximum tolerated dose (MTD) of bi-weekly C and daily S. Secondary aims are efficacy, overall response rate, and duration of response. **Methods:** 19 pts with metastatic B or G tumors were enrolled to assess MTD and safety of C 1000mg bid flat dosing on days 1-7 and 15-21 of a 28 day cycle and S, 200mg AM/400mg PM given on a continuous basis. DLT definitions were predefined. Responses were defined using RECIST 1.0. **Results:** 19 pts with median age 55 (range 34-79) were treated. 14 pts had metastatic breast cancer; 5 pts had GI cancers. Median # of prior lines of chemotherapy in the metastatic setting was 1 (range 0-7). 2 pts are still on study. Median # cycles on study were 2 (range 1-5). Cycle 1 DLT were grade 3 pain in extremity (2 pts); grade 4 increased lipase (1 pt). Other grade 3/4 toxicities are summarized in Table. 16 pts are evaluable for response (12B, 4G). 2 pts with B tumors had partial response, 5 pts (3B, 2G) had stable disease, and 9 pts (7B, 2G) had disease progression. **Conclusions:** MTD was C 2,000mg 7 days on/7 days off and S 600mg daily. Despite overlapping toxicities of C and S combination, this dosing schedule is well tolerated and has sufficient clinical activity in pts with heavily pretreated metastatic breast and GI cancers to suggest further testing. Clinical trial information: NCT01640665.

**2562 General Poster Session (Board #25), Sun, 8:00 AM-11:45 AM**

**Phase I/IIa trial of the novel microtubule inhibitor BAL101553 in advanced solid tumors: Phase I completed.** *Presenting Author: L Rhoda Molife, Drug Development Unit at The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

**Background:** BAL101553 is a prodrug of the small molecule BAL27862, a novel microtubule-targeting agent (MTA) with potent activity in tumor models refractory to conventional MTAs. Its anti-cancer activity is related to cytotoxic effects on tumor cells as well as vascular disruption at higher doses. A NSCLC xenograft mouse model demonstrated similar BAL27862 tumor exposure (AUC) at the MTD and a sub-MTD dose, with the lower dose resulting in higher peak intratumoral levels. Phase I objectives of this trial included determination of maximum tolerated dose (MTD) and dose-limiting toxicity (DLT), evaluation of pharmacokinetics, pharmacodynamics (PD) and anti-tumor activity. **Methods:** Eligible patients (pts) with advanced solid tumors, having failed standard therapy, received BAL101553 as a 2-h IV infusion on days 1, 8 and 15 of a 28-day cycle (accelerated dose-escalation). Adverse events (AEs) were assessed by CTCAEv4 grade (G); tumor response was assessed every 2 cycles by RECIST 1.1. **Results:** 24 pts (12 males; median age 54.5 years; range 29-80) were treated at 15, 30, 45, 60 or 80 mg/m$^2$ of BAL101553. At 80 mg/m$^2$, 2 out of 6 evaluable pts experienced a DLT of G2-3 gait disturbance (fully or partially reversible with follow-up ongoing) related to G1-2 peripheral neuropathy. 60 mg/m$^2$ was defined as MTD with 1 DLT observed out of 6 pts (G3 reduced mobility with dizziness). Frequent drug-related AEs up to the MTD included injection site reactions, nausea, vomiting, diarrhea, fatigue, peripheral neuropathy (all G1-2) and asymptomatic hypertension (G2-3, transient during the infusion; responding to nifedipine). 1 confirmed partial response (ampullary cancer, for >2 years) and 5 stable diseases were observed, predominantly at sub-MTD doses. Reproducible exposure to BAL27862 was seen across all dose levels. Comparison of post- to pre-treatment tumor biopsies indicated PD effects on tumor cell proliferation and vascularization. **Conclusions:** BAL101553 is well tolerated up to the MTD of 60 mg/m$^2$. As a lower dose may be preferred (providing cytotoxic and intermediate anti-vascular effects), treatment at MTD and a lower dose is being considered for the randomized Phase IIa part. Clinical trial information: NCT01397929.

**2563 General Poster Session (Board #26), Sun, 8:00 AM-11:45 AM**

**Targeting argininosuccinate synthetase-deficient advanced solid tumors in a phase I trial of ADI-PEG20 plus cisplatin.** *Presenting Author: Siqing Fu, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Besides its selective activity to induce autophagy and caspase-independent apoptosis in argininosuccinate synthetase (ASS)-deficient cancer cells, ADI-PEG20 (pegylated arginine deiminase) synergized with the antitumor activity of cisplatin in vitro and in vivo. Accordingly we conducted a phase I study of ADI-PEG20 plus cisplatin in patients with ASS-deficient advanced solid tumors (NCT01665183). **Methods:** Primary objective was to establish the maximum tolerated dosage (MTD) following a standard 3+3 design. Secondary objectives were safety, antitumor activity and pharmacodynamics and immunogenicity effects. Patients with adequate organ functions, ECOG performance status of 1 or better, and ASS deficient advanced solid tumors were eligible. Dose escalation over 6 dose levels starting at ADI-PEG20 18 mg/m$^2$ IM weekly plus cisplatin 20 mg/m$^2$ IV weekly x 3 every 4 weeks and dose expansion at the MTD were included. Toxicity and efficacy were evaluated according to CTCAE 4.0 and RECIST 1.1, respectively. **Results:** A total of 37 patients with a median age of 62 were enrolled: 26 melanoma (18 cutaneous, 7 uveal, and 1 mucosal), 8 sarcoma, 1 prostate, 1 cervical, and 1 head and neck cancer. The MTD was established at ADI-PEG 36 mg/m$^2$ IM weekly plus cisplatin 30 mg/m$^2$ IV weekly x 3 every 4 weeks. Dose limited toxicities (DLT) included grade 4 neutropenia and neutropenic fever. Antitumor activity showed 2 partial responses (PR, 5%) and 8 stable disease ≥ 4 months (SD≥4 months, 22.2%). In patients with cutaneous melanoma, 2/18 PR (11 %) and 2/18 SD≥4 months (11%) were observed, associated with a median progression-free (PFS) and overall survivals of 2.6, and 5.8 months, respectively. Of 7 uveal melanoma patients, a median PFS of 4.7+ months was observed with 3 still on study, 2 off study but still alive, and 2 off study and dead (survived 11.6 and 1.5 months respectively). **Conclusions:** ADI-PEG 36 mg/m$^2$ IM weekly plus cisplatin 30 mg/m$^2$ IV weekly x 3 every 4 weeks was determined as the recommended phase 2 dosage, which was safe and demonstrated antitumor activity in patients with ASS-deficient advanced solid tumors. Further evaluation in patients with metastatic uveal and cutaneous melanoma is warranted. Clinical trial information: NCT01665183.

**2564 General Poster Session (Board #27), Sun, 8:00 AM-11:45 AM**

**First-in-human study of 4SC-205 (AEGIS), a novel oral inhibitor of Eg5 kinesin spindle protein.** *Presenting Author: Klaus B. Mross, KTB Klinik für Tumorbiologie, Freiburg, Germany*

**Background:** 4SC-205 is a potent small molecule inhibitor of the kinesin spindle protein Eg5 with broad anti-tumour activity in vitro and in vivo. Currently, 4SC-205 is the only oral available Eg5 inhibitor at clinical stage. Oral availability allows for flexible dosing in order to determine an optimal therapeutic window. **Methods:** Patients (pts) with solid tumors were dosed either once weekly (ow) at days 1 and 8 or twice weekly (tw) at days 1, 4, 8, and 11 or continuously (con) within a 21-day cycle. Dose escalation followed a 3+3 design. Primary objectives comprised safety, tolerability, definition of MTD/DLT and pharmacokinetic (PK) characterization. Secondary objectives include assessment of anti-tumour effect, measurement of M30/M65 cytokeratin-18 and pH3 in skin biopsies. **Results:** 56 Pts were enrolled at dose levels of 25mg (N=3), 50mg (N=3), 100mg (N=6), 150mg (N=6) and 200mg (N=13) ow; at 50mg (N=3), 75mg (N=7), and 100mg (N=5) tw; and at 10mg (N=3), 20mg (N=3) and 30mg (N=4) con. DLT was reached at 200mg (ow) and at 100mg (tw). MTD is established at 150mg (ow) and at 75mg (tw). These findings are in line with a dose proportional PK, resulting in similar cumulative AUCs for DLT and MTD for ow and tw dosing, respectively. The most common dose limiting adverse event was neutropenia. Prophylactic treatment with G-CSF at 200mg (ow) did not result in additional benefit. Interim analysis of exposure-toxicity data using a population PK/PD model for neutropenia suggested an opportunity for continuous dosing. Neutropenia occurred at dose level of 30mg (con). A dose-dependent biomarker response was observed in skin biopsies. Response acc. to RECIST was not observed. 28% of patients were stabilized into follow-up after 6 weeks. The maximum treatment duration was > 300 days. Currently, 3 more patients are entrolled in 20mg con. However,the data of 56 patients allows for reliable evaluation. **Conclusions:** 4SC-205 could be safely administered up to 200mg (ow), 100mg (tw) and 30mg (con). Neutropenia was the main dose limiting toxicity. The compound exhibits dose-proportional pharmacokinetics with $t_{1/2}$ ~ 10h. Plasma exposure exceeds average *in vitro* $GI_{50}$ 20x at the highest dose level over a period of 24h. Clinical trial information: NCT01065025.

**2565 General Poster Session (Board #28), Sun, 8:00 AM-11:45 AM**

**Joint cell-line and patient modeling of drug sensitivity reveals novel molecular biomarkers for targeted and conventional chemotherapy.** *Presenting Author: Charles Ferte, Department of Medical Oncology, Institut Gustave Roussy, Villejuif, France*

**Background:** The unresponsiveness to anticancer drugs in patients outlines the need to identify novel and robust biomarkers of response to therapy. The recent release of large molecular cell line datasets labeled for drug sensitivity enables the development of such predictors. Cell line based models poorly reflect the extent of molecular heterogeneity existing at the patient level. We aimed to overcome this limitation by combining cell line with patient data to uncover novel molecular traits associated with drug response at the patient level. **Methods:** We used both patients and cell lines data from the following publicly available datasets: CCLE (1057 cell lines, 24 drugs), Sanger (790 cell lines, 130 drugs) and TCGA (patients: breast cancer, colorectal cancer, lung squamous carcinoma, lung adenocarcinoma, ovarian cancer, endometrial cancer and melanoma). A two-step Elastic Net approach was used to model the drug sensitivity using gene-expression, copy-number alteration, and somatic mutation data. As validation, we used the dataset of 420 cancer patients prospectively enrolled in the ongoing MOSCATO molecular screening program (Gustave Roussy, France). **Results:** As positive control, we were able to recover all of the recognized landmark biomarkers across drug - tissue combination (e.g. Erlotinib: EGFR mutation in lung adenocarcinoma; Lapatinib: ERBB2 amplification in breast cancer; Vemurafenib: BRAF mutation in melanoma, etc). We uncovered novel molecular traits (copy, number mutations) associated (FDR<20%) with drug response (e.g. erlotinib: CDKN2A deletion in lung adenocarcinoma, lapatinib: CDH1 deletion in breast cancer, etc.). The validation of our framework in the MOSCATO patients' cohort will be presented. **Conclusions:** We provide a comprehensive annotation of mutations and copy-number events predicted to be associated with sensitivity and resistance in 142 anti-cancer drugs and across 7 tumor types. This approach is likely to exert a major impact on precision medicine programs in oncology.

**2566 General Poster Session (Board #29), Sun, 8:00 AM-11:45 AM**

**A phase I and pharmacokinetic study of a weekly dosing schedule of paclitaxel injection concentrate for nano-dispersion (PICN) in patients with advanced solid tumors.** *Presenting Author: Wen Wee Ma, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** PICN is a novel Cremaphor-free composite of paclitaxel nano-particles stabilized with polymer and lipid using NanotectonTechnology. PICN started development with every-3-week schedule of PICN +/- carboplatin (ASCO 2013; #2557). This study aimed to determine the maximum tolerated dose (MTD) and pharmacokinetic (PK) profile of PICN dosed using a weekly schedule. **Methods:** Patients (pt) with solid malignancies and ECOG PS 0-1 were eligible, and the dose escalation was conducted per a '3+3' design. PICN was administered i.v. weekly for 3 weeks then1 week rest (28 days per cycle) at planned dose levels 80, 100, 125 and 150 mg/m$^2$. The 125 mg/m$^2$level was intolerable in pts who previously received multiple lines of chemotherapy (Arm A), and the study was amended to continue dose escalation in pts who previously received 2 or less lines of treatment (Arm B). Only standard anti-emetic premedications were used. Adverse events (AEs) were graded using CTCAE 4.0 and tumor response by RECIST 1.1 **Results:** A total of 22 pts were enrolled from 2 US academic centers and 15 evaluable for dose limiting toxicity (DLT). Number of pts at each level were n=3 at 80, n=6 at 100, n=3 at 125 (Arm A) and n=3 at 125 mg/m$^2$ (Arm B). The DLTs observed were: dose delay for > 7 days for Gr1 ANC at 100 mg/m$^2$; Gr3 fatigue and Gr3 weakness at 125 mg/m$^2$ (Arm A). Anti-tumor efficacy was observed in breast (PR, 80 mg/m$^2$), ovarian (SD for > 12 months; 100 mg/m$^2$), and urothelial (PR; 125 mg/m$^2$) cancers. Previous treatments received in the ovarian pt included platinum(P)/paclitaxel, P/docetaxel and P/gemcitabine; and, P/gemcitabine in the urothelial pt. The dose level of 125 mg/m$^2$(Arm B) was tolerable and enrollment to higher dose levels are underway. PK analysis showed dose-proportional increase in total plasma paclitaxel level. **Conclusions:** When administered on a weekly schedule (3-weeks-on/1-week-off), 100 mg/m$^2$ was the MTD in heavily pretreated pts. 125 mg/m$^2$ was tolerable in pts who received 2 or less previous lines of chemotherapy. Anti-tumor efficacy was observed in breast, ovarian and urothelial cancers. Final PK, toxicity and efficacy data will be reported at the conference. Clinical trial information: NCT01305512.

**2567 General Poster Session (Board #30), Sun, 8:00 AM-11:45 AM**

**A phase I study of pemetrexed in combination with docetaxel in advanced solid tumor patients.** *Presenting Author: Lee D. Cranmer, The University of Arizona Cancer Center, Tucson, AZ*

**Background:** Pemetrexed is an anti-folate targeting the purine and pyrimidine synthetic pathways. Docetaxel is a third generation cytotoxic that modulates microtubule dynamics, inhibiting cell division. Our primary objective is to determine the MTD for the combination in a biweekly regimen in advanced solid tumors. Secondary endpoints include characterizing the adverse events (AEs) profile, anti-tumor activity, and recommended phase 2 dose (RPTD). **Methods:** Pemetrexed and docetaxel were administered on days 1 and 15 of a 28-day cycle. The dose escalation scheme consisted of 7 planned dose levels ranging from 300-600 mg/m$^2$ pemetrexed and 30-60 mg/m$^2$ docetaxel. Cohorts of 3-6 patients were enrolled in each dose level using the classical 3+3 dose escalation design. AEs were classified using CTCAE 3.0. Upon determination of MTD, an expansion phase was implemented to include 12 patients treated at the MTD level. **Results:** 33 advanced solid tumor patients were enrolled; 32 received treatment (1 ineligible). 28/32 patients received at least one prior line of chemotherapy. Three (3) patients were removed from the study before completing one cycle: 1 due to disease progression, 1 refused further treatment, 1 experienced dose-limiting toxicity (grade 3 gastrointestinal AE).Most frequent, treatment-related AEs were fatigue (85%), leukopenia (73%), nausea (69%), elevated aminotransferases (54%–62%), anemia (62%), and neutropenia (62%). MTD was deemed to be 500 mg/m$^2$ pemetrexed and 40 mg/m$^2$ docetaxel. Twenty-six (26) patients were evaluable for response: 19% PR (5: 2 sarcoma, 2 NSCLC, 1 renal cell kidney cancer), 50% SD (13: 7 sarcoma, 4 NSCLC, 1 bladder cancer, 1 thymoma), and 31% PD (8: 6 sarcoma, 2 NSCLC). **Conclusions:** Administration of pemetrexed and docetaxel was feasible without unexpected toxicities. The combination demonstrated preliminary evidence of significant anti-tumor activity in pretreated patients with advanced solid tumors. It may also be a useful alternative doublet in patients with non-squamous NSCLC unable to tolerate platinum. The RPTD is 500 mg/m$^2$ pemetrexed and 40 mg/m$^2$ docetaxel. Given the preliminary anti-tumor activity, the combination deserves further investigation, particularly in sarcoma. Clinical trial information: NCT01172028.

**2568 General Poster Session (Board #31), Sun, 8:00 AM-11:45 AM**

**Aurora-A mitotic kinase and induction of endocrine resistance through downregulation of er$\alpha$ expression in initially er$\alpha$+ breast cancer cells.** *Presenting Author: Mateusz Opyrchal, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** Development of endocrine resistance during tumor progression represents a major clinical challenge in the management of ER$\alpha$+ breast tumors and is an area under intense investigation. Although the underlying mechanisms are still poorly understood, many studies point toward the 'cross-talk' between ER$\alpha$ and MAPK signaling pathways as the key in the development of estrogen-independent growth of initially ER$\alpha$+ and hormone sensitive breast cancer cells. **Methods:** In this study we employed a metastatic, Mcf-7, ER$\alpha$+, breast cancer xenograft model harboring constitutive activation of Raf-1 oncogenic signaling to investigate the mechanistic linkage between aberrant MAPK activity and development of endocrine resistance. Patient samples were tested for expression of Aurora-A. **Results:** In vitro cells showed resistance to endocrine therapies. Development of endocrine resistance was functionally linked to ER$\alpha$ down-regulation both in vitro and in vivo. Because resistant cells also overexpressed Aurora-A kinase, we investigated the causal role of Aurora-A kinase in regulating ER$\alpha$ expression. Inhibition of Aurora-A kinase activity employing a specific inhibitor, Alisertib, resulted in re-expression of ER$\alpha$ and increased sensitivity to endocrine therapies as well as decreased p~SMAD5. The role of SMAD5 was also tested by overexpressing SMAD5 in MCF-7 cells, which led to loss of ER$\alpha$ expression. Aurora-A over-expression in ER$\alpha$+ patient breast tumor tissues was associated with increased risk of recurrence. **Conclusions:** We demonstrate for the first time the causal role of Aurora-A kinase in the development of endocrine resistance through activation of SMAD5 nuclear signaling and down-regulation of ER$\alpha$ expression in ER$\alpha$+ breast cancer cells. This contribution is highly significant for the treatment of endocrine refractory breast carcinomas. Our findings may lead to the development of novel molecular therapies targeting the Aurora-A/SMAD5 axis to eradicate endocrine resistant cancer cells and suppress tumor progression and the onset of distant metastases with consequent clinical benefit to breast cancer patients.

**2569 General Poster Session (Board #32), Sun, 8:00 AM-11:45 AM**

**Phase I: Veliparib with cisplatin (CP) and vinorelbine (VNR) in advanced triple-negative breast cancer (TNBC) and/or *BRCA* mutation-associated breast cancer.** *Presenting Author: Eve T. Rodler, Seattle Cancer Care Alliance, Seattle, WA*

**Background:** Poly(ADP-ribose) polymerase inhibitors (PARPi) have activity in tumors with DNA repair defects, including BRCA 1/2 deficient cancers. CP is synergistic with the PARPi veliparib in xenografts, and has anti-tumor activity in TNBC and BRCA1 deficient breast cancer. VNR shows preclinical synergy with CP and the combination has efficacy in metastatic breast cancer (MBC). We hypothesize that veliparib combined with CP and VNR is active in TNBC and will be most effective in tumors with DNA repair defects. **Methods:** To determine maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic profiles, and anti-tumor activity, patients (pts) with TNBC and/or *BRCA1/2*+ MBC received CP 75 mg/m$^2$ day 1, VNR 25 mg/m$^2$days 1, 8 and escalating doses of veliparib (V) orally BID days 1-14, every 21 days for 6-10 cycles followed by maintenance V. **Results:** 45 pts enrolled in 9 cohorts. Treatment was tolerated well; MTD was not reached. 36 pts (80%) had at least 1 prior metastatic regimen (range 1-11). *BRCA* mutation status was: *BRCA1*+ (n=9); *BRCA2*+ (n=3); negative (n=24); unknown (n=9). BID V dose cohorts were: 20 mg (n=4); 30 mg (n=3); 40 mg (n=6); 60 mg (n=8); 80 mg (n=5 ); 120 mg (n=6); 160 mg (n=3); 200 mg (n=7); and 300 mg (n=3). DLT occurred at 40 mg BID in 1 pt with grade (gr) 4 thrombocytopenia, 60 mg BID (gr 4 neutropenia + fever, n=1), and 200 mg BID (gr 3 neutropenia + fever, n=1). Most common adverse events (AEs) were nausea, anemia, fatigue, mainly gr 1/2. Most common gr 3/4 AEs were neutropenia (n=13), anemia (n=11), thrombocytopenia (n=6). Of 38 evaluable pts, 21 (55%) responded (2 CR, 19 PR), 13 (34%) had SD, and 4 had PD, as best response. One pt with CR remains on trial for 42+ cycles. Response was 73% in *BRCA* 1/2+ pts (6/11 PR; 2/11 CR), 53% in *BRCA*1/2- pts (11/21 PR) and 33% in unknown status pts (2/6 PR). Analyses of PK and correlative predictors of response will be presented. **Conclusions:** Veliparib at the recommended phase II dose of 300mg BID combined with CP and VNR is well tolerated. *BRCA* mutation carriers and pts with sporadic TNBC, including heavily pretreated pts, responded. We plan to investigate the contribution of veliparib to cisplatin-based therapy in a randomized trial. Clinical trial information: NCT01104259.

**2570 General Poster Session (Board #33), Sun, 8:00 AM-11:45 AM**

**Final results of a phase 1 study of single-agent veliparib (V) in patients (pts) with either BRCA1/2-mutated cancer (BRCA+), platinum-refractory ovarian, or basal-like breast cancer (BRCA-wt).** *Presenting Author: Shannon Leigh Huggins-Puhalla, University of Pittsburgh Cancer Institute, Magee-Womens Hospital of UPMC, Pittsburgh, PA*

**Background:** Veliparib (V) (ABT-888) is a potent, oral PARP 1/2 inhibitor with preclinical and clinical efficacy in BRCA+ malignancies. As there are known similarities between BRCA+ cancers, serous ovarian cancer, and basal-like breast cancer, we postulated potential for V activity in these groups also. We sought to establish the maximum tolerated dose (MTD), dose-limiting toxicities (DLT), pharmacokinetic (PK) and pharmocodynamic properties, and preliminary efficacy of chronically-dosed V. **Methods:** A 3+3 dose-escalation phase I trial was performed. Nine dose levels ranging from 50 mg BID to 500 mg BID dosed continuously were enrolled to determine a maximum tolerated dose (MTD) and recommended phase II dose (RP2D). A biopsy cohort in BRCA+ patients was enrolled at the RP2D. Correlative studies included assessment of BRCA reversion mutation analysis, DNA repair pathway analysis, and BRCA promoter methylation status. **Results:** A total of 88 pts (60 BRCA+ and 28 BRCA-wt) were enrolled to date. DLTs occurred at the following dose levels: BRCA+: gr 3 nausea/vomiting at 400 mg BID, gr 2 seizure at 500 mg BID; BRCA-wt: gr 2 seizure at 400 mg BID. The RP2D was established at 400 mg BID. The most common all-grade toxicities were nausea, fatigue, and lymphopenia. PK was linear and non-saturable with t ½ of 5.2 h. Fifty-two BRCA+ patients (28 ovary, 13 breast, 11 other) were evaluable for response. In BRCA+ patients at all dose levels, the ORR (CR+PR) was 23% with a clinical benefit rate (CBR; CR + PR + stable disease) of 58%. At the MTD and RP2D, 28 BRCA+ patients were evaluable, with an ORR of 40%, and a CBR of 68%. Twenty-four BRCA-wt pts (21 breast and 3 ovary) were evaluable for response, and the ORR was 4% with a CBR of 38%. **Conclusions:** Single-agent V is well-tolerated with evidence of anti-tumor activity seen in both BRCA+ and BRCA-wt tumors comparable to other single agent PARP inhibitors. Evidence of potential dose responsiveness was observed. Correlative studies from archival tissues and mandatory biopsy cohort, with final data to be presented, will provide early insights on potential mechanisms of response and resistance. Clinical trial information: NCT00892736.

**2571 General Poster Session (Board #34), Sun, 8:00 AM-11:45 AM**

**Intraoral JP4-039 to ameliorate irradiation-induced mucositis in tumor-bearing Fanconi anemia (FA) mouse model.** *Presenting Author: Ashwin Shinde, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** The DNA repair defect in Fanconi anemia (FA) patients makes radiotherapy of head and neck cancers a challenge due to mucositis as a dose limiting toxicity. We tested intraoral delivery of mitochondrial-targeted antioxidant, JP4-039, in a novel F15 emulsion, to reduce mucositis in fractionated irradiated FA mice with orthotopic tumors. **Methods:** *Fancd2*$^{+/+}$, *Fancd2*$^{+/-}$, and *Fancd2*$^{-/-}$mice from C57BL/6J background with palpable tumors, measureable by calipers, were irradiated to single 28 Gy or 8 Gy x 4 daily fractions to the oral cavity. Subgroups of mice (N=4/group) received intraoral JP4-039/F15 (100 ul containing 4 mg/ml of drug) 10 minutes prior to irradiation, F15 alone or irradiation alone. Tumor size was measured daily. Five days after the last radiation dose, mice were sacrificed, and tumors and tongue tissue removed for histopathology. Statistical analysis was performed using Students t-test, with a p-value $<$ 0.05 considered significant. **Results:** Intraoral JP4-039/F15 prior to irradiation significantly decreased oral cavity ulceration ($p < 0.001$). Following 8 Gy x 4, F15-JP4-039 treated *Fancd2*$^{-/-}$ knockout mice had 47.8 $\pm$ 11.1% of the tongue ulcerated compared to 81.7 $\pm$ 11.6% ulceration in untreated mice ($p < 0.001$). Results in JP4-039/F15 treated irradiated heterozygotes and wild-type *Fancd2*$^{+/+}$ mice (34.1 $\pm$ 21.2 or 16.9 $\pm$ 12.6% ulceration, respectively) were also improved compared to untreated irradiated mice (88.3 $\pm$ 8.0 or 76.3 $\pm$ 17.2% ulceration, respectively) ($p <$ 0.001 for all groups). F15 alone did not reduce ulceration. JP4-039/F15 treated FA mice had increased ulceration compared to *Fancd2*$^{+/+}$ mice (47.8 $\pm$ 11.1% and 16.9 $\pm$ 12.6% respectively, $p < 0.0001$). Both single fraction and fractionated radiation treatment controlled tumors at 5 days in *Fancd2*$^{+/+}$, *Fancd2*$^{+/-}$, and *Fancd2*$^{-/-}$ mice (0.4 $\pm$ 0.3, 0.05 $\pm$ 0.05, or 0.1 $\pm$ 0.1 mm$^3$, respectively) compared to nonirradiated controls (2.1 $\pm$ 0.4, 1.9 $\pm$ 0.5, or 3.1 $\pm$ 0.1 mm$^3$, respectively, $p < 0.027$). Tumor size was comparably reduced in all irradiated groups. **Conclusions:** Intra oral JP4-039 protects normal tissue in irradiated FA mice without associated tumor protection.

**2572 General Poster Session (Board #35), Sun, 8:00 AM-11:45 AM**

**Early phase I study of the PARP inhibitor veliparib (ABT-888) alone or in combination with carboplatin/paclitaxel (CP) in patients with varying degrees of hepatic or renal dysfunction: A study of the NCI-Organ Dysfunction Working Group (ODG).** *Presenting Author: Hussein Abdul-Hassan Tawbi, University of Pittsburgh Cancer Institute, Pittsburgh, PA*

**Background:** PARP inhibitors are promising anti-cancer agents with clinical activity as single agents or in combination with chemotherapy. Alteration of hepatic or renal function could affect the pharmacokinetic (PK) characteristics of veliparib (V) and thus, impact adversely on its safety. We conducted a multi-center Phase I study through the NCI-Organ Dysfunction Working Group (ODG) to determine: (1) the maximum tolerated dose (MTD) of V in combination with CP in pts with varying degrees of renal or hepatic dysfunction; and (2) the PK of V. **Methods:** Pts with advanced solid malignancies, ECOG PS 0-2, and normal bone marrow were enrolled to the following cohorts: normal (N); moderate (R2; CrCL= 30-59mL/min), severe (R3; CrCL<30mL/min) renal dysfunction, and hemodialysis (R4); mild (H2; bilirubin(B)<1.25x ULN), mild with transaminase elevation (H3; B<1.25x ULN and ALT/AST(T)>3xULN), moderate (H4; B>1.25-2xULN and T<10xULN), and severe (H5; B>2-5xULN and T<10xULN) hepatic dysfunction. Pts with both renal and hepatic dysfunction were excluded. All pts received a single 80 mg oral dose of V for extensive PK sampling 1 week prior to the initiation of combination therapy. V dose escalation up to 80 mg PO BIDx5d followed the standard "3+3" design within each cohort with C AUC 6 and P 175 mg/m$^2$ on d3 of a 21-d cycle. C and P were dose-adjusted to the degree of organ dysfunction following FDA dosing guidelines. DLTs were defined based on myelosuppression or worsening organ function. **Results:** A total of 59 pts were enrolled of which 45 were evaluable: N: 13, R2: 11, R3: 6, H2: 7, H3: 3, H4: 4. All pts enrolled on DL1 and DLminus1 of H4 experienced DLTs closing accrual to this cohort and H5. PK data on V and its inactive metabolite M8 were available on all pts treated with a single fixed dose V. **Conclusions:** V combined with CP is not safely deliverable in pts with moderate to severe hepatic dysfunction, though V PK appeared unaffected by hepatic dysfunction. Renal dysfunction did result in increased V and M8 exposure. These data will guide potential dose reductions in pts with hepatic or renal dysfunction. Clinical trial information: NCT01366144.

**2573 General Poster Session (Board #36), Sun, 8:00 AM-11:45 AM**

**Phase 1/2 study of oral rucaparib: Final phase 1 results.** *Presenting Author: Rebecca Sophie Kristeleit, University College London Cancer Institute, London, United Kingdom*

**Background:** Rucaparib is a potent, oral PARP inhibitor (PARPi) that induces synthetic lethality in homologous recombination deficient (HRD) tumors (e.g. BRCA mutation). The primary objectives of the Phase 1 portion were to define the MTD, RP2D and PK of continuous rucaparib. **Methods:** A 3+3 dose escalation design was used. Intra-patient dose escalation was allowed. Patients (pts) aged ≥18 with advanced solid tumors that had progressed on standard treatments were recruited. Measurable disease was not required. Rucaparib was taken orally QD or BID continuously. Plasma PK assessments included full profile and trough levels. **Results:** Phase 1 is complete with 56 pts (median age 51 yrs [range 21-71]; 51 female; 29 ECOG PS=0; 27 breast cancer (BC), 20 ovarian/peritoneal cancer (OC), 9 other tumor) enrolled in 10 dose cohorts (40 QD-840 mg BID). 600 mg BID was identified as the optimal RP2/3D based on maximum exposure, manageable toxicity and promising clinical activity. Exposures exhibited dose proportional kinetics up to the RP2/3D with low inter- and intra-pt variability, an important attribute for uniform flat dosing strategies. At 360 mg BID, 1 pt had a DLT of Grade (G) 3 nausea, with no others at higher dose levels. The incidence and severity of myelosuppression, a known PARPi effect, was dose-dependent with ~50% of pts at the RP2/3D having at least one G2 or G3 event (% G2/G3): anemia (29%/29%), thrombocytopenia (0/14%), neutropenia (29%/0). All G3 events were post-Cycle 1 and were successfully managed with dose reduction. Treatment-related AEs (mostly G1/2) reported in ≥10% of all pts include fatigue (30%), nausea (30%), vomiting (23%), diarrhea (13%), anorexia (11%). No G4 AEs have occurred. RECIST and/or CA-125 responses occurred at doses ≥ 300 mg QD (2 CRs, 7 PRs, 3 CA-125). At these doses, disease control rate (CR+ PR + SD≥24 weeks) was 70% (7/10) in gBRCA OC pts. At the RP2/3D, 4/5 (80%) OC (3/4) and BC (1/1) pts had a RECIST or CA125 response. All responders had a BRCA 1/2 mutation. Responses were seen in platinum-sensitive and platinum-resistant OC pts. **Conclusions:** Rucaparib has a desirable PK profile and is well tolerated with promising clinical benefit in OC, BC, and pancreatic cancer. Three studies are ongoing in OC pts (ARIEL2, ARIEL3, Phase 2 portion of this trial). Clinical trial information: NCT01482715.

**2574 General Poster Session (Board #37), Sun, 8:00 AM-11:45 AM**

**A phase 1 dose-escalation study of veliparib with bimonthly FOLFIRI in patients with advanced solid tumors.** *Presenting Author: Jordan Berlin, Vanderbilt-Ingram Cancer Center, Nashville, TN*

**Background:** Veliparib (V; ABT-888), a potent, competitive poly (ADP-ribose) polymerase (PARP)-1 and -2 inhibitor enhances the activity of irrinotecan (IRI). This study seeks to establish the maximum tolerated dose (MTD) and recommended Phase 2 dose (RPTD) of V in combination with bimonthly FOLFIRI. **Methods:** Solid tumorpatients (pts; ≤3 prior DNA-damaging regimens) were administered V BID (days 1-5; 15–19) and FOLFIRI in three parts (P) : (P1) IRI 150 mg/m$^2$; (P2) IRI 180 mg/m$^2$ with 5-FU 400 mg/m$^2$ bolus; or (P3) IRI 180mg/m$^2$. All regimens included folinic acid 400 mg/m$^2$, immediately followed by 5-FU 46-hour continuous infusion. Dose escalation began with V 10 mg BID in P1 and 100 mg BID in P2 and P3. Two expansion cohorts were evaluated in gastric or colorectal cancer pts with no prior PARP inhibitor therapy. **Results:** 96 pts (median age 54.5 years; range, 24–77) were enrolled in cohorts from 10–300 mg BID V. Tumor types were: other (n=30); gastric (n=20); pancreatic (n=14); ovarian, breast, and colorectal (each, n=9). 88 pts discontinued: 83 due to progressive disease; 2 withdrew consent; and 3 other. Most common AEs (>40% pts) were diarrhea (61%), nausea (60%), neutropenia (59%), vomiting (48%), fatigue (47%), anemia and alopecia (each, 41%). Grade 3/4 AEs (>30 pts) were neutropenia (47%), nausea (38%), and diarrhea (34%). Four DLTs occurred: neutropenia (n=3; P1, 160 mg and 270 mg BID V; P2, 100 mg BID V); and gastritis and vomiting (P1, 270 mg BID V). 12 pts (gastric, n=3; ovarian, breast, pancreatic, and other, each n=2; colorectal, n=1) achieved a partial response and 1 (ovarian) a complete response. V exposure was approximately dose-proportional in combination with FOLFIRI. FOLFIRI PKs were comparable with or without V administration, indicating the lack of drug-drug interaction. **Conclusions:** V in combination with chemotherapy was generally well-tolerated without drug-drug interactions. Ovarian and breast cancer pts experienced the greatest anti-tumor activity with an objective response rate of 33% and 22%, respectively. The RPTD was 200 mg BID V with bimonthly FOLFIRI (IRI 150 or 180 mg/m$^2$ without 5-FU bolus). This study supports further evaluation of V in combination with FOLFIRI in specific tumor types. Clinical trial information: NCT01123876.

**2575 General Poster Session (Board #38), Sun, 8:00 AM-11:45 AM**

**Phase I dose-escalation study of an oral administration of the pan-histonedeacetylase inhibitor abexinostat combined with a fixed dose of doxorubicin in patients with solid tumors.** *Presenting Author: Arnaud Scherpereel, University Hospital of Lille Nord de France, Lille, France*

**Background:** Preclinical data indicate that abexinostat enhances sensitivity to DNA-damaging agents, such as doxorubicin, particularly when administered 48h before infusion. A phase I dose-escalation study of abexinostat in combination with doxorubicin was performed in candidate patients to determine the maximum tolerated dose (MTD) and dose-limiting toxicities (DLT), and establish the recommended phase II dose (RP2D). **Methods:** Abexinostat was given 4 consecutive days weekly, 3 out of 4 weeks, and fixed doxorubicin dose of 25 mg/m$^2$ was administered on day 3 of each weekly abexinostat schedule, for a maximum of 6 cycles. **Results:** 35 patients were included and treated: 23 in the dose-escalation phase in cohorts receiving abexinostat 30 to 75 mg/m$^2$ bid, and 12 in the confirmation phase at the RP2D. In the dose-escalation phase, MTD was 75 mg/m$^2$ bid with 3 DLTs 2 grade 4 thrombocytopenia, 1 grade 2 neutropenia >7 days. In the confirmation phase (RP2D 60 mg/m$^2$ bid), there were 4 DLTs (33% patients): 2 grade 4 thrombocytopenia, 1 grade 3 fatigue, 1 failure to restart treatment due to prolonged grade 2 neutropenia. Most abexinostat-related adverse events were grade 1 or 2 (79%), with 18% grade 3 and 3% grade 4; they were mostly hematological (51%), gastrointestinal (23%), or general disorders (10%). Preliminary pharmacokinetics of the combination showed no interaction between the two drugs. Preliminary efficacy results on 27 evaluable patients showed 3 partial responses (2 at C4 and 1 at C6) and 12 stable disease with median duration of 2 cycles (range C2-C6) as best response. 13 patients received the combination for at least 4 cycles and 11 patients completed 6 cycles. **Conclusions:** Combination of abexinostat 60 mg/m$^2$ bid 4 consecutive days weekly, 3 out of 4 weeks, with doxorubicin at 25 mg/m$^2$ on the third day of each abexinostat cycle appears to be well tolerated in patients with advanced solid tumors. Preliminary efficacy results were observed at different dose levels. Clinical trial information: ISRCTN55052510.

**2576 General Poster Session (Board #39), Sun, 8:00 AM-11:45 AM**

**A phase I trial of pazopanib and vorinostat: The role of *TP53* mutations.** *Presenting Author: Ming-Mou Hou, Chang Gung Memorial Hospital, Taoyuan, Taiwan*

**Background:** VEGF inhibition-mediated tumor hypoxia promotes invasive growth by transcriptional activation of hypoxia-induced factors mediated by tumor hypoxia. Accordingly, we conducted this phase 1 study of pazopanib plus vorinostat to overcome resistance to antiangiogenesis (NCT01339871). **Methods:** Primary objective of this phase I trial was to define the maximum tolerated dosage (MTD) and the safety profile following a zone-based, modified 3 + 3 dose escalation design (12 dose levels). Toxicity and efficacy were evaluated according to CTCAE 4.0 and RECIST 1.1. **Results:** A total of 78 evaluable patients enrolled. Six patients (7.7%) experienced dose-limiting toxicity (DLT): 2 hypertension, 2 diarrhea, 1 thrombocytopenia, and 1 skin rash. The most frequent drug-related grade 2 or higher adverse events were thrombocytopenia, neutropenia, fatigue, hypertension, diarrhea, and vomiting in 39 patients (50%). Pazopanib plus vorinostat (800 mg/200 mg [4A], 600 mg/300 mg [4B], 400 mg/400 mg [4C] PO daily) in zone 4 were defined as the MTDs, with dose reduction in 67%, 33% and 57% of patients, respectively. The dose level 4B was chosen for further evaluation. Four patients (5.1%) achieved partial response (PR) and 9 patients (11.5%) experienced stable disease for at least 6 months (SD≥6months). This cohort of patients showed a median progression-free survival (PFS) of 2.2 months (95% CI, 1.8-2.6) and a median overall survival (OS) of 8.3 months (95% CI, 6.2-10.4). Further evaluation revealed that patients with *TP53* mutations (n=10) showed a median PFS of 3.5 months and a median OS of 12.7 months (95% CI, 2.2-23.2), compared favorably with 2.0 months (95%CI, 1.9-2.1; $p$=0.08), and 7.5 months (95%CI, 5.0-9.4; $p$=0.12) in those with *TP53* mutation undetected (n=21), respectively. In 13 patients who achieved PR/SD≥6months, 4 patients had *TP53* mutations, 2 undetected, and 7 unknown. **Conclusions:** Dose level 4B (pazopanib 600 mg PO daily plus vorinostat 300 mg PO daily) was considered as the recommended phase II dosage. Antitumor activity in patients with advanced solid tumors was demonstrated. Early clinical evidence indicated that further evaluation of the efficacy and safety of this regimen, and role of *TP53* mutations in treatment sensitivity is warranted. Clinical trial information: NCT01339871.

**2577 General Poster Session (Board #40), Sun, 8:00 AM-11:45 AM**

**Phase I study of pazopanib (PAZ) in combination with abexinostat (ABX) in patients (Pts) with metastatic solid tumors.** *Presenting Author: Rahul Raj Aggarwal, University of California, San Francisco, San Francisco, CA*

**Background:** PAZ is a tyrosine kinase inhibitor of VEGFR, PDGFR, and C-KIT approved for use in renal cell carcinoma (RCC) and soft tissue sarcoma (STS). ABX is a potent pan-HDAC inhibitor (HDACi). Pre-clinical models suggest that epigenetic modulation with an HDACi potentiates PAZ's efficacy and prevents the outgrowth of a resistant phenotype. We therefore designed a Phase I clinical trial combining ABX with PAZ in pts with advanced solid tumors. **Methods:** The primary objective was to determine the maximal tolerated dose (MTD) of PAZ plus ABX in pts with advanced solid tumor malignancies. Secondary objectives included pharmacokinetics (PK) and efficacy. Altered histone acetylation post treatment denoted HDACi activity and served as pharmacodynamic (PD) markers in peripheral blood mononuclear cells. PAZ was dosed daily and ABX on days 1-5, 8-12, 15-19 of a 28-day cycle, at a starting dose of 400 mg/day and 45 mg/m$^2$ orally twice daily for PAZ and ABX respectively. **Results:** 22 patients with advanced solid tumors were enrolled. There were five dose-limiting toxicities (DLTs) (fatigue: N = 2, thrombocytopenia: N = 2; grade 2 elevated AST with fever: N = 1). The MTD was PAZ 600 mg/day + ABX 30 mg/m$^2$ BID. The most common grade ≥ 3 drug regimen-related adverse events observed include thrombocytopenia (12%), fatigue (12%), and diarrhea (8%). 3 of 15 evaluable pts (20%) (including 2 RCC pts) had a confirmed objective partial tumor response, including one pt with prior progression in single agent PAZ. 5 out of 17 evaluable pts (29%) have experienced disease stabilization or better for ≥ 6 months. PK and PD analyses are ongoing. An alternate dosing schedule is being explored with ABX administered on D1-4, 8-11,15-18 of a 28-day cycle. The current dose level is 45 mg/m$^2$ BID and PAZ at 600 mg/day with no DLTs observed thus far (N = 2). **Conclusions:** This is the first trial to explore the combination of ABX with PAZ in RCC and other solid tumor malignancies. The optimal dosing schedule may be ABX taken 4 days/week but requires further investigation. Encouraging preliminary evidence of anti-tumor activity was observed including in a pt with prior disease resistance to PAZ monotherapy. An expansion cohort with 20 pts in RCC and sarcoma is planned. Clinical trial information: NCT01543763.

**2578 General Poster Session (Board #41), Sun, 8:00 AM-11:45 AM**

**A phase 1 trial and pharmacokinetic study of RRx-001, a novel ROS-mediated pan-epigenetic agent.** *Presenting Author: Tony R. Reid, University of California, San Diego, La Jolla, CA*

**Background:** RRx-001 the first of a new class of pan-epigenetic anticancer agents, binds hemoglobin and drives RBC-mediated redox reactions under hypoxia. RRx-001 inhibits HDACs and Dnmt1 and 3a expression, affecting multiple aspects of cancer cell-cycle regulation and survival, including caspase activation, cyclin-dependent kinase activities, and p53 gene expression. The objectives of this dose-escalation trial were to investigate safety, DLTs, and PK of RRx-001. **Methods:** Eligible patients had advanced solid tumors; ECOG PS 0-2; adequate bone marrow function. In a 3+3 escalation design, RRx-001 was administered IV for up to 6h weekly for 8 weeks to patients in successive dose-escalating cohorts. Tumor response (CT, PET-CT, biopsy) was determined every 4 or 8 weeks. Subjects were evaluable if they had a baseline CT scan and at least one follow up scan after at least one dose of RRx-001. **Results:** 25 pts were dosed over 6 cohorts (10, 16.7, 24.6, 33, 55, 83 mg/m$^2$). Tumor types were pancreas (3), CRC (11), head and neck (4), melanoma (1), cholangiocarcinoma (1), ovarian (1), lung (2) and HCC (1) and oligodendroglioma (1). RRx-001 was well tolerated with no DLTs and no formal MTD was established. No RRx-001-induced systemic toxicities were observed. The only drug-related AE across all cohorts was acute and transient injection-site pain and vasodilation, moderate in severity and generally managed by lengthening infusion time, using peripheral venous access and corticosteroids. 20 pts were evaluable for response per protocol criteria, 1 with partial response (parotid adenoid cystic carcinoma), durable for one year. 9 pts (45%) had stable disease of ≥ 4 months. OS for all pts was 16.8 months. PK analysis of the GSH adduct was not representative of exposure to RRx-001. Two pts became responsive to previously failed FOLFIRI post RRx-001, as shown by changes in CEA and by imaging. As responses were seen in all cohorts, 33 mg/m$^2$ was selected as the Phase 2 dose. **Conclusions:** RRx-001 was well tolerated with infusion-site pain as the only observed AE to date. Toxicities normally associated with anticancer agents were absent. Single agent activity and a renewed response to previously failed chemotherapy was observed. Clinical trial information: NCT01359982.

**2579 General Poster Session (Board #42), Sun, 8:00 AM-11:45 AM**

**Effects of aprepitant on the pharmacokinetics of controlled-release oral oxycodone in cancer patients.** *Presenting Author: Yutaka Fujiwara, Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo, Japan*

**Background:** Oxycodone is a $\mu$-opioid receptor agonist widely used in the treatment of cancer pain. The predominant metabolic pathway of oxycodone is CYP3A4-mediated N-demethylation to noroxycodone, while a minor proportion undergoes 3-O-demethylation to oxymorphine by CYP2D6. The aim of this study was to investigate the effects of the mild CYP3A4 inhibitor aprepitant on the pharmacokinetics of orally administered controlled-release (CR) oxycodone. **Methods:** This study design was an open-label, single-sequence with two phases in cancer patients with pain who continued to be administered orally with multiple doses of CR oxycodone every 8 or 12 hours. Plasma concentration of oxycodone and its metabolites were measured up to 8 hours after administration as follows; on day 1, CR oxycodone was administered alone; on day 2, CR oxycodone was administered with aprepitant (125 mg, at the same time of oxycodone dosing in the morning). The steady-state trough concentrations (Css) were measured from day 1 to day 3. **Results:** Aprepitant increased the area under the plasma concentration-time curve ($AUC_{0\text{-}8}$) of oxycodone by 25% ($p<0.001$) and of oxymorphine by 34% ($p<0.001$), as well as decreased the $AUC_{0\text{-}8}$ of noroxycodone by 14% ($p<0.001$). Moreover, aprepitant increased Css of oxycodone by 57% ($p=0.001$) and of oxymorphine by 36% ($p<0.001$) and decreased Css of noroxycodone by 24% ($p=0.02$) at day 3 compared to day 1. **Conclusions:** Aprepitant increased the exposure levels of oxycodone by inhibiting its CYP3A4-mediated N-demethylation. Clinical trial information: UMIN000003580.

**2580 General Poster Session (Board #43), Sun, 8:00 AM-11:45 AM**

**A presurgical study of oral silybin-phosphatidylcholine in patients with early breast cancer.** *Presenting Author: Matteo Lazzeroni, European Institute of Oncology, Milan, Italy*

**Background:** Silybin-phosphatidylcholine (Siliphos) is an orally bioavailable complex of silybin, a poorly absorbable polyphenolic flavonolignan derived from milk thistle and endowed with potential anticancer activity in preclinical models. The purpose of the window of opportunity trial (code n. R621-IEO661/511) was to determine the tissue distribution of silybin-phosphatidylcholineand its effect on cell proliferation and other biomarkers in breast cancer (BC) patients. **Methods:** Twelve BC patients received silybin-phosphatidylcholine, 2.8 g daily for 4 weeks prior to surgery. Silybin levels were measured before (SIL) and after (TOT SIL) enzymatic hydrolysis by HPLC-MS/MS in biological samples (plasma, urine, BC tissue and surrounding normal tissue). Fasting blood samples were taken at baseline, before the last administration (end) and 2 hours after. **Results:** All patients were fully compliant and completed the treatment program. No toxicity was observed. SIL and TOT-SIL were undetectable in baseline samples. Median SIL and TOT-SIL concentrations after supplementation are shown in the table. Median TOT-SIL concentration was higher in the tumor as compared to the adjacent normal tissue (P=0.018). Despite a high between-subject variability, plasma SIL levels significantly correlated with the low concentration in normal tissue (Spearman coefficient=0.690, P=0.027). **Conclusions:** We show for the first time that oral silybin-phosphatidylcholine can attain biologically relevant breast tumor tissue levels and high blood concentrations of silybin. These results provide the basis for future clinical studies of Siliphos in breast carcinogenesis prevention. Circulating and tissue biomarkers of activity will be presented at the conference.

**Median (Q1-Q3) concentrations after supplementation.**

**2581 General Poster Session (Board #44), Sun, 8:00 AM-11:45 AM**

**Phase 1 study assessing dovitinib (TKI258) on the pharmacokinetics of caffeine, diclofenac, omeprazole, and midazolam in patients with advanced solid tumors.** *Presenting Author: Ding Wang, Josephine Ford Cancer Center/Henry Ford Health System, Detroit, MI*

**Background:** Dovitinib (TKI258) is an oral tyrosine kinase inhibitor targeting kinases involved in tumor cell proliferation and survival, including FGFR, VEGFR, PDGFR, c-KIT, and FLT3. In vitro, dovitinib induced CYP1A2, CYP2C9, and CYP2C19 activity and increased the mRNA level of CYP3A4. Here, we evaluated the impact of dovitinib on the pharmacokinetics (PK) of caffeine, diclofenac, omeprazole, and midazolam, the probe drugs metabolized by these cytochrome P450 isoforms. **Methods:** Patients (pts) ≥ 18 years of age with advanced solid tumors were given a cocktail of oral caffeine (100 mg), diclofenac (25 mg), omeprazole (20 mg), and midazolam (2 mg) on days 1 and 13, and dovitinib (500 mg oral once daily, 5 days on/2 days off) starting on day 2. Blood PK samples for each probe were collected predose and for 24 hours after drug cocktail dosing. Area under the curve (AUC) and maximum concentration ($C_{max}$) values were log-transformed and analyzed with a linear mixed-effects model. Following the drug-drug interaction phase, pts were allowed to continue dovitinib at the same dose and schedule. **Results:** Of 58 pts screened, 39 were treated, of which 28 and 26 pts were evaluable for PK analysis for drug interaction with caffeine and the remaining probe drugs, respectively. Dovitinib decreased the exposure (AUC and $C_{max}$) of caffeine and omeprazole, decreased the $C_{max}$of diclofenac, but increased the exposure of midazolam (Table). The most common adverse events regardless of study drug relationship were diarrhea (69%), fatigue (69%), nausea (64%), and vomiting (62%). **Conclusions:** Dovitinib is a strong inducer of CYP1A2, a moderate inducer of CYP2C19, and has limited impact on CYP2C9. Different from in vitro data, dovitinib is a moderate inhibitor of CYP3A4/5 in humans. Clinical trial information: NCT01596647.

**Analysis of impact of post-treatment biopsies in phase I clinical trials.** *Presenting Author: Randy F. Sweis, University of Chicago, Chicago, IL*

**Background:** It is commonly believed that post-treatment biopsies for pharmacodynamic biomarkers (PD-BM) positively impact drug development. We sought to determine the utility of PD-BM in phase I trials, based on their impact on subsequent studies. **Methods:** We identified publications on phase I clinical trials in oncology that incorporated a biomarker by searching PubMed using a broad search algorithm. Articles were restricted to 2003-2006 in order to allow adequate time for publication of subsequent trials citing the phase I trial. Articles covering pediatric populations, hematologic malignancies, topical/local therapies, gene therapy, immunotherapy, or radiation therapy were excluded. Characteristics of identified trials were analyzed and trials that included post-treatment biopsies were selected for further analysis. Citing articles were identified using PubMed and Google Scholar, and those articles were then reviewed. Fisher's exact test was used to compare groups. Statistics were carried out using JMP 11.0.0. **Results**: We identified 2,136 publications on phase I trials in oncology from 2003 to 2006. The use of any biomarker, as defined by our search algorithm was found in 200 (9.4%) publications, including 22 with a PD-BM. None of those PD-BM studies included a pre-specified statistical plan for the biomarker analysis. Only one study described performance characteristics of the assay. The number of reported biomarker tests ranged from 1-12, but no study included a correction for multiple testing. A statistically significant result on the PD-BM was reported in 3 (14%) studies, which was more likely to occur in industry-sponsored studies (P=0.04). A biomarker conclusion and statement of impact on future studies was found in 17 (77%) and 9 (41%) studies, respectively. Articles reporting subsequent phase 2/3 trials cited 19 (86%) of these PD-BM studies, but none used prior biomarker results in regard to phase 2/3 dose or schedule. Only a minority of the citing publications (8, 36%) mentioned the prior PD-BM studies. **Conclusions:** The impact of post-treatment biopsies for pharmacodynamic biomarkers is of uncertain value for subsequent drug development. This issue requires further evaluation, given the risk and cost of such studies.

**2583 General Poster Session (Board #46), Sun, 8:00 AM-11:45 AM**

**Pazopanib (P) and cisplatin (CDDP) in patients with advanced solid tumors: A UNICANCER phase I study.** *Presenting Author: Veronique Dieras, Institut Curie, Paris, France*

**Background:** P is an effective anti-angiogenic agent currently investigated in a wide variety of tumors outside its authorized indication. In a dose-escalation phase I study, we investigated the safety and tolerability of combining P with CDDP. **Methods:** Patients (pts) with metastatic refractory solid tumors eligible for CDDP chemotherapy were treated with oral P given once daily, in fasted condition, starting 8 days (d) before the first CDDP infusion. CDDP was given every 3 weeks (q3w) in a 1-hour iv infusion. Five dose levels (DL) were planned to investigate the occurrence of dose limiting toxicities (DLT) over cycle 1 and 2, and to determine the maximum tolerated dose (MTD). **Results:** 35 pts were enrolled with median age of 59 y., PS≤1. Tumor types were: ovary (8), H&N (5), sarcoma (5), breast (4), colorectal (4), choroidal melanoma (3), other (6). DLs explored are shown in the Table. MTD was confirmed at DL1. An inverted schedule (IS) was added at the MTD starting with CDDP followed by P to explore PK interaction. DLT were 2 Grade (G) 3 ALAT elevation, one associated with G4 hyponatremia (DL1 and DL2 respectively), 2 G3 thrombopenia + neutropenia (DL2), 1 G2 neutropenia (DL2), 2 G3 pulmonary embolism (DL1 and IS). Mean number of 21d-cycles was 3 for CDDP and 4.7 for P. 15 pts discontinued treatment for unacceptable toxicity, 5 pts are still under treatment. 2 complete (DL2) and 2 partial responses (DL1 and DL2) were achieved. Mean (CV% for interindividual variability) CDDP clearance was 13.6 L/h (27%) and not influenced by P. However, mean of P clearance was 0.78 L/h (69%) at d-1 (before CDDP), 24.5% lower at d1 (CDDP + aprepitant), and 30% lower at d2 (aprepitant), likely due to competitive inhibition of P metabolism and efflux by aprepitant. The plasma P exposures observed at 400 mg (at d-1) were similar to those observed at 800 mg of P during the first-in-man phase 1 [Hurwitz et al]: 676.2 μg.h/mL (47%) vs. 743.3 μg.h/mL (76%), respectively. A nonsignificant trend of higher P AUC was observed in patients with DLT. **Conclusions:** Despite activity observed in some patients, the potential to combine P and CDDP appears limited due to the safety profile and the PK interactions within the combination. Clinical trial information: NCT01165385.

**Evaluation of pharmacokinetic (PK) drug-drug interactions (DDI) between trebananib (AMG 386) and paclitaxel (PTX) in patients (pts) with advanced solid tumors.** *Presenting Author: Jennifer Robinson Diamond, University of Colorado Cancer Center, Aurora, CO*

**Background:** Trebananib (AMG 386) is an investigational peptide-Fc fusion protein that inhibits angiogenesis by preventing the interaction between angiopoietin-1/2 and Tie2. In a phase 3 study, trebananib 15 mg/kg QW plus PTX improved progression-free survival in women with recurrent ovarian cancer compared with placebo plus PTX. PTX was chosen because it is a standard of care in ovarian cancer, and both PTX and trebananib are dosed weekly. This open-label phase 1b DDI study evaluated PK of PTX with/without trebananib. **Methods:** Pts with advanced solid tumors who were candidates for PTX treatment, had evaluable/measurable disease per RECIST v1.1, and ECOG performance status ≤2 received PTX 80 mg/m$^2$ IV QW (3 wks on/1 wk off) beginning wk 1 and trebananib 15 mg/kg IV weekly QW beginning wk 2 until disease progression, unacceptable toxicity, or withdrawal of consent. Intensive PK sampling occurred in wks 1 (PTX only), 6 (PTX+trebananib), and 8 (trebananib only). CT/MRI was performed every 8±1 wks. The primary endpoint was $C_{max}$/AUC of PTX with/without trebananib. **Results:** Thirty-five pts were enrolled. Most had ovarian (n=11) or bladder cancer (n=9). Mean PTX $C_{max}$ and $AUC_{inf}$ were similar with/without trebananib, and mean trebananib $C_{max,ss}$ and $AUC_{tau,ss}$ were similar with/without PTX (Table). All pts had ≥1 adverse event (AE), most commonly fatigue (any grade/grade 3 or 4, 57%/14%), nausea (54%/3%), peripheral edema (51%/6%), and peripheral neuropathy (46%/3%). 34% of pts discontinued trebananib due to AEs. Among 26 pts with measurable disease, 5 had partial response and 8 had stable disease (per RECIST) as best response. **Conclusions:** There was no evidence of clinically meaningful PK DDI between trebananib and PTX. Toxicity was as anticipated for the combination of trebananib plus weekly PTX; no new toxicity signals were identified. Clinical trial information: NCT01992341.

**Clinical pharmacokinetic (PK)/pharmacodynamic (PD) model for Debio 1143, a novel antagonist of IAPs in cancer treatment.** *Presenting Author: Elisabeth Rouits, Debiopharm International SA, Lausanne, Switzerland*

**Background:** Inhibitors of apoptosis proteins (IAPs) modulate multiple processes, including caspase activation and NF-kB signaling. Expression and/or overexpression of IAPs have been reported for a variety of tumor types and are correlated with tumor growth and resistance to apoptosis induced by standard chemo and radiation therapies. The small molecule Debio 1143 is an orally-active IAP antagonist able to promote apoptosis in tumor cells. **Methods:** In a first-in-human Phase I study in patients with advanced cancer, Debio 1143 was given orally once daily on days 1-5 every 2 or 3 weeks. Ten dose levels ranging from 5 mg to 900 mg were explored. Blood samples were taken on days 1-5 for PK (Debio 1143) and PD assessments (IAPs levels, blood markers of apoptosis and inflammation) with rich sampling at day 1 and day 5. A population PK model was built within NONMEM 7.2. Further to a graphical PK vs PD check, population PK/PD models were explored. **Results:** The PK of Debio 1143 was well described by a two-compartment model with two absorption pathways. Debio 1143 bioavailability appeared to decrease after repeated administrations, suggesting a possible time-dependent PK. Graphically, markers of target engagement (cIAP1 PBMCs levels) and apoptosis (caspase-3 generated cytokeratine-18 fragments plasma levels [CK18-M30]) showed changes with Debio 1143 PK. cIAP1 levels could be fitted using an indirect response model where the elimination of cIAP1 was stimulated by Debio 1143. The CK18-M30 data was best fitted by a model with a delayed effect, onsetting after the first day. Simulations of d14q21 treatment predicted a clear decrease in cIAP1, with small differences between 100 mg and 200 mg dosing. A CK18-M30 increase ranging from 20 to 200% is predicted at day 14 after 200 mg qd. **Conclusions:** Debio 1143PK is compatible with oral administration q5d21. A clear relationship between PK and markers of target engagement or apoptosis was evidenced over the dose range explored. Findings from the q14d21 simulations indicate a promising PK/PD relationship for such schedule. Results from ongoing studies including PK/safety and PK/efficacy exploration will also feed the model to support Debio 1143 treatment optimization.

**2586 General Poster Session (Board #49), Sun, 8:00 AM-11:45 AM**

**Pharmacokinetics of the BCL2-targeted DNA interference (DNAi) nanoparticle PNT2258 in patients with recurrent or refractory non-Hodgkin lymphoma.** *Presenting Author: Wael Harb, Horizon Oncoloy Center, Lafayette, IN*

**Background:** PNT2258 contains PNT100, a DNA interference (DNAi) oligonucleotide encapsulated in a lipid nanoparticle. PNT2258 targets the BCL2 gene and is undergoing evaluation in patients with r/r NHL (NCT01733238). PNT2258 exhibits single-agent anti-tumor effect (50% ORR) in patients with r/r follicular or diffuse large B-cell lymphoma. The study also evaluated pharmacokinetic (PK) parameters in this target population, as reported here. **Methods:** Patients received 120 mg/m$^2$of PNT2258 IV on days 1-5 of a 21-day cycle. The concentrations of PNT2258 (measured as total PNT100) were determined pre-infusion and at 30, 60, 90, 120 and 150 minutes and at 24 hours by a validated hybridization-ligation bioanalytical method that measured PNT100 content using a complementary template probe followed by visualization by ELISA. **Results:** No free PNT100 was found in the plasma samples and detergent solubilization of intact PNT2258 in plasma was required to release encapsulated PNT100, indicating the stability of the PNT2258 liposome in serum. PNT2258 infusion resulted in minimal inter-patient variability when measuring encapsulated PNT100 concentrations on days 1 and 4. Day 4 plasma concentrations were consistently higher than day 1 levels without evidence of cumulative toxicity. Preliminary data indicate a serum half-life ($t_{½}$) of 9-12 hours. AUC exposure levels on days 1 and 4 were 87300 and 208000 ng.hr/ml, respectively, and additional day 4 values include $T_{max}$ = 2.39 hr (SD 0.22 hr), $C_{max}$ = 13,800 ng/ml (SD 10,000 ng/ml) and $R_{AUC\ Days\ 1\text{-}4}$ = 10.1. **Conclusions:** Pre-clinically, levels of > 22,377 ng.hr/ml PNT2258 resulted in activity in WSU-DLCL2 xenograft models. Clinical PK data confirm serum levels of the BCL2-targeted oligonucleotide that were 4-9 times greater than what was required to exhibit anti-tumor effect in the preclinical models. The data provided in this abstract indicate that the BCL2-targeted DNAi oligonucleotide PNT2258 is the first of this new class of therapeutic to provide systemic exposure, a manageable clinical safety profile and measureable anti-tumor effect warranting further clinical development. Clinical trial information: NCT01733238.

**2587 General Poster Session (Board #50), Sun, 8:00 AM-11:45 AM**

**Population pharmacokinetic (PK) analysis from phase 1 and 2 studies of the HER3 inhibitor patritumab in patients with advanced non-small cell lung cancer (NSCLC) or solid tumors.** *Presenting Author: Satoshi Yoshiba, Daiichi Sankyo Co., Ltd., Tokyo, Japan*

**Background:** Patritumab is a fully human antibody specific to HER3, a HER family receptor implicated in tumor resistance to anticancer treatment. In order to support patritumab dose recommendations, a population PK model was developed for phase 1 and 2 patritumab studies to characterize its PK and identify influencing factors. **Methods:** Population PK analysis was performed using data from the international phase 1b/2 HERALD study of patritumab (18 mg/kg every three weeks [q3w] or 18 mg/kg loading dose followed by 9 mg/kg q3w maintenance dose) in combination with erlotinib in EGFR treatment-naïve patients with advanced NSCLC after failure of ≥1 prior chemotherapy. Data from an open-label, phase 1 study of patritumab (9 mg/kg q3w or 18 mg/kg q3w) in Japanese patients with advanced solid tumors were also included. The effects of gender, baseline body weight (BW), creatinine clearance, eGFR, and albumin as covariates for clearance (CL), and gender and baseline BW as covariates for volume of central compartment (Vc) were investigated. PK simulations were performed to compare interpatient variability of patritumab exposure following fixed or BW-based dosing. **Results:** In total, 833 serum concentrations from 145 patients (136 NSCLC, 9 solid tumor) were included in the analysis. Serum patritumab concentrations were described by a two-compartment intravenous model with first-order elimination. Linear PK were observed at doses of 9 mg/kg and 18 mg/kg. CL, Vc, and volume of peripheral compartment were estimated as 0.0238 L/h, 3.62 L, and 2.50 L, respectively. BW and baseline albumin were significant covariates of CL ($p<.05$) and BW was a significant covariate of Vc ($p<.05$). PK simulations showed that BW-based dosing reduces interpatient variability in exposure compared with fixed dosing. **Conclusions:** Results showed that Vc was approximately serum volume and that CL was relatively low, indicative of a long terminal half-life. BW and albumin were significant factors affecting PK. The analysis supports an 18 mg/kg loading dose and 9 mg/kg q3w maintenance dose, and suggests that BW-adjusted dosing reduces interpatient variability. Clinical trial information: NCT01211483.

**2588 General Poster Session (Board #51), Sun, 8:00 AM-11:45 AM**

**A phase 1b trial of PI3K inhibitor copanlisib (BAY 80-6946) combined with the allosteric-MEK inhibitor refametinib (BAY 86-9766) in patients with advanced cancer.** *Presenting Author: Ramesh K. Ramanathan, TGen - Virginia G. Piper Cancer Center at Scottsdale Healthcare, Scottsdale, AZ*

**Background:** Dual inhibition of the PI3K and MAPK signaling pathways is a promising strategy for optimal anticancer therapy. In this phase 1b trial we determined the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D) of the combination of the pan-PI3K inhibitor copanlisib (C) and the allosteric-MEK inhibitor refametinib (R). **Methods:** Eight dose cohorts combining increasing doses and varying schedules of C (0.2-0.8 mg/kg IV; 3W on/1W off and QW) and R (30 mg and 50 mg bid po; continuous or 4 days on/3 days off) on 28-day cycles were studied. PK of C was assessed on Days 1 and 15 and PK of R on Days 14 and 15. In a 15-patient mutation-selected expansion cohort in mixed solid tumors, plasma samples are being assessed for tumor mutations (N-RAS, K-RAS, B-RAF, and PI3KCA) in circulating DNA by BEAMing and paired tumor biopsies undergoing biomarker analyses (including pERK and pAKT). **Results:** The study has completed accrual, with 49 patients treated in the dose escalation part of this study, of which 44 were evaluable for safety and efficacy. DLT's included Grade 3 AST or ALT elevation (n=2), hyperglycemia (1); hypertension (2); diarrhea (2), mucositis (2) and rash (1). The most common drug-related adverse events (>20%) in the dose escalation part were: diarrhea, nausea, hyperglycemia, fatigue, rash, anorexia, and hypertension. The MTD and RP2D for the C + R combination were: C 0.4 mg/kg IV QW and R 30 mg bid po. These doses are below the MTDs of either compound alone: C 0.8 mg/kg IV 3wks on/1 wk off and R 50 mg bid or 100 mg qd po. PK exposures of R and C were not affected by concomitant administration. Clinical activity included one PR in a patient with endometrial cancer, and stable disease lasting >4 cycles in 9 patients. Treatment discontinuations were due to disease progression (n=13), drug or tumor-related adverse events (n=24), or patient/physician discretion (n=12). Preliminary signals of antitumor activity have been observed in the fully accrued expansion cohort. **Conclusions:** The C+R combination was generally well tolerated with the MTD and RP2D below the individual tolerated doses of either compound. Preliminary evidence of clinical efficacy has been observed. Clinical trial information: NCT01392521.

**2589 General Poster Session (Board #52), Sun, 8:00 AM-11:45 AM**

**Phenformin combines with selumetinib in targeting KRAS mutant non-small cell lung cancer cells with alternative LKB1 status.** *Presenting Author: Jun Zhang, Winship Cancer Institute of Emory University, Atlanta, GA*

**Background:** Combining with docetaxel, the MEK inhibitor selumetinib holds the promise in treating KRAS mutant non-small cell lung cancer (NSCLC). However, a previous co-clinical trial based on genetically engineered mouse model (GEMM) suggested that concomitant loss of LKB1 might confer primary resistance. Since LKB1 inactivation was recently shown to sensitize NSCLC cells to the metabolism drug phenformin, which may also activate AMPK in LKB1 wild-type NSCLC, we therefore investigated whether phenformin could enhance the therapeutic effect of selumetinib in KRAS mutant NSCLC with different status of LKB1. **Methods:** NSCLC cell lines harboring RAS/RAF mutations that were tested with selumetinib were identified from literature to study the correlation of LKB1 status with selumetinib sensitivity. Then, the isogenic derivatives of A549 cell line namely $A549^{LKB1}$ (stably expressing wild-type LKB1) and $A549^{pBabe}$ (empty vector, LKB1 deficient) were used for actual studies of selumetinib, phenformin, their combination and dosing sequence. Phenformin was also investigated in GEMM derived cell lines 634 ($Kras^{G12D/wt}/p53^{-/-}/LKB1^{wt/wt}$) and t2 ($Kras^{G12D/wt}/p53^{-/-}/LKB1^{-/-}$). **Results:** 29 NSCLC cell lines were identified which showed concomitant LKB1 mutation significantly correlated with selumetinib resistance (IC50>1uM, p=0.0025). Consistently, $A549^{LKB1}$ cells were more sensitive to selumetinib. In contrast, $A549^{pBabe}$ (as well as t2) cells showed stronger response to phenformin. Their synergism was observed in both the proliferation and colony formation assays, and confirmed via CalcuSyn calculation. While phenformin helped induce much more robust apoptosis in $A549^{pBabe}$ cells, it also activated AMPK and potently enhanced the inhibition of S6 phosphorylation by selumetinib in $A549^{LKB1}$cells. Interestingly, when the drugs were applied sequentially in single agent, selumetinib followed by phenformin was ~ 3 folds more efficient in inducing apoptosis than the reverse order. **Conclusions:** Phenformin may synergize the anti-tumor effect of selumetinib in KRAS mutant NSCLC irrespective of the LKB1 status. Their combination offers a potential new therapy for this subtype of NSCLC.

**2590 General Poster Session (Board #53), Sun, 8:00 AM-11:45 AM**

**Tyrosine kinase inhibitors and QTc intervals: A class effect.** *Presenting Author: Jacqueline S.L. Kloth, Erasmus MC-Cancer Institute, Department of Medical Oncology, Rotterdam, Netherlands*

**Background:** Tyrosine kinase inhibitors (TKIs) are reported to be associated with prolongation of the QTc interval on the ECG. QTc interval prolongation increases the risk for life threatening arrhythmias. However, studies evaluating the effects of TKIs on QTc intervals are limited and consist of small patient numbers. **Methods:** We screened all patients from 4 centers in the Netherlands and Italy, who were treated with TKIs. To evaluate the effects of TKIs on the QTc interval we investigated ECGs prior to and during treatment with sunitinib, vemurafenib, sorafenib, pazopanib, imatinib, erlotinib, lapatinib or gefitinib. All ECGs were reviewed by a single cardiologist (CN). Outcomes of this study were quantitative change in QTc interval (ΔQTc) after start of TKI treatment and chance of becoming a high risk individual, defined as QTc ≥ 470 milliseconds (ms), adjusted for risk factors such as for $K^+/Ca^{2+}$levels, co-medication, age, gender and co-morbidity. **Results:** A total of 363 patients had ECGs taken prior to and during TKI treatment and were therefore eligible for the analyses (see Table). In the entire group, start of TKI resulted in a significant increase in QTc interval ($QTc_{baseline}$ = 401 ms *vs* $QTc_{treatment}$ = 415 ms, p < 0.0001). After correction for possible confounders (site, tumor type, ethnicity, TKI, time between ECGs), sunitinib, vemurafenib, sorafenib, imatinib and erlotinib showed a significant increase in QTc interval after start of treatment (p < 0.01). Especially patients treated with vemurafenib are at increased risk of having QTc ≥ 470 ms (p < 0.05). **Conclusions:** These observations show that most TKIs give rise to a significant increase in QTc interval. In vemurafenib treated patients, the incidence of patients who are at risk for arrhythmias is increased. Therefore, especially in case of combined risk factors, frequent ECG controls in patients treated with TKIs are required.

| | | QTc (ms) | | | N QTc ≥ 470 ms | | ΔQTc ≥ 30 ms |

**Cytochrome P450 interacting medication use in adult advanced solid tumor and phase I trial patients.** *Presenting Author: Kari Braun Wisinski, University of Wisconsin Carbone Cancer Center, Madison, WI*

**Background:** Cancer patients often take multiple medications increasing the potential for drug-drug interactions. There is limited data regarding the frequency of cytochrome P450 (CYP) medication use in advanced cancer patients or among subjects enrolling in phase I trials. The objective of this study was to characterize medication use in adult advanced solid tumor patients, including those in phase I trials. **Methods:** We evaluated the electronic health record for medication use in adult patients with advanced solid tumors seen at the University of Wisconsin from 1/2008-7/2011. Two cohorts (metastatic and phase I) were established. Demographics, co-morbidities, and medications were abstracted. Each medication's CYP-interaction was classified using Lexicomp. We also reviewed charts from NCI-sponsored phase I trials from 1/2007- 12/2009 involving CYP interacting drugs. The CYP pathway affected, concurrent and contraindicated medications, and changes in medications for study eligibility were recorded. **Results:** Data from 1,773 patients were analyzed: 1,489 in the metastatic cohort [median age 62 (18-93), 52% female] and 284 in the phase I cohort [median age 59 (18-80), 57% female]. Polypharmacy was seen in both groups (95% phase I vs. 80% metastatic; p<0.001). The majority of the metastatic cohort were taking CYP interacting medications (87% ≥ 1 inhibitor , 45% ≥ 1 inducer and 79% ≥ 1 sensitive substrate). Use of moderate-strong inducers or inhibitors was also common: ≥ 1 inducer (40% and 36%) and ≥ 1 inhibitor (61% and 66%), metastatic and phase I, respectively. Separately, 4 phase I trials were evaluated, involving 294 screened subjects – 3.8% screen failed due to interacting medications. Charts from 74 enrolled subjects revealed 655 concurrent medications (average 8.9/subject). 93 medications were CYP-interacting and 51(69%) subjects were on ≥1 interacting medication. Of the 93 medications: 38 (41%) were stopped and 41 (44%) were changed for study. **Conclusions:** CYP-interacting medication use is common in patients with advanced cancer. Medications are frequently discontinued or changed for enrollment in phase I trials. This has important implications for translating phase I results into practice.

**The pharmacokinetics and safety of idelalisib in subjects with moderate or severe hepatic impairment.** *Presenting Author: Feng Jin, Gilead Sciences, Foster City, CA*

**Background:** Idelalisib (IDELA) is a potent inhibitor of PI3Kδ, which has been shown to be prominently expressed in cells of hematopoietic origin. IDELA is metabolized primarily by aldehyde oxidase to form GS-563117 and to a lesser extent by CYP3A and UGT1A4. The mass balance study of IDELA in healthy subjects showed the radioactive dose administered was recovered mainly in feces (~78%). The objective of this study was to evaluate the PK and safety of IDELA/GS-563117 in subjects with moderate or severe hepatic impairment following administration of a single oral dose of IDELA. **Methods:** Eligible subjects categorized by the Child-Pugh-Turcotte (CPT) classification system with moderate (Class B: CPT score 7-9) or severe (Class C: CPT score 10-15) hepatic dysfunction and matched healthy subjects received a single oral dose of IDELA at 150 mg under fed condition. Blood samples were collected and IDELA/GS-563117 levels were measured. Geometric least-squares mean ratio and 90% confidence interval of PK exposure parameters in the hepatic impairment group(s) versus matched controls were calculated, with clinically relevant exposure change defined as ≥ two-fold increase. Safety assessments were performed throughout the study. **Results:** A total of 32 subjects were enrolled in the study. The majority of subjects were white (87.5%) males (71.9%) and median age was 52 years. Most treatment-emergent AEs and laboratory abnormalities were Grade 1 or 2 in severity. Overall study treatments were generally well tolerated. IDELA $C_{max}$was generally comparable in the subjects with moderate or severe hepatic impairment vs healthy controls, while mean AUC was higher (58% to 60%). GS-563117 exposures were lower in hepatic impaired vs healthy control subjects, likely due to lower formation in the setting of liver impairment. These changes are not considered to be clinically relevant. Exploratory analyses indicated no relevant relationships between the IDELA or GS-563117 plasma exposures and CPT score. **Conclusions:** No clinically relevant changes in IDELA and GS-563117 exposures were observed in subjects with moderate or severe hepatic impairment versus matched healthy subjects. Single oral doses of IDELA 150 mg were well tolerated.

**2593 General Poster Session (Board #56), Sun, 8:00 AM-11:45 AM**

**Drug interaction profile of idelalisib and its major metabolite, GS-563117.** *Presenting Author: Feng Jin, Gilead Sciences, Foster City, CA*

**Background:** Idelalisib (IDELA), a potent PI3Kδ inhibitor in Phase 3 studies for hematological malignancies, is metabolized mainly by aldehyde oxidase to GS-563117 and partially by CYP3A. In vitro, IDELA inhibits Pgp, OATP1B1, and 1B3 and GS-563117 is a time-dependent CYP3A inhibitor. Accordingly, the present study evaluated the effects of IDELA on these transporters/enzyme, and rifampin (RIF), a strong inducer, on IDELA pharmacokinetics (PK). **Methods:** Single oral dose of probe Pgp (digoxin; DIG), OATP1B1/1B3 (rosuvastatin; ROS), and CYP3A (midazolam; MDZ) substrates were given alone or with IDELA 150 mg BID. IDELA 150 mg single dose was given alone or with RIF 600 mg QD. PK of IDELA, GS-563117, and probes were determined (N = 11 to 12). Lack of PK interaction was defined as 90% confidence interval of the geometric mean ratio within 70-143% (combination vs alone). Safety was assessed throughout the study. **Results:** The study enrolled mainly white males (N=24) with median age of 38 years. Upon treatment, most common adverse events (AE) were headache and pyrexia; Gr 3 transaminase increases (5/24 subjects) were reversible. Two subjects had serious AEs after treatment completion. No clinically relevant changes in vital signs/ECGs were noted. IDELA did not affect DIG or ROS PK but increased MDZ plasma exposure, consistent with GS-563117 CYP3A inhibition in vitro. RIF reduced IDELA and GS-563117 exposures, indicating enhanced IDELA metabolism by CYP3A with a strong inducer. **Conclusions:** IDELA does not affect common drug transporters and is a moderate inhibitor of CYP3A due to GS-563117. Strong inducers of CYP3A decrease IDELA exposure.

**The impact of gastric acid suppression therapy on tyrosine kinase inhibitors in advanced cancer patients.** *Presenting Author: Michael Patvin Chu, Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada*

**Background:** Oral tyrosine kinase inhibitors (TKIs) are used across tumor subtypes. Oral drug absorption is dependent on numerous factors including gastric acidity. Few studies have examined effects of gastric acid suppressants such as proton pump inhibitors (PPIs) on TKI outcomes. This study aims to determine if concurrent PPIs and TKIs impair progression free (PFS) and overall survival (OS) in patients (pts). **Methods:** Advanced/metastatic non-small cell lung cancer (NSCLC) patients receiving erlotinib from 2007 to 2012 and renal cell cancer (RCC) patients receiving sunitinib from 2007 to 2013 were retrospectively reviewed. The review included the Alberta outpatient/retail pharmacy databases. Pts with ≤ 1 week of therapy were excluded. Aside from demographics, pts were identified as concurrently receiving acid suppression if their pharmacy records included a PPI with prescription dates that overlapped by ≥ 20% of TKI treatment duration. PFS and OS were primary endpoints. **Results:** Of 545 NSCLC and 383 RCC pts, 507 and 231 were included, respectively. PPIs given concomitantly with erlotinib was detrimental to both PFS (hazard ratio [HR] 1.71, 95% CI: 1.39-2.11, p<0.0001) and OS (HR 1.29, 95% CI: 1.05-1.59, p=0.016). PPIs also affected sunitinib PFS (HR 1.42, 95% CI: 1.00-2.01, p=0.050) and OS (HR 1.27, 95% CI: 0.88-1.82, p=0.202). In pooled analysis, PPIs negatively impacted TKI PFS (HR 1.60, 95% CI: 1.34-1.91, p<0.0001) and OS (HR 1.34, 95% CI: 1.09-1.57, p=0.003). Considering performance status, acid suppression impaired PFS (HR 1.56, 95% CI: 1.31-1.87, p<0.0001) and OS (HR 1.24, 95% CI: 1.04-1.49, p=0.019) in both RCC and NSCLC. **Conclusions:** Despite limitations of a retrospective study, this large cohort study shows PPIs negatively interact with oral TKIs in NSCLC and RCC pts. Our results lend support that PPIs impair TKI absorption leading to poorer survival. This interaction is not found in electronic drug interaction sources and patients embarking on TKI therapy should be made aware that gastric acid suppressants may limit TKI efficacy. Further investigation as to whether this effect is seen in other TKIs is underway.

**2595 General Poster Session (Board #58), Sun, 8:00 AM-11:45 AM**

**Pharmacokinetics (PK) of eribulin mesylate in cancer patients (pts) with normal and impaired renal function.** *Presenting Author: Antoinette R. Tan, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

**Background:** Eribulin mesylate is a novel microtubule dynamics inhibitor. The effect of renal impairment on eribulin PK was evaluated following a single dose in adult pts with advanced solid tumors no longer responding to standard therapy. **Methods:** This phase 1 sequential cohort study grouped pts by renal function according to the Cockcroft-Gault formula: moderate impairment (creatinine clearance [CrCL]: 30–50 mL/min), severe impairment (CrCL: 15–29 mL/min), or matched-normal (CrCL: ≥80 mL/min). During cycle 1, the iv eribulin mesylate dose on days 1 and 8 were 1.4 mg/m$^2$ and 1.1 mg/m$^2$ for moderate; 0.7 mg/m$^2$ days 1 and 8 for severe; 1.4 mg/m$^2$ days 1 and 8 for normal; the dose for severely impaired pts was based on an interim PK analysis of the moderate group. Blood was collected up to 168 hours after the first dose (cycle 1); PK parameters were calculated by non-compartmental analysis. **Results:** Nineteen pts were enrolled (12 women; median [range] age 70 [33–82] years: moderate, n = 7; severe, n = 6; normal, n = 6). Mean dose-normalized (DN) area under the curve (AUC) was increased for pts with moderate and severe renal impairment when each was compared with pts with normal renal function (ratio for both: 1.49; 90% confidence interval [CI] 0.9, 2.45). The magnitude of increase in DN maximum plasma concentration was 1.31-fold (90% CI 0.84, 2.05) for pts with moderate impairment and 2.02-fold (90% CI 1.27, 3.21) for those with severe impairment. Renal impairment decreased eribulin clearance (CL). Regression analysis of CL and renal function showed a positive correlation with a numerically small slope (0.0184; 90% CI −0.00254, 0.0394), indicating a small effect of renal impairment on eribulin disposition. Simulations of expected AUC values showed that dose reduction to 1 mg/m$^2$ for pts with moderate and severe renal impairment led to similar eribulin exposure as with 1.4 mg/m$^2$ in pts with normal renal function. Similar toxicity profiles were observed between groups and there were no unexpected AEs. **Conclusions:** Renal impairment decreased eribulin clearance and increased eribulin exposure in pts with advanced solid tumors. PK evaluation supports eribulin dose reduction to 1 mg/m$^2$ in pts with moderate and severe renal impairment. Clinical trial information: NCT01418677.

**2596 General Poster Session (Board #59), Sun, 8:00 AM-11:45 AM**

**Choice of starting dose for biopharmaceuticals in first-in-human phase I cancer clinical trials.** *Presenting Author: Aaron Richard Hansen, Princess Margaret Cancer Center, University Health Network, Division of Medical Oncology & Hematology, Department of Medicine, University of Toronto, Toronto, ON, Canada*

**Background:** The conventional paradigm used to set a safe human starting dose (SD) in phase I trials with anti-cancer agents of low molecular weight is derived from 1/10$^{th}$ the severely toxic dose in 10% ($STD_{10}$) of rodents or 1/6$^{th}$the highest nonseverely toxic dose (HNSTD) in nonrodents. There is no consensus on whether this paradigm can be safely applied to biotechnology derived products (BDP). **Methods:** A comprehensive search was conducted to identify all BDP (excluding immune checkpoint inhibitors and antibody drug conjugates) with sufficient nonclinical and clinical data to assess safety of hypothetical use of 1/6$^{th}$ HNSTD from a relevant species in a phase I trial. The HNSTD in nonrodents was compared to the maximum tolerated dose (MTD) or in the absence of the MTD, the maximum administered dose (MAD) in patients. In addition, 1/6$^{th}$HNSTD was compared to the actual SD chosen for the first in human (FIH) trial, which employed a wide range of pharmacologic and toxicologic parameters to set the SD. **Results:** The search identified 23 BDP, of which 21 were monoclonal antibodies. The median ratio of MTD or MAD to the actual FIH SD was 36 (range 8 to 500). The majority of the BDP (21 of 23) were administered without reaching MTD in phase 1 trials. Hypothetical use of 1/6$^{th}$ HNSTD would not have exceeded MTD or MAD for all 23 BDP and would have reduced the median ratio of MTD or MAD to SD to 2.2 (range 1.2 to 10). While use of 1/6$^{th}$ HNSTD would have decreased the number of cohorts to reach MTD or MAD, hypothetical dose escalation of 1/6$^{th}$ HNSTD would have surpassed MTD or MAD for 10 of 23 (43%) BDP after 1 dose doubling. Only 7 of the 23 BDP included pharmacodynamic (PD) markers in animal models; however these markers were useful to determine the maximally biologic active dose in animals. **Conclusions:** Use of 1/6$^{th}$ HNSTD in nonrodents would not have resulted in unacceptable toxicities for the 23 BDP evaluated. Absence of MTD in animals and humans underscores the need to identify and utilize pharmacokinetic (PK) endpoints and PD biomarkers to guide SD selection for FIH phase I cancer trials. This approach could help reduce the number of dose-escalations needed to reach the optimum biological dose in phase 1 studies and limit unnecessary exposure to high drug levels in humans.

**2597 General Poster Session (Board #60), Sun, 8:00 AM-11:45 AM**

**Effect of toxicity-adjusted dose (TAD) of sunitinib on intra-patient variation of trough levels: A longitudinal study in metastatic renal cell cancer (mRCC).** *Presenting Author: Alison Yan Zhang, Crown Princess Mary Cancer Centre, Westmead, Australia*

**Background:** It has been proposed that trough levels of sunitinib (S) + metabolite of >50ng/mL may be associated with better anti-cancer effect. Large inter-patient variations of trough S have been reported in patients (pts) with mRCC at standard doses. However, little is known about the intra-patient variation of S levels over time. **Methods:** Dose and schedule of S was adjusted to ensure grade 1 or 2 toxicity on >10 days (d) of each 42 d cycle. Trough levels of S and its active metabolite, N-desethyl-sunitinib (NdS) were determined by HPLC-mass spectrometry every 6 weeks. Total trough level (TTL) was defined as the sum of S + NdS. Pts achieving a TTL target of >50ng/mL at stable dose were determined. **Results:** 27 pts with mRCC received S for a median of 7 months (range 0.5 to 11 months) with doses ranging from 25 to 87.5mg/day in the dose adjustment period. There was no correlation between dose and S trough level (r=0.14; P=NS). However there was a positive correlation between dose and NdS level (r=0.54; P<0.01), and dose and TTL (r= 0.34; P<0.01). The mean stable dose was 41.8mg (range 25-75mg) usually on a 14/7 schedule. Dose was significantly lower for females (32.5 vs 42.5 mg; P=0.05). Between pts, TTL ranged from 3.61 to 190.8 ng/mL (mean 68.0 ng/mL, coefficient of variation 42.3%). In contrast, mean intra-patient variability of TTL in pts at stable dose was 16.2% (range 0.4% to 32.2%). 24/27 patients (88.9%) reached the target TTL >50 ng/mL using the TAD protocol. **Conclusions:** Using a novel TAD protocol almost 90% of pts achieved the target TTL. This study demonstrates that individuals on stable dose had negligible variation in trough level over time and has implication for therapeutic drug monitoring. The study is ongoing to correlate TTL at stable dose with outcome. Clinical trial information: NCT01711268.

**2598 General Poster Session (Board #61), Sun, 8:00 AM-11:45 AM**

**Comparison of chemosensitivity testing of CETCs and spheroids in cancer patients with solid tumors.** *Presenting Author: Katharina Pachmann, Transfusion Center Bayreuth, Bayreuth, Germany*

**Background:** In vitro chemosensitivity testing of circulating epithelial tumor cells (CETCs) provides real-time information about the sensitivity of the tumor cells present in the patient and correlates with treatment success. Nevertheless, a fraction of CETCs can survive after conventional chemotherapy and grow into distant metastasis. A subpopulation of CETCs with proliferation activity has the ability to form spheroids in suspension culture. Spheroids exhibit stem cell-like properties and may be responsible for chemo therapeutic resistance. Therefore, the aim of our study was the comparison of the efficacy of chemo therapeutics on CETCs and on spheroids originated from the same individuals. **Methods:** The enumeration of CETCs collected from patients with solid tumors in clinical stage 1-4 were performed using the maintrac method. Subsequently, viable CETCs were cultured in suspension culture system allowing for spheroid formation. To evaluate the cytotoxic effect CETCs and spheroids were exposed to anticancer drugs in short time culture in different concentrations and for different periods of time. **Results:** Theresponse to chemotherapeutics was different between CETCs and spheroids. In contrast to CETCs, spheroids from the same patients were significantly more chemoresistant. Whereas active drugs led to membrane permeability in single CETCs with subsequent staining of the nuclei with propidium iodide, the same drugs led to disintegration of tumorspheres with destruction of part of the cells but often part of the cells in the spheres were able to survive. Epirubicin and, interestingly, and especially salinomycin, a polyether ionophore antibiotic isolated from *Streptomyces albus*, showed the best effects. Docetaxel, cyclophosphamide and 5-Fluoruracil showed almost no cytotoxic effects onto the cells in the spheres. **Conclusions:** Our results show, for the first time that stem cells circulating in peripheral blood, capable of forming spheroids are way more resistant to anticancer drugs than the remnant circulating tumor cells. We, furthermore, demonstrate that salinomycin efficiently destroys spheroids cultured from CETCs, strengthening its role as promising anti-cancer therapeutic.

**2599 General Poster Session (Board #62), Sun, 8:00 AM-11:45 AM**

**Effect of food on the pharmacokinetics (PK) of olaparib after oral dosing of the capsule formulation.** *Presenting Author: Ignace Vergote, Division of Gynecologic Oncology, University Hospitals Leuven, Leuven, Belgium*

**Background:** The oral PARP inhibitor olaparib is well tolerated at doses ≤400 mg bid (capsule formulation) and has shown efficacy in patients (pts) with BRCA-mutated ovarian cancer (Ledermann et al ASCO 2013). This is the first study to evaluate the effect of food on olaparib PK. **Methods:** InPart A of this open-label, randomized, crossover Phase I trial (NCT01851265), adult pts with refractory/resistant advanced solid tumors received a single oral dose of olaparib 400 mg (8 x 50 mg capsules) in each of 3 prandial states, after (1) an overnight fast (2) a high-fat meal and (3) a standard meal (5–14 days' washout between doses). Blood samples were taken pre-dose and regularly up to 72 h post-dose. Part B was an extension phase to further evaluate safety, where pts completing Part A could receive continuous dosing with olaparib 400 mg bid (capsules) whilst deriving clinical benefit. AE data were collected in both phases. **Results:** 32 pts (ECOG PS 0/1: n=30; PS 2: n=2) entered the study (female, 84%; median age, 59.5 y; most common tumor types, ovarian [44%], breast [19%], rectal [13%]). 30 pts contributed to statistical analysis (2 pts were excluded: n=1, previous gastric surgery; n=1, withdrawal after first dose [grade 1 vomiting]). The effect of food was similar for both meals. The rate of absorption was slower in the presence of food ($t_{max}$ delayed by ~2 h) resulting in little impact on $C_{max}$ whilst the extent of absorption (AUC) was increased by ~20% in the fed state. AE data from Part A were consistent with the known safety profile of olaparib. Part B is ongoing. **Conclusions:** The PK of olaparib following oral dosing of the capsule formulation is affected by food. Olaparib capsule doses should be taken on an empty stomach. Clinical trial information: NCT01851265.

**Evaluation of the potential for QT/QTc interval prolongation for therapeutic biotechnology products.** *Presenting Author: Sarah J Schrieber, U.S. Food and Drug Administration, Silver Spring, MD*

**Background:** The implementation of the 2005 ICH E14 has included clinical evaluation of QTc prolongation for Therapeutic Biotechnology Products (TBPs). The ability of monoclonal antibodies (mAbs) to cause a QT effect via indirect mechanisms was uncertain. Therefore, we compiled a database of TBPs under development to assess the study designs and outcomes to guide future FDA regulatory recommendations on evaluation of the QT/QTc interval prolongation potential for TBPs. **Methods:** FDA reviews for QT/QTc study reports of TBPs were collected. Therapeutic drug class and molecular weight, study design features, ECG data analyses, study results, and regulatory recommendations were compiled and analyzed. **Results:** Fifteen TBPs with completed QT/QTc studies were identified including 13 mAbs and 2 antibody drug conjugates (ADCs). The study designs were varied by study population (patients vs. healthy subjects), dosing (single vs. multiple dosing), and active control (moxifloxacin was used in 2 studies). No large QT/QTc interval changes were observed for any of the mAbs evaluated. **Conclusions:** The available data suggest that mAbs are unlikely to cause QT/QTc interval prolongation. This finding supports our proposal that no dedicated QT assessment is necessary and clinical ECG monitoring may follow ICH E14 guidelines under negative 'thorough QT' (TQT) scenario except in cases where off-target cardiac-related adverse events are observed for specific mAbs. Conclusions cannot be made on the potential QT effect for other TBPs at this time, and the recommendations for well-designed QT studies to generate useful data for this assessment will continue.

**2601 General Poster Session (Board #64), Sun, 8:00 AM-11:45 AM**

**Results of a phase I trial combining ridaforolimus (mTOR inhibitor) and MK-0752 (Notch inhibitor) in patients with advanced solid tumors.** *Presenting Author: Sarina Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** The PI3K/AKT/mTOR signaling pathway is aberrantly activated in a variety of cancers. Ridaforolimus (R) is an mTOR inhibitor with activity in a broad range of cancers. MK-0752 inhibits the Notch receptor through its significant inhibition of gamma secretase and has evidence of antiangiogenic effects. R + MK-0752 may lead to complementary blockade of the PI3K pathway. **Methods:** The primary objective of this Phase I dose-escalation study (NCT01295632) was to define the dose limiting toxicities (DLTs) and maximum tolerated dose (MTD); a secondary objective was assessment of antitumor activity. Patients (pts) received a 5-day lead-in of R as monotherapy before beginning combination dosing. Rising doses of R were orally administered 5 days/week. MK-0752 dosing was fixed at 1800 mg given orally once per week. **Results:** For the 28 treated pts R doses were escalated from 20 to 30 mg/d. The MTD was determined to be 20 mg qd R 5 days/week + 1800 mg weekly MK-0752 (dose level 1). Among the 14 evaluable patients at the MTD, one DLT was reported: Grade 2 stomatitis, second episode. Among the 8 evaluable patients in dose level 2 (R=30mg), three DLTs were reported: 1 patient each with Grade 3 stomatitis, Grade 3 diarrhea, and Grade 3 asthenia. Other ≥G3 treatment-related adverse events (AEs) at the MTD were anemia (2 pts), stomatitis (2pts), diarrhea (1 pt), fatigue (1 pt), ALT elevation (1 pt), AST elevation (1 pt), hypokalemia (1 pt), hemoglobin decreased (1 pt) and hypophosphatemia (1 pt) (all Grade 3). The most common treatment-related Grade 2 toxicities at the MTD were: stomatitis (3 pts) and diarrhea (2 pts). One pt (squamous cell carcinoma [SCC] of the head/neck) had confirmed partial response (PR). Stable disease (SD) ≥6 mo was seen in 2 pts with SCC of the head/neck, including 1 pt with SD > 20 mo. **Conclusions:** The combination of R + MK-0752 shows activity in SCC of the head/neck (3/14). This combination resulted in disease responses though there were tolerance issues. The most common drug-related AEs occurring in >20% of patients treated at the MTD were diarrhea (32%), stomatitis (32%) and decreased appetite (32%) with 42% of patients experiencing Grade 3 drug-related AEs of any kind at this dose. Clinical trial information: NCT01295632.

**2602 General Poster Session (Board #65), Sun, 8:00 AM-11:45 AM**

**Pharmacokinetics of MEDI4736, a fully human anti-PDL1 monoclonal antibody, in patients with advanced solid tumors.** *Presenting Author: David Fairman, MedImmune, Cambridge, United Kingdom*

**Background:** MEDI4736 is a human immunoglobulin G1 kappa (IgG1$\kappa$) monoclonal antibody directed against human programmed death ligand 1 (PD-L1). MEDI4736 blocks inhibitory interaction of PD-L1 with the PD-1 (CD279) and B7-1 (CD80) molecules, and enhances T-cell activation. The primary objectives of this analysis were to assess the pharmacokinetics (PK), pharmacodynamics (PD), and immunogenicity of MEDI4736 in patients with advanced solid tumors. **Methods:** Data were collected from a Phase 1 study (NCT01693562) designed to evaluate safety, tolerability and PK following 0.1, 0.3, 1.0, 3.0, and 10 mg/kg every 2 weeks (Q2W) and 15 mg/kg every 3 weeks (Q3W) intravenous (IV) doses of MEDI4736. A total of 32 patients provided evaluable data. PK, ADA and soluble PD-L1 (sPD-L1) as PD were measured using validated electrochemiluminescence assays in human serum. Data analysis was performed using Phoenix Winnonlin and NONMEM software. **Results:** Area under the curve (AUC) increased more than dose-proportionally over the dose range of 0.1 to 10 mg/kg Q2W and approached linearity at ≥3 mg/kg Q2W. Soluble PD-L1 was fully suppressed over the entire dosing interval with doses ≥ 0.3 mg/kg Q2W. MEDI4736 PK profiles were best described using a 2-compartment model with both linear and nonlinear (target mediated) clearances. The linear clearance, volume of distribution and concentration at half maximal elimination ($K_M$) were 240 mL/day, 3.6 L and 0.4 $\mu$g/mL, respectively. The half-life was ~23 days at doses ≥ 3 mg/kg Q2W. Greater than 99% target saturation (soluble and membrane bound) is expected at ≥40 $\mu$g/mL of MEDI4736. PK simulations indicate that following 10 mg/kg Q2W, >90% patients are expected to maintain PK exposure ≥40 $\mu$g/mL throughout the dosing interval. Three of 31 patients were ADA positive with an impact on PK and PD in 1 subject. Based on preclinical/clinical PK, PD, and safety data, a dose of 10 mg/kg Q2W was selected for the ongoing expansion phase. **Conclusions:** MEDI4736 exhibited non-linear (dose-dependent) PK and yielded dose-dependent sPD-L1 suppression. Evidence of ADA impacted exposure in 1 (3%) patient. A monotherapy dose of 10 mg/kg Q2W is currently being evaluated in multiple tumor types in the expansion phase.

**2603 General Poster Session (Board #66), Sun, 8:00 AM-11:45 AM**

**A phase I study to assess the safety, tolerability, and PK of dovitinib (D) in combination with gemcitabine (G) and capecitabine (C) in patients with advanced solid tumors.** *Presenting Author: Gerald J. Fetterly, Roswell Park Cancer Institute, Buffalo, NY*

**Background:** Fibroblast growth factor receptor (FGFR) signaling is implicated in many cancer types. D is a potent multikinase inhibitor of FGFRs, VEGFRs and PDGFR. D's preclinical anti-cancer effect was most pronounced in pancreatic cancer (PC) with enhanced FGFR signaling. The trial aimed to determine the MTD, toxicity and PK profile of D plus G/C. **Methods:** Patients (pts) with advanced solid tumors in whom G/C was appropriate and ECOG PS 0-1 were eligible. Dose escalation was conducted per a 3+3 design (Part A) with an expansion cohort (Part B; n=20) at the MTD with advanced PC and biliary cancers. Dose levels were D 300/400/500 mg oral daily on a '5-days-on/2-days-off' schedule with G 1000 mg/m$^2$ i.v. weekly x 2 and C 650 mg/m$^2$twice-daily x 14 days (1 cycle = 21 days). Adverse events (AEs) were graded using CTCAE 4.0 while tumor response by RECIST 1.1. Plasma samples were collected up to 48 hr post-dose. D, G, and C concentrations were determined using LC/MS/MS, and PK analysis was performed. **Results:** 18 pts were enrolled in total. 6 of 9 pts enrolled to Part A were evaluable for DLT. One of 6 pts treated at D 300 mg level experienced dose-limiting Gr3 colitis; 2 pts experienced non dose-limiting Gr2 neuropathy (reversible) after multiple cycles requiring D dose reduction. Dose escalation was halted and D 300 mg level used for Part B, which enrolled 9 pts so far. D 300 mg level was tolerable when dosed over multiple cycles. Preliminary efficacy included PFS > 12 months in 2 PC pts (1$^{st}$ line and post-FOLFIRINOX respectively). Common (>15%) ≥Gr 2 AEs included asthenia, elevated LFTs, N/V, hypertension, neutropenia and thrombocytopenia. Median $C_{max}$ and $AUC_{24}$ for D were similar after 3 weeks of dosing; 181 (Day 1) vs. 221 ng/ml (Day 19) and 3419 vs. 3854 ng*hr/mL, indicating no presence of autoinduction of D metabolism. Median $T_{1/2}$ of D was 13.1 hr. G and C PK were similar to literature. **Conclusions:** D 300 mg level was determined to be the recommended phase II dose and tolerable when dosed over multiple cycles. The PK analysis showed no drug-drug interaction. A clinical trial of D/G/nab-paclitaxel in PC is currently underway. Full toxicity and PK profile will be presented at the conference. Clinical trial information: NCT01497392.

**2604 General Poster Session (Board #67), Sun, 8:00 AM-11:45 AM**

**Risk of serious infection with mTOR inhibitors everolimus and temsirolimus in the treatment of cancer: A meta-analysis of randomized controlled trials.** *Presenting Author: Christine Ann Garcia, Stony Brook University Hospital, Stony Brook, NY*

**Background:** Everolimus and temsirolimus are inhibitors of mammalian target of rapamycin (mTOR), and utilized in the treatment of a variety of cancers. The use of mTOR inhibitors is associated with serious infections. This meta-analysis of randomized controlled trials (RCTs) was conducted to determine the overall risk of infection with mTOR inhibitors in cancer patients. **Methods:** Databases from PubMed and abstracts presented at the American Society of Clinical Oncology annual meetings up to October 2013 were searched for relevant studies. Eligible studies included randomized controlled clinical trials in which everolimus or temsirolimus was compared to controls in cancer patients. Data on all-grade and high-grade (grade 3 and 4) infections were extracted from the safety profiles of each clinical trial. Incidence and relative risk (RR) were calculated using random- or fixed-effects models. **Results:** A total of 10 RCTs with 3,535 patients (mTOR 1,911, controls 1,624) of various tumors were included in the analysis. The incidence of all-grade and high-grade infections were 21.0% (95% CI 15.0-28.9%) and 4.0% (95% CI: 2.2-7.0%), respectively. In comparison with controls, mTOR inhibitors significantly increased the risk for developing all-grade (RR: 1.82, 95% CI: 1.08-3.08, P=0.03), and high-grade infections (RR: 2.86, 95% CI: P<0.001). The increased risk of high-grade infection was observed for both everolimus (RR: 3.91, 95% CI: 1.67- 9.13, P=0.002) and temsirolimus (RR: 2.42, 95% CI: 1.30-4.50, P=0.005). However, the increased risk did not vary significantly with different mTOR inhibitors (everolimus vs temsirolimus: P=0.37) and among different tumor types (P=0.47). There was also no significant difference between mTOR inhibitors alone and their combination with other agents (P=0.68). **Conclusions:** The mTOR inhibitors everolimus and temsirolimus are associated with a significantly increased risk of high-grade infections in cancer patients. Further studies are needed to identify the risk factors for high-grade infection.

**2605 General Poster Session (Board #68), Sun, 8:00 AM-11:45 AM**

**Phase I trial of daily PI3K$\alpha$ inhibitor BYL719 plus letrozole (L) or exemestane (E) for patients (pts) with hormone receptor-positive (HR+) metastatic breast cancer (MBC).** *Presenting Author: Payal Deepak Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Hyperactivation of phosphatidylinositol 3-kinase (PI3K) signaling is implicated in endocrine therapy resistance. Addition of an $\alpha$-selective PI3K inhibitor to hormonal therapy may be tolerable and beneficial in hormone resistant HR+ MBC. **Methods:** This 3+3 dose-escalation trial studied daily oral PI3K inhibitor (BYL719) added to standard dose aromatase inhibitor L (Arm A) or E (Arm B). Pts with HR+ MBC, any/no *PIK3CA* mutation, and on L/E were eligible. A cycle (C) was 28 days. Endpoints were dose-limiting toxicity (DLT), tolerability (CTCAE 4.0), and efficacy (RECIST v1.1). Paired tumor biopsies were performed for genomic and proteomic correlatives. **Results:** 14 pts (median (M) age: 55 (30-69) yrs), 7 per arm, received a M of 2 (<1-7) cycles. All were evaluable for toxicity. *PIK3CA* status was mutant/wild-type/unknown in 8/5/1 pts. M number of prior MBC therapies was 2 (1-12) in Arm A and 6 (2-14) in Arm B. BYL719 was given at 2 dose levels (DL0, 300mg; DL-1, 250mg). Both arms had similar toxicities. DLTs were maculopapular rash (N=2), hyperglycemia (N=2), and abdominal pain (N=1). Toxicity required dose de-escalation (4pts) and study discontinuation (2 pts). Treatment-related events included: G2 mucositis (21%), hyperglycemia (14%), dyspepsia (14%), fatigue (14%); G3 maculopapular rash (50%; 6/7 cases occurred on days 10-14 of C1; skin biopsies showed non-specific inflammation), hyperglycemia (7%) and abdominal pain (7%). There were no G≥4 treatment-related events. Of 9 pts evaluated for efficacy, 8 week best response was SD in 5 pts (included 1 pt with -29%, 1 with -19%) and PR in 1 pt with heavily pre-treated (including prior L) *PIK3CA*-mutated MBC to liver (C5+ on Arm A after initial DLT). **Conclusions:** Continuously dosed BYL719 with L or E shows promising antitumor activity in this hormone-refractory population. Early onset maculopapular rash results in frequent dose de-escalations. We are now exploring the addition of supportive dermatologic measures and non-continuous BYL719 dosing schedules. Examination of pharmacodynamic markers of PI3K inhibition and tumor genotype is ongoing. Further safety and efficacy data will be presented. Clinical trial information: NCT01870505.

**2606 General Poster Session (Board #69), Sun, 8:00 AM-11:45 AM**

**PI3K/AKT/mTOR genomic alterations in 94 patients with metastatic breast cancer in the phase I clinic at MD Anderson: Prevalence and association with response.** *Presenting Author: Jennifer J. Wheler, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Activation of the PI3K/AKT/mTOR pathway has a key role in breast cancer development and therapeutic resistance. Next generation sequencing (NGS) has expanded our understanding of this pathway. **Methods:** Genomic libraries were selected for all exons of 236 (or 182) cancer-related genes sequenced to average depth of >500× in a CLIA laboratory (Foundation Medicine, Cambridge, MA, USA) and analyzed for all classes of genomic alterations. **Results:** We report NGS profiles on 94 patients with metastatic breast cancer (MBC), median age 50 (range 23-69), including 41 (44%) with hormone receptor (HR)+/HER2- tumors; 4 (4%) that were HR+/HER2+; 2 (2%) that were HR-/HER2+; and 47 (50%) with HR-/HER2- (a disproportionate number of HR-/HER2- patients were seen in clinic). 46 patients (49%) had tumors with at least one molecular alteration (6 patients > 1) in the PI3K/AKT/mTOR pathway including: *PIK3CA* mutations (28 patients) and amplifications (2); *PIK3R1* mutations (4); *PTEN* mutations (4) and deletions (8); *AKT1* mutation (1) and amplification (1); and *AKT3* amplifications (4). Frequency of alterations was similar for HR+ and HR- tumors. 74 of 94 patients received treatment and are evaluable for response. The remaining 20 patients had not yet been treated in the phase I clinic. 31 of 74 evaluable patients had alterations in the PI3K/AKT/mTOR pathway *and* received therapy directly matched to that alteration ('matched'). 15 of 74 patients with a molecular alteration in this pathway did not receive matched therapy ('unmatched'). 28 of the 74 patients did not have an alteration in the pathway and were excluded from response analysis. Of patients on 'matched' therapy, 15 of 31 (48%) achieved partial response (PR) or stable disease (SD) ≥6 months compared to 2 of 15 (13%) patients who were 'unmatched' (*P*=0.02). **Conclusions:** Almost half of these patients with MBC cancer referred for Phase I trials had at least one molecular alteration in the PI3K/AKT/mTOR pathway. Patients treated with 'matched' therapies had significantly better outcomes than patients treated with 'unmatched' therapies. Prospective studies of NGS profiling are ongoing to validate this preliminary data.

**2607 General Poster Session (Board #70), Sun, 8:00 AM-11:45 AM**

**TAX-TORC: A phase I trial of the combination of AZD2014 (dual mTORC1/mTORC2 inhibitor) and weekly paclitaxel in patients with solid tumors.** *Presenting Author: Desamparados Roda, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

**Background:** AZD2014 (A) is a dual mTORC1/mTORC2 inhibitor and a previous phase I study determined the maximal tolerated dose (MTD) of A to be 50 mg BD 7/7. We have shown high p-P70S6K levels in cancer cells derived from ascites is associated with resistance to subsequent chemotherapy in ovarian cancer. Additive apoptosis was seen when A was added to paclitaxel (P) in preclinical models. We thus set up a multicentre phase I trial to evaluate this combination. **Methods:** The aims of the study were to determine the MTD, profile safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and antitumor activity of the combination of A+P. Dose escalation was performed using a 3+3 design. Patients (pts) with advanced cancers received 6 doses of weekly P (80 mg/m$^2$) and escalating doses of A, BD 3/7, starting on the same day as P in 49-day cycles. **Results:** 12 pts have been evaluated so far at a fixed dose of P (80 mg/m$^2$) and escalating doses of A; 25 mg (n=3), 50 mg (n=6) and 75 mg (n=3). Two pts had dose-limiting toxicities at 75 mg BD of A (grade 3 fatigue and grade 3 mucositis). The most frequently observed adverse events were fatigue (8/12), diarrhea (6/12), anemia (6/12), mucositis (5/12) and anorexia (4/12). However, of these, only fatigue (2/12) and mucositis (1/12) were grade 3 toxicities and occurred above the MTD. At the dose level of 50 mg BD, the AUC and $C_{max}$of A was 926.8 ng/mL and 2821.6 ng.hr/mL, respectively. Updated PD data will be presented. Currently, 3/5 pts with taxane pre-treated ovarian cancer have had a GCIG CA125 partial response (PR) (2 of these pts had a RECIST PR). 2/2 pts with squamous non small cell lung cancer (both previously pre-treated with docetaxel) had significant central necrosis of their tumors and one of these pts achieved a RECIST PR. **Conclusions:** The maximal tolerated dose of P is 80 mg/m$^2$q weekly and for A is 50 mg BD 3/7. This dose/schedule is well tolerated and has shown potentially promising clinical activity. A further intermittent schedule is being tested following which dose expansions in ovarian and lung cancer are planned. This study was supported by AstraZeneca, Cancer Research UK, Experimental Cancer Medicine Centre and Biomedical Research Centre initiatives. Clinical trial information: EudraCT number: 2012-003896-20.

**2608 General Poster Session (Board #71), Sun, 8:00 AM-11:45 AM**

**A study of risk of infection with drugs targeting the PI3 kinase (PI3K), AKT, and mTOR pathway.** *Presenting Author: Saeed Rafii, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

**Background:** Infection is a recognised side effect of chemotherapy, however its incidence varies across non-myelotoxic targeted agents. We studied the incidence of infection across phase I studies of the PI3K-AKT-mTOR inhibitors (PAMi) and compared them to other targeted therapies. **Methods:** This is a retrospective case-control study of electronic records of patients who were treated at the Royal Marsden Hospital, UK between 06/2008 and 05/2013. **Results:** A total of 366 pts treated in 12 phase I (Ph1) clinical trials with single agent PAMi were compared with a control group of 92 randomly selected patients from 10 other non-PAMi Ph1 trials. Median age was 56.3 and 54.6 years for the cases and controls (p:0.1). ECOG PS, tumour types and characteristics were balanced between the cases and controls. There were 99/366 (27%) infective events requiring antibiotics (Abx) in cases versus 8/92 (8.6%) in the controls (OR: 3.89, 95% CI: 1.8-8.3, $p<0.0005$). Grade 3/4 infective events requiring hospital admission and IV Abx were 30 (8.1%) in cases and 2 (2.17%) in the controls (OR: 4.0, 95% CI: 0.9- 17.1, $p=0.06$). The incidence of infection was similar between PI3K, AKT or mTOR inhibitors (Anova, $p = 0.76$). In addition to the 366 cases of single agent PAMi, we also collected data from 42 patients on 2 trials of PAMi combined with MEK inhibitors (MEKi) and 24 patients on 3 trials combined with chemotherapy. The all grade infective events were 26/42(62%) and 15/29 (62.5%), while G3/4 infective events were 3/42 (7.1%) and 4/29 (16.6%) in MEKi and chemotherapy combination trials respectively. **Conclusions:** This study shows for the first time that the overall risk of infection is significantly increased in patients treated with PAMi compared with other non-myelotoxic targeted agents. The incidence of G3/4 infective events was higher in the PAMi treated patients compared to the control group, although it was not statistically significant. In the cohort studied, there was no difference in the risk of infection between PI3K, AKT or mTOR inhibitors. With the increased use of PAMi in clinical practice, the risk of infection with these drugs either as single agents or in combinations should be taken into consideration when designing and conducting clinical trials.

**2609 General Poster Session (Board #72), Sun, 8:00 AM-11:45 AM**

**Correlation of intratumoral metabolic changes measured with 18F-FDG PET parametric response maps with concentrations of CC-223, a TORC 1/2 kinase inhibitor, in human glioblastoma.** *Presenting Author: Benjamin M. Ellingson, Department of Radiological Sciences, Biomedical Physics, and Bioengineering; University of California, Los Angeles, Los Angeles, CA*

**Background:** CC-223 is a potent selective inhibitor of mTOR kinase. Through inhibition of TORC1, TOR kinase inhibitors may result in down regulation of genes involved in glucose metabolism. A decrement in 18F-FDG PET uptake might represent early response of mTOR kinase inhibition. PET parametric response maps (PRMs) are a new technique involving voxel-by-voxel quantification of changes in PET uptake before and after therapy. This study explored relationships between intratumoral metabolic changes with PET PRMs, intratumoral and plasma drug concentration in a Phase I, surgical dose-expansion study in GBM. **Methods:** Eight evaluable patients with recurrent GBM received CC-223 daily for $15\pm7$days before planned salvage tumor resection. Tumor and plasma samples were obtained at surgery. MRI and $^{18}$F-FDG PET scans were obtained prior and after CC-223treatment. MRI and FDG standard uptake value (SUV) maps were aligned to baseline images. Voxel-wise percentage change and volume of changing FDG uptake in enhancing tumor was correlated with intratumoral and plasma measures of CC-223. **Results:** A positive linear correlation was found between tumor volume with decreasing FDG SUV and CC-223 concentration within resected tumor ($R^2=0.63$, $P=0.02$), suggesting a higher penetration of CC-223 results in a larger decrease in FDG metabolism within tumor. The volume of tumor with increasing FDG SUV correlated with maximum CC-223 plasma concentration ($R^2=0.52$, $P=0.04$), suggesting that lower plasma CC-223 concentration may result in a higher volume of growing tumor. There was a negative trend between the proportion of enhancing tumor with increasing FDG SUV and maximum CC-223 concentration in tumor ($R^2=0.39$, $P=0.1$), suggesting more drug penetration results in a lower proportion of tumor with increasing metabolic activity. Results are preliminary based on a sparse sample size. **Conclusions:** The volume and proportion of tumor with changing FDG uptake may correlate with plasma and intratumoral CC-223 concentration, suggesting FDG PET PRMs may provide non-invasive insight into CC-223 brain penetration and changes in intratumoral metabolic activity.

**2610 General Poster Session (Board #73), Sun, 8:00 AM-11:45 AM**

**Phase 1 dose escalation study of copanlisib (BAY 80-6946) in combination with gemcitabine or gemcitabine-cisplatin in advanced cancer patients.** *Presenting Author: Richard D. Kim, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Copanlisib (BAY 80−6946) is a potent and reversible pan-class I PI3K inhibitor with significant activity against PI3K-$\delta$ and PI3K-$\alpha$ isoforms. We report the results of an open-label, Phase 1 study of copanlisib in combination with gemcitabine alone and with gemcitabine plus cisplatin in advanced cancer patients. **Methods:** On Treatment A, patients received gemcitabine at 1000 mg/m$^2$ IV and 2 dose levels of copanlisib 0.6 mg /kg or 0.8 mg/kg IV on days 1, 8 and 15 of a 28-day cycle to determine whether the single agent maximum tolerated dose (MTD) of copanlisib (0.8mg/kg) was tolerable with the chemotherapy. On Treatment B, patients received cisplatin at 25 mg/m$^2$ IV, gemcitabine 1000 mg/m$^2$ IV and copanlisib IV on days 1 and 8 of a 21-day cycle at the MTD determined in Treatment A. The primary objective was to determine the safety, tolerability, and MTD of copanlisib in combination with gemcitabine and gemcitabine-cisplatin. **Results:** A total of 29 patients were treated with copanlisib. In Treatment A, 8 patients received copanlisib at 0.6 mg/kg and 8 at 0.8 mg/kg in combination with gemcitabine. There were no reported dose-limiting toxicities (DLTs) and the 0.8 mg/kg dose was the maximum tested dose. In Treatment B, 13 patients received copanlisib at 0.8 mg/kg with gemcitabine-cisplatin and no DLTs were observed. The most frequently observed drug-related adverse events reported in >20% of the patients were hyperglycemia, nausea, diarrhea, anemia, and fatigue. There were no treatment-related deaths. Pharmacokinetic evaluations showed comparable results across treatment groups indicating the absence of relevant PK interactions. Of the 2 patients enrolled in treatment schedule B with biliary tract cancer (BTC), one achieved a complete response (CR) and one a partial response (PR) according to RECIST criteria. An expansion cohort in patients with BTC with treatment schedule B is now ongoing, and one PR has been observed to date. **Conclusions:** The combination of copanlisib with gemcitabine alone or with gemcitabine plus cisplatin is generally well tolerated, with an early efficacy signal seen in patients with BTC. Clinical trial information: NCT01460537.

**2611 General Poster Session (Board #74), Sun, 8:00 AM-11:45 AM**

**Analysis of inactivation of PI3K/AKT/mTOR signaling pathway using neoadjuvant BKM120 in PI3KCA mutated early breast cancer.** *Presenting Author: Estevez G Laura, Centro Integral Oncológico Clara Campal, Madrid, Spain*

**Background:** The PI3K/AKT/mTOR signaling pathway plays a key role for the growth and survival of breast cancer cells and aberrations such as phosphatidylinositol-3-kinase (*PIK3CA*) mutations are common. BKM120 is an oral pan-class I *PIK3CA* inhibitor. The aim of this study was to evaluate neoadjuvant BKM120 in *PIK3CA* mutated early breast cancer in order to assess the effect in PI3K/Akt/mTOR signalling pathway. **Methods:** Patients (pts) with previously untreated invasive, non-metastatic histologically confirmed breast cancer, with a tumor size ≥ 1,5cm and non-urgent surgical treatment were enrolled. Only women with ER+ / HER2- and *PIK3CA* gene mutated were eligible. *PIK3CA* as well as *KRAS* mutation were evaluated at the diagnosis core biopsy .Patients received treatment with BKM120 (100mg/day; administered orally) during 4 weeks. Subsequently, surgery was performed. Inmunohistochemical analysis of p*Akt* and pRS6 (the H-score intensity x %) were evaluated on tumor tissue at surgery. H score < 150 was related with inactivation of PI3K signalling pathway. **Results:** To date 54 patients has been included (median age, 52,5 years; range 38-69 years;). 20 out of 54 (37%) had *PIK3CA* mutated and 19 have completed BKM120 treatment. *PIK3CA* mutation: Exon 20, 9 pts; exon 9, 7 pts; exon 4, 2 pts, exon 7, 1 pts and exon 1, 1 pts. None of the tumors had mutations in *KRAS* at the core biopsy. One patient discontinued treatment due to adverse event (nausea grade 2). The most relevant adverse events included transitory increase of transaminases. No serious or grade 4 adverse events were observed. Preliminary results of 19 pts showed inactivation of pRS6 (H score < 150) in 14 pts (74%) with no change in the reminder 5 pts. Inactivation of pAkt was only observed in 4 out of 11 tumors. **Conclusions:** Four weeks of neoadjuvant BKM120 produced a noticeable decrease level of the downstream effector pRPS6 in 74% of the tumors. However, decrease level of p*Akt* was only observed in 4 out of 11 tumors. In our experience, measurement of p*Akt* in tissue required very stringent conditions for sampling and handling. Thus, assessment of pRS6 seems more reliable and a more appropriate target. Final p*Akt* analysis will be presented along with updated results. Clinical trial information: CBKM120XES01T.

**2612 General Poster Session (Board #75), Sun, 8:00 AM-11:45 AM**

**Complications of hyperglycemia in phase 1 trials targeting the PI3K-akt-mTOR (PAM) pathway.** *Presenting Author: Elena Geuna, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

**Background:** PAM inhibitors (PAMi) are targeted agents increasingly being used as single agents or in combinations to treat metastatic cancer. Hyperglycemia has often been reported as an on-target toxicity of agents inhibiting this pathway and will become increasingly important with their use in larger number of patients (pts). We aimed to compare the incidence and degree of hyperglycemia across a range of PAMi phase I clinical trials. **Methods:** Retrospective case-control study of 510 pts with advanced solid tumours treated on 28 different phase 1 clinical trials at the Royal Marsden Hospital, UK, between June 2008 and May 2013. Data were collected on pt treatment and tumor characteristics, baseline and highest blood sugar levels during the trial. **Results:** 400 pts were treated in 18 trials with PAMi (82 pts with PI3Ki, 139 with mTORi, 150 with AKTi and 29 with PI3K/mTORi). A control group of 110 pts treated in 10 trials of targeted agents not targeting the PAM pathway were randomly selected. Baseline characteristics were well balanced between both study groups. There was no difference in the incidence of all grade hyperglycemia in the PAMi and control group, 347/400 (86.7%) and 89/110 (80.9%), OR 1,55 (95% CI 0.89-2,69 p=0.124). Importantly there was increased grade 3-4 hyperglycemia in pts in PAMi versus controls respectively, (28/400 vs 0/110, p = 0.005). Within the PAMi treated group the incidence of grade 3-4 hyperglycemia was 1.2%/11.3%/ 2.9%/20% in PI3K, AKT, m-TOR and PI3K/mTOR inhibitors, respectively and these differences were statistically significant (p = 0.001). In the PAMi group the study drug was stopped in 9 pts (2.3%) due to hyperglycemia. Only 27 pts (7%) required treatment for hyperglycemia; n=23 (6%) metformin and n=4 (1%) insulin. No pts developed severe metabolic complications, e.g. diabetic ketoacidosis or hyperosmolar hyperglycemic state. **Conclusions:** PAMi are associated with a significantly increased risk of high-grade hyperglycemia, compared with controls but high-grade hyperglycemia was not found to be associated with severe metabolic complications. These data confirm that hyperglycemia is a common, predictable and manageable toxicity which should not impair the development of these agents.

**2613 General Poster Session (Board #76), Sun, 8:00 AM-11:45 AM**

**Presurgical evaluation of the AKT inhibitor MK-2206 in patients with operable invasive breast cancer.** *Presenting Author: Kevin Kalinsky, Columbia University Medical Center, New York, NY*

**Background:** The PI3K/Akt signaling pathway is an important signaling pathway in breast cancer (BC). MK-2206 is the first allosteric Akt inhibitor in clinical development. The purpose of this pre-surgical study is to determine the biologic effects of MK-2206 on tumor and blood markers in newly diagnosed operable BC. **Methods:** In this trial, 2 doses of weekly MK-2206 were administered in pts with stage I-III invasive BC (at least T1c): first dose at day -9 and second at day -2 from surgery (goal n=30). The primary endpoint was reduction of $pAkt^{Ser473}$. Secondary endpoints included change in downstream proteomic changes, tumor proliferation (ki-67), and blood based-markers [phospho-markers in peripheral blood mononuclear cells (PBMCs)]. To maintain tumor quality, samples were processed rapidly by a standardized protocol. Paired t-tests were used to compare biomarker changes before and after MK-2206. **Results:** From 8/11-3/13, 12 pts were enrolled. The mean age was 53.1 years (SD: 11.2). At diagnosis, the mean tumor size was 2.5 cm (SD: 1.1). Eight pts had HR+/HER2- BCs, 1 HR+/HER2+ BC, and 3 triple negative BCs. At 200 mg (n=4), 2 pts experienced grade III rash and/or pruritus (Table), requiring 1 pt delay to surgery for 11 days. The dose was lowered to 135 mg (n=3), with 1 pt experiencing grade III rash/pruritus. Upon dose reduction to 90 mg (n=5), 1 pt had grade III rash. In PBMCs for 2 pts treated at 200 mg, reduction was seen in pS6 [mean fluorescence intensity (pre- vs. post-MK-2206); 5034 vs. 1749] and pAKT (5595 vs. 4165), with an increase in IGFR1 (6740 vs. 8653). Biomarker assessment is ongoing. **Conclusions:** We observed a high rate of toxicity that resulted in study suspension despite 2 dose reductions. Preliminary biomarker analysis demonstrates MK-2206 interacts with the proposed target *in vivo*, with up-regulation of upstream tyrosine kinase levels. If confirmed, this may identify mechanisms in which anti-tumor activity is attenuated. Clinical trial information: NCT01319539.

**Toxicities.**

**2614 General Poster Session (Board #77), Sun, 8:00 AM-11:45 AM**

**Phase 1 study of combination carboplatin, paclitaxel, and ridaforolimus in patients with solid, endometrial, and ovarian cancers.** *Presenting Author: Hye Sook Chon, Department of Gynecologic Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Ridaforolimus (RIDA) is a mTOR inhibitor that has demonstrated tolerability as intravenous (IV) and oral formulations. PI3K/AKT/mTOR signaling is associated with taxane resistance. In cancer cells, inhibition of mTOR signaling counteracts AKT-mediated resistance to drugs inhibiting tubulin. Paclitaxel and carboplatin (PC) have broad anti-cancer activity, and mTOR inhibition with PC has synergistic and additive effects in solid tumors. This 3+ 3 phase I study was to determine the maximal tolerated dose and R2PD of oral RIDA with PC during the first cycle of treatment. **Methods:** Solid cancer patients (pts) with measureable disease and <4 prior therapies received P (175mg/m2 IV) and C (AUC 5 to 6 mg/ml/min IV) on day (D)1 of each 3-week (wk) cycle. RIDA in escalating cohorts of 10-40 mg is administered orally daily for 5 days per wk (D1-5, D 8-12, D 15-19) in phase IA cohorts. Samples were collected for pharmacokinetics of RIDA and P and pharmacodynamics. > 1 DLT of thrombocytopenia or neutropenia in latter cycle shifted RIDA to alternate schedule (D1-5, D 8-12). **Results:** 22 pts have been enrolled; 9 ovarian/fallopian/peritoneal, 5 endometrial, 3 cervical, 2 esophageal, 1 urethral, 1 vaginal, 1 mesothelial. Median age was 63 (ranged 30-72). There were two Grade 4 neutropenias as DLT in dose level 1, thus a switch to predefined alternate dosing schedule (D1-5, D8-12). Dose escalation continued to PC(AUC5) + 40 mg RIDA with 1 of 4 DLTs. Total 166 cycles (ranged 1-12) were administered. Sixteen of 22 pts were evaluable for response: PR (32%), SD (27%), and PD (14%). One non-related to drug death was reported (non-related to drug). Grade 3/4 toxicities were observed in 21 of 22 pts (118 cycles of treatment) and were predominately myelosuppression. **Conclusions:** Treatment with RIDA combined with PC has no new unanticipated toxicities with activity in pretreated cancers. The RP2D is PC(AUC5) + RIDA 30mg D1-5, D8-10 q 3wk. Clinical trial information: NCT01256268.

**2615 General Poster Session (Board #78), Sun, 8:00 AM-11:45 AM**

**First-in-human (FIH) phase I study of a selective VEGFR/FGFR dual inhibitor sulfatinib with milled formulation in patients with advanced solid tumors.** *Presenting Author: Jian-Ming Xu, Cancer Center, 307 Hospital, Academy of Military Medical Science, Beijing, China*

**Background:** Sulfatinib is a highly selective oral small molecule tyrosine dual inhibitor of vascular endothelial growth factor receptors (VEGFR) and fibroblast growth factor receptors (FGFR). The FIH phase I data of the original formulation was reported in ASCO 2013(abs#3040). A milled formulation was subsequently developed to improve the PK property of this compound. **Methods:** This phase I dose-escalation study was to determine the maximum tolerated dose (MTD), dose-limiting toxicities (DLTs), pharmacokinetic (PK) profiles, and preliminary antitumor activity of sulfantinib when given orally in continuous cycles of 28 days, until disease progression or unacceptable toxicity. **Results:** Totally 60 pts have been enrolled (43 were treated with original formulation and 17 with milled formulation). For the 17 pts treated with milled sulfatinib at doses of 200mg, 300mg and 350mg once daily, the median age was 57 (23-69) yrs, with 82% male. Common adverse events included hypertension, nausea, diarrhea and elevated AST/ALT, mostly grade1/2. No DLT was observed. MTD has not been reached. PK analyses showed that drug exposures in terms of Cmax and AUC was increased while the inter- and intra-individual variability was reduced with milled formulation comparing to original formulation, indicating improved oral absorption. A reasonable 2-fold accumulation was observed at steady-state with $t_{1/2}$ of 20.2±4.75 h and 15.4±3.66 h at 200 and 300 mg, respectively. Among 13 evaluable pts, partial response (PR) was observed in 4 pts (ORR 30%) including 1 HCC in 200mg QD cohort, 1 liver neuroendocrine tumor (NET) and 1 NET with unknown primary site in 300mg cohort, and 1 lymph node NET in 350mg cohort. 7 (54%) pts had stable disease. **Conclusions:** Sulfatinib in milled formulation was well tolerated at doses up to 350 mg daily and demonstrated improved oral absorption and reduced exposure variability. Encouraging preliminary clinical efficacy including PR in pts with HCC and NET was observed. Further clinical development with sulfatinib milled formulation is warranted. Clinical trial information: CTR20131070.

**2616 General Poster Session (Board #79), Sun, 8:00 AM-11:45 AM**

**A phase I, open-label, nonrandomized trial of OPB-31121, a STAT3 inhibitor, in patients with advanced hepatocellular carcinoma (HCC).** *Presenting Author: Masafumi Ikeda, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

**Background:** OPB-31121 is an orally administered novel STAT3 inhibitor. STAT3 is found to be activated in the majority of HCC with poor prognosis. Following phase I studies for solid tumors, this multicenter phase I study was performed to evaluate the safety, recommended dose (RD), pharmacokinetics, and antitumor activity of OPB-31121 in patients (pts) with advanced HCC. **Methods:** HCC pts with Child-Pugh A or B who progressed on or were intolerant to sorafenib were eligible. A standard 3 + 3 dose-escalation design was used with a 28-day cycle. The tested dose levels were 50, 100, 200, and 400 mg/day. Tumor response was assessed by modified RECIST. **Results:** Twenty-three pts were enrolled. All pts had previously received median 2 different regimens (range, 1-5) of chemotherapy. Median age was 65 (range, 45-79) and 20 pts were male. ECOG PS 0/1=15/8, HBV/HCV=8/7, Child-Pugh A/B =22/1. The most common toxicities of all grades were nausea (87%), vomiting (83%), diarrhea (70%), fatigue/malaise (57%), and peripheral sensory neuropathy (26%). These toxicities were predominantly grade 1 or grade 2. The dose-limiting toxicities were persisting grade 2 nausea which needed a drug withdrawal at 200 mg and grade 3 nausea, diarrhea, peripheral sensory neuropathy and gait disturbances at 400 mg. The RD for OPB-31121 in advanced HCC pts was determined to be 200 mg. PK analysis showed that T1/2 was approximately 30 h and Tmax was around 8 h at 200 mg. Both Cmax and AUC exhibited dose proportionality. The mean Cmax value at 200 mg was 2-3 times higher than IC50 values for inhibitory effect against cell proliferation and phosphorylated STAT3 in human HCC cell lines in vitro. In 200 mg, 3 pts (44%) had stable disease among 7 pts. **Conclusions:** A 200mg/day of OPB-31121 was well-tolerated in pts with advanced HCC and toxicities were manageable. Further clinical development of OPB-31121 will be considered after getting results from an ongoing phase I study of another novel, chemically related compound with similar pharmacologic activities. Clinical trial information: NCT01406574.

**2617 General Poster Session (Board #80), Sun, 8:00 AM-11:45 AM**

**A phase I dose escalation study of weekly BI 836845, a fully human, affinity-optimized, insulin-like growth factor (IGF) ligand neutralizing antibody, in patients with advanced solid cancers.** *Presenting Author: Chia-Chi Lin, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan*

**Background:** The IGF signaling pathway has an important role in neoplasia and is associated with cancer progression, prognosis, and resistance to anti-cancer treatment. IGF-1 and IGF-2 are up-regulated in many tumors and exert multiple cellular activities through endocrine, autocrine, and/or paracrine manner. BI 836845 binds to and neutralizes the function of IGF-1 and IGF-2. The ligand-targeting approach differs from receptor-targeting by additional inhibition of IGF-2 signaling through IR-A. Objectives of this first-in-human trial were to assess the MTD or relevant biological dose (RBD), safety, PK, pharmacodynamics, and anti-tumor activity of weekly BI 836845 in cancer patients. **Methods:** In a 3+3 design, sequential cohorts of 3 to 6 patients (pts) with advanced or metastatic solid cancers refractory or not amenable to standard therapy received a weekly 1-hour intravenous infusion of BI 836845 following an AE-guided dose escalation. Treatment was continued in the absence of progressive disease and undue AE. The primary endpoints were DLT, MTD and/or RBD. **Results:** 48 pts, median age 57.5 (19-76) years were treated with BI 836845 at 14 dose levels (range: 10 to 1800 mg). Only one DLT, potentially drug-related grade 3 pulmonary hemorrhage originating from a tumor-adjacent vessel, was observed at 450 mg. The other of the two reported grade 3 drug-related AEs was lymphocyte decrease. No drug-related grade 4 or 5 AE was reported. Infusion-related reaction or drug-related hyperglycemia was not reported. MTD was not reached. BI 836845 showed a dose-proportional PK with a terminal half-life of about 6 days, a volume of distribution of 5.8 L, and a total plasma clearance of 0.5 mL/min. A RBD for further clinical development was selected at 1000 mg weekly. There were two confirmed PRs (nasopharyngeal carcinoma, at 800 mg; peripheral primitive neuroectodermal tumor, at 1050 mg) and 12 pts (25%) with confirmed SD. **Conclusions:** Weekly infusion of BI 836845 is well tolerated in cancer patients in the dose range tested without determination of a MTD. Preliminary anti-tumor activity has been observed. Clinical trial information: NCT01403974.

**2618 General Poster Session (Board #81), Sun, 8:00 AM-11:45 AM**

**Heregulin expression level as a predictive biomarker for patritumab efficacy.** *Presenting Author: Matthias Schneider, U3 Pharma GmbH, Martinsried, Germany*

**Background:** Activation of the receptor tyrosine kinase HER3 and its oncogenic downstream signaling pathways are thought to be critically involved in the development of various cancer types, including non-small cell lung cancer (NSCLC). HER3 serves as a scaffold for PI3K/AKT signaling via heterodimeric interaction with other HER family members, which can be mediated by binding of heregulin (HRG), the natural high affinity ligand for HER3. Patritumab (P) is an internalizing, fully human anti-HER3 monoclonal antibody that competes with HRG for receptor binding. We examined whether HRG expression correlates with P efficacy in vitro and in vivo. **Methods:** Protein and phosphoprotein levels in tumor cell lines were determined by western blot. Endogenous HRG mRNA expression was analyzed by RT-PCR. To examine signaling in vitro, tumor cells were treated with 10 $\mu$g/ml of P. Cells then remained untreated or were stimulated with recombinant HRG for 1 hour prior to lysis. Cell lysates were analyzed for HER3/pHER3- and AKT/pAKT-levels. To determine the efficacy of P in vivo, mice bearing ~200 $mm^3$ tumor xenografts were treated with P twice weekly, and tumor volumes were assessed. **Results:** Cell lines endogenously expressing HRG showed decreased HER3- and AKT-phosphorylation following treatment with 10 $\mu$g/ml of P, whereas no inhibitory effects of P were observed in HRG-negative cell lines. Remarkably, while HCC1569 cells are normally insensitive to P, the addition of exogenous HRG conveyed sensitivity to these cells. In line with these in vitro observations, HRG expression was found to correlate with P single-agent efficacy in 13/15 in vivo tumor models, from a range of tissue types. In contrast, neither levels of HER3 expression nor levels of HER3 phosphorylation were found to consistently correlate with P single-agent efficacy. **Conclusions:** Unlike HER3 expression or activation, HRG expression reliably correlated with P-mediated inhibition of signaling in vitro and tumor growth inhibition in vivo. Based on these data, HRG expression levels were nominated as the primary predictive biomarker for P efficacy and were clinically evaluated in the HERALD phase 1b/2 trial in patients with NSCLC (Mendell-Harary et al., von Pawel et al. ASCO 2014).

**2619 General Poster Session (Board #82), Sun, 8:00 AM-11:45 AM**

**Pharmacokinetics and pharmacodynamics of the dual syk/jak inhibitor PRT062070 (cerdulatinib) in patients with advanced B-cell malignancies.** *Presenting Author: Ian Flinn, Sarah Cannon Research Institute, Nashville, TN*

**Background:** Syk and Jak appear to have independent but cooperative roles in promoting the survival of certain B cell malignancies. Syk is upstream of BTK and PI3K on the B cell antigen receptor (BCR) signaling pathway, and Jak mediated survival signals have been observed in leukemia and lymphoma. Combined knockdown of Syk and Jak results in greater cell kill in B cell lymphoma cell lines relative to knock down of either alone (Ma, et al, 2013), suggesting dual pharmacological targeting of these pathways may be an effective treatment strategy. PRT062070 is a potent and selective inhibitor of Syk, JAK1, JAK3, and Tyk2. Here we present PK and PD data from a dose escalation study with PRT062070 in patients with NHL, CLL, and SLL. **Methods:** Patients were enrolled in a 3+3 dose escalation study beginning at 15 mg orally daily. PK/PD relationships were determined using a variety of whole blood assays measuring Syk (BCR-mediated) and Jak (IL2-, IL4-, and IL6-mediated) kinase activity. Specificity controls included GM-CSF (JAK2 mediated) and phorbol 12-myristate 13-acetate (PKC-mediated) stimulations. Plasma concentrations were assessed on Days 1, 8, 15, and 22 of the first treatment cycle with standard LC/MS/MS methods. **Results:** The average elimination $T_{1/2}$ at steady state (SS) is ~12 hours and $T_{max}$ ~2 hours. The SS peak-to-trough ratio is 3:1. The mean $C_{maxss}$ value was 80% higher than the Day 1$C_{max}$. Increases in $C_{max}$ and exposure were dose proportional from the 15 to 30 mg dose. Relative to pre-dose, assays measuring Syk (BCR) and Jak (IL2, IL4, IL6) activity at SS were inhibited by 25-50% at the 15 mg dose level, and 50-70% at the 30 mg dose level. No corresponding inhibition of JAK2 or PKC-mediated signaling was observed. The PK/PD relationship is consistent with pre-clinical in vitro experiments. **Conclusions:** PRT062070 demonstrates a favorable PK profile, supporting once daily dosing. The PD data demonstrate selective target inhibition with $IC_{50}$'s consistent with that observed pre-clinically. Data to date suggest that high levels of Syk and Jak inhibition in peripheral blood can be safely achieved following oral dosing. Clinical trial information: NCT01994382.

**2620 General Poster Session (Board #83), Sun, 8:00 AM-11:45 AM**

**A phase 1 expansion cohort of the fibroblast growth factor receptor (FGFR) inhibitor AZD4547 in patients (pts) with advanced gastric (GC) and gastroesophageal (GOJ) cancer.** *Presenting Author: Hendrik-Tobias Arkenau, Sarah Cannon Research Institute UK, London, United Kingdom*

**Background:** AZD4547 is a potent selective inhibitor of FGFR 1, 2, and 3 tyrosine kinases. Pre-clinically, gastric cancer cell lines and patient-derived xenograft models with *FGFR2* gene amplification were sensitive to AZD4547, resulting in reduced cell proliferation and tumor regression. **Methods:** A multicentre phase-1 study assessed the safety, pharmacokinetics, pharmacodynamics (PD) and antitumor activity of AZD4547 (80 mg bd) in an expansion cohort of pts with advanced/metastatic GC/GOJ cancer (NCT00979134) who were prospectively selected for *FGFR1/2* amplification using fluorescent in situ hybridization (FISH) analysis of archival or fresh tumors. **Results:** 238 GC/GOJ pts were pre-screened, of which 38 pts (16%) had the pre-specified *FGFR1/2* amplification (*FGFR*:Centromeric ratio ≥2). 13 pts were treated (9 m: 4 f, mean age 57yrs). 6 had high *FGFR* amplification (*FGFR*:Centromeric ratio ≥ 2.8), 3 had low amplification (FGFR:Centromeric ratio >2 to < 2.8), and 4 were of a cluster type (FGFR gene amplification clusters in > 10% cells). A total of 136 treatment-emergent adverse events (CTC-AE all grades) were reported including vomiting (8 pts; 61.5%), decreased appetite and diarrhoea (7 pts each; 53.9%), fatigue and nausea (6 pts each; 46.2%), hyperphosphatemia, constipation and dry eye (4 pts each, 30.7%). 8 pts (61.5%) reported epithelial and mucosal dryness, 5 pts (38.5%) stomatitis, and 4 pts (30.8%) retinal pigment epithelial detachment. Preliminary exploratory analysis revealed an increase in serum phosphate following dosing. 1 PR was observed in a patient with a tumor that had clusters of FGFR gene amplification and 4 pts had stable disease (3 with high FGFR amplification and 1 with clusters). **Conclusions:** AZD4547 was well-tolerated in pts with *FGFR1* amplified advanced/metastatic GC/GOJ cancer but did not meet its pre-specified efficacy endpoint, in terms of overall response rate, for continuation. The increase in plasma phosphate concentration observed in this study, provides evidence that AZD4547 at this dose and schedule causes pharmacologic target inhibition. Clinical trial information: NCT00979134.

**2621 General Poster Session (Board #84), Sun, 8:00 AM-11:45 AM**

**Identifying actionable targets in advanced cancer patients: Preliminary results from the Profiler program.** *Presenting Author: Philippe Cassier, Centre Léon Bérard, Lyon, France*

**Background:** The ProfiLER study was designed to characterize tumor genomic alterations (GAs) in a panel of selected genes in patients (pts) with advanced malignancies. Whether the presence of GAs may guide treatment (trt) decision regardless of histological subtype remains unclear. **Methods:** Pts with advanced solid and hematologic cancers were offered a genetic profiling of their tumor. DNA extracted from archival or freshly collected tumor samples was analyzed by sequencing of 59 cancer-related genes (NGS, Ion Torrent PGM system) and whole genome CGH array (Agilent platform). A multidisciplinary panel of clinicians and scientists reviewed results to determine the relevance of GAs and recommended molecular targeted therapies (MTT) when relevant. **Results:** From March to October 2013, 431 pts from a single center were consented and 283 (66%) had their tumor analyzed, either by NGS+CGH (186 pts, 66%), NGS alone (86, 30%) or CGH alone (11, 4%). 137 (48%) had at least one actionable target (AT) with a recommended MTT: 20% were breast cancers, 17% head and neck, 15% lung, 9% sarcoma, 8% colon and 31% other tumor types. NGS was conclusive for 132 pts, identifying actionable mutations (hot spot or described in COSMIC database) mainly in *PIK3CA* (15% of pts), *EGFR* (9%), *MET* (4%), *MTOR* (4%), *ALK* (4%), *PTEN* (4%), *ERBB2* (3%), *BRAF* (2%) (median nb of mutations/pt: 1 [range: 0-11]). Main ATs identified with CGH (n=105 pts) were amplifications of *CCND1* (17%), *FGFR1* (11%), *MDM2* (7%), *EGFR* (5%), *ERBB2* (5%), *CDK4* (4%), *CDK6* (3%), homozygous deletion of *CDKN2A* (21%) and *PTEN* (5%) (median nb of copy number variations/pt: 1 [0-6]). 19/137 pts (14%) have so far received an MTT, mainly mTOR inhibitors (7 pts, 37%), ALK/MET inhibitors, anti-HER2, FGFR inhibitors or anti-VEGF (2 pts each, 10%). Best responses were PR (2/19, 10%), SD (6/19, 32 %), PD (9/19, 47%) and not evaluable in 2 pts. Median trt duration was 2.2 months [0.8–7.5] (Data, censored on December 1st2013, will be updated). **Conclusions:** Systematic tumor profiling is feasible in routine practice, highly attractive for pts with advanced malignancies and identifies ATs in nearly 50% of the pts. Clinical trial information: NCT01774409.

**2622 General Poster Session (Board #85), Sun, 8:00 AM-11:45 AM**

**Phase I dose escalation study of 3-weekly BI 836845, a fully human, affinity optimized, insulin-like growth factor (IGF) ligand neutralizing antibody, in patients with advanced solid tumors.** *Presenting Author: Karim Rihawi, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, London, United Kingdom*

**Background:** Insulin-like growth factor signaling is reported to play a role in the pathogenesis of several tumours. BI 836845 is a HumAb of the IgG1 isotype against the human insulin-like growth factors IGF-1 and IGF-2, which are up-regulated in many tumors. This ligand-targeting approach is broader than specific IGF-1 receptor blockade. This first in man Phase I trial of 3-weekly i.v. BI 836845 was pursued to evaluate safety, tolerability, MTD and relevant biological dose (RBD). Secondary objectives included assessment of tumor response, PK and PD. **Methods:** Patients (pts) with advanced solid tumours, ECOG PS 0-2, and adequate organ function were recruited in a 3+3 dose escalation design. BI 836845 was administered at escalating doses in 3-weekly (21 day) cycles until progression or unacceptable toxicity. A past history of diabetes was an exclusion criterion. **Results:** 33 pts across 11 cohorts were enrolled and treated, median age 59.0 (23 – 79) years. Tumor types were colorectal (6), adrenal (4), NSCLC (2), head and neck (2), pancreas (2), prostate (2), ovary (2) and others (13). No DLT was observed in any of the 11 dose levels explored (range 10 to 3600 mg); MTD was not reached. The most common (> 5% of pts) related AEs were abdominal pain, constipation, decreased appetite, fatigue, lethargy and nausea all being ≤ Grade 2. 2 pts had Grade 3 related AEs (hyponatremia and diarrhea). 0 had Grade 4 related AEs. No drug-related hyperglycemia was observed. BI 836845 plasma exposure ($AUC_{0-\infty}$ and $C_{max}$) increased dose-proportionally with steady state volume of distribution ($V_{ss}$) of about 5.8 L and a total plasma clearance (Cl) of 0.5 mL/min. The terminal half-life was about 6 days. There were no objective responses but confirmed SD was achieved in 4 pts. RBD of 1000 mg weekly was selected based on integration of preclinical and clinical data from this study and a study investigating weekly dosing. **Conclusions:** BI 836845 is well tolerated in patients with advanced solid tumours. An RBD of 1000 mg weekly was identified. An expansion phase is ongoing and recruiting patients with Ewing sarcoma or all tumor types with biopsiable disease. Clinical trial information: NCT01317420.

**2623 General Poster Session (Board #86), Sun, 8:00 AM-11:45 AM**

**Phase I trial of bortezomib daily dose: Safety, pharmacokinetic profile, biological effects, and early clinical evaluation in patients with advanced solid tumors.** *Presenting Author: Rastislav Bahleda, Drug Development Department (DITEP), Gustave Roussy Institute, Villejuif, France*

**Background:** Bortezomib (BTZ) is proteasome inhibitor with activity in multiple myeloma used as a weekly or twice-weekly subcutaneous regimen. BTZ showed modest activity in solid tumors, potentially related to sub-optimal tumor penetration. **Methods:** This is a dose escalation study to define the MTD of daily low dose schedule of BTZ given SC on days 1-5, 8-12, 15-19 of 28 day cycle based on 3+3 design. Primary objective: to establish the MTD. Secondary objectives: safety, efficacy, PK and PD. Patients ≥ 18 years with advanced solid tumors, ECOG ≤ 1, adequate organ functions, without pre-existent neuropathy were included. Biomarkers for proteasome inhibition, pre- and post-treatment tumor biopsies, circulating proteins were evaluated. **Results:** As of Sep 2013, 18 pts have been treated (8 M/10 F), median age 57.5 years (range 41-76). BTZ dose cohorts were (no. pts): 0.5 mg/m$^2$ (3), 0.6 mg/m$^2$ (11), 0.7 mg/m$^2$(4). 11 pts received 1 cycle; 4, 2 and 1 pts received 2, 5 and 6 cycles, respectively (total 35 cycles, 13 with full doses). Three DLTs were observed in 3 pts: Sweet's syndrome (at 0.6 mg/m$^2$), G3 anorexia with asthenia (2 pts at 0.7 mg/m$^2$). The most common study drug-related AEs (all grades) were fatigue (56%), thrombocytopenia (56%), rash (39%), anorexia (39%) and neuropathy (39%). 4 additional pts were enrolled at 0.6 mg/m$^2$ considered as RP2D. Dose-normalized mean systemic exposure to BTZ was time-independent, with similar BTZ PK on day 5 and day 19. Maximum proteasome inhibition was observed at day 19 in blood, and subsequently recovered until last time point measured at day 26. Proteasome inhibition was compared in tumor/blood (n = 3) and % inhibition on day 5 varied between 0.95 – 2.01 , indicating a good correlation between tumor and blood. One PR has been observed in pt with heavily pre-treated GIST and 2 minor responses (-20%) in pt with melanoma and mesothelioma. **Conclusions:** Daily BTZ administration showed an acceptable safety profile, dose dependent plasma exposure, evidence of target inhibition, and preliminary signs of clinical activity. RP2D of daily above-mentioned regimen of BTZ is 0.6 mg/m$^2$. Additional clinical, PK and PD data will be presented. Clinical trial information: eudraCT 2009-014354-15.

**2624^ General Poster Session (Board #87), Sun, 8:00 AM-11:45 AM**

**Safety, activity, and pharmacokinetics of an oral anaplastic lymphoma kinase (ALK) inhibitor, ASP3026, observed in a "fast follower" phase 1 trial design.** *Presenting Author: Michael L. Maitland, University of Chicago Medicine, Chicago, IL*

**Background:** The efficient early development of agents intended for selected patient populations is challenging. ASP3026 is a selective, ATP-competitive, kinase inhibitor with in vitro $IC_{50}$for ALK of 3.5 nM. **Methods:** Advancedsolid tumor patients (pts) received oral ASP3026 under fasting conditions without interruption in 3+3 dose escalation cohorts from 25 to 800 mg once daily (QD). The primary endpoint was to identify the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of ASP3026. To identify rapidly evidence of therapeutic activity a previously cleared cohort could enroll up to an additional 3 pts with advanced *ALK*driven solid malignancies(ALK+) . A planned phase Ib expansion cohort was opened at the R2PD. RECIST 1.1 was used to determine response. **Results:** The dose escalation phase enrolled 33 pts, including 3 ALK+ pts , and the expansion cohort enrolled another 13 ALK+ pts [total pts N = 46; 48% men; median (range) age = 61 (19-77) years]. Three dose-limiting toxicities (DLTs) were observed: grade 2 nausea and vomiting leading to dose reduction at 525 mg QD; grade 3 rash at 800 mg QD leading to dose reduction and grade 3 ALT/AST elevation leading to study withdrawal at 800 mg QD, making 525 mg daily the MTD and RP2D. The most common adverse events of the entire cohort were: fatigue (44%), vomiting (39%), nausea (37%), and constipation (24%). Of 15 pts with ALK+ non-small cell lung cancer (NSCLC) who progressed on prior crizotinib 7 (44%) had a partial response (PR) and 8 (50%) had stable disease as the best response. The median progression free survival in the ALK+ pts was 5.9 (95% CI: 3.8-9.4) months. Eight pts were still receiving treatment at data cut off. There was no correlation between response and plasma ASP3026 concentrations (AUC and Cmax) in the ALK+ pts. ASP3026 demonstrated dose-proportionality for AUC and Cmax with a terminal half-life compatible with QD dosing. **Conclusions:** The "fast follower" design enabled enrollment of ALK+ pts who had partial responses before the MTD of 525mg QD was determined. ASP3026 had clinical activity in ALK+ NSCLC pts who progressed on crizotinib. Clinical trial information: NCT01401504.

**2625 General Poster Session (Board #88), Sun, 8:00 AM-11:45 AM**

**MAPK/ERK as a biomarker for cisplatin resistance in squamous cell carcinoma (SCC).** *Presenting Author: Li Ren Kong, Cancer Science Institute, Singapore, Singapore*

**Background:** Significant progress in therapy of non SCC of the lung has been made through genomic profiling and subtyping according to oncogenic drivers. In SCC, cisplatin-based therapy remains the mainstay, and resistance to treatment is common. We sought to understand the molecular underpinnings of cisplatin resistance in SCC. **Methods:** SCC of patients were characterized by Next-Generation Sequencing. *In vitro* drug sensitivity in lung SCC cell lines (n= 3) was determined by MTS assay, transcriptomic analysis was performed with microarray and signalling regulation was investigated with phospho-kinase array. Cisplatin-mediated cellular signalling identified by transcription and phospho-kinase array was validated in SCC cell lines by Western blotting (n= 3). Expression of p-Erk in SCC specimens was detected with IHC staining. **Results:** We verified the paucity of oncogenic driver mutations in 45 lung SCC specimens. H596, H1869, H226 and ChaGo-k-1 cell lines were deemed sensitive while Calu-1, H2170, SW900 and H2066 resistant to cisplatin. MAPK/Erk pathway proteins were up-regulated in resistant compared to sensitive cell lines by gene expression and phospho-kinase arrays. p-Erk1/2 was activated in cisplatin-resistant cell lines in increasing cisplatin doses, while gene silencing (siRNAs) and pharmacological inhibition (MEK inhibitors) of Erk1/2 reversed cisplatin resistance and enhanced cisplatin sensitivity in lung SCC cells. High p-Erk1/2 expression in HNSCC tumours was found correlated with shorter progression-free survival of SCC patients treated with cisplatin. **Conclusions:** Our data suggest that 1) therapeutic targeting of MAPK/Erk signalling is potentially effective in abrogating cisplatin resistance in SCC, and 2) p-Erk1/2 is a predictive biomarker for cisplatin treatment in SCC tumours.

**2626 General Poster Session (Board #89), Sun, 8:00 AM-11:45 AM**

**Concomitant blockade of EGFR and MEK overcomes acquired resistance to anti-EGFR therapy in colorectal cancer cells and patients' avatars.** *Presenting Author: Alberto Bardelli, IRCC Institute for Cancer Research and Treatment, University of Torino, Medical School, Candiolo, Candiolo, Italy*

**Background:** The anti-EGFR antibodies cetuximab and panitumumab are approved for the treatment of RAS wild-type colorectal cancer (CRC) patients. The clinical efficacy of EGFR targeted antibodies is limited by the development of acquired (secondary) resistance. Here we investigated the molecular bases of relapse to anti-EGFR blockade in CRC cells and patients' samples and use xenotransplants to define a clinically applicable strategy to overcome acquired resistance. **Methods:** Molecular profiling of circulating tumor DNA was used to identify the emergence of mutations in plasma samples of patients who relapsed after anti EGFR therapies. Xenografted tumors (avatars) from patients who relapsed after EGFR blockade were established and exploited to assess the efficacy of drugs aimed at bypassing acquired resistance. **Results:** Emergence of concomitant mutations in KRAS and NRAS was detected in samples from 5 CRC patients who developed resistance to anti-EGFR antibodies. Acquired resistance to cetuximab and panitumumab was modeled in 4 CRC cell models. Resistant cells were a mixture of clones bearing alterations in KRAS, NRAS and BRAF thus closely recapitulating the patients' findings. Pathway analyses revealed that, although genetically polyclonal, resistant cells consistently displayed MEK and ERK activation but, surprisingly, were refractory to MEK inhibition. However, the resistant derivatives were sensitive to the concomitant inhibition of MEK and EGFR independently from their genetic status. Mouse xeno-transplants of lung and liver biopsies from two CRC patients who responded and subsequently relapsed upon EGFR therapy showed exquisite sensitivity to combinatorial treatment with the MEK inhibitor pimasertib and EGFR blockade with cetuximab. **Conclusions:** These observations provide a rational strategy to overcome the clonal heterogeneity that emerges when CRCs are treated with anti EGFR antibodies. We propose that MEK inhibitors, in combination with cetuximab or panitumumab, should be evaluated in CRC patients who become refractory to anti-EGFR therapies. A clinical trial (ARES) has been initiated to test this hypothesis.

**2627 General Poster Session (Board #90), Sun, 8:00 AM-11:45 AM**

**A phase 1 study of the c-Met inhibitor tivantinib (ARQ 197, IND#112603) in children with relapsed or refractory solid tumors: A Children's Oncology Group study.** *Presenting Author: James I. Geller, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

**Background:** Tivantinib is an oral small molecule that inhibits the c-Met receptor tyrosine kinase (RTK), which is dysregulated in many pediatric cancers. A phase I and pharmacokinetic (PK) trial evaluating tivantinib was conducted in children with refractory solid and CNS tumors. **Methods:** Oral tivantib capsules were administered bid, continuously in 28-day cycles. Three dose levels (170, 200 or 240mg/$m^2$/dose) were evaluated using a rolling 6 design (Part A). In Part B, patients received tivantinib powder sprinkled on food at the RP2D from Part A. Serial PK (day 1) and trough samples (day 28) were obtained in Cycle 1. CYP450 genotyping was performed in all participants. **Results:** Thirty-six patients were enrolled (24 male, median age 12.1 years (range, 3.8-21): 20 in Part A, 6 to a PK expansion cohort, and 10 to Part B. Fifteen patients had primary CNS tumors and 21 had solid tumors. Twenty-six patients were evaluable for toxicity assessment and 32 for response. In Part A there were 0/5, 0/6 and 0/5 pts with DLT at dose levels 1-3. There was 1 grade (GR) 4 intracranial hemorrhage in a patient with a progressive brain tumor in the expanded PK cohort (240 mg/$m^2$). Non dose-limiting toxicities at least possibly attributable to tivantinib included grade 3 or 4 myelosuppression [lymphopenia (3), neutropenia (2), anemia (2), and thrombocytopenia (1)]; Gr 1 or 2 toxicities occurring in $>$ 10% of evaluable patients included fatigue (9), leukopenia (7), vomiting (5), nausea (5), anemia (12), neutropenia (5), lymphopenia (3), hypoalbuminemia (4), and thrombocytopenia (3). PK analysis showed marked inter-patient variability (20-fold) in the $C_{max}$ and $AUC_{last}$ across all dose levels. Sprinkling tivantinib powder over food did not appear to alter exposure. The average terminal elimination $t_{1/2}$ was 2.5 hours. **Conclusions:** The RP2D of tivantinib given with food is 240 mg/$m^2$/dose. PK of tivantinib in children demonstrated high variability. Clinical trial information: NCT01725191.

**TPS2628 General Poster Session (Board #91A), Sun, 8:00 AM-11:45 AM**

**A phase I trial of dabrafenib (BRAF inhibitor) and pazopanib in *BRAF*-mutated advanced malignancies.** *Presenting Author: Sigurdis Haraldsdottir, The Ohio State University Comprehensive Cancer Center - Arthur G. James Cancer Hospital and Richard J. Solove Research Institute, Columbus, OH*

**Background:** BRAF inhibitor therapy is associated with an impressive albeit short-lived response rate in the treatment of malignant melanoma. Mechanisms of resistance include upregulation of the MAPK pathway through mutations in *NRAS*, *MEK* and *BRAF* alternate splicing; furthermore upregulation of PDGFR-$\beta$ can cause resistance. Some malignancies, such as thyroid malignancies, have upregulation of VEGF pathways and also carry a *BRAF* mutation. Combination of therapies targeting VEGF and MAPK pathways could enhance the effects of both agents as well as target potential pathways of resistance. We are conducting a NCCN-sponsored phase I trial combining both agents in the treatment of advanced *BRAF* mutated malignancies. **Methods:** This is a phase I dose-escalation trial with a conventional 3+3 approach. Dose escalation of pazopanib preceeds escalation of dabrafenib doses as dabrafenib is a CYP3A4 inducer and might therefore cause more rapid metabolism of pazopanib, a CYP3A4 substrate. Inclusion criteria include any advanced malignant tumor carrying a mutation in the *BRAF* gene. Prior use of dabrafenib or pazopanib is not allowed and only 3 prior tyrosine kinase inhibitor regimens are allowed. Patients with a history of *BRAF* mutated malignancies within 5 years of study enrollment are allowed on the study. Starting doses on dose level 1 are 50 mg bid for dabrafenib and 400 mg qd for pazopanib, escalating to 150 mg bid for dabrafenib and 800 mg qd for pazopanib on dose level 5. Both agents are given continuously on a 28 day schedule. Cohorts 1 and 2 have been completed without dose-limiting toxicities. Enrollment to cohort 3 began in November 2013. Correlative studies include quantification of the copy number of the *BRAF V600E* mutant allele in circulating plasma. Clinical trial information: NCT01713972.

**TPS2629^ General Poster Session (Board #91B), Sun, 8:00 AM-11:45 AM**

**First-in-human phase I "basket" study of Debio1347 (CH5183284), a novel FGFR inhibitor, in patients with FGFR genomically activated advanced solid tumors.** *Presenting Author: Martin Henner Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Deregulated fibroblast growth factor receptor (FGFR) signalling is associated with tumorigenesis. Debio 1347 is an orally-available ATP competitive inhibitor of FGFR 1, 2 and 3 with preclinical data showing high target-specificity and antitumor activity across models of FGFR amplified, mutated or translocated tumors for various human malignancies. **Methods:** This first-in-human, phase I dose-escalation multiple tumor type "basket" study enrols patients with advanced solid malignancies harbouring defined activating alterations of FGFR 1, 2, or 3. These include amplifications and translocation events with known activating effect as well as somatic mutations previously reported as activating or located in genomic regions of relevance for kinase activity. The dose-escalation part of the trial enrols patients with advanced solid tumour malignancies and presence of any such alteration. Genetic screening is performed independently at each site with post-hoc centralised confirmation of molecular status by Next Generation Sequencing (NGS). The primary endpoint is determination of maximum tolerated dose (MTD). Patients receive Debio 1347 orally once daily and are assessed for dose-limiting toxicities (DLT) during the first 4 weeks. With a starting dose-level of 10 mg the study follows a 3+3 algorithm with dose-escalation on a modified Fibonacci sequence. The MTD is defined as the level where $\geq$ 2/6 patients suffer a DLT. All the patients receive dietary phosphate restriction.The secondary objective is exploration of antitumor effect in the various tumor types enrolled on trial. Pharmacokinetics is evaluated after single and repeated administration. Pharmacodynamics biomarkers including phosphate and FGF23 are explored in plasma samples. Pre- and post-treatment skin and tumor biopsies are used for pharmacodynamics analyses. Recruitment started in September 2013. Cohort 1 has been completed. Cohort 2 began in January 2014. Subsequent dose expansion is planned at the final recommended dose across pre-defined disease-specific baskets to evaluate safety and efficacy in the setting of specific FGFR alterations of relevance to each disease. Clinical trial information: NCT01948297.

**TPS2630 General Poster Session (Board #92A), Sun, 8:00 AM-11:45 AM**

**A phase 1 dose-escalation study of EC1456, a folic acid-tubulysin small-molecule drug conjugate, in adult patients (pts) with advanced solid tumors.** *Presenting Author: Wael A. Harb, Horizon Oncology Center, Lafayette, IN*

**Background:** The folate receptor (FR) is expressed in alarge number of epithelial tumors and is a valid anticancer target. EC1456 is a potent folic acid-tubulysin B hydrazide (TubBH) small-molecule drug conjugate that exerts its antitumor effects by inhibiting the polymerization of tubulin into microtubules and arresting cells in metaphase. EC1456 acts as a cell-specific cytotoxic agent and preferentially targets TubBH to cancer cells that express FR. **Methods:** This is a phase 1, multicenter, open-label, nonrandomized dose-escalation study (NCT01999738) to evaluate the maximum tolerated dose (MTD) of biweekly (BIW) EC1456 treatment in pts with solid tumors (part A) and assess preliminary efficacy in pts with FR-expressing tumors treated at the MTD (part B). Key eligibility criteria include: age $\geq$18 years; histologically confirmed metastatic or locally advanced solid tumor; Eastern Cooperative Oncology Group (ECOG) performance status 0–1. At baseline all pts undergo a $^{99m}$Tc-etarfolatide scan to determine FR status. For part B, only FR(100%) pts, in whom all target lesions (Response Evaluation Criteria in Solid Tumors [RECIST] 1.1 criteria) express FR, are included. EC1456 is given intravenously BIW on weeks 1 and 2 (days 1, 4, 8, and 11) of a 4-week cycle. The dose-escalation scheme is shown in the Table. Cohorts will consist of 3–6 pts/dose level, and EC1456 escalation is via the standard 3+3 schema. All pts in a cohort must complete cycle 1 dose-limiting toxicity (DLT) evaluation before dosing is initiated at the next higher level. DLTs observed in cycle 1 will determine whether additional pts should be enrolled at the same dose, or a lower/higher dose level. The primary objective is to determine the MTD and recommended phase 2 dose of EC1456 in pts with advanced tumors. The secondary objectives include safety and pharmacokinetic analysis of EC1456 in pts with solid tumors, and preliminary efficacy evaluation in selected pts at MTD (part B). Enrollment to cohort 1 began in November 2013. Clinical trial information: NCT01999738.

| Level | Dose (mg/m$^2$) |
|---|---|
| **1** | 0.5 |
| **2** | 1 |
| **3** | 1.5 |
| **4** | 2 |
| **5** | 2.5 |
| **6** | 3.5 |
| **7** | 4.5 |
| **8** | 6 |

**TPS2631^ General Poster Session (Board #92B), Sun, 8:00 AM-11:45 AM**

**Phase I, dose-escalation study of the investigational drug D07001-F4, an oral formulation of gemcitabine HCl, in patients (pts) with advanced solid tumors.** *Presenting Author: Chia-Chi Lin, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan*

**Background:** Gemcitabine HCl is a nucleoside analogue that exhibits antitumor activity and is approved for IV use in the world. Oral dosing of gemcitabine HCl would simplify administration and extend the systemic exposure time after a dose relative to an intravenous exposure profile, which has been correlated with increased activity of gemcitabine in both preclinical and clinical studies. Nonetheless, in a reported clinical study, the systemic exposure to oral gemcitabine was low due to extensive first-pass metabolism to dFdU. D07001-F4 is a unique oral formulation of gemcitabine HCl that is expected to enhance the systemic exposure to difluorodeoxycytidine (dFdC) and ultimately dFdCTP, intracellularly. **Methods:** D07001-F4 is being evaluated of in an open-label, dose escalation study in patients with advanced solid tumors or lymphoma. Eligibility: pts with evaluable tumors, age $^3$a 20 yrs, PS 0–2 and with adequate oral therapy absorption. Primary objects includes determination of maximum tolerated dose, dose-limiting toxicity(ies) and the recommended phase 2 dose of D07001-F4. Secondary objectives include characterization of pharmacokinetic (PK) and assessment of safety, tolerability and anti-tumor activity. Sequential cohorts of 3 to 6 patients receive doses ranging from 2 mg to 80 mg oral D07001-F4 on Days 1, 3, 5, 8, 10, and 12 of a 21-day cycle. MTD is determined based on DLTs in cycle 1. Tumor response is determined according to RECIST or Cheson criteria. Plasma and peripheral blood samples were obtained for PK analysis in cycle 1. Accrual has completed in Cohorts 1 (2 mg) to 4 (20mg). Accrual is underway for Cohort 5 (30 mg). Clinical trial information: NCT01800630.

**TPS2632^ General Poster Session (Board #93A), Sun, 8:00 AM-11:45 AM**

**The HALO study: A phase I-II of the oral HSP90 inhibitor Debio0932 in combination with SOC in first- and second-line therapy of advanced NSCLC.** *Presenting Author: Jesus Corral, University Hospital Virgen del Rocío, Seville, Spain*

**Background:** Debio0932 is an oral second-generation Heat Shock Protein 90 (HSP90) inhibitor, structurally unrelated to geldanamycin. In multiple pre-clinical models Debio0932 has demonstrated anti-tumor activity both as monotherapy and in combination with conventional anticancer agents. Debio0932 monotherapy was well tolerated in cancer patients up to 1000 mg daily (QD) and showed signs of activity in patients with Non-Small Cell Lung Cancer (NSCLC). **Methods:** The HALO (HSP90 inhibition And Lung cancer Outcomes) study is recruiting patients with Stage IIIb or IV NSCLC (EGFR wild type or unknown mutation) and consists of three parts. Part A is an open-label dose escalation of Debio0932 administered QD in 21-day treatment cycles in combination with standard of care (SOC) for first and second line treatment of advanced NSCLC. Cisplatin + gemcitabine (SCC) or cisplatin + pemetrexed (Non SCC NSCLC) are used as first-line SOC whereas docetaxel is used for later lines of therapy. The starting dose is 100 mg and will be escalated up to 1000 mg. Part B is a double-blind, placebo-controlled study in which 138 untreated advanced NSCLC patients will be randomized to receive placebo or Debio0932 at the dose recommended in part A in combination with first-line SOC. The primary endpoint of Part B is 6-month progression free survival (PFS); secondary endpoints include best overall response rate (ORR), duration of objective response, change in tumor size from baseline until 6 months and overall survival (OS). Patients who subsequently develop progressive disease are newly randomized to double-blind treatment with docetaxel +/- Debio0932 (Part C). Approximately 100 patients are expected to enter part C. The primary endpoint of part C is the change from baseline tumour size at month 6; secondary endpoints include best ORR, duration of objective response, 6-month PFS, and OS. Extensive PK, PD and pharmacogenomic assessments are included. As of January 2014 58 patients have been enrolled in the study Part A at all dose levels (Debio0932 100 mg to 1000 mg QD). MTD was not reached yet. One DLT occurred in the cisplatin + gemcitabine arm at Debio0932 250 mg dose and one in the docetaxel arm at Debio0932 1000 mg dose. Clinical trial information: NCT01714037.

**TPS2633 General Poster Session (Board #93B), Sun, 8:00 AM-11:45 AM**

**Transforming the clinical trial process: The I-SPY 2 trial as a model for improving the efficiency of clinical trials and accelerating the drug-screening process.** *Presenting Author: Meredith B. Buxton, University of California San Francisco, San Francisco, CA*

**Background:** The I-SPY 2 TRIAL is a standing, phase 2 trial that screens novel, targeted chemotherapeutic regimens in the neoadjuvant setting for women with stage II/III breast cancer. I-SPY 2 compares the efficacy of novel agents in combination with standard chemotherapy versus standard therapy alone, using pathologic complete response as the primary endpoint. Using an adaptive design, the goal is to identify/graduate regimens that have ≥85% Bayesian predictive probability of success (statistical significance) in a 300-patient biomarker-linked Phase 3 neoadjuvant trial defined by hormone-receptor (HR), HER2 status and MammaPrint. **Methods:** I-SPY 2 opened to accrual in March 2010, and is currently enrolling at 18 sites in the US, with 2 additional sites opening in 2014 (one in Canada and one in the US). As of January 2014, I-SPY 2 has screened 961 patients, enrolled 541 patients, and 326 patients have completed surgery. Seven novel regimens have entered the trial from 5 different pharmaceutical companies. In 2013, the trial announced the graduation of 2 regimens for two different biomarker signatures – veliparib+carboplatin (HR-/HER2-) and neratinib (HR-/HER2+). The I-SPY 2 TRIAL incorporates many innovative procedures and tools to increase the efficiency of the clinical trial process including: developing a standing trial consortium of academic, industry, governmental and nonprofit partners; involving key stakeholders from the development to implementation to ongoing management phases; democratizing data access; and driving organization efficiencies including testing drugs by class, developing a "Master" IND and protocol to accommodate testing multiple agents, sharing a control arm across multiple treatment arms, focusing on the collection of critical data elements, and utilizing previously and newly developed informatics tools to create an IT bundle to support next generation trials. The I-SPY Program includes a series of linked standing trials (I-SPY 2 and I-SPY 3, a confirmatory phase 3 trial) that may allow for a more efficient process for new chemotherapeutic agents to obtain both accelerated and full FDA approval. Clinical trial information: NCT01042379.

**TPS2634 General Poster Session (Board #94A), Sun, 8:00 AM-11:45 AM**

**Patient preference trial comparing capecitabine and S-1 in metastatic breast cancer patients.** *Presenting Author: Daigo Yamamoto, Department of Surgery, Kansai Medical University, Moriguchi, Japan*

**Background:** Capecitabine and S-1 are an orally administered fluorinated pyrimidine with high activity in metastatic breast carcinoma (MBC). We reported the activity and safety of two oral fluoropyrimidines, capecitabine or S-1, in breast cancer patients (ASCO, 2013). While capecitabine was as efficacious as S-1 for the treatment of MBC, there were differences between the two drugs with respect to their toxicity profiles. **Methods:** This study is an open-label, multicentre, phase II patient preference trial with two treatment arms, comparing capecitabine and S-1 in patients with MBC. Patients are required to be between 25 and 75 years of age, with ECOG performance status <3. Patients are centralized by Japan Breast Cancer Research Network. Oral capecitabine is administered at a dose of 1,657 mg/m2 twice daily on days 1–21 every 4 weeks. S-1 is 40–60mg two times daily according to body surface area on days 1–28 every 6 weeks. In this cross-over study, patients receive either two cycles of S-1 followed by three cycles of capecitabine, or three cycles of capecitabine followed by two cycles of S-1 and then patients are asked about their preference. After 12 weeks patients are asked to choose which of the two regimens they preferred. Therapy is given unless there is any sign of progression or severe toxicity or the patient wants to discontinue the therapy. Patients with stable disease (SD) or partial response (PR) after two treatment cycles, could continue on their regimen of choice thereafter. Tumor response is assessed according to the RECIST criteria. The primary end point is to investigate patient preference. The secondary end point is PFS, OS, address quality of life (EORTC-30), and anxiety and depression (HADS). NCI-CTCAE, ver. 4.0 and PRO-CTCAE are used to assess toxicity. We estimate that 70% of the patients in S-1 treatment group and 30% in the capecitabine group would like to continue the same treatment after three months after the treatment initiation. About 30 patients in each group are needed to detect the difference of the preference proportion with two-sided significance level 0.05 and 80% power. Chi-squared test will be used to test the null hypothesis for the primary analysis. Clinical trial information: UMIN000013045.

**TPS2635 General Poster Session (Board #94B), Sun, 8:00 AM-11:45 AM**

**Phase I study of IGF-methotrexate conjugate in the treatment of refractory malignancies expressing IGF-1R.** *Presenting Author: Rozina A. Chowdhery, University of Illinois at Chicago, Chicago, IL*

**Background:** The insulin-like growth factor 1 receptor (IGF-1R) is overexpressed in multiple malignancies, including breast, prostate, lung, colorectal, CLL, T-ALL, and mantle cell lymphoma. Activation of IGF-1R through binding of IGF-1 and IGF-2 induces activation of the MAPK and PIRK/ATK/mTOR pathways, resulting in inhibition of cell differentiation, resistance to apoptosis, chemotherapy resistance, and metastasis. Serum IGF binding proteins (IGFBP1-6) regulate IGF-1 and IGF-2 bioavailability. IGF-IR down-regulation leads to massive apoptosis; in vitro and in vivo IGF-IR inhibition leads to anti-proliferative effects and appears synergistic with chemotherapy. IGF-Methotrexate (IGF-MTX) is a novel conjugate of methotrexate (MTX) and 765IGF, a variant of IGF-1 with high affinity for IGF-1R and reduced affinity for IGFBP; in vivo studies confirmed tumor control at lower doses than free MTX. Targeting IGF-MTX towards malignancies overexpressing IGF-1R is a novel therapeutic strategy. **Methods:** This is a single center Phase I dose escalation study with a modified toxicity probability interval design to determine the MTD of 765IGF-MTX in patients with previously treated advanced malignancy expressing IGF-1R. Primary objectives: establish the MTD, safety and toxicity. Secondary objectives: pharmacokinetics (PK) / pharmacodynamics (PD) /biomarker profiles, and preliminary antitumor activity in patients with refractory malignancies expressing IGF-1R. Inclusion **criteria:** IGF-1R expression > 10% on tumor tissue via IHC or IGF-1R density > 0.1% on flow cytometry, ECOG PS 0-2, good organ function and a rest period of 2-6 weeks from their last treatment (duration based on previous therapy). Exclusion criteria: previous MTX use, or uncontrolled chronic illness. Administration and design: 765IGF-MTX is given IV over 1 hour on days 1, 8 and 15 of a 28 day cycle. This study has two components: first, an initial dose finding component with up to 7 cohort dose levels (0.05, 0.10, 0.20, 0.40, 0.80, 1.6, 2.5 μeq/kg), and second, an expansion cohort of 9 patients at MTD, with PK/PD/biomarker profile. The study is currently enrolling patients. Clinical trial information: NCT02045368.

**TPS2636 General Poster Session (Board #95A), Sun, 8:00 AM-11:45 AM**

**A phase 1 study of a novel inhibitor of protein phosphatase 2A alone and with docetaxel.** *Presenting Author: Vincent M. Chung, City of Hope, Duarte, CA*

**Background**: Protein phosphatase 2A (PP2A) is a target of several viral oncoproteins suggesting that it contributes to tumor suppression. Several human cancers have decreased PP2A function by mutations or by increased cellular PP2A inhibitors, CIP2A and SET, including about 40% of NSCLC and 60% of prostate cancers. Tumors with decreased PP2A activity may be particularly vulnerable to further PP2A inhibition. Recently, several groups have shown that inhibition of PP2A activity with a novel small molecule, LB-100, enhances the effectiveness of anticancer agents (temozolomide, docetaxel, doxorubicin, cisplatin) and radiation against different human cancer cell types in vivo without significantly enhancing toxicity. LB-100 inhibition of PP2A appears to potentiate cytotoxic therapy by altering regulation of cell cycle with enhanced S-phase entry and delayed mitotic exit and inhibition of DNA-damage-response including suppression of p53 induction and homologous recombination repair (HRR). Impaired HRR in PP2A deficient cells increases their sensitivity to PARP inhibition (PARPi), leading to the suggestion that PP2A status may indicate cancer cell vulnerability to PARPi. Based on these data, we sought to determine the maximum tolerated dose of LB-100 as a single agent, and in combination with docetaxel. **Methods**: The aims of this two-part phase I study are to determine the MTD of LB-100 alone given intravenously over 15 minutes daily for 3 days every 3 weeks, and the MTD when given with docetaxel on day 2. In part 2, the dose of LB-100 will start two levels lower than its MTD as a single agent with docetaxel given at 60mg/m$^2$. LB-100 will then be escalated to its MTD, if tolerated, and docetaxel will be escalated to 75mg/m$^2$. Eligible patients are >=18 y with progressive or metastatic tumors who have failed available standard treatment. In part 2, docetaxel naïve patients will be entered who have failed standard treatment. All patients must have an ECOG performance status of 0 or 1, have recovered from acute adverse effects of prior therapies, and have adequate bone marrow, renal, and hepatic function. Clinical trial information: NCT01837667.

**TPS2637 General Poster Session (Board #95B), Sun, 8:00 AM-11:45 AM**

**Phase I/IB trial of eribulin and everolimus in patients with triple-negative metastatic breast cancer.** *Presenting Author: Thehang H. Luu, City of Hope Cancer Center/Beckman Research Institute, Duarte, CA*

**Background:** Eribulin mesylate is a synthetic analog of halichondrin B via tubulin-based anti-mitotic mechanism, leads to G2/M cell cycle arrest, disruption of mitotic spindles, apoptotic cell death and inhibits the phosphorylation of AKT in TNBC cells. Everolimus inhibits mTOR pathway. With mTOR inhibition, pAKT is enhanced, seen at 24 hours with everolimus alone in TNBC cell lines Ser473 and SKBR3. Combination of eribulin and everolimus suppressed both pAKT and pS6K1 at 24 hours. Based on our preclinical findings, we hypothesize that everolimus and eribulin will have a synergistic effect with inproved clinical activity in metastatic TNBC. **Objectives:** phase I/IB trial of everolimus plus eribulin in metastatic TNBC. Phase I determines the safety & tolerability and the recommended Phase II dose (RP2D), while the Phase IB will evaluate event free survival rate at RP2D. **Methods:** Eligibility: Metastatic TNBC who progressed on anthracyclines/taxanes, and previous chemotherapy for metastatic disease (up to 3 prior lines). Dose schedule: eribulin 1.4 mg/m2 on days 1,8 every 21 days. Everolimus will be started at 5mg oral daily day 1 to 21 and escalated to maximum of 10mg. Study Design: Phase I use toxicity equivalence range design with dose-limiting toxicities is 0.20-0.35, levels of ≥0.51 will be too toxic. Patients enter in cohorts of three. Phase I will end when 12 patients at a single dose level with toxicity level <0.51. Phase IB will use Simon's Optimal two-stage design which will enroll up to 15 patients to evaluate event-free survival (EFS) rate at RP2D. Based on the EMBRACE trial, the 4-month EFS is 45% for eribulin and we target a 4-month EFS rate of ≥70% (25% improvement) for the combination. The secondary endpoints include response rate using RECIST, overall survival, toxicity, and pharmacokinetics since both drugs are substrates for the membrane transporter P-glycoprotein. Further secondary objective is proteomic analysis of PI3K pathway. Blood and skin punch biopsy from normal skin will be performed. Analysis performed by Luminex and mass spectrometry, and western blotting for pAKT (Ser473), and AKT, p4E-BP1 (ser65/Thr70) and 4E-BP1, pS6K1 (Thr389) and S6K1, and pS6 (Ser235/236) and S6. Clinical trial information: na.

**TPS2638 General Poster Session (Board #96A), Sun, 8:00 AM-11:45 AM**

**A phase II study of sirolimus and erlotinib in recurrent/refractory germ cell tumors.** *Presenting Author: Theodore Willis Laetsch, The University of Texas Southwestern Medical Center, Dallas, TX*

**Background:** Germ cell tumors (GCTs) affect children and young adults, with testicular germ cell tumor the most common cancer in young men. While platinum-based treatment has been successful for many GCTs, patients whose tumors are platinum-refractory have a poor prognosis. We have previously shown that non-seminomatous germ cell tumor cell lines are dependent on EGFR and mTOR signaling for survival and that the combined inhibition of these two targets in the same pathway results in >1000-fold sensitization to drug in vitro (Rakheja, AACR Peds Cancer 2013). The combination of the EGFR inhibitor erlotinib and the mTOR inhibitor sirolimus has been studied in other tumors, but never in germ cell tumors. Previous studies have not included assessment of pharmacodynamic inhibition of the targets in patients. Recently, flow cytometry based methods for detection of intracellular phosphorylated forms of S6 (downstream of mTOR), and ERK and AKT (downstream of EFGR) in peripheral blood mononuclear cells (PBMC) have been developed. This is the first pediatric trial to determine target inhibition in patients treated with the combination of EGFR and mTOR inhibitors. **Methods:** Eligible patients are those aged 1-50 years with relapsed or refractory germ cell tumors who have failed at least two prior platinum containing regimens. Patients with CNS disease are excluded. Patients receive daily sirolimus adjusted to a trough of 10-15 ng/mL and daily erlotinib at a starting dose of 120 mg/m$^2$. As the development of rash may be a biomarker of response to erlotinib, patients who don't develop grade II or worse rash during cycle 1 receive 150mg/m$^2$ for subsequent cycles. Pharmacokinetics and target inhibition in PBMCs using phospho-flow cytometry are measured during cycles 1 and 2 and correlated with response. The primary endpoint is progression free response (PFR) after 16 weeks of therapy. Using a Simon 2-stage design, 11 patients will be enrolled in the first cohort and an additional 16 patients in the second if 2 or more of the initial 11 patients have PFR. This regimen will be considered beneficial if greater than or equal to 6 of the 27 evaluable patients have PFR (response rate of 20%). This study began enrollment in January 2014 and no results are yet available. Clinical trial information: NCT01962896.

**TPS2639 General Poster Session (Board #96B), Sun, 8:00 AM-11:45 AM**

**A phase 1 trial of vandetanib (multikinase inhibitor of EGFR, VEGFR, and RET) in combination with everolimus (mTOR inhibitor) in patients with advanced malignancies.** *Presenting Author: Manojkumar Bupathi, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Preclinical models have shown that concurrent inhibition of the mammalian target of rapamycin (mTOR) pathway signaling cooperates with epidermal growth factor (EGFR)/vascular endothelial growth factor (VEGFR) and RET inhibitors to overcome primary and / or acquired resistance to tumors sensitive and resistant to anti-EGFR/VEGFR/RET inhibitors. EGFR, VEGF, RET and mTOR are validated targets in numerous malignancies. Tumor responses induced by these single agents are transient and patients can develop secondary resistance. The predominant mechanism underlying resistance to these agents is unknown but likely due to activation of several concomitant pathways. Therefore, multi-kinase targeting of EGFR, VEGFR and mTOR may improve results compared to either agent alone. Based on this hypothesis, we are conducting an investigator initiated phase I trial combining vandetanib and everolimus for patients with advanced malignancies. **Methods:** This is a phase I dose escalation and expansion trial with a conventional "3+3" design. During the escalation phase, vandetanib and everolimus were given at the following respective doses: level 0 (100 mg, 2.5 mg), level 1 (200mg, 2.5mg), level 2 (200mg, 5mg), level 3 (300 mg, 5mg), and level 4 (300mg, 10mg). The inclusion criterion includes any patient with advanced cancer which is refractory to standard therapy, relapsed after standard therapy, or those who have no standard therapy options. Both study drugs are given continuously on a 28 day schedule. Dose adjustments for everolimus were done if patients were on CYP3A4 inducers or inhibitors so that appropriate serum concentration is reached. At this time all dose levels have been completed and the study is in a dose expansion phase. Dose expansion is being done in patients with genomic alternations in *RET, EGFR, VEGFR, KDR, or P13K,PIK3R1, TSC1/2 and AKT* aberrations and patients with tumor types for which vandetanib or everolimus is individually FDA approved. Clinical trial information: NCT01582191.

**TPS2640 General Poster Session (Board #97A), Sun, 8:00 AM-11:45 AM**

**A phase I trial of MK-2206 and hydroxychloroquine(HCQ) in solid tumors, melanoma, renal, and prostate cancer to examine the role of autophagy in tumorigenesis.** *Presenting Author: Amanda D. Kaveney, Cancer Insti of New Jersey-Robert Wood Johnson Hospital, New Brunswick, NJ*

**Background:** AKT is a frequently hyperactivated oncogenic kinase in human cancers (Degenhardt 2006). Inhibition of AKT activates autophagy, promoting tumor survival, and hence AKT inhibitors may limit their own efficacy. HCQ inhibits autophagy and may prevent this survival mechanism. Treating renal cell carcinoma lines with temsirolimus, an mTOR inhibitor, promoted autophagy-mediated stress tolerance and the concomitant inhibition of autophagic degradation with chloroquine, enhanced tumor cell death (Bray 2012, Xie 2013). A similar phenomenon was reported with AKT inhibition (Degtyarev 2008, Cheny 2011) We hypothesize that Akt inhibition by the allosteric inhibitor MK-2206 will induce autophagy which may be inhibited by the addition of HCQ, potentially enhancing cell death and improving therapeutic outcomes. The purpose of this study is to define the maximum tolerated dose of MK-2206 and HCQ when used in combination, to determine the pharmacokinetic (PK) profile of the combination and to assess surrogate markers of autophagy modulation in blood and tumor samples from these patients. **Methods:** We designed an open-label Phase I trial using a 3+3 design to enroll patients with advanced solid tumors who were refractory to or declined standard therapy with the primary objective of determining the MTD of the combination. Treatment cycles were 3 weeks in length. Patients received MK-2206 alone in Cycle (C) 1 with HCQ beginning on C2, Day 1. Dose level (DL1) enrolled patients at a dose of MK-2206 135 mg weekly, with HCQ given at 200 mg twice a day (BID). Dose escalation is planned to a maximum dose of 200mg weekly and a maximum dose of 600mg BID for MK-2206 and HCQ respectively. We will assess changes in PK parameters of MK-2206 and HCQ co-administration. We will examine expression of Beclin1 and LC3, known to accumulate with autophagy inhibition. Surrogate markers will be used to assess the activation of the AKT pathway. Correlations between steady-state plasma concentration of HCQ and the degree of autophagy inhibition will be assessed. To date, twenty-seven patients have been enrolled and enrollment continues with HCQ 600mg BID and MK-2206 135mg/day. Clinical trial information: NCT01480154.

**TPS2641 General Poster Session (Board #97B), Sun, 8:00 AM-11:45 AM**

**A phase Ib study of BKM120 combined with abiraterone acetate for castrate-resistant, metastatic prostate cancer.** *Presenting Author: Akash Patnaik, Beth Israel Deaconess Medical Center/Dana Farber Harvard Cancer Center, Boston, MA*

**Background:** There is significant cross-talk between PI3-kinase (PI3K) pathway and androgen receptor (AR) signaling pathways, respectively, which are both critical for cell survival in castrate-resistant prostate cancer (CRPC). The primary study objective is to determine the safety profile and maximum tolerated dose (MTD) of BKM120 (pan-PI3K inhibitor) in combination with abiraterone/prednisone (A/P) in CRPC patients. The secondary study objectives are to assess the impact of PTEN status on duration of response/time to progression in the expansion cohort, and to evaluate the impact of BKM120 on a PI3-kinase activation fingerprint in metastatic bone or lymph node tissue samples. An exploratory objective of the study is to assess the effect of BKM120 on transcription of a set of AR-regulated genes in metastatic bone biopsy samples. **Methods:** The trial design involves a 14 day lead-in phase with BKM120 alone, to assess single-agent toxicity and perform correlative studies. A/P is combined with BKM120 at the end of 14 days using the standard 3+3 dose-escalation design with 3 dose levels of BKM120 (80 mg, 100 mg, 120 mg, respectively), and participants are assessed for safety and MTD on the combination therapy. The MTD dose will be used in the expansion cohort to assess safety of the combination. To determine pharmacodynamic impact of single agent BKM120 on the PI3K activation signature at a metastatic site, a mandatory CT-guided bone or lymph node biopsy is performed prior to BKM120 initiation and at the end of 2 weeks on BKM120 single-agent therapy. Immunohistochemical (IHC) stains for four markers (p-AKT, p-S6, PTEN and stathmin) are used to obtain a PI3K activation score, based on the quartile levels of continuous staining scores of each marker. Clinical trial information: NCT01741753.

**TPS2642 General Poster Session (Board #98A), Sun, 8:00 AM-11:45 AM**

**NCI mpact: National Cancer Institute molecular profiling-based assignment of cancer therapy.** *Presenting Author: Shivaani Kummar, Division of Cancer Treatment and Diagnosis and Center for Cancer Research, National Cancer Institute, Bethesda, MD*

**Background:** There is growing interest in matching targeted agents to genetic aberrations found in tumors of patients in early phase trials. MPACT is a randomized trial designed to assess whether response rate (CR+PR) and progression-free survival (PFS) are improved following treatment with agents chosen based on the presence of specific mutations in patient tumors compared to treatment regimens assigned from the complementary set not prospectively identified to target one of their mutations. **Methods:** Eligible adult patients have refractory solid tumors that had progressed following at least one line of standard therapy (std) and/or for which no std has been shown to improve survival. Patients are required to undergo tumor biopsy, which will be sequenced in a CLIA-certified lab for the presence of specific actionable mutations of interest (aMOIs) in 20 genes belonging to 3 pathways: DNA repair, PI3K, and RAS/RAF (total of 391 aMOIs). Patients in whom an aMOI is detected will be randomized 2:1 into Arms A or B using a rules-based, locked algorithm: Arm A will receive an agent prospectively identified to target that mutation/pathway; Arm B will receive an agent from the complementary set (not prospectively identified to target one of their mutations). Patients in Arm B will be allowed to cross over at time of disease progression to a treatment regimen based on their mutational analysis. Targeted drugs are administered at recommended Phase 2 doses and schedules: ABT-888 (PARP inhibitor) with temozolomide, or MK-1775 (Wee1 inhibitor) plus carboplatin for defects in the DNA repair pathway; everolimus (mTOR inhibitor) for mutations in the PI3K pathway; trametinib DMSO (MEK inhibitor) for mutations in the RAS pathway. A total of 180 evaluable patients will be randomized; the comparison of response rates will have 88% power to detect an overall difference of 20% vs. 5% objective response, conducted at the 1-sided, 0.04 significance level. The comparison of PFS will have 90% power to detect an increase of 80% in median PFS, conducted at the 1-sided, 0.01 significance level. The trial is currently open and accruing at the NIH Clinical Center in Bethesda, Maryland. Clinical trial information: NCT01827384.

**TPS2643 General Poster Session (Board #98B), Sun, 8:00 AM-11:45 AM**

**A randomized, parallel-dose phase 1 study of onapristone (ONA) in patients (pts) with progesterone receptor (PR)-expressing cancers.** *Presenting Author: Paul H. Cottu, Institut Curie, Paris, France*

**Background:** ONA is a type I PR antagonist, which prevents PR-induced DNA transcription. Presence of transcriptionally activated PR (APR), could indicate potential for ONA anticancer activity and could be used as a predictive biomarker. Development of an IHC companion diagnostic which identifies distinct subnuclear PR distribution patterns is ongoing, and could help select patients with PR-positive cancers most likely to respond to ONA, including endometrial and breast cancers. ONA anti-cancer activity has been documented in multiple preclinical models. Prior ONA clinical studies led to objective responses in pts with hormone therapy-naïve or tamoxifen-resistant breast cancer. ONA appeared well tolerated with the exception of LFT abnormalities, which would not preclude development in oncology. An extended-release (ER) tablet formulation of ONA was designed to address the LFT elevations seen with immediate-release (IR) ONA, by reducing the $C_{max}$. **Methods:** This is a multi-center, open-label, randomized, parallel-group, 2-stage phase 1 study with an expansion component (total n~60). Female pts ≥18 years with tumors expressing PR are eligible. Tumor tissue is required to determine PR (both A and B isotypes) and APR status. The primary endpoint is determination of the recommended phase 2 dose (RP2D) of ER ONA, with a 57-day period for observation of dose-limiting toxicity (DLT). Secondary endpoints include safety/tolerability, efficacy, and real-time PK. Tissue specimens will be used to determine relationship of APR to preliminary efficacy. Six pts per cohort are receiving ONA ER tablets 10, 20, 30, 40 or 50 mg BID, or ONA IR tablets 100 mg QD until progressive disease or intolerable safety Stage 1: Six dose cohorts are randomized in parallel. A data review committee (DRC) monitors/reviews safety signals and all DLTs. Stage 2: when sufficient pts have been treated for 8 weeks, the DRC will review all safety, PK and efficacy data to determine the RP2D. The RP2D dose cohort will be expanded by enrolling 24 additional pts to confirm the safety profile and provide a preliminary assessment of anti-tumor activity. Stage 1 is open for accrual. Clinical trial information: NCT02052128.

**TPS2644 General Poster Session (Board #99A), Sun, 8:00 AM-11:45 AM**

**Phase I study combining MLN8237 with nab-paclitaxel in patients with advanced solid malignancies.** *Presenting Author: Kian-Huat Lim, Division of Oncology, Washington University School of Medicine, St. Louis, MO*

**Background:** MLN8237 is a small molecule inhibitor against Aurora A kinase, a key serine/threonine kinase that is commonly overexpressed in human cancers, particularly in pancreatic cancer. Abraxane is an albumin-bound paclitaxel (nab-paclitaxel) that effectively disrupts mitosis and is approved by the FDA for treatment of pancreatic, breast and non-small cell lung cancers. Several preclinical studies showed that suppression of Aurora A kinase by RNA interference or MNL8237 effectively blocks mitosis and key oncogenic signaling. Blocking Aurora A kinase has been shown to reverse resistance to paclitaxel in preclinical studies, therefore investigation of MLN8237 combined with nab-paclitaxel in patients with solid tumors is warranted. **Methods:** This phase I study employs the standard 3+3 design with the primary objective of defining the maximum tolerated dose (MTD) and dose-limiting toxicities (DLT). The starting dose for MLN8237 is 20 mg twice daily, day 1-3 of each week for 3 weeks out of a 4-week cycle, while nab-paclitaxel is 100 mg/m$^2$ weekly for 3 weeks out of a 4-week cycle. The secondary objective is to observe early signals of anti-tumor activity in an expanded cohort (N=15) of patients with advanced pancreatic cancer. Other exploratory objectives include assessment of pharmacodynamic markers such as mitotic catastrophe, apoptotic index, phosphorylation of Aurora A at threonine 288, and phosphorylation of Histone H3 at serine 28 (pHisH3 Ser28) from skin punch biopsies before and after administration of MLN8237. Additionally, we plan to investigate the impact of Aurora A genotypic polymorphisms such as 91A>T and 169G>A, on MLN8237 metabolism. To date, this trial is ongoing without any safety concerns. Clinical trial information: NCT01677559.

**TPS2645^ General Poster Session (Board #99B), Sun, 8:00 AM-11:45 AM**

**BARIS: A phase I trial to evaluate the safety and tolerability of combined BIBF 1120 and RAD001 in solid tumors and to determine the maximum tolerated dose (MTD) of the combination.** *Presenting Author: Matthias Scheffler, Lung Cancer Group Cologne, Department I of Internal Medicine and Center for Integrated Oncology, University Hospital Cologne, Cologne, Germany*

**Background:** Simultaneous inhibition of several signalling pathways involved in angiogenesis as well as in tumor cell growth regulation by kinase inhibitor combination therapy may increase therapeutic efficacy. Here we evaluate the combination of the mTOR-inhibitor RAD001 (everolimus) and the triple kinase (FGFR, VEGFR, PDGFR) inhibitor BIBF 1120 in a phase I trial in advanced solid tumors. In addition we use DCE-MRI for early identification of patients with benefit from BIBF 1120 **Methods:** Patients in arm A receive 5 mg of RAD001 and 2 x 150 mg BIBF 1120, in arm B 10 mg RAD001 and 2 x 150 mg BIBF 1120 will be administered, whereas in arm C, 10 mg of RAD001 and 2 x 200 mg BIBF 1120 will be given. Eligible are all patients with relapsed or refractory advanced/metastatic solid tumors and an ECOG performance state of 0-1 for whom no further standard therapies are available. All patients will start with a 2-week run-in phase of 2 x 200 mg BIBF 1120. Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) scans will be performed at baseline staging, on day 3 and day 14. On day 14, there will also be 12 hours-pharmacokinetic (PK) assessment. Combination therapy starts on day 15. On day 29, a DCE-MRI scan and 12-hours PK will be performed. Restaging is performed on day 57. Patients who experience clinical benefit (i. e., response or stable disease) on day 57 with adequate tolerability of the combination will further receive the medication, as long as the benefit lasts. **Results:** 15 patients have been enrolled so far in arm A and B, and one patient started in arm C. Of the enrolled patients, the majority (9 patients) had non-small cell lung cancer (NSCLC) as the underlying tumor. Two patients turned out to be screening failures in arm B. The trial procedures proved to be feasible. **Discussion:** So far, the combination of BIBF 1120 and RAD001 has reached its predefined third dosage step. We expect the termination of the trial by summer 2014. In case of efficacy in a molecular defined subset of patients, an expansion phase (phase II) is planned. Clinical trial information: NCT01349296.

**TPS2646^ General Poster Session (Board #100A), Sun, 8:00 AM-11:45 AM**

**The signature program, a series of tissue-agnostic, mutation-specific signal finding trials.** *Presenting Author: Eric Daniel Slosberg, Novartis Oncology, East Hanover, NJ*

**Background:** Here we are introducing a novel signal-finding clinical trial protocol series, termed the Novartis "Signature" program. These are tissue-agnostic, mutation specific protocols that do not include pre-identified clinical trial sites. In part these are responsive to the increased frequency of molecular profiling in the oncology community, and the incidence of patients whose tumors are identified with actionable mutations yet without access to drugs targeting those alterations. As these patients are identified via routine physician-directed profiling, we bring the 'Protocol to the Patient', utilizing a rapid study start-up process, such that a de novo site can have one of these trials opened within weeks of the originating patient being identified. **Methods:** The core of this rapid start-up process includes mandating the use of a non-negotiable standard contract, budget and informed consent, and the use of central IRB. We allow any research experienced site in the US accepting our study model and with a pre-identified patient to participate. The primary endpoints of these trials are to assess clinical benefit associated with study compound. A novel statistical design is incorporated to adaptively cluster patients of like indications into cohorts for independent analysis for futility or efficacy, with subsequent consideration of the initiation of confirmatory trials. Currently the 5 open protocols include buparlisib (PI3Ki), dovitinib (multi-kinase inhibitor), binimetinib (MEK162, MEKi), encorafenib (LGX818, RAFi) and sonidegib (LDE225; SMOi) [NCT01833169, NCT01831726, NCT01885195, NCT01981187 and NCT02002689]. 5 additional single agent and novel-novel protocols are planned to open in 2014. At the time of this submission, 73 patients have been consented at 46 network, academic, and community sites. The average time from a new site approaching Novartis with a potential patient, through site start-up activities, to patient consent and screening, was 4 weeks. This program should enable the enrollment of molecularly profiled patient populations with mutations linked to targeted agents, with expedited timelines, and the evaluation of clinical activity in these (potentially rare) populations. Clinical trial information: NCT01833169, NCT01831726, NCT01885195, NCT01981187 and NCT02002689.

**TPS2647 General Poster Session (Board #100B), Sun, 8:00 AM-11:45 AM**

**Biomarker-driven access to crizotinib in ALK-, MET-, or ROS1-positive malignancies in adults and children: Feasibility of the French National Acsé Program.** *Presenting Author: Gilles Vassal, SFCE, Gustave Roussy, Cancer Campus, Villejuif, France*

**Background:** Crizotinib (czb) is registered only for the treatment of patients (pts) with ALK+ lung cancer. Czb targets (ALK, MET, ROS1) are also altered (translocation, amplification, mutation) in a wide range of malignancies in adults and children. To avoid off label use and allow for a nationwide safe and controlled access to czb for pts with an ALK, MET or ROS1 positive tumor, the French National Cancer Institute (INCa) launched the AcSé program: access to tumor molecular diagnosis in the 28 INCa molecular genetic centers along with an exploratory phase II trial. **Methods:** Biomarker identification is proposed to pts ≥ 1 year with an advanced disease among more than 15 malignancies (such as colon, gastric, liver, thyroid, renal and breast cancers, cholangiocarcinoma, lymphoma, neuroblastoma, sarcomas, and ROS1 or MET lung cancer) (such as colon, gastric, liver, thyroid, renal and breast cancers, cholangiocarcinoma, lymphoma, neuroblastoma, sarcomas, and ROS1 lung cancer) known from literature to harbor a genomic alteration in a czb target. If not eligible for any other academic or industry trial targeting the same alteration, a patient with an ALK, MET or ROS1 positive tumor may enter one of the 22 specified cohorts defined as a disease and a type of target alteration, and receives czb (adult: 250 mg x 2; child: 280 mg/m2 x 2). Pts with an altered czb target as evidenced through a pangenomic tumor profiling program are also eligible. Tumor response is evaluated every 2 months using RECIST criteria. Three statistical 2-stage designs are considered for cohorts to anticipate 3 situations in terms of expected response rate and incidence. Accrual stops if 0 response / N1 pts; else N2 additional pts are recruited. 10,000 to 15,000 molecular tests and 490 pts treated in 150 centers are planned over 3 years. From Aug. 2013 to Jan. 2014, 22 pts have been accrued. The AcSé program is currently being expanded to other targeted drugs. Clinical trial information: NCT02034981.

**3000 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Randomized comparison of two doses of the anti-PD-1 monoclonal antibody MK-3475 for ipilimumab-refractory (IPI-R) and IPI-naive (IPI-N) melanoma (MEL).** *Presenting Author: Omid Hamid, The Angeles Clinic and Research Institute, Los Angeles, CA*

**Background:** MK-3475 has shown durable antitumor activity in MEL across multiple doses and schedules. We compared the efficacy and safety of 2 MK-3475 doses in MEL patients (pts). **Methods:** In separate cohorts, IPI-N and IPI-R pts were randomized 1:1 to MK-3475 2 or 10 mg/kg every 3 wk (2 Q3W or 10 Q3W). IPI-N pts received ≤2 prior systemic therapies. IPI-R pts had any number of prior therapies and unequivocal or confirmed PD per immune-related response criteria (irRC) after ≥2 IPI doses; all *BRAF*-mutant pts were previously treated with BRAF inhibitors. Primary endpoint was ORR assessed by RECIST 1.1 every 12 wk by independent central review. Investigator-assessed response by irRC was also obtained. **Results:** A total of 276 pts were randomized (103 IPI-N [2 Q3W, n = 51; 10 Q3W, n = 52] and 173 IPI-R [2 Q3W, n = 89; 10 Q3W, n = 84]. In both cohorts, treatment arms were well balanced for known prognostic factors. As of the 10/18/2013 cutoff, all IPI-N and 47% of IPI-T pts had ≥9 mo of follow-up. Among evaluable pts, no significant differences in ORR by RECIST were observed between doses in IPI-N (33% vs 40%) or IPI-R (26% vs 26%) pts. By RECIST, response duration ranged from 6+ wk to 39+ wk in both cohorts (median not reached), with ~90% of responses ongoing. PFS by RECIST was similar between doses. The safety profile was generally similar between pts treated with 2 Q3W and 10 Q3W. There were no drug-related deaths. **Conclusions:** MK-3475 2 mg/kg Q3W and 10 mg/kg Q3W provided similar efficacy and safety in both IPI-N pts and IPI-R pts. Treatment was well tolerated with acceptable toxicity profile. The high ORR provided by MK-3475 comes with long durability in both IPI-N and IPI-R MEL. Clinical trial information: NCT01295827.

**3001^ Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**A phase 1 study of MEDI4736, an anti–PD-L1 antibody, in patients with advanced solid tumors.** *Presenting Author: Jose Lutzky, Mount Sinai Comprehensive Cancer Center, Miami Beach, FL*

**Background**: Immune-suppressing molecules such as PD-L1 can be co-opted by cancer cells to suppress the natural immune response to cancer. Upregulation of PD-L1 and inhibition of antitumor T-cell activation is observed in several tumor types. MEDI4736 is a human IgG1 antibody which binds specifically to PD-L1, preventing binding to PD-1 and CD80. **Methods:** An ongoing phase 1 multicenter, open-label study (NCT01693562) is evaluating safety, pharmacokinetics (PK), and antitumor activity of MEDI4736 given IV every 2 (q2w) or 3 wks (q3w) in a 3+3 dose escalation with a 28-day (q2w) or 42-day (q3w) dose-limiting toxicity (DLT) window, followed by expansion in 8 solid tumors. Response was assessed by immune-related response criteria in escalation. **Results:** As of Jan 17, 2014, 26 patients (pts) (13 NSCLC, 8 melanoma, 5 other) in dose escalation (median age 59 yrs; 35-77), all PS 0-1, with a median of 4 prior treatments, received a median of 5 (1-25) q2w and 4.5 (1-7) q3w doses of MEDI4736 across 6 cohorts (0.1 – 10 mg/kg q2w; 15 mg/kg q3w). MEDI4736 showed dose-dependent PK. Evidence of ADA impacted PK exposure in only 1 patient. No DLTs or maximum tolerated dose were identified for q2w or q3w dosing. Treatment-related AEs occurred in 34% of pts, all Grade 1-2; none led to discontinuation of study drug. The most frequent treatment-related AEs were diarrhea, fatigue, rash, and vomiting (12% each). No pneumonitis, colitis, or hyperglycemia occurred. Of 26 pts, 4 PRs (3 NSCLC, 1 melanoma) and 5 additional pts with tumor shrinkage not meeting PR were observed. Disease control rate (PR + SD ≥ 12 wks) was 46%. Tumor shrinkage, as early as 6 wks, was seen at all dose levels, and benefit was durable; 11 pts remain on study as of the data cutoff (2+ to 14.9+ mos). Expansion cohorts opened Sep 2013 using a 10 mg/kg q2w dose; 151 pts have been dosed, with the opportunity to enroll > 600 pts. Preliminary clinical activity has been observed with acceptable safety across a range of tumors including SCCHN, pancreatic, gastric, NSCLC, and melanoma. **Conclusions:** MEDI4736 has demonstrated an acceptable safety profile and durable clinical activity in this dose-escalation study. Expansion in multiple cancers and development of MEDI4736 as monotherapy and in combination is ongoing. Clinical trial information: NCT01693562.

**3002^ Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Preliminary data from a multi-arm expansion study of MEDI4736, an anti-PD-L1 antibody.** *Presenting Author: Neil Howard Segal, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Checkpoint blockade of the PD-1/PD-L1 and CTLA-4 pathways has shown to be active in multiple tumor types. MEDI4736 is a human IgG1 monoclonal antibody which binds specifically to PD-L1, preventing binding to PD-1 and CD80. In phase I, MEDI4736 showed acceptable safety (no maximal tolerated dose identified). With evidence of clinical activity in phase I, an expansion study was initiated in multiple cancer types including NSCLC, melanoma (cutaneous and ocular), gastroesophageal, hepatocellular carcinoma, pancreatic, SCCHN and triple negative breast cancer. **Methods:** 10 - 20 pts were initially enrolled per tumor type, with expansion allowed upon observation of clinical activity. MEDI4736 was administered as 10 mg/kg IV every 2 weeks for 12 months. Retreatment was permitted for progression after 12 months of therapy. Response was assessed by RECIST v1.1. **Results:** The expansion cohorts were initiated in Sep 2013. As of Jan 17, 2014, 151 pts had received ≥1 dose of MEDI4736. Safety data are available for 105 pts (median age 60y; 36-84), 59% male, ECOG 0/1 (27%/71%), with a median of 3 (1-8) prior treatments, who received a median of 3 (1-8) doses. The safety profile was consistent with previous reports. Treatment-related AEs occurred in 33% of pts, with related ≥ Grade 3 AEs in 7%; none led to discontinuation of study drug. The most frequently observed treatment-related AEs were fatigue (13%), nausea (8%), rash (6%), vomiting (5%), and pyrexia (5%). One pt developed Grade 2 pneumonitis which resolved with drug interruption and steroids. There were no reports of colitis or hyperglycemia of any grade. With a median follow-up of 6 weeks, tumor shrinkage is already detectable in multiple tumor types including pts with melanoma, pancreatic, head and neck, and gastroesophageal cancer. The study continues to enroll pts and generate more mature follow-up data. **Conclusions:** Preliminary data in expansion suggest the safety of MEDI4736 is acceptable, even in heavily pre-treated pts. Early evidence of clinical activity was reported in multiple tumor types. Further evaluation of MEDI4736 as monotherapy and in combination with a variety of immunomodulators and targeted agents is ongoing. Clinical trial information: NCT01693562.

**3003 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**The neoantigen landscape underlying clinical response to ipilimumab.** *Presenting Author: Alexandra Snyder Charen, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Ipilimumab, an antibody against cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4), prolongs overall survival and can produce durable tumor regression in patients with advanced melanoma. Ipilimumab activates cytotoxic T-lymphocytes and enables them to destroy tumor cells. However, the molecular determinants of response to ipilimumab are unknown. **Methods:** Fresh frozen tumor DNA (and matching blood) from 25 melanoma patients treated with ipilimumab was subjected to whole exome sequencing. Exon capture was performed using the SureSelect Human All Exon 50MB kit (Agilent). Enriched exome libraries were sequenced on the HiSeq 2000 platform (Illumina) to a mean coverage of 103X. Somatic mutations and candidate somatic neoantigens generated from these mutations were identified and characterized. **Results:** Our cohort included complete responders (CR) and nonresponders (NR). Mutational burden ranged from 1-1121 mutations per tumor. Mutational load was significantly associated with clinical response (p=0.028, CR vs. NR, Fisher's Exact Test), but alone was not sufficient to predict response. Using genome-wide somatic neoepitope analysis, we defined candidate tumor neoantigens and identified a neoantigen landscape that is specifically present in tumors with complete responses to ipilimumab. These somatic neoepitopes share consensus sequences with experimentally validated antigens from a variety of pathogens. Furthermore, in four of six CR patients, a mutation led to the generation of a consensus amino acid sequence previously identified as necessary for T-cell recognition of melanoma antigen recognized by T-cells (MART-1). **Conclusions:** Somatic mutations and concomitant generation of neoepitopes in melanoma tumors confers enhanced antigenicity and response to the immune checkpoint modulator ipilimumab. Our study defines the neoantigen landscape in responders to ipilimumab, provides a rationale for examining the exomes of patients for whom ipilimumab is being considered, and builds a foundation for understanding the molecular determinants of response to cancer immunotherapy.

**3004 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Germline genetic determinants of immunotherapy response in metastatic melanoma.** *Presenting Author: Christina Adaniel, New York University Medical Center, New York, NY*

**Background:** Ipilimumab-based immunotherapy has substantially increased survival for patients with advanced melanoma, however, the benefit is observed only in a small portion of treated patients. It is highly plausible, yet completely unexplored, that germline genetic factors modulate immunotherapy outcome. In this study we performed whole-exome sequencing (WES) to discover novel germline determinants of response to ipilimumab. **Methods:** Blood samples were collected from >60 metastatic melanoma patients treated by ipilimumab at the New York University Langone Medical Center. WES was performed on objective responders (OR) and non-responders (NR), defined by immune-related response criteria, using the Nextera platform (Illumina) at average 30x coverage. We have implemented a novel modified method for testing the association between OR and NR by variant, gene and enrichment of molecular networks. Gene-Set Enrichment Analysis and Pathway Studio were used to test the pathway associations. **Results:** The preliminary data comparing an initial subset of 30 ORs and 30 NRs identified significant associations with ipilimumab response for several loci including RPS6KB1 (p=0.001) and LNX2 (0.001). In addition, the pathway analysis showed significant associations for SMAD 3 (p=0.04) and interleukin 1 (p=0.04) related pathways. **Conclusions:** Preliminary findings provide promising evidence supporting the presence of germline genetic factors associated with response to ipilimumab therapy and pointing to immune-related pathways associated with outcomes. As the study is still in progress, the anticipated accrual of a larger sample collection is underway. This will further increase the analytical power of the discovery phase, but will also allow expanded validation of the current findings, suggesting for the first time that germline genetic factors modulate immunotherapy response.

**3005^ Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Clinical efficacy and correlation with tumor PD-L1 expression in patients (pts) with melanoma (MEL) treated with the anti-PD-1 monoclonal antibody MK-3475.** *Presenting Author: Richard Kefford, Westmead Hospital and Melanoma Institute Australia, University of Sydney, Westmead, Australia*

**Background:** MK-3475 demonstrated antitumor activity and acceptable safety in a phase I MEL cohort. We provide updated efficacy data and correlation with tumor PD-L1 expression. **Methods:** 135 pts received MK-3475 10 mg/kg Q2W (n = 57), 10 mg/kg Q3W (n = 56), or 2 mg/kg Q3W (n = 22). Response was assessed every 12 wk by RECIST 1.1 by independent central review and by immune-related response criteria (irRC) by investigator. Biopsy was required in the 60 d before MK-3475. Tumor PD-L1 expression was assessed by IHC. A preliminary cutoff of 1% of stained tumor cells defined PD-L1 positivity. **Results:** As of 10/18/2013, all pts had ≥13 mo follow-up. Median time on treatment was 23 wk (range, 1 dose to 97 wk). In pts with measurable disease, ORR was 41% by RECIST (Table). Objective responses were observed as late as 64 wk, with some conversions to CR seen as late as 72 wk. Median response duration was not reached; responses were ongoing for 87% of responders. Median PFS was 31 wk. Median OS was not reached, and OS rate at 1 y was 81%. Tumor PD-L1 expression was evaluable in 71 pts with measurable disease and ≥1 tumor evaluation (77% PD-L1$^+$). Of these pts, PD-L1 expression was associated with improved ORR by RECIST (51% vs 6%, $P$ = .0012 [Fisher's exact]) and PFS (median 12 vs 3 mo, HR 0.31, 95% CI 0.16-0.61, $P$ = .0004 [log-rank]). 1-y OS rate was 84% in PD-L1$^+$ and 69% in PD-L1$^-$ pts ($P$ = .2146 [log-rank]). There were no treatment-related deaths; 14% of pts experienced drug-related grade 3/4 AEs. **Conclusions:** MK-3475 induces durable responses and favorable 1-y OS with acceptable safety in MEL. Although tumor PD-L1 positivity was associated with improved ORR and PFS, antitumor activity was also observed in pts with low baseline PD-L1 expression. These preliminary data require confirmation. Clinical trial information: NCT01295827.

**3006^ Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**Evaluation of immune-related response criteria (irRC) in patients (pts) with advanced melanoma (MEL) treated with the anti-PD-1 monoclonal antibody MK-3475.** *Presenting Author: F. Stephen Hodi, Dana-Farber Cancer Institute, Boston, MA*

**Background:** Unique response patterns have been observed with immunotherapies, and both objective response and prolonged disease stabilization can occur after an initial increase in tumor size. irRC were developed to better characterize response to immunotherapy, but it is unclear how irRC perform in pts treated with PD-1 blockade. Here, we describe unique patterns of response to MK-3475 in MEL pts and evaluate irRC as an alternative criterion for comprehensive response assessment. **Methods:** Source population was pts from 3 MEL cohorts treated with MK-3475 2 mg/kg every 3 wk (Q3W), 10 mg/kg Q3W, or 10 mg/kg Q2W in a phase I trial. Tumor imaging was performed every 12 wk. Response was assessed by irRC and RECIST 1.1 by central review; irRC was used for pt management. Tumor flare and atypical delayed response were identified by using centrally assessed irRC data among pts on MK-3475 for ≥28 wk. Tumor flare was defined as unconfirmed PD at assessment 1 (ie, wk 12) and non-PD at assessment 2. Atypical delayed response was defined as PD at any time point followed by non-PD and then response. Survival data were analyzed in pts who had PD by RECIST but CR/PR/SD by irRC. **Results:** Among the 411 pts enrolled across the 3 MEL cohorts, 192 were on MK-3475 for ≥28 wk as of the analysis cut-off of 10/18/2013. Tumor flare was seen in 7 (3.6%) pts. In these pts, best overall response per irRC was CR (n = 1), PR (n = 4), and SD (n = 2). Atypical delayed response was seen in 6 (3.1%) pts. The 51 pts with PD by RECIST but CR/PR/SD by irRC had favorable OS compared with the 145 pts with PD by both criteria (Table). **Conclusions:** MEL pts treated with MK-3475 may experience unique patterns of response and should be managed accordingly. Similar to what has been observed with ipilimumab, conventional criteria such as RECIST may underestimate the benefit of MK-3475 in approximately 10% of treated pts. An updated version of response criteria that incorporate new data on PD-1 inhibitors may be appropriate for future consideration. Clinical trial information: NCT01295827.

|---|---|---|---|
| | 3 mo | 6 mo | 12 mo |
| Pts with CR/PR/SD by RECIST and irRC (n = 215) | 100% | 98% | 92% |
| Pts with PD by RECIST but CR/PR/SD by irRC (n = 51) | 100% | 94% | 67% |
| Pts with PD by RECIST and irRC (n = 145) | 79% | 53% | 34% |

**3007 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**A phase 1 study of PF-05082566 (anti-4-1BB) in patients with advanced cancer.** *Presenting Author: Neil Howard Segal, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** 4-1BB agonists markedly enhance cytotoxic T-cell responses, resulting in anti-tumor activity in several models. PF-05082566 is a fully humanized IgG2 agonist monoclonal antibody targeting 4-1BB.This portion of the first-in-human phase I study assessed the safety, pharmacokinetics (PK), pharmacodynamics (PD) and antitumor activity of PF-0508256 monotherapy in patients with advanced cancer. **Methods:** An open-label, dose escalation study was conducted in patients with advanced malignancies for which no curative therapy was available. Cohorts of 3-6 patients were enrolled initially using a 3+3 design (0.006 to 0.3 mg/kg), then a Time-To-Event CRM design for higher doses (0.6 to 5 mg/kg). Patients received PF-05082566 via intravenous infusion every 4 weeks (one cycle) with an 8 week period for assessment of dose-limiting toxicity (DLT). Radiographic assessments were conducted every 8 weeks, using RECIST 1.1. **Results:** 27 patients have been treated with PF-05082566 up to the 0.3 mg/kg dose level, including colorectal cancer (n=11), Merkel cell carcinoma (n=6), pancreatic adenocarcinoma (n=2), and one each of nasopharyngeal cancer, ampullary cancer, squamous cell lung cancer, carcinoma of unknown primary, melanoma, sarcoma, follicular lymphoma, and lymphocytic lymphoma (SLL). 25 patients completed the DLT assessment period and 7 patients remain on therapy. All discontinuations from treatment were due to disease progression. Median number of cycles ranged from 2 (at 0.006 mg/kg) to 7 (at 0.24 mg/kg). There was no apparent relationship between increasing doses and the frequency or severity of treatment emergent adverse events, which were mostly Grade 1. One patient treated at 0.06 mg/kg had Grade 3 elevation in alkaline phosphatase. No additional significant elevations in liver enzymes and no DLTs have occurred to date. Preliminary PK data suggests a linear increase in drug exposure with increasing dose, and a half life of ~10 days. A best overall response of stable disease was observed in 22% (6/27) patients. **Conclusions:** PF-05082566 was well tolerated, with evidence of disease stabilization in multiple patients. Enrollment continues at higher dose levels to obtain additional safety, PK, PD, and efficacy data. Clinical trial information: NCT01307267.

**LBA3008 Oral Abstract Session, Tue, 9:45 AM-12:45 PM**

**HPV-targeted tumor-infiltrating lymphocytes for cervical cancer.** *Presenting Author: Christian S. Hinrichs, National Cancer Institute, Bethesda, MD*

**The full, final text of this abstract will be available at abstracts.asco.org at 7:30 AM (EDT) on Monday, June 2, 2014, and in the *Annual Meeting Proceedings* online supplement to the June 20, 2014, issue of the *Journal of Clinical Oncology*. Onsite at the Meeting, this abstract will be printed in the Monday edition of *ASCO Daily News*.**

**3009 Poster Highlights Session (Board #1), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Updated survival, toxicity, and biomarkers of nivolumab with/without peptide vaccine in patients naive to, or progressed on, ipilimumab (IPI).** *Presenting Author: Jeffrey S. Weber, Moffitt Cancer Center, Comprehensive Melanoma Research Center, Tampa, FL*

**Background:** PD-1 antibodyNivolumab was administered with/without a multi-peptide vaccine to 105 patients (pts) with unresectable melanoma that failed at least one regimen and were IPI naïve, or progressed after IPI, to assess its toxicity especially in those with prior dose limiting immune related adverse events (irAEs) to IPI, and to update survival data, characterize T cell gene expression and immune cell subsets. **Methods:** HLA A0201 IPI-naïve pts received nivolumab at 1, 3 or 10 mg/kg (34 pts); additional pts that failed prior IPI received nivolumab at 3 mg/kg: two cohorts of pts were A*0201 positive and had either grade 2 or less IPI-related irAE (10 pts), or grade 3-4 dose limiting irAE (20 pts); 41 pts had grade 2 or less irAE, were not HLA restricted and received nivolumab alone. Pre- and 12 week post-treatment peripheral blood was analyzed. **Results:** Median follow-up for all pts was 15 months (mos);median progression-free survival (PFS) was 4.2 mos, and estimated median overall survival (OS) was 16.7 mos (95% CI: 14.4, not reached) with 1 year OS of 65%. Median OS was similar for IPI-naïve or IPI-relapsed pts (15.9 vs. 18 mos, $p=0.6$), older or younger than 62 ($p=0.44$) and by dose ($p=0.86$). ORR, median PFS and OS were longer in males than females (all $p<0.05$). Of 20 pts with prior IPI-induced grades 3-4 irAEs, only 1 had a subsequent grade 3-4 irAE with nivolumab and it was different than seen with prior IPI, but treatment emergent grades 1-2 rash and injection reactions were common. Biomarker studies showed that circulating HLA-DR lo/CD14+/CD11b+ myeloid-derived suppressor cells (MDSC, $p=0.028$), and FCRL2+ CD8 T cells ($p=0.009$) were associated with progression. Decreased regulatory molecules BTLA and LAG3 on CD8+ T cells were associated with response ($p=0.04$). Principal component analysis of genes expressed by flow sorted CD8 T cells showed clustering by response ($p = 6.01E-10$) **Conclusions:** Median OS of 16.7 mos and PFS of 4.2 mos with nivolumab was observed in previously treated melanoma patients naïve to or failing IPI. Prior irAEs to IPI were not replicated with nivolumab. Novel biomarkers of outcome were found on circulating blood cells, including MDSC and CD8 T cell FCRL2 pre-treatment. Clinical trial information: NCT01176461.

**3010 Poster Highlights Session (Board #2), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Preliminary results from a phase 1/2 study of INCB024360 combined with ipilimumab (ipi) in patients (pts) with melanoma.** *Presenting Author: Geoffrey Thomas Gibney, Moffitt Cancer Center, Comprehensive Melanoma Research Center, Tampa, FL*

**Background:** Indoleamine 2,3-dioxygenase 1 (IDO1) is a tryptophan-catabolizing enzyme that is overexpressed in cancers and induces immune tolerance by suppressing T-cell responses. INCB024360, a potent, selective IDO1 inhibitor, was generally well tolerated as monotherapy up to 700 mg BID. Preclinical data support anti-tumor synergy for INCB024360 when administered with antibody antagonists to checkpoint receptors. **Methods:** This is an ongoing dose-escalation study of INCB024360 combined with ipi (3 mg/kg IV q 3 wks x 4) in pts with metastatic melanoma. Enrollment in 2 cohorts (300 mg BID, 25 mg BID) is complete. Toxicity, ORR (irRC), Duration of Response (DoR), and OS were evaluated. The DLT evaluation period was 8 wks andassessments for response were every 9 wks. **Results:** Seven pts were enrolled at 300 mg BID. When 5 pts developed clinically significant ALT elevations after 30–76 days on treatment, enrollment was stopped. ALT elevations were reversible with corticosteroids and treatment discontinuation. Six of 7 pts had evaluable on-study scans prior to discontinuation and all showed irSD. Time to subsequent therapy was >90 days in all 7 pts and >180 days in 4 of 7 pts. Enrollment was restarted at 25 mg BID (n=8), where 1 pt with progression of prior extensive liver metastases had a DLT (G3 AST elevation). Immune-related AEs (irAEs) were generally G1/2 and manageable with continued dosing or temporary dose interruption; 1 pt each discontinued for G3 colitis and G3 salivary amylase elevation. Six of 8 pts had tumor reduction by the 1st evaluation. Confirmed disease control rate was 75% (6/8). Three pts had confirmed irPR (2 occurred by the 1st or 2nd scan); DoR was 179, 148, and >127 (ongoing) days. Three pts had irSD for 116, >173 (ongoing), and >187 (ongoing) days. Pharmacodynamic effects at 25 mg BID were similar to those that were sufficient in preclinical models to achieve maximal therapeutic effect. A 50 mg BID cohort is enrolling. **Conclusions:** INCB024360 25 mg BID with ipi was generally well tolerated and irAEs previously observed with ipi were reversible with appropriate management. Tumor response and duration data suggest the potential for enhanced melanoma patient outcomes compared to ipi monotherapy. Clinical trial information: NCT01604889.

**3011 Poster Highlights Session (Board #3), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Combinatorial TGF-$\beta$ signaling blockade and anti-CTLA-4 antibody immunotherapy in a murine $BRAF^{V600E}$-PTEN-/- transgenic model of melanoma.** *Presenting Author: Brent Allen Hanks, Duke University Medical Center, Durham, NC*

**Background:** T cell-targeted checkpoint inhibitor immunotherapy for melanoma and other solid tumor malignancies only benefits a subpopulation of patients. Our work has shown that melanoma-expressed factors including TGF-$\beta$ can generate an immune privileged site by suppressing the function of critical dendritic cell populations within the local immune microenvironment. We hypothesized that inhibiting TGF-$\beta$ signaling in the tumor microenvironment could augment the efficacy of anti-CTLA-4 antibody therapy in a murine transgenic model of melanoma. **Methods:** Upon primary melanoma development in *Tyr::CreER;*$Braf^{CA/+}$*;*$PTEN^{lox/lox}$mice, the LY2157299 type I TGF-$\beta$ receptor serine/threonine kinase inhibitor was administered daily by oral gavage accompanied by intra-peritoneal delivery of anti-CTLA-4 monoclonal antibody (mAb) every three days. Tumor development was monitored by caliper and photodocumentation/imaging analysis. After 14 days, tumor tissue, tumor-draining lymph node (TDLN) tissue, and lung tissue was resected for whole tissue Western blot analysis, T cell flow cytometry, immunohistochemistry, and indoleamine 2,3-dioxygenase (IDO) enzymatic activity assays. **Results:** While LY2157299 and anti-CTLA-4 mAb monotherapy failed to suppress melanoma progression, LY2152799-anti-CTLA-4 mAb combination therapy synergistically suppressed both primary melanoma tumor growth as well as melanoma metastasis in this physiologically-relevant transgenic melanoma model. These observations correlated with significant increases in the $CD8^+$ T cell/$CD4^+FoxP3^+$regulatory T (Treg) cell ratio in melanoma tissues. In addition, LY2152799 effectively suppressed TDLN-derived dendritic cell IDO enzyme activity and this was found to correlate with diminished levels of Tregs in both TDLN and primary melanoma tissues. **Conclusions:** TGF-$\beta$ signaling inhibition is a promising strategy for augmenting the anti-tumor efficacy of immune checkpoint blockade in melanoma. The pharmacological manipulation of the tumor microenvironment to reverse local immune evasion mechanisms and enhance anti-tumor immune responses represents an important avenue for future studies.

**3012 Poster Highlights Session (Board #4), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase 1 study of MEDI3617, a selective angiopoietin-2 inhibitor, alone and in combination with carboplatin/paclitaxel, paclitaxel, or bevacizumab in patients with advanced solid tumors.** *Presenting Author: David Michael Hyman, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** MEDI3617 (M) is an investigational monoclonal antibody that inhibits angiogenesis by preventing the interaction of angiopoietin-2 (Ang2) ligands with the Tie2 receptor. **Methods:** This is a 3+3 dose-escalation (monotherapy [mTx] and combination) study in adults with advanced solid tumors with mTx expansion in platinum-resistant ovarian cancer (prOC) (NCT01248949). Patients (pts) with Karnofsky performance status ≥70, and adequate organ function were treated in 21 or 28 day cycles with M alone or in combination with carboplatin/paclitaxel (CT), paclitaxel (T), or bevacizumab (B). Objectives included safety, pharmacokinetics, pharmacodynamics, and antitumor activity. **Results:** As of 22 Jan 2014, 95 pts (median age 61; 54% female) were enrolled: 25 in M mTx dose-escalation, 7 in M mTx prOC dose-expansion, and 63 in combination arms. The maximum tolerated dose was not defined in either mTx or combination arms. In the mTx arms, 72% (n=32) of pts had treatment-related adverse events (trAEs): 63% grade ≤2, 6% grade 3, and 3% grade 4. Non-hematologic grade 3 trAEs in the mTx arms included increased weight (6.3%), peripheral edema (3.1%), lymphedema (3.1%) and pleural effusion (3.1%). The grade 3 peripheral edema and lymphedema that occurred in 2 pts in the prOC expansion arm persisted despite discontinuation of M. In the mTx arms, 3 pts (9.4%) discontinued treatment due to trAEs. Exposure of M approached a linear range beyond 100 mg Q3W or 60 mg Q2W. Circulating serum Ang2 levels were >95% saturated at doses ≥500 mg. Objective responses in the combination arms included 5 partial responses plus 1 unconfirmed in: prOC (1 each in M/B and M/T, 1 unconfirmed in M/CT), renal cell cancer (1 in M/B), cervical cancer (1 in M/B), and lung cancer (1 in M/T). In the mTx arms, 1 unconfirmed partial response in a prOC pt was observed and 7 pts had stable disease for >12 weeks. **Conclusions:** MEDI3617 alone and in combination had an acceptable safety profile. Combination therapy exhibited signs of antitumor activity across a variety of tumor types. Enrollment in the mTx prOC expansion cohort is ongoing. Clinical trial information: NCT01248949.

**3013 Poster Highlights Session (Board #5), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Magnitude and quality of tumor-infiltrating T-cell response upon poxvirus-based active immunotherapy alone and in combination with CTLA-4 immune checkpoint inhibition.** *Presenting Author: Susan P Foy, Bavarian Nordic Inc., Mountain View, CA*

**Background:** PROSTVAC PSA-targeted immunotherapy for metastatic castration-resistant prostate cancer is being tested in the PROSPECT Phase 3 trial. Another poxvirus-based immunotherapy product, MVA-BN-HER2, has been tested in early-phase clinical trials for breast cancer. The potential for synergistic benefit from combination active immunotherapy plus immune checkpoint inhibition is hypothesized. Survival benefit plus magnitude and quality of immune responses were evaluated in non-clinical studies following MVA-BN-HER2 dosing alone and in combination with CTLA-4 immune checkpoint inhibition. **Methods:** In a therapeutic CT26-HER2 lung metastasis model, mice were treated with MVA-BN-HER2 without and with anti-CTLA-4 antibody. Tumor infiltrating and peripheral antigen-specific CD4 and CD8 T cells were evaluated by FACS. **Results:** Combining MVA-BN-HER2 immunotherapy with CTLA-4 inhibition in therapeutic mouse tumor models demonstrated synergistic efficacy for median overall survival ($p<0.001$). Improved survival following MVA-BN-HER2 administration was accompanied by a 30 fold increase in tumor infiltrating antigen-specific CD8 T cells (CD8 TILs) compared to no treatment, which was augmented to 90 fold in combination with anti-CTLA-4. By contrast, single agent CTLA-4 inhibition provided a 10 fold increase in antigen-specific CD8 TILs over no treatment. The CD8 T cell response was characterized by an activated IFN$\gamma$+TNF$\alpha$+ signature following poxvirus active immunotherapy compared to an IFN$\gamma$+TNF$\alpha$- response with CTLA-4 inhibition alone. Infiltrating ICOS+ CD4 T cells were primarily FoxP3+ regulatory T cells in untreated and anti-CTLA-4 treated mice, but were FoxP3- effector T cells in mice treated with MVA-BN-HER2 alone or in combination with anti-CTLA-4. **Conclusions:** In non-clinical studies, poxvirus-based immunotherapy induces a robust, functional tumor-infiltrating T cell response for improved survival that is augmented significantly in combination with CTLA-4 immune checkpoint inhibition.

| Therapy | Median survival (days) |
|---|---|
| **Untreated** | 30 |

| **MVA-BN-HER2** | 49.5 |
| **MVA-BN-HER2 + $\alpha$-CTLA-4** | not reached by day 100 |

**3014 Poster Highlights Session (Board #6), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase II study of autologous mRNA electroporated dendritic cells (TriMixDC-MEL) in combination with ipilimumab in patients with pretreated advanced melanoma.** *Presenting Author: Bart Neyns, Universitair Ziekenhuis Brussels, Brussels, Belgium*

**Background:** Autologous monocyte-derived mRNA electroporated dendritic cells (TriMixDC-MEL) are immunogenic and have anti-tumor activity in patients (pts) with pretreated advanced melanoma (Wilgenhof S. et al. Ann Oncol 2013). Ipilimumab (ipi) is a monoclonal antibody directed against the CTLA-4 receptor that counteracts physiologic suppression of T-cell activation and improves the overall survival of pts with advanced melanoma. **Methods:** The activity and safety of TriMixDC-MEL ($4.10^6$ cells id and $20.10^6$ iv, q3wks x4) combined with ipi (10 mg/kg q3wks x4), followed by ipi maintenance therapy (10 mg/kg q12w, in pts who are progression-free at week 24) was investigated in pts with advanced pretreated melanoma according to a Simon two-stage phase II study design. The primary endpoint was the 6-mths disease control rate (DCR) by irRC. **Results:** 39 pts initiated study treatment (16F/23M; median age 46y [range 24-70]; AJCC stage IIIc/IV M1a/-M1b/-M1c: 1/6/4/28; prior therapy: BRAF- or MEK-inhibitor: 23 pts, chemotherapy: 18 pts). Following DC-administration, gr2 skin injection site reactions were observed in all pts, post-infusion chills (< gr2) in 15 (38%), and transient flu-like symptoms (< gr2) in 33 pts (85%). Most frequent grade 3/4 adverse events of special interest were: dermatitis (2 pts [5%]); diarrhea/colitis (2 pts [5%]), hypophysitis/hypopituitarism (7 pts [18%]), hepatitis (5 pts [13%]), and pneumonitis (3 pts [8%]). Systemic corticotherapy was used to treat irAE in 18 pts (46%). Best overall tumor response by irRC: 8 CR, and 7 PR (BORR 38%), 6 SD, and 18 PD. All CR, and 3 PR are ongoing after a median duration of 19 mths (range 3-29 mths). The 6-mths DCR by irRC is 50% (95% CI 34-66). Median PFS and OS are respectively 6.2 (95% CI 3-9), and 14.4 mths (95%CI 10-18). **Conclusions:** This phase II trial of autologous mRNA electroporated dendritic cells in combination with ipilimumab in patients with pretreated advanced melanoma achieved its primary endpoint and resulted in an encouraging rate of durable tumor responses. Further clinical investigation of autologous mRNA electroporated DC-therapy in combination with immune checkpoint modulators is warranted. Clinical trial information: NCT01302496.

**3015 Poster Highlights Session (Board #7), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Baseline tumor size as an independent prognostic factor for overall survival in patients with metastatic melanoma treated with the anti-PD-1 monoclonal antibody MK-3475.** *Presenting Author: Richard Wayne Joseph, Mayo Clinic, Jacksonville, FL*

**Background:** We explored baseline tumor size (BTS) as a prognostic factor in addition to standard prognostic variables for overall survival (OS) in pts with metastatic melanoma treated with MK-3475. **Methods:** In a phase I clinical trial, 411 pts received MK-3475 2 mg/kg Q3W, 10 mg/kg Q3W, or 10 mg/kg Q2W. Response was assessed every 12 wk by RECIST 1.1 by independent central review. BTS was quantified as the sum of the longest dimensions of all RECIST target lesions. Log-rank, Kaplan-Meier (KM), and Cox proportional hazards regressions were used to identify independent prognostic factors for OS. Cutpoints and combinations of prognostic factors were determined by binary tree analysis. **Results:** Of the 411 melanoma pts studied, 365 had measurable tumors at baseline and a median follow-up duration of 10 mo as of the 10/18/2013 cutoff date. Median OS was not reached, and 1-y OS was 71% in all 411 pts and 69% in the 365 pts included in this analysis. By univariate analysis, the following traditional factors were associated with OS: elevated LDH, ECOG performance status of 1, and M-stage 1c (Table). BTS (median 97.8 mm, range 10.4-895 mm) was significantly and strongly associated with OS using log-rank tests, Cox models, KM methods, and binary tree analysis. Binary tree analysis provided a cutpoint of 90 mm BTS as an independent factor. While tumor size >90 mm was associated with a worse prognosis, these pts did have a median OS of 14 mo in the combined data set, suggesting they derive benefit from MK-3475. **Conclusions:** Baseline tumor size is the strongest independent prognostic factor in pts with metastatic melanoma treated with MK3475. If further validated, baseline tumor size could serve as an additional factor when randomizing pts for future clinical trials using anti-PD1 therapies. Clinical trial information: NCT01295827.

**Association of maintenance of pre-existing memory T-cell responses following anti-CTLA-4 antibody treatment with improved overall survival.** *Presenting Author: Lawrence Fong, University of California, San Francisco, San Francisco, CA*

**Background:** While treatment with anti-CTLA-4 antibody can induce clinical responses in advanced cancer patients, the immunobiology and biomarkers associated with improved clinical outcomes is unknown. **Methods:** We used a next-generation sequencing to track changes in the T cell repertoire in 46 patients with metastatic castration resistant prostate cancer (CRPC) or metastatic melanoma (MM). Peripheral blood mononuclear cells were obtained from patients prior to and during treatment with anti-CTLA-4 antibody. mRNA was amplified with locus-specific primer sets for T cell receptor (TCR) beta, and the amplified products were sequenced. Sequence reads were used to quantitate absolute TCR frequencies using standardized clonotype determination algorithms with normalization by spiked reference TCR sequences. Following clonotype quantitation, the kinetics of specific T cell clonotypes were tracked with anti-CTLA-4 treatment. Naïveand memory T cells were also sorted and sequenced to define changes in these subsets. **Results:** CTLA-4 blockade resulted in both expansion and loss of T cell clonotypes, consistent with a global turnover of the T cell repertoire. While this treatment increased TCR diversity as reflected in the number of unique TCR clonotypes, the vast majority of change occurred in the memory T cell pool. Whereas the number of clonotypes that increased with treatment was not associated with clinical outcome, declines of the highest frequency clonotypes following treatment were associated with short overall survival. These declines were not evident in patients with longer overall survival. This association was seen in both CRPC ($p<0.05$) and MM patients ($P<0.01$, two-sided Mann Whitney). **Conclusions:** Together, these results indicate that CTLA-4 blockade induces T-cell repertoire evolution and diversification. However, improved clinical outcomes are associated with maintenance of pre-existing high frequency memory T cells during treatment. These clones may represent the presence of pre-existing T cells that may be relevant in the anti-tumor response. Detection of these high frequency T cell clones could help to identify patients that benefit from treatment.

**3017 Poster Highlights Session (Board #9), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Biomarker characterization using mass cytometry in a phase 1 trial of urelumab (BMS-663513) in subjects with advanced solid tumors and relapsed/refractory B-cell non-Hodgkin lymphoma.** *Presenting Author: Cariad Chester, Department of Medicine, Division of Oncology, Stanford University, Stanford, CA*

**Background:** Anti-CD137 antibody was shown in both murine cancer models and in a first-in-human, phase I trial (Sznol et al., 2008) to increase peripheral activated CD8 T cells and IFN-inducible genes, thereby facilitating a cytolytic, antitumor, Th1 response. A multiparametric immune pharmacodynamic assessment of the effects of anti-CD137 therapy has not been previously performed. **Methods:** We employed the novel technology of mass cytometry time of flight (CyTOF) to investigate the patient's global immune status prior to and during a phase 1 study (NCT01471210) of Urelumab, a fully human anti-CD137 antibody, administered once per 3-week cycle in patients with solid tumors and B-cell non-Hodgkin's lymphoma. Peripheral blood was obtained at 4 time points throughout treatment (baseline, 24-hrs after 1st dose of cycle 1, immediately before cycle 2, and post cycle 3 at response evaluation, C3R). PBMCs were isolated and stimulated for 4 hours with PMA/ionomycin. Immune cell characterization and function were analyzed in FlowJo and SPADE from mass cytometry results. **Results:** Preliminary findings from 4 patients show an increase in CD8 T cells up to 40.6% (SEM+/-13%) and NK cells up to 61.7% (SEM+/-20%) with a decrease in CD4 T cells up to 23.2% (SEM+/-6.5%) and regulatory CD4 T cells up to 17.8% (SEM+/-15%) comparing C3R to baseline. CyTOF cytokine analysis, revealed increases in GMCSF and IFN-gamma by C3R. CyTOF cytokine analysis, revealed increases in GMCSF and IFN-gamma by C3R. **Conclusions:** These preliminary data are consistent with anti-CD137 agonism and generate hypotheses of putative biomarkers of clinical activity now being investigated and to be reported from the ongoing clinical trial. Clinical trial information: NCT01471210.

**3018 Poster Highlights Session (Board #10), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Association of epithelial-mesenchymal transition status with PD1/PDL1 expression and a distinct immunophenotype in non-small cell lung cancer: Implications for immunotherapy biomarkers.** *Presenting Author: Yanyan Lou, MD Anderson Cancer Center, Houston, TX*

**Background:** Programmed cell death 1 (PD-1) and its ligand PD-L1 have emerged as a critical inhibitory pathway that maintains immune suppression in the tumor microenvironment. Patients with non-small-cell lung cancer (NSCLC) have responded to PD-1/PD-L1 blockade, indicating the crucial role of immune suppression in NSCLC. It is imperative to understand the immune features of NSCLC and identify biomarkers to select which patients may benefit from checkpoint blockade. Epithelial-mesenchymal transition (EMT) is a key process driving metastasis. Our previous study developed a robust EMT gene signature predicting resistance to EGFR and PI3K/Akt inhibitors, highlighting differential patterns of drug responsiveness for epithelial and mesenchymal cells. **Methods:** We used this EMT gene signature and gene expression profiles in adenocarcinoma from The Cancer Genome Atlas (TCGA) and the PROSPECT database at MD Anderson Cancer Center (tumors collected in 240 patients undergoing surgical resection with curative intent) to study the tumor microenvironment immune profile. Tumor samples were first classified by our validated EMT signature as epithelial (low EMT scores defined by EMT scores $\leq$ lowest 1/3) or mesenchymal (high EMT scores defined by EMT scores $\geq$ highest 1/3). Gene expression profiles of immune related genes in each tumor were then analyzed. **Results:** Mesenchymal NSCLC is highly associated with a distinct immune phenotype in the tumor microenvironment as compared to epithelial NSCLC. Overexpression of genes for immune inhibitory molecules including PD-L1 ($P = 1.6 \times 10^{-13}$), PD-1 ($P = 9.5 \times 10^{-5}$), CTLA-4, TIM3, BTLA, IL-10, IL-6, and TGF-b ($P<0.0001$ for all others) are associated with mesenchymal NSCLC in both the TCGA and PROSPECT databases. **Conclusions:** This study demonstrates mesenchymal NSCLC (high EMT scores) is associated with distinct immune phenotypes with increased expression of immune inhibitory molecules. This study provides a potential mechanism for EMT associated immunosuppression. It suggests EMT may be a biomarker for checkpoint inhibitors and potentially other immunotherapy agents.

**3019 Poster Highlights Session (Board #11), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Clinical outcome and CD4+ differentiation in anti-CTLA-4/radiation and anti-CTLA-4/steroid therapy.** *Presenting Author: Anuj Bapodra, New York University Langone Medical Center, Department of Pathology, New York, NY*

**Background:** Combination of anti-CTLA-4 and radiation therapy with or without steroids are common in the management of melanoma patients. However, their clinical results and effects on immunity have not been examined in depth. In this study we observe the clinical and immune response of melanoma patients treated with anti-CTLA-4/radiation therapy and anti-CTLA-4/steroids. **Methods:** We anlayzed a cohort of patients treated with anti-CTLA-4 antibody therapy at NYU Medical Center. We examined differences in overall survival using log-rank test in patients treated with 1) anti-CTLA-4 with radiation therapy; 2) anti-CTLA-4 with steroids. Corticosteroids were administered to control symptoms (n=26) and/or toxicity (n=24). T cells were purified from patients; each represented by a minimum of two individual samples (before and after anti-CTLA-4 treatment). CD4+ T-helper cell subset phenotypes were characterized by their cytokine profiles by bead-based cytokine assays after stimulation using CD3/CD28 activation beads. Subsequently, we determined the association between treatment type and concentrations of cytokine production. **Results:** Patients treated with anti-CTLA-4 and radiation therapy given before, concomittant or after anti-CTL4 treatment (n=53) had better overall suvival prognosis compared to patients treated with anti-CTLA-4 alone (N=83; $p=0.02$). Anti-CTLA-4 therapy with steroids (n=50) conferred better prognosis compared to anti-CTLA-4 alone ($p=0.037$). The combination of anti-CTLA-4 and radiation therapy induced T cells to produce more IL-2, IL-17a and TNFa over the 4 cycles of treatment compared to anti-CTLA-4 alone. Similarly, anti-CTLA-4 with steroid treatment increased the production of IL-2 and IL17a, but not TNFa, compared to anti-CTLA-4 alone. No trend differences in IFN-g, IL-4, IL-6 or IL-10 production were detected. **Conclusions:** Our data suggests the enhanced immune response may be explained by effects of radiation therapy and corticosteroids. Increased production of IL-17a and TNFa indicate skewing towards Th17 CD4+ subset since other cytokines showed no trend. The polarized Th17 has clinical sgnificance due to higher anti-tumor activity than unpolarized Th subsets.

**3020 Poster Highlights Session (Board #12), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Effects of ipilimumab on expanded tumor-infiltrating lymphocytes in patients with stage IV malignant melanoma.** *Presenting Author: Jon Bjoern, Center for Cancer Immune Therapy, Herlev, Denmark*

**Background:** Adoptive cell therapy (ACT) is currently one of the most effective treatments for stage IV malignant melanoma. Clinical studies have indicated a link between prior anti-CTLA-4 treatment (e.g. Ipilimumab), and a favorable response to subsequent ACT. **Methods:** We compared phenotype and functionality of T cells generated from melanoma biopsies harvested from Ipilimumab naïve patients with patients that had received treatment with Ipilimumab within six month prior to tumor removal. Tumor biopsies were obtained from 32 stage IV melanoma patients (16 treated with Ipilimumab and 16 ipilimumab naive). T cells were cultured and expanded according to the rapid expansion protocol. Cells were stained for intra- and extracellular markers and subjected to flow cytometric analysis. Additionally, combinatorial coding with MHC-I multimers and co-culture assays with autologous tumor cells were performed in order to assess tumor-specific responses. **Results:** Analysis for phenotypic markers revealed several significant differences related to prior treatment. Importantly, cultured cells from Ipilimumab treated patients showed a median ten-fold higher expression of CD27 in CD8+ T cells, compatible with a more naïve phenotype, and two-fold higher expression of intracellular CTLA-4 in both CD4+ and CD8+ positive T cells. Furthermore, both TIM-3 and LAG-3 were more abundantly expressed in CD8+ T cells from Ipilimumab treated patients. We detected no difference in reactivity towards autologous tumor cells. Combinatorial coding revealed frequent responses toward common tumor associated antigens in both groups of patients. **Conclusions:** Despite several weeks of culture, Ipilimumab appeared to have lasting impact on the phenotype of expanded tumor infiltrating T cells. We observed higher expression of CD27, which previously has been linked to a favorable outcome of ACT, and up regulation of markers associated with immune suppression, possibly due to homeostatic regulation of the T cells. Over all, results indicate that influx of T cells with a less exhausted phenotype may underlie the favorable effect of pretreatment with Ipilimumab and ACT in the setting of metastatic malignant melanoma.

**3021 Poster Highlights Session (Board #13), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**T-cell receptor (TCR) DNA deep sequencing to evaluate clonality of tumor-infiltrating lymphocytes (TILs) in early-stage breast cancer patients (pts) receiving preoperative cryoablation (cryo) and/or ipilimumab (ipi).** *Presenting Author: David B. Page, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** In mice, cryo combined with cytotoxic T lymphocyte antigen 4 (CTLA-4) blockade increases antigen-specific TILs, generating a synergistic rejection of secondary tumors. In humans, breast cancer antigens are shared across pts in low frequency and are incompletely characterized. Thus, to evaluate for antigen-specific TILs in pts receiving cryo and/or the anti-CTLA-4 antibody, ipi, we employed deep sequencing of TCR CDR3 region DNA, which provides a quantitative measurement of the frequency of individual T cell clones, each putatively reactive to a unique antigen. **Methods:** 19 pts were treated with cryo (7 pts), single-dose ipi at 10mg/kg (6 pts), or cryo+ipi (6 pts). Core biopsy (Bx) +/- cryo was performed 7-10 days prior to standard-of-care mastectomy and ipi was given 1-5 days before core Bx. From available specimens, DNA was sequenced using the immunoSEQ™ assay. Utilizing CDR3 sequence copy number, the frequency of each unique T cell clone was determined. Nonparametric analyses were conducted on derivative metrics including T cell %, clonal overlap, and clonality. **Results:** In core Bx's, T cell % (median 6.8%, 0.6-30.7%) and clonality (median 0.13, 0.09-0.4) varied across pts, with a higher T cell % in poorly differentiated lesions ($p=.03$). Cryo reduced T cell counts but induced a polyclonal infiltrate ($p=.02$) with low clonal overlap, indicating influx of new clones. For the 3 ipi alone pts for whom Bx and mastectomy tissue were available, clonal repertoire appeared closer to baseline, as measured by clonality and overlap. Combination cryo+ipi frequently expanded the proportion of the most dominant (top 5) clones (3/6 cases), an effect which was rarely observed with monotherapy (1/8 cases). **Conclusions:** Cryo-associated polyclonality and influx of new clones may be related to cryo-mediated cell death, antigen release, and T cell engagement. A cryo+ipi mediated surge of the most dominant clones may reflect synergistic activation of a clonal subset. These findings call for further characterization of therapy-induced dominant clones, and support repertoire analyses in breast cancer. Clinical trial information: NCT01502592.

**3022 Poster Highlights Session (Board #14), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Graded potency of chimeric antigen receptor (CAR)-engineered T cells for cancer immunotherapy.** *Presenting Author: Michel Sadelain, Memorial Sloan-Kettering Cancer Center, New York, NY*

**Background:** Second generation chimeric antigen receptors (CARs) are recombinant receptors for antigen that retarget and reprogram T cell function. We and others have recently demonstrated that CAR-modified, CD19-targeted T cells can induce complete remissions in patients with relapsed or refractory B cell malignancies, especially acute lymphoblastic leukemia. While CARs endowed with either CD28 or 4-1BB costimulatory endodomains have shown significant therapeutic potential, we previously reported that combined CD28 and 4-1BB signals direct even greater tumor eradication. We have now thoroughly compared these graded levels of therapeutic potency and examined their mechanism of action. **Methods:** Using a xenogeneic B-ALL leukemia model, we titrated CD19-targeted human T cells engineered to receive CD28 and/or 4-1BB signals and compared their therapeutic potency. Purified T cell subsets were analyzed by genome wide expression to correlate costimulatory patterns and therapeutic outcomes. **Results:** We show here that combining a second generation CD28-based CAR, in which CD28 signaling is provided through the CAR's cytoplasmic domain,with 4-1BBL, which auto-costimulates T cells through their endogenous 4-1BB receptor, generates very highly efficacious T cells. We rigorously quantified the tumor eradication potential of T cell populations provided with CD28, 4-1BB or CD28+4-1BB costimulation. The most potent T cell populations were found to evade regulation by endogenous CTLA-4 and induce expression of the type I response pathway, which directly impacted on T cell expansion and function. **Conclusions:** We show here that T cell populations with graded therapeutic potency can be engineered through different CAR designs and costimulatory combinations. Our study further unravels a novel synergy between CD28 and 4-1BB signaling that is distinct from enhanced T cell proliferation or persistence, and results in increased therapeutic potency through the activation of the type I interferon response pathway. These findings open new perspectives for T cell engineering strategies intended to modulate the tumor microenvironment and augment tumor eradication.

**3023 Poster Highlights Session (Board #15), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**A phase I, first-in-human study of ARGX-110, a monoclonal antibody targeting CD70, a receptor involved in immune escape and tumor growth in patients with solid and hematologic malignancies.** *Presenting Author: Ahmad Awada, Institut Jules Bordet – Université Libre de Bruxelles, Brussels, Belgium*

**Background:** Distribution of CD70, a TNF superfamily receptor involved in transient, rapid-onset immune response, is normally restricted to subsets of T-, B-, and dendritic cells. It is chronically over-expressed in patients with malignancies in whom it mediates tumor growth and immune escape. ARGX-110, a monoclonal IgG1 SIMPLE Antibody glyco-engineered for enhanced ADCC (POTELLIGENT), is undergoing Phase 1 testing (ClinicalTrials.gov Identifier: NCT01813539). **Methods:** As of December 2013, 19 patients (median age: 56 years; prior chemo: 82%; prior biologics/TKIs: 29%) with > 10% tumor cells staining positive for CD70 by immunohistochemistry were treated at 0.1, 1, 5, and 10 mg/kg IV q3 weeks; n = 6, 5, 3, and 5) and received a total of 82 cycles (median = 4; range 1-11). **Results:** The most common drug-related adverse events (AE) observed in 14 patients were: infusion-related reaction (26%), fatigue (21%) and diarrhea (16%). Drug-related Grade 3 AEs (hypoxia, anorexia, fatigue) were observed in 2 patients. No immune-related AE was observed. Pharmacokinetics were dose-linear (T 1/2 = 11 days). Saturated target-mediated clearance ($C_{target}$) was observed as of 1 mg/kg. ADCC and depletion of circulating CD70+ cells (qPCR) were demonstrated in all patients. Complement-derived cytotoxicity (CDC) was maximal at > 0.1 mg/kg. Circulating $T_{regs}$ were reduced by ≥ 50% in most patients treated at the highest doses. One CR (in blood) was confirmed in a patient with stage IVA (T2NxM0B2) Sézary syndrome. Five patients maintained SD for > 6 months (RCC, parotid, myoepithelial, platinum-resistant ovarian, mesothelioma). **Conclusions:** Based on the clinical and immunological parameters an intermediate dose level of 2 mg/kg is being studied. Full results will be presented. Clinical trial information: NCT01813539.

**3024 Poster Highlights Session (Board #16), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase I evaluation of an agonist anti-CD27 human antibody (CDX-1127) in patients with advanced hematologic malignancies.** *Presenting Author: Stephen Maxted Ansell, Division of Hematology, Mayo Clinic, Rochester, MN*

**Background:** CD27, a member of the TNF receptor superfamily, is a co-stimulatory molecule that regulates T cell activation, survival, and memory responses through interaction with a tightly regulated ligand, CD70. CDX-1127 is an anti-CD27 human antibody shown to activate human T cells when combined with T cell receptor stimulation, and mediate anti-tumor activity in human CD27 transgenic mice challenged with syngeneic tumors. **Methods:** In a 3+3 dose-escalation (DE), patients (pts) with advanced B-cell lymphoma received CDX-1127 (0.1, 0.3, 1.0, 3.0 or 10 mg/kg IV) as a single dose with 28-day observation, followed by up to 5 treatment cycles (4 weekly doses / Day 85 restaging), until progression. **Results:** 19 pts (3 Hodgkin (HL), 5 follicular, 9 diffuse large B-cell, 2 unspecified non-Hodgkin) have received CDX-1127. DE has exceeded 3 mg/kg with no DLT; enrollment at 10 mg/kg is ongoing. Treatment-related toxicity, generally Grade 1-2, included fatigue, nausea, decreased appetite and anemia. A pt with Stage IV Hodgkin lymphoma who had previously failed chemotherapy, autologous stem cell transplant, and brentuximab vedotin experienced a complete response (CR) and remains in remission at 8.6+ months. IHC analysis of archived tumor for the 3 HL pts showed CD27-negative reed-sternberg cells and CD27-expressing infiltrating lymphocytes. The highest tumor CD27 expression was noted for the pt who had CR. Three additional pts had stable disease (4.5, 5.6 and 14.0 months), including a pt with follicular lymphoma who has completed 3 cycles of therapy and a pt with marginal zone lymphoma with 36% shrinkage in measurable disease. Response data are pending for the 10 mg/kg dose level. Immune correlates including serum cytokines, soluble CD27 levels, and changes in circulating lymphocyte populations are being investigated. **Conclusions:** Emerging results suggest that weekly dosing of CDX-1127 is well tolerated with promising biological and clinical activity in pts with B-cell lymphoma. A DE in pts with T cell malignancies is underway. Single agent safety and activity data support planned combination studies with both conventional and immune-based therapies. Clinical trial information: NCT01460134.

**3025^ Poster Highlights Session (Board #17), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Updated phase I data of AFM13: A bispecific tandem antibody (TandAb) in relapsed/refractory (R/R) Hodgkin lymphoma (HL).** *Presenting Author: Achim Rothe, Formerly of University Hospital of Cologne, Department of Internal Medicine I, Cologne, Germany*

**Background:** AFM13 is a bispecific anti-CD30, anti-CD16A antibody construct which recruits NK cells for targeted lysis of $CD30^+$ tumor cells. HL cells are characterized by CD30 positivity and represent a promising target for AFM13. 30-40% of HL patients (pts.) relapse after standard chemotherapy ± radiation. 2nd line therapies induce durable remission in only 50% of the patients. Hence, there is a high medical need in R/R HL. **Methods:** This was a dose escalation trial in heavily pre-treated R/R HL pts. AFM13 was infused weekly (0.01-7.0 mg/kg) or twice weekly (4.5 mg/kg) over 4 weeks. The primary objectives were safety and tolerability, secondary objectives were pharmacokinetics (PK), pharmacodynamics (PD), and efficacy measured using Cheson criteria. **Results:** 28 pts. were recruited, 26 were eligible for efficacy. 4 pts. were treated twice weekly. AFM13 was well tolerated with mainly mild to moderate adverse events (AEs). The maximum tolerated dose was not reached. Only one relevant, possibly treatment-related toxicity was observed in the 0.5 mg/kg cohort: hemolytic anemia CTCAE Grade 4. The most common AEs were pyrexia (53.6%) and chills (39.3%). 8 pts. (26.8%) experienced serious AEs. PK data revealed that a weekly dose regimen is suboptimal, the half-life was 10-22 hours. PD data showed a dose dependent activation of NK cells ($CD69^+$). Clinical activity was observed over all dose levels but was more pronounced at dose levels ≥1.5 mg/kg (n=13). In this cohort 3 PR (23%), 7 SD (54%), 3 PD (23%) were observed with a disease control rate of 77%. Pts. were not followed-up for duration of response. The time to next treatment (TTNT) was assessed retrospectively for pts. with PR and SD. Mean TTNT was 5.14 months (1.5 – 9.0). 6/7 patients refractory to most recent brentuximab vedotin (BV) therapy achieved SD under AFM13. Mean time between end of BV and start of AFM13 treatment was 1.86 months (1 – 3). **Conclusions:** AFM13 was well tolerated and demonstrated clinical activity also in pts. refractory to BV. The dose regimens investigated seem to have been suboptimal to demonstrate the full clinical potency of AFM13. A phase II study with a modified dose regimen is in preparation. Clinical trial information: NCT01221571.

**3026 Poster Highlights Session (Board #18), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Correlation of immune response with clinical outcomes in melanoma patients receiving adjuvant therapy of pegylated interferon alpha-2b combined with gp100 peptide vaccine.** *Presenting Author: Luis M Vence, The University of Texas MD Anderson Cancer Center, Houston, TX*

**Background:** Vaccination using tumor-associated antigen peptides alone has shown limited clinical benefit. Preclinical studies have demonstrated interferon-alpha promotes vaccine-induced tumor-specific T-cell responses. Our randomized 3-arm study explored the optimal biological dosing (OBD) schedule of pegylated IFN-alpha-2b (PEG-IFN) when combined with gp100 vaccine in patients (pts) with resected melanoma, while demonstrating safety with acceptable toxicity. **Methods:** After definitive surgical resection, melanoma pts were randomized into 1 of 3 PEG-IFN arms [Induction Phase (6 mcg/kg/wk)/Maintenance Phase (3 mcg/kg/wk)]: (1) Arm 1: 4 wk/20 wk; (2) Arm 2: 8 wk/16 wk; (3) Arm 3:12 wk/12 wk. All pts were vaccinated with $gp100_{209\text{-}2M}$ every 3 wk x 8. Toxicity and gp100-specific T-cell responses were assessed every 3 wk. **Results:** 30 pts (8 stage II, 22 stage III) were enrolled and treated in 3 arms (11 Arm 1, 9 Arm 2, 10 Arm 3). All 3 dosing schedules were found to be safe and well tolerated. Despite PEG-IFN-induced lymphopenia [CD8+ T-cells decreased from average 326.5 to 169.7 cells/microL ($P<0.0001$)], gp100-specific CD8+ T-cell frequency increased from baseline 0 cells/ml to 15.5 cells/ml of blood at the end of 24-wk study ($p = 0.0007$). Arm 2 pts showed the highest median maximum gp100-specific T-cell response. Median time to reach maximum T-cell response was 16 wk for Arm 1, and 19 wk for Arms 2 and 3. At median follow-up of 3 years (range 21-54 mo), 11 pts developed recurrent disease, 4 of whom died of metastases. Although median RFS and OS were not reached, the proportion of pts alive and free of distant metastasis at 3 years was 85% among those with maximum gp100-specific T-cell response > 0.025% of CD8+ T-cells, compared to 50% among those with ≤ 0.025% T-cell response ($P=0.04$; HR=0.24). **Conclusions:** In our study, Arm 2 demonstrated the OBD schedule of PEG-IFN combined with gp100 vaccination. The increased T-cell response induced by PEG-IFN correlated with improved clinical outcomes. Clinical trial information: NCT00861406.

**3027 Poster Highlights Session (Board #19), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Immunologic activity of an activating anti-CD27 antibody (CDX-1127) in patients (pts) with solid tumors.** *Presenting Author: Jeffrey R. Infante, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

**Background:** CD27 is a co-stimulatory molecule that regulates T cell activation, survival, and memory responses through interaction with a tightly regulated ligand, CD70. CDX-1127 is an anti-CD27 antibody shown to activate T cells when combined with T cell receptor stimulation, and mediate anti-tumor activity in human CD27 transgenic mice challenged with syngeneic tumors. **Methods:** In a 3+3 dose-escalation (DE), 25 pts with advanced solid tumors received a single dose of CDX-1127 (0.1, 0.3, 1.0, 3.0 or 10 mg/kg IV) with 28-day observation, followed by up to 5 treatment cycles (4 weekly doses / Day 85 restaging), until progression. 16 melanoma and 11 renal cell carcinoma (RCC) pts have been enrolled in expansion (EX) cohorts (target n=15 each). Pharmacokinetic (PK) and immune parameters were assessed on serum and PBMC collected during study. **Results:** DE completed at 10 mg/kg with one dose-limiting toxicity, grade 3 transient asymptomatic hyponatremia, at 1.0 mg/kg. Treatment-related toxicity, generally grade 1-2, included fatigue, rash, nausea, decreased appetite and headache. 3 mg/kg was selected for EX based on DE immunological activity, PK and preclinical modeling. Stable disease has been seen in 4/25 DE pts (3.0, 3.8, 5.7 and 16.8+ months duration); 3/14 evaluable melanoma EX pts (2.6+, 3.1+, 5.7+ months); and 2/6 evaluable RCC EX pts (2.8+, 2.9+ months). In DE, sustained serum CDX-1127 levels were consistent with expected PK profile and correlated with binding to circulating lymphocytes; rapid and transient increases in serum IP-10 (mean [pg/ml]: Day 1 = 215, peak (6 hours post) = 731 [$p<0.0001$]); lesser increases in IL-6 and MCP-1; a significant reduction in regulatory T cells (mean [% of lymphocytes]: Day 1 = 1.66, Day 85 = 0.68 [$p = 0.01$]) and increase in NK cells. Ex vivo analysis demonstrated an increase in T cells responding to melanoma antigens in select melanoma pts. Gene expression analysis of RNA from PBMC is ongoing. **Conclusions:** In pts with solid tumors, CDX-1127 is well tolerated and induces immune activation consistent with CD27 co-stimulation. These results support combination studies with both conventional and immune-based therapies, which have shown synergistic activity in preclinical models. Clinical trial information: NCT01460134.

**3028 Poster Highlights Session (Board #20), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Phase 2 open-label study of MEDI-551 and bendamustine versus rituximab and bendamustine in adults with relapsed or refractory CLL.** *Presenting Author: Douglas Gladstone, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

**Background**: Patients (pts) with relapsed/refractory (RR) chronic lymphocytic leukemia (CLL) need therapies that induce prolonged disease control. MEDI-551, an affinity-optimized anti-CD19 antibody, destroys CLL cells by antibody-dependent cellular cytotoxicity. A phase 2 randomized, open-label study (NCT01466153) is evaluating the clinical activity and safety/tolerability of 2 doses of MEDI-551 + bendamustine compared to rituximab + bendamustine in RR CLL patients. **Methods:** Pts were initially randomized to receive bendamustine + MEDI-551 2 or 4 mg/kg or rituximab (R). Safety assessments include adverse events (AEs) and laboratory parameters. Disease response was determined using 2008 International Working Group criteria. **Results:** The safety population comprised 124 pts across all arms. Median age was 66y (range 41–81); with deletion (del) (17p): 9%, del (11q): 22%, del (13q): 31%, trisomy 12: 11%. Median number of treatment cycles: 4 (range 1–6). The most common (≥20%) treatment-related AEs with MEDI-551 were infusion-related reaction (IRR), fatigue and nausea; neutropenia and nausea were most common with R; most treatment-related AEs were grade 1/2; grade 3/4 treatment-related AEs are listed in Table 1. 20% of pts receiving MEDI-551and 18% patients receiving R discontinued treatment due to AEs. An interim analysis of the MEDI-551-treated pts (25 per arm) showed response rates of 48 vs. 64% in the 2 vs. 4 mg/kg arms. **Conclusions:** MEDI-551 in combination with bendamustine has a manageable toxicity profile that appears to be different compared to rituximab in RR CLL patients. MEDI-551 dosed at 4 mg/kg as compared to 2 mg/kg may have a greater efficacy without any increase in toxicity. Clinical trial information: NCT01466153.

**Correlation of anti-calreticulin antibody titers with improved overall survival in a phase 2 clinical trial of algenpantucel-L immunotherapy for patients with resected pancreatic cancer.** *Presenting Author: Gabriela R. Rossi, NewLink Genetics, Ames, IA*

**Background:** Algenpantucel-L immunotherapy consists of allogeneic pancreatic cancer cells that have been genetically modified to express the carbohydrate α(1,3)Gal, to which humans have an inherent pre-existing immunity. It is αGal that is primarily responsible for the hyperacute rejection of foreign tissue via this potent immune defense mechanism in humans. Algenpantucel-L leverages this mechanism to educate the immune system towards components of the patients' own tumor cells. Calreticulin is a calcium-binding chaperone protein that functions in the immune response by folding major histocompatibility complex (MHC) class I molecules and influencing antigen presentation to cytotoxic T cells. In pre-clinical models, drugs that induce cell surface CALR confer enhanced tumor protection. Components of algenpantucel-L express cell surface CALR. **Methods:** An open-label, 71 patient multicenter phase II study evaluating algenpantucel-L plus standard of care gemcitabine with 5-FU-XRT for resected pancreatic cancer was conducted. Endpoints included DFS at 1 year, OS, and immunologic analysis. Evaluable patients (n=64) were tested for the induction of anti-CALR Ab by ELISA. Increased titers greater than 20% relative to baseline were considered significant ($p<0.001$). **Results:** The study reached its endpoint at 1 year with DFS of 62% and OS of 86%. Thirty-one of 64 patients (48%) had increased anti-CALR Ab. Patients responding with an increase in anti-CALR Ab had a median OS of 35.8 months compared to 19.2 months for patients without an increase. The positive correlation between increased anti-CALR Ab and improved median OS was statistically significant ($p=0.03$). **Conclusions:** This study of algenpantucel-L with SOC for resected pancreatic cancer compared favorably to historical controls. Induction of anti-CALR Ab after therapy correlates with improved survival. Immunological monitoring of algenpantucel-L immunotherapy with this biomarker is feasible and might predict patient response to therapy. Follow up studies are in progress in a multi-institutional, phase III study which recently completed enrollment. Clinical trial information: NCT00569387.

**3030 Poster Highlights Session (Board #22), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**Matrix metalloproteinase-23 as a new immunotherapeutic checkpoint target in melanoma.** *Presenting Author: Duane Moogk, NYU School of Medicine, New York, NY*

**Background:** Matrix metalloproteinase-23 (MMP-23) can inhibit T cell activation by selectively blocking the voltage-gated potassium channel Kv1.3, and may also alter T cell activity and phenotype through cleavage of proteins affecting cytokine and chemokine signaling. We therefore tested the hypothesis that MMP-23 can negatively regulate the anti-tumor T cell response in human melanoma. **Methods:** We characterized MMP-23 expression in primary melanoma patients who received adjuvant immunotherapy. We examined the association of MMP-23 with the intrinsic anti-tumor immune response - as assessed by the prevalence of tumor-infiltrating lymphocytes and $Foxp3^+$ regulatory T-cells. Further, we examined the association between MMP-23 expression and response to immunotherapy. Considering also an *in trans* mechanism, we examined the association of melanoma MMP-23 and melanoma Kv1.3 expression. **Results:** Our data revealed an inverse association between primary melanoma MMP-23 expression and the anti-tumor T-cell response, as demonstrated by decreased tumor-infiltrating lymphocytes (TIL) ($P=0.05$), in particular brisk TILs ($P=0.04$), and a trend towards an increased proportion of immunosuppressive $Foxp3^+$ regulatory T-cells ($P=0.07$). High melanoma MMP-23 expression is also associated with recurrence in patients treated with immune biologics ($P=0.037$) but not in those treated with vaccines ($P=0.64$). Further, high melanoma MMP-23 expression is associated with shorter periods of progression-free survival for patients receiving immune biologics ($P=0.025$). On the other hand, there is no relationship between melanoma MMP-23 and melanoma Kv1.3 expression ($P=0.27$). **Conclusions:** Our data support a role for MMP-23 as a potential immune checkpoint blockade target in melanoma, as well as a possible biomarker for informing melanoma immunotherapies.

**3031 Poster Highlights Session (Board #23), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**CALM study: A phase II study of an intratumorally delivered oncolytic immunotherapeutic agent, coxsackievirus A21, in patients with stage IIIc and stage IV malignant melanoma.** *Presenting Author: Robert Hans Ingemar Andtbacka, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

**Background:** Coxsackievirus A21 is an oncolytic immunotherapy consisting of a bio-selected oncolytic strain of Coxsackievirus A21. Following intratumoral injection, preferential tumor infection causes cell lysis and enhancement of a systemic anti-tumor immune response. We present interim findings of the open-labeled, multicenter Phase II Coxsackievirus A21 in Late stage Melanoma (CALM) study. **Methods:** The CALM study investigated the efficacy and safety of intratumoral Coxsackievirus A21 in 57 patients with treated or untreated unresectable Stage IIIC-IVM1c melanoma. Patients received up to $3 \times 10^8$ $TCID_{50}$Coxsackievirus A21intratumorally on study days 1,3,5 and 8 and then every three weeks for a further 6 injections. Patients displaying immune-related progression-free survival (irPFS) or better at 6 months were eligible for 9 additional injections. Key eligibility criteria were ≥ 18 yrs old, ECOG 0-1, and at least 1 injectable cutaneous, subcutaneous, or nodal melanoma metastasis >1.0 cm. The primary endpoint was to achieve >9 of 54 evaluable patients with irPFS at 6 months. The irPFS was calculated as the proportion of patients demonstrating a Complete Response, Partial Response or Stable Disease by immune-related RECIST 1.1 (irRECIST 1.1) criteria 6 months after the initiation of treatment. Secondary endpoints included 1-year survival, irRECIST1.1 best overall response and safety. **Results:** The primary endpoint of the study was achieved with 14 of 40 (35%) evaluable patients displaying irPFS at 6 months. The number of patients surviving 1-year from the initial treatment is 13 of 21 (62%). Best overall response rate (irRECIST 1.1) is 24% (9 of 38 evaluable patients). Patients received on average 8.3 series of injections, with the most common side effects being Grade 1 fatigue, chills, local injection site reactions and fever. There were no Grade 3 or 4 product-related AE's. **Conclusions:** Intralesional Coxsackievirus A21 is a promising novel oncolytic immunotherapeutic agent in the treatment of unresectable Stage IIIC-IV M1c melanoma based on good patient tolerability, with both local and distant tumor responses. A randomized phase 2 clinical trial is planned. Clinical trial information: NCT01227551.

**3032 Poster Highlights Session (Board #24), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**IMMU-132, an SN-38 antibody-drug conjugate (ADC) targeting Trop-2, as a novel platform for the therapy of diverse metastatic solid cancers: Clinical results.** *Presenting Author: Alexander Starodub, Indiana University Health Goshen Center for Cancer Care, Goshen, IN*

**Background:** IMMU-132 is an ADC of the internalizing, humanized, anti-Trop-2 antibody, hRS7, conjugated by a pH-sensitive linker, to SN-38, the active metabolite of CPT-11 (mean drug-antibody ratio = 7.6). Trop-2 is a type I transmembrane, calcium-transducing, protein expressed at high density (~1 x 10*5), frequency, and specificity by many human carcinomas, with limited normal tissue expression. **Methods:** We report the initial Phase I trial of 25 patients (pts) who had failed multiple prior therapies (some including topoisomerase-I/II inhibiting drugs), and the ongoing Phase II extension that focused on pts with colorectal (CRC), small-cell lung (SCLC) and triple-negative breast (TNBC) cancers. **Results:** Trop-2 is not detected in serum, but was strongly expressed (≥2+) in most archived tumors. In a 3+3 trial design, IMMU-132 was given on days 1 and 8 in repeated 21-day cycles, starting at 8 mg/kg/dose, then 12 and 18 mg/kg before dose-limiting neutropenia. To optimize cumulative treatment with minimal delays, phase II is focusing on 8 and 10 mg/kg (n=22 and 14, respectively). Most common non-hematological toxicities were fatigue (17 ≤G2 ,4 G3), nausea (20 ≤G2), diarrhea (12 ≤G2, 3 G3), alopecia (14), and vomiting (10 ≤G2) ; 2 pts had a rash. Homozygous UGT1A1 *28/*28 was found in 5 pts, 2 of whom had more severe hematological and GI toxicities. Over 80% of 24 assessable pts in Phase I had stable disease or tumor shrinkage (17 SD; 3 PR [CRC, TNBC, SCLC]) as best CT response; median TTP = 18 weeks for all pts, except pancreatic cancer. Of the 36 pts in the Phase II, 14 had their first response assessment by CT: 6 PD, 7 SD; 1 PR (SCLC) by RECIST1.1. Tumor markers (CEA, CA19-9) correlated with responses. No anti-hRS7 or anti-SN-38 antibodies were detected despite dosing over months. The conjugate clears within 7 days, consistent with *in vivo* animal studies where 50% of the SN-38 is released daily. **Conclusions:** These results indicate that this novel SN-38-containing ADC is active in metastatic solid cancers, with manageable diarrhea and neutropenia. The Phase II continues, while also accruing in other epithelial tumors. Clinical trial information: NCT01631552.

**3033 Poster Highlights Session (Board #25), Mon, 1:15 PM-4:15 PM and 4:45 PM-6:00 PM**

**ELYPSE-7: A randomized, placebo-controlled, phase 2a study evaluating the impact of IL-7 on CD4 count, hematological toxicity, and tumor progressionin metastatic breast cancer (MBC) patients (pts).** *Presenting Author: Jean-Yves Blay, University Claude Bernard Lyon I, Centre Léon Bérard, Lyon, France*

**Background:** Lymphopenia is an independent predictive and prognostic factor for chemotherapy (CT)-induced death, febrile neutropenia, overall survival and progression in several cancers, including breast carcinoma. CYT107 is a glycosylated recombinant human IL-7 (CYTHERIS) able to increase lymphocyte pool in man. Whether IL-7 can correct lymphopenia in cancer pts receiving CT and improve patient outcome is not known. **Methods:** Using a 2x2 factorial design, 20 lymphopenic (<1000/$\mu$L) MBC pts, treated with capecitabine (2.5g/m2/d1-14, d1=21), were randomly allocated to 4 arms to receive 1) before the 1$^{st}$ cycle of CT : IL-7 (CYT107:10$\mu$g/kg, SC, weekly) or placebo (pbo), then 2) during the 3$^{rd}$cycle of CT: IL-7 weekly or pbo. The primary endpoint was CD4 count changes before (D0 to D21) and during CT (D57 to D78). Secondary endpoints were toxicity, safety and PFS. Quantitative and functional changes in immune cells were also analyzed. **Results:** From Nov. 2011 to Jun. 2013, 20 pts (median CD4 count D0 : 242 /$\mu$L) were enrolled. Before CT (n=20), IL-7 induced a significant increase of CD4 count (median relative change : +148.1% in IL-7 groups vs +9.9% in placebo [Wilcoxon, p=0.002]), CD8 as well as naïve and memory T cell subsets. During CT (n=11), IL-7 increased CD4 count (+58.6% in IL-7 group vs -2.4% in pbo group [p=0.121]), as well as CD8CD45RO memory cells. CYT107 was well tolerated with injection site reactions as the main AE, no anti-IL-7 antibodies, and no IL-7-related ≥ Grade 3 AE. Interestingly, IL-7 during CT reduced the incidence of Grade 3 haemotological AE compared to placebo (0 vs 5 events, respectively). With a median follow-up of 14 [7-15] months, 6/10 and 2/10 deaths were observed in the groups having received pbo or IL-7 before CT, respectively. 3 objective responses (OR) were observed in pts receiving IL-7 (before and/or during CT) vs 1 OR in pts receiving only pbo. Survival data will be presented at the meeting. **Conclusions:** IL-7 treatment was safe, restored CD4 and T cell subsets in lymphopenic pts with severe haematological toxicity. Further investigations of IL-7 in oncology are warranted. Clinical trial information: NCT01368107.

**3034 General Poster Session (Board #101), Sun, 8:00 AM-11:45 AM**

**Dose-seeking phase I trials (DSP1T) for currently approved molecular-targeted therapies (MTT): We are still far from using appropriate designs.** *Presenting Author: Nuria Kotecki, Centre Oscar Lambret, Lille, France*

**Background:** To explore the use of innovative and more appropriate designs (Continual Reassessment method [CRM], dose-escalation driven by PK or target inhibition . . .). **Methods:** We have reviewed fully published (2001-2013) single-agent DSPT1 (n=38) investigating MTT (n=20), currently approved for solid tumors treatment. **Results:** Eligible criteria included target expression/molecular profiling in only 6 trials (15%). In all cases but one, the trials were based on dose-escalation, mainly toxicity-driven (36 trials, 94%). In 33 trials, the period for assessing DLTs was ≤28 days (87%). DLTs were defined in 31 DSPT1; these definitions took into account the drugs mechanism of action in only 8 cases (25%). In 23 trials, the definitions were strictly similar to those used for cytotoxic agents (75%). "3+3 design", CRM and randomization were used in 17 (44%), 2 (5%) and 3 (8%) DSPTA, respectively. The dose increment was based on "Fibonacci-like" schema, PK or CRM in 25 (65%), 3 (8%) and 2 (5%) DSPT1, respectively. Median numbers of pts and dose-levels were 53 (12-206) and 6 (1-21). There was an expanded cohort at P2RD in 24 trials (63%) with a median number of pts of 12 (3-82). The P2RD was defined in 22 trials (58%). P2RD was identical to the latter approved dose in only 20 trials. The selection of the P2RD also integrated clinical activity (10 trials, 26%), PK (31, 81%), target inhibition or PD (4, 11%) and the results of parallel DSP1T (3, 8%). The probability to experience DLT at the P2RD was ranged from 0% to 33% (median 14%). **Conclusions:** Most of the designs of DSP1T investigating MTT are old-fashioned. The period for assessing DLTs was too short and might be not appropriate in the perspective of long-term drug administration scheduling. This may underestimate the MTT toxicity profile. It is of utmost importance to move ahead to more adapted and innovative designs.

**3035 General Poster Session (Board #102), Sun, 8:00 AM-11:45 AM**

**Cancer patients (pts) being replaced in dose-seeking phase I trials (DSP1T): Occurrence, outcome, and risk factors.** *Presenting Author: Sophie Cousin, Centre Oscar Lambret, Lille, France*

**Background:** Selection of pts entering in DSPT1 remains challenging. Some predictive scores for early death (within 90 days) or overall survival (OS) have been validated. There is currently no predictive model for identifying pts that will be replaced, whereas this condition interferes with the dose-escalation process and recruitment. **Methods:** We retrospectively reviewed all consecutive pts enrolled in DSP1T in 4 centers. Royal Marsden Score (RMS) was calculated as follows: 1 point for each of the following parameters: albumin<35 g/l, LDH>ULN and ≥2 metastatic sites (Olmos JCO 2012). Using logistic regression and decision-tree analyses, we have developed a predictive model for excluding pts of high-risk for being replaced. This model maximized the Specificity (Sp) and the Negative predictive value (NPV). **Results:** Of 332 enrolled pts, 16 pts had to be replaced (4.8%). In all cases, the main reason for early study discontinuation was rapid deterioration of general condition. The median duration of study participation was 18 vs 66 days (p=0.001). The median OS was 45 days vs 480 days (p<0.0001). The 90-day mortality rates were 6/16 (37.5%) vs 19/316 (6.0%). In univariate analysis, the risk factors for being replaced were performance status (PS)=2 (RR=8.2 [2.1-37.4), RMS=3 (RR=35.4 [8.3-150.5]), and enrolment in a study investigating a combination (RR=6.29 [1.98-20.0]). Multivariate analysis had retained PS≥2 and RMS=3 as independent predictive factors for being replaced. We have identified 2 pt subgroups: low-risk of being replaced (RMS≤2 and PS≤1) and high-risk for being replaced (RMS=3 or PS≥2). Rate of being replaced were 8/247 (3.2%) and 8/22 (36.4%) in low and high-risk pts, respectively. Sp and NPV were 94.5% and 94.4%, respectively. **Conclusions:** About 5% of enrolled pts have to be replaced. These pts experienced very poor outcome. RMS=3 or PS≥2 are predictive for being replaced.

**Cancer genomics-based approach for development of new immunotherapeutics for lung cancers.** *Presenting Author: Yataro Daigo, Institute of Medical Science, University of Tokyo, Tokyo, Japan*

**Background:** Oncoantigens are oncogenic and high immunogenicity proteins specifically expressed in cancer cells, and are promising targets for immunotherapy. **Methods:** We have established a strategy as follows to identify new oncoantigens; (1) screening of highly expressed genes in the majority of 120 llung cancers using cDNA microarray representing 27,648 genes, (2) verification of no expression of each gene in normal tissues, (3) validation of the clinicopathological significance of its high level of expression with tissue microarray covering 400 lung cancers, (4) characterization of a critical role of each gene in the growth or invasiveness of cancer cells by RNAi and cell growth/invasion assays, (5) screening of the epitope peptides recognized by HLA-A*0201- or A*2402-restricted cytotoxic T lymphocyte (CTL) for clinical trials. **Results:** We identified 40 oncoantigens and identified dozens of 10-amino-acid peptides, each of which was a candidate to be presented on the surface of HLA-A*0201 or HLA-A*2402 that induced *in vitro* CTL response. We conducted a phase I study for HLA-A*2402-positive, advanced non-small cell lung cancer patients who failed to standard therapy, using the combination of 1, 2 or 3 mg/body of each peptides from LY6K, CDCA1, and KIF20A mixed with adjuvant once a week. 18 evaluable patients have been enrolled, and this cancer vaccine therapy demonstrated tolerability and had very high immunogenicity of even 1 mg/body dose to induce antigen-specific CTLs in cancer patients. The clinical response of the vaccination was evaluated according to RECIST; one complete response case was observed, 8 patients showed stable disease, and 9 showed progressive disease, indicating that disease control rate was 50%. We are also screening predictive and monitoring biomarkers for peptide vaccine therapy through immunogenomics approach by analyzing pattern of CTL response, genomic/proteomic profiles of CTLs and cancer tissues, and genetic variation of patients. **Conclusions:** The cancer vaccine therapy using the cocktail of three peptides demonstrated good tolerability as well as the promising disease control rate, and therefore warrants further clinical studies with screening of their companion diagnostics. Clinical trial information: NCT01069575.

**3037 General Poster Session (Board #104), Sun, 8:00 AM-11:45 AM**

**Prognostic significance of the neutrophil-lymphocyte ratio (NLR) in phase 1 clinical trial patients.** *Presenting Author: Rajiv Kumar, The Institute of Cancer Research, London, United Kingdom*

**Background:** Inflammation has a critical role in the pathogenesis and progression of tumours. A high pre-treatment NLR has been associated with a poor prognosis. Its prognostic utility in patients (pts) being treated on Phase I trials remains uncertain. **Methods:** We identified 300 pts treated on Phase 1 clinical trials at the RMH, between January 2007 and November 2013. Data was collected on pt, treatment and tumour characteristics, including baseline RMH score, neutrophil count and lymphocyte count. **Results:** Overall, 47% of the pts were male; 35% had ECOG 0 and 64% ECOG 1. Tumour types included 15% breast, 13% colorectal, 13% ovarian, 13% non-small cell lung, 14% prostate and 32% other. The RMH score was 0 in 23%, 1 in 43%, 2 in 31% and 3 in 3%. The median NLR was 3.08 (IQR 2.06 – 4.49). Median overall survival (OS) for the NLR quartiles was 10.5 mths for quartile 1, 10.3 mths for quartile 2, 7.9 mths for quartile 3 and 6.5 mths for quartile 4 ($P<0.0001$ for trend). In a univariate model for OS, median OS for a low vs high RMH score was 10.6 vs 5.8 mths (HR 0.55, $P<0.0001$). In addition, ECOG (0 vs 1-2) was significant (HR 0.62, $P=0.002$), as was the NLR when assessed for the binary thresholds defined by the quartiles (NLR25: HR 0.79, $P = 0.04$; NLR 50: HR 0.57, $P = 0.0001$; NLR 75: HR 0.50, $P= 0.0001$). Age, gender and steroid use, were not significant. In a multivariate model for OS, the RMH score and ECOG remained significant (HR 0.63, P=0.002 and HR 0.71, P 0.03, respectively). When the NLR measures were added, NLR (continuous variable) remained a significant prognostic factor (HR 1.06, P <0.0001) as did $Log_{10}$NLR (HR 2.61, P=0.001. The interaction test between the RMH score and the NLR measures was negative. ROC curve analysis showed that the RMH score had a C-index of 0.630, P = 0.0002. The models assessed included: RMH + NLR, RMH + $Log_{10}$NLR, RMH x NLR, and RMH x $Log_{10}$NLR. However, pairwise comparisons of the C-indices from these models to the RMH score alone showed no significant improvement in C-index. **Conclusions:** NLR is prognostic for OS in a Phase I population, independent of the RMH score, in a multivariate analysis.

**3038 General Poster Session (Board #105), Sun, 8:00 AM-11:45 AM**

**Biomarkers for immunotherapy: Results from the analysis of an HLA-status double-blind, biologically randomized phase II study of five therapeutic epitope-peptides with oxaliplatin-based chemotherapy as first-line therapy for advanced colorectal cancer (FXV study).** *Presenting Author: Shoichi Hazama, Digestive Surgey and Surgical Oncology, Yamaguchi University Graduate School of Medicine, Ube, Japan*

**Background:** Biomarkers to predict the efficacy of immunotherapy have been awaited. A phase II study of five therapeutic epitope-peptides with oxaliplatin-based chemotherapy as first-line therapy for advanced colorectal cancer (CRC) using five novel HLA-A*2402-binding peptides derived from not only three oncoantigens, RNF43, TOMM34, and KOC1 but also antiangiogenic cancer vaccine targeting VEGFR1 and VEGFR2 was presented at 2013 ASCO Oral Abstract Session (No. 3006). We further explored the predictive biomarker for the response to immunotherapy. **Methods:** Between February 2009 and November 2012, 96 chemotherapy naïve CRC pts were enrolled in this study. Each of the five peptides (3 mg each) was mixed with 1.5 ml of IFA and subcutaneously administered weekly for 12 weeks and after then biweekly. Chemotherapy was performed simultaneously as mFOLFOX6 (n=93) or XELOX (n=3) with bevacizumab (n=5). All enrolled pts had received the therapy without knowing HLA-A status double-blindly, and the HLA-A genotypes were key-opened at analysis point. Pretreatment serum IL-6 and CRP, lymphocyte%, neutrophil/lymphocyte (N/L) ratio and comprehensive expression profiles microRNA of the tumor were evaluated between HLA-A*2402 positive (treatment) group and HLA-A*2402 negative (placebo) group. **Results:** IL-6 <1.0 (pg/ml) and Lymphocyte% >15% were the significant predictive markers (p=0.007, 0.034) for the long survival, which was observed only in HLA-A*2402 positive group. In the patients with IL-6 <1.0 or lymphocyte% >15, obvious trend to long survival in HLA-A*2402 positive group was observed. MiR-a and miR-b (will be opened in the meeting) were selected for the predictive biomarkers. Patients with low miR-a (<550) or low miR-b (<350) were significantly survived longer than high miR groups (p=0.002, 0.012), which significances were observer only in HLA-A*2402 group. **Conclusions:** Serum IL-6, Lymphocyte%, and miRs expression were the predictive biomarkers for the response to peptides vaccine and the selection of patients. Clinical trial information: UMIN000001791.

**3039 General Poster Session (Board #106), Sun, 8:00 AM-11:45 AM**

**Tumor cells/leukocytes ratio (TLR) in peritoneal fluids as a biomarker in patients with peritoneal metastasis of gastric cancer.** *Presenting Author: Joji Kitayama, Department of Surgical Oncology, University of Tokyo, Tokyo, Japan*

**Background:** Peritoneal carcinomatosis (PC) is the most frequent and life-threatening types of metastasis in patients with gastric cancer (GC). Although the presence of tumor cells in peritoneal cavity is evaluated with microscopic observation by pathologists (Cy) or detection of mRNA of tumor specific molecules, no reliable method is available to quantify the accurate frequency of tumor cells. **Methods:** A total of 380 samples of acsites or peritoneal lavages were recovered from 243 patients with GC and 22 patients with liver cirrhosis (LC). Peritoneal fluids were obtained by laparotomy or paracentesis, and from subcutaneous intraperitoneal access port in case of the patients who received repeated intraperitoneal (IP) chemotherapy for PC. Cells were recovered by centrifugation of peritoneal fluids and immunostained with mAbs to CD45 and to CD326 (EpCAM). Using flowcytometry, the number of CD326(+)CD45(-) and CD45(+)CD326(-) cells, which were determined as tumor cells (T) and leukocytes (L), respectively, were calculated in $10^4$~$10^5$acquired cells, and T/L ratio (TLR) was calculated. **Results:** Median (M) of TLR of the GC patients with PC(+) patients was 0.19% (0%-1868.44%, n=281), which was significantly higher than those of PC(-) patients (M=0%, 0%-0.30%, n=77, p<0.001) and LC (M=0%, 0%-0.028%, n=22, p<0.001). In PC(+) patients, 168 samples which was determined as positive cytology (Cy+) showed higher TLR as compared with 113 samples with Cy (-) (M=1.33%, 0%-1868.44% vs M=0%, 0%-1.13%, p<0.0001). In 37 patients who underwent repeated IP chemotherapy, TLR was markedly decreased after chemotherapy and the response was more sensitive than the changes in Cy or mRNA of CEA. Moreover, TLR of the patients with PC(+) GC before chemotherapy was significantly associated with their outcome. Median survival times (MST) of the patients whose initial TLR were <1.0%, 1.0%~10%, <10% were 765, 394, 271 days, respectively (p<0.001). **Conclusions:** TLR measured with flowcytometry well reflects the relative volume of living tumor cells in peritoneal cavity and thus could be a useful biomarker to predict the prognosis as well as the effectiveness of IP chemotherapy in patients with PC.

**3040 General Poster Session (Board #107), Sun, 8:00 AM-11:45 AM**

**Comprehensive reassessment of plasma VEGFA (pVEGFA) as a candidate predictive biomarker for bevacizumab (Bv) in 13 pivotal trials (seven indications).** *Presenting Author: Carlos Bais, Genentech Inc., South San Francisco, CA*

**Background:** Baseline (BL) pVEGFA level has been investigated as a predictive biomarker for the clinical efficacy of anti-VEGF therapy with Bv in 13 trials (7 indications).Three studies, AVADO (breast cancer [BC]), AVAGAST (gastric cancer), and AVITA (pancreatic cancer [PC]), reported that a high BL pVEGFA level was associated with prolonged PFS or OS, but contrasting data were obtained in other Bv clinical trials. Therefore, pVEGFA as a potential predictive factor of Bv activity in specific oncological indications and individual pts remains poorly understood. **Methods:** To investigate the potential value of BL pVEGFA level (from EDTA-plasma) as a predictive biomarker for Bv activity, sensitivity analyses were carried out on pVEGFA assay data from 13 pivotal Bv trials. In all trials, a VEGFA assay with preferred sensitivity toward the short VEGFA isoforms was used (IMPACT platform, currently used for pt stratification in the MERiDiAN BC trial). **Results:** In the AVADO study, a high BL pVEGFA level was associated with improved PFS in pts treated with Bv 7.5mg/kg but not Bv 15mg/kg. Additionally, while BL pVEGFA levels were predictive of OS and PFS in the AVITA trial, these results were not replicated in a second PC trial (CALGB 80303). Parallel sensitivity analyses of the IMPACT VEGFA assay and assays that recognize all VEGFA isoforms similarly, suggested that preferential detection of the short isoform of VEGFA was not required to assess outcome correlations (AVADO trial). Sensitivity analysis of pVEGFA data from the AVADO trial also indicated an 11% difference in Spearman's rank correlation between different VEGFA assays, which resulted in a loss of the interaction p-value. Finally, longitudinal analysis of VEGFA level in plasma samples from healthy donors showed substantial intra-pt variability in pVEGFA concentration over time. **Conclusions:** These data suggest that pVEGFA level is not a robust predictive biomarker for Bv activity; stratification of pts based on a single BL measurement of pVEGFA is unlikely to be successfully implemented in clinical practice. Further assessment of this hypothesis awaits the prospective analysis of pVEGFA data from MERiDiAN.

**3041 General Poster Session (Board #108), Sun, 8:00 AM-11:45 AM**

**Predictive markers for clinical outcome after neoadjuvant radiochemotherapy in breast cancer patients.** *Presenting Author: Christiane Matuschek, University of Düsseldorf, Düsseldorf, Germany*

**Background:** Neoadjuvant radiochemotherapy (NRT-CHX) in locally advanced noninflammatory breast cancer (LABC) is still under debate. Proliferation markers are the majority of genes included in RNA-based prognostic gene signatures applied for breast cancer patients. **Methods:** During 1991-1998, a total of 315 LABC patients (cT1-cT4/cN0-N1) were treated with NRT-CHX. Preoperative radiotherapy (RT) consisted of external beam radiation therapy (EBRT) of 50 Gy (5 × 2 Gy/week) to the breast and the supra-/infraclavicular lymph nodes combined with an electron boost in 214 cases afterwards or -in case of breast conservation- a 10-Gy interstitial boost with (192)Ir after loading before EBRT. Chemotherapy was given prior to RT in 192 patients, and concomitantly in 113; 10 patients received no chemotherapy. The impact of age, tumor grade, nodal status, hormone and growth factor receptor status (ER, PR, EGFR), p53, ki-67, HER2/neu, and bcl-2 on pathological complete response pCR and disease-free survival were examined in uni- and multivariate terms. **Results:** Hormone receptor status, proliferative activity, bcl-2, EGFR-status and clinical tumor size had a significant impact on clinical outcome. Age, cN, grading, p53, and HER2/neu status failed to reach a significant correlation to complete remission. All examined immunohistochemical factors with the exception of EGFR, and all clinical factors displayed an univariately significant impact on DSF. Particularly, while HER-2/neu had no predictive value for pCR it displayed the highest impact on DSFafter complete response (n=92) , even in a multivariate setting with clinical tumor size and nodal status. Complementary, p53 was the most superior immunhistochemical factor for prognosis after neoadjuvant incomplete remission (n=223). **Conclusions:** Her2/neu is a predictive marker for overall survival independent from the pCR. Furthermore it has no predictive value for the pCR. P53 is a prognostic marker for patients with incomplete remission. Prospective studies are needed to evaluate their use for decisions to further individualize adjuvant treatment after neoadjuvant radiochemotherapy.

**3042 General Poster Session (Board #109), Sun, 8:00 AM-11:45 AM**

**Evaluation of changes on tumor-infiltrating lymphocytes and regulatory T-cells in tissue and peripheral blood after neoadjuvant chemotherapy in breast cancer patients and relation with pathologic complete response.** *Presenting Author: Luis de la Cruz Merino, Clinical Oncology Department. Hospital Universitario Virgen Macarena, Seville, Spain*

**Background:** Some clinical trials in breast cancer have reported imppressive outcomes related to laboratory immune findings in the neoadjuvant setting. We designed a protocol to analyze immune profile before, during and after neoadjuvant chemotherapy (CT) in breast cancer in blood and tissue, and their eventual relation with pathological complete response (pCR). **Methods:** From March 2011 to January 2014, 47 patients (18 Her2+/ 29 Her2-) with T2-4 N0-3 breast carcinoma treated with neoadjuvant chemotherapy in the Breast Cancer Unit of the Hospital Universitario Virgen Macarena (Seville, Spain) were included in the study. CD3+, CD8+, CD8-16-56+ and Foxp3+ cell infiltrates were detected by immunohistochemistry before and after neoadjuvant CT in tissue specimens. Blood samples were collected in EDTA-K3 tubes before every cycle of CT to determine the immunophenotype profile. Cell populations were determined by flow cytometry analysis of whole blood, including the study of CD3-CD4-CD25low and CD3-CD4-CD25high (regulatory) T cells. **Results:** By January 2014, 47 patients (18 Her2+/29 Her2-) were operated. Pathological complete responses (pCR) or near pCR (grade 4/5 Myller&Payne) were attained in 20 patients (42,6%). pCR was achieved in 66,66% (12/18) of tumors overexpressing Her2, but in only a 27,5% (8/29) of Her2-negative tumors. Absence and/or disappearance of Tregs in tissue (Black grading system=0) was more frequent after neoadjuvant CT (11,11 vs 62,2%). Average whole blood CD3-CD4-CD25high (regulatory) T cells were 126,36 before CT and 91,19 cells/microliter after neoadjuvant CT (p 0,010). Overall Tregs diminished in the pCR and non pCR groups without statistically significant differences. **Conclusions:** Neoadjuvant CT decreases Tregs immunosuppressive infiltrates in tissue and CD3-CD4-CD25high (regulatory) T cells in peripheral blood in all the population. Although differences among subgroups (pCR/non-pCR and Her2+/Her2-) were not statistically significant, these data support the role of Tregs as an interesting biomarker with eventual therapeutic implications.

**3043 General Poster Session (Board #110), Sun, 8:00 AM-11:45 AM**

**Development of an IHC-based detection method for studying indoleamine 2,3-dioxygenase 1 (IDO1) expression in human cancers.** *Presenting Author: Alton Hiscox, Ventana Medical Systems, Tucson, AZ*

**Background:** Indoleamine 2,3-dioxygenase-1 (IDO1) mediates oxidative cleavage of tryptophan, an amino acid essential for cell proliferation and survival. The depletion of tryptophan and the generation of tryptophan metabolites have been shown to suppress immune functions via several cellular mechanisms, allowing tumor escape from host immune surveillance. IDO1 is induced by interferons and TLR agonists and is expressed in a variety of human cancers as well as the invading immune infiltrate and the tumor-draining lymph nodes. High IDO1 expression is significantly associated with more rapid disease progression and poor prognosis in multiple cancer types. Thus, inhibition of IDO1 activity may have therapeutic potential in cancer and furthermore, IDO1 expression could serve as a biomarker for selecting patients that are responsive to an IDO1 inhibitor-based treatment regimen. **Methods:** We generated and selected an anti-human IDO1 rabbit monoclonal antibody. The specificity of the antibody for IDO1 was confirmed using Western blot analyses of lysates from cells expressing human IDO1, IDO2, or TDO. **Results:** INCB024360, a novel IDO1-selective inhibitor, is currently being evaluated in clinical trials of cancer patients. To support the clinical development of INCB024360, we developed an immunohistochemistry (IHC)-based method for the detection of IDO1 protein in human tissues. To further evaluate the specificity and reactivity of the antibody against IDO1 in human tissues, an IHC staining protocol was established, standardized and used to stain various human normal and tumor tissues, as well as IDO1-expressing cells. We have examined IDO1 expression in several human tumors including lung, ovarian, melanoma, gastric, and pancreatic cancers. **Conclusions:** In summary, we have developed and standardized an IHC-based method for the specific detection of IDO1 protein in human tissues. The method will be useful to determine the prevalence of IDO1 expression in a variety of human cancers. Furthermore, incorporating this detection method into ongoing clinical trials may identify patients that are likely responsive to IDO1 inhibitor-based treatment regimens.

**3044 General Poster Session (Board #111), Sun, 8:00 AM-11:45 AM**

**Enhancement of cetuximab-induced antibody-dependent cellular cytotoxicity (ADCC) with lenalidomide in advanced solid tumors: A phase 1 trial.** *Presenting Author: Erin Marie Bertino, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

**Background:** Antibody-dependent cellular cytotoxicity (ADCC) is one mechanism of action of monoclonal antibody therapy. ADCC occurs via the innate immune system's ability to recognize mAb coated cancer cells and activate effector cells. Lenalidomide is an immunomodulatory agent with capacity to stimulate T cell proliferation, activate natural killer cells, and effect immune cytokines including IL-2, IL-12, and interferon gamma (INF-g). Pre-clinical and clinical data demonstrate the ability of lenalidomide to increase ADCC activity of mAb therapy. This phase 1 trial evaluated the combination of cetuximab with lenalidomide to enhance ADCC activity in advanced colorectal (CRC) and head and neck squamous cell cancers (HNSCC). **Methods:** This phase 1 dose escalation (3+3) trial included pts with metastatic CRC or HNSCC. Treatment consisted of cetuximab 500 mg/m2 IV every 2 weeks with lenalidomide orally days 1-21 every 28 days. Three dose levels of lenalidomide were evaluated (15, 20, and 25 mg). Correlative studies include measurement of ADCC using an in vitro chromium release assay, bioplex cytokine profiles, and Fc gamma receptor (FcR) polymorphisms. For ADCC assay, target cell line was HT29 (CRC KRAS WT cell line). **Results:** 22 pts were treated (19 CRC, 3 HNSCC); 20 pts had received prior cetuximab or panitumumab. Grade 3 fatigue was the only DLT. One partial response was observed and 7 patients had stable disease as best response.The recommended phase II dose is cetuximab 500 mg/m2 with lenalidomide 25 mg daily. ADCC assay demonstrated increased cell lysis with increasing doses of lenalidomide, particularly with lenalidomide 25 mg. Patient with PR demonstrated increase in ADCC as well as upregulation of IL-2, IL-12, INF-g with downregulation of FGF and VEGF. No high affinity FcR polymorphisms were identified. **Conclusions:** Cetuximab and lenalidomide are well-tolerated with minimal toxicity. There was evidence of anti-tumor activity and clinical efficacy. Correlative studies also demonstrate improved immunologic activity as demonstrated by ADCC assays with increasing doses of lenalidomide although no high affinity FcR polymorphisms were identified. Clinical trial information: NCT01254617.

**3045 General Poster Session (Board #112), Sun, 8:00 AM-11:45 AM**

**Endogenous anti-$\beta$-glucan antibodies as a potential predictive biomarker for clinical response to imprime PGG immunotherapy in non-small cell lung cancer (NSCLC) patients.** *Presenting Author: Nandita Bose, Biothera, Inc., Eagan, MN*

**Background:** Imprime PGG (IPGG) is a yeast-derived $\beta$-1,3/1,6 glucan that primes innate immune cells to kill antibody-targeted cancer cells via a complement receptor 3 (CR3)-dependent mechanism. In humans, naturally occurring anti-$\beta$-glucan antibodies (ABA) are required for binding of IPGG to CR3 and subsequent changes in innate cell functions. **Methods:** In a 32-donor healthy volunteer study, using a qualified quantitative ELISA assay, ABA levels and the threshold for binding and modulation of innate immune functions were evaluated, including a) complement activation, b) complement receptor expression, c) activation marker modulation, and d) selective chemokine production. The potential of the ABA level as a clinical biomarker for clinical response to IPGG was evaluated in a Phase 2 clinical trial by retrospectively segregating subjects into populations at or above the ABA threshold (biomarker positive; $BM^+$) or below the ABA threshold (biomarker negative; $BM^-$). Advanced NSCLC patients received cetuximab, carboplatin and paclitaxel without (Control) or with IPGG 4mg/kg on Days 1, 8 and 15 of each 3-week treatment cycle for the first 4 to 6 cycles. Maintenance treatment with cetuximab alone or with IPGG was continued in subjects achieving radiographic disease control (RECIST 1.0). **Results:** The objective response rate (ORR; primary endpoint) was 23% in the control group (6/26), 48% in the entire IPGG group (22/46; p= 0.047 *vs* control), 67% in the $BM^+$ IPGG group (10/15; p=0.009 *vs* control) and 39% in the $BM^-$ IPGG group (12/31; p=0.26 *vs* control). Median overall survival was 11.3 mo in the control group, 12.4 mo in the entire IPGG group (HR 1.04; p=0.88 *vs* control), 16.7 mo in the $BM^+$ IPGG group (HR 0.70; p=0.37 *vs* control) and 9.4 mo in the $BM^-$ IPGG group (HR 1.28; p=0.43 *vs* control). Three-year survival was 0% in the control group, 7% in the entire IPGG group, 17% in the $BM^+$ IPGG group and 0% in the $BM^-$ IPGG group. **Conclusions:** In summary, the addition of Imprime PGG to carboplatin, paclitaxel and cetuximab resulted in improved outcomes in $BM^+$ patients, suggesting the potential clinical use of ABA level as a predictive biomarker for response to Imprime PGG. Clinical trial information: NCT00874848.

**3046 General Poster Session (Board #113), Sun, 8:00 AM-11:45 AM**

**Clinical and pathologic correlation of the activated form of the estrogen receptor beta (ER$\beta$) in breast cancer (BC).** *Presenting Author: Emilie Hutt, Centre Oscar Lambret, Lille, France*

**Background:** ER$\beta$ is antagonized by anti-estrogens and has been associated with a better prognosis although its role is unclear. Experimentally, ER$\beta$ has a nuclear biology common to the steroid nuclear receptors. In the absence of estrogenic ligand, it is evenly distributed in nuclei; when exposed to ligand, ER$\beta$ migrates to form sub-nuclear aggregates that can be detected by immunofluorescence microscopy. Thus, two distinct nuclear patterns, diffuse (D) or aggregated (A) are observed which correspond to the receptors' functional states. Similarly to previous work on ER$\alpha$ and PR (ASCO 2013 abstr.# e11535 & 593), an immunohistochemistry (IHC) method has been developed to characterize the nuclear distribution patterns which may indicate whether ER$\beta$ is transcriptionally active or not in PEFF tissues. The goal of the study is to analyze whether activated ER$\beta$ is associated with anti-estrogen treatment outcome. **Methods:** 662 archived BC biopsies have been obtained along with clinical and pathological data. Biopsies were analyzed for standard HES, ER$\alpha$, ER$\beta$, PR and Ki67. ER$\beta$ positivity was determined with the 14C8 antibody (Abcam) and the nuclear distribution pattern analyzed at x1000 magnification. **Results:** 392 cases have been analyzed to date. Mean Age: 57 (17-89). Median follow up 36 months (mo). Histology: ductal 82% lobular 15% other 3%; $ER\alpha^{pos}$ 78% $PR^{pos}$ 78%. Adjuvant chemotherapy 46%, Hormone therapy 85%. Stage I 44%, II 48%, III 8%. Grade I 25%, II 50%, III 25%. ER$\beta$ was positive in 57% of the cases ($ER\beta^{pos}$). ER$\beta$ was activated (A- ER$\beta$) in 35% of the $ER\beta^{pos}$ biopsies, and non-activated (D- ER$\beta$) in 65% $ER\beta^{pos}$ . A-ER$\beta$ was associated with higher grade ($p < 0.000$, $p = 0.007$); ER$\beta$, PR, HER2, Ki67, staging were not associated with $ER\beta^{pos}$ nor A-ER$\beta$. Local or distant Progressive disease (PD) was evident in 19% of cases and was not associated with $ER\beta^{pos}$ or A-ER$\beta$ (p=0.87). With DFS defined as time to PD or death (5 year cut-off), neither $ER\beta^{pos}$nor A-ER$\beta$ were associated with a better DFS (HR: 1.02 and 0.98). **Conclusions:** In contrast to ER$\alpha$, preliminary results show that ER$\beta$ positivity and ER$\beta$ activation status were associated with higher pathological grade but not with other pathological or clinical variables.

**3047 General Poster Session (Board #114), Sun, 8:00 AM-11:45 AM**

**Expansion of peptide-specific T cells from human melanoma-draining lymph nodes.** *Presenting Author: Madeleine Strohl, Case Western Reserve University School of Medicine, Cleveland, OH*

**Background:** Adoptive immunotherapy using T lymphocytes is a novel therapy under investigation in patients with advanced stage melanoma. We have evidence that melanoma-draining lymph nodes (MDLN) from patients with stage III disease can be cultured to result in the generation of melanoma specific T cells. These T cells have demonstrated the ability to stop and reverse the progression of disease *in vitro* and in mouse models. We hypothesized that a proportion of our cultured T cells from MDLNs will demonstrate specific, measurable responses to one or more of known melanoma antigens *in vitro*. **Methods:** Human lymph nodes derived from patients with melanoma (IRB CASE 3610) containing T cells, B cells, monocyte/macrophages and dendritic cells were cultured with anti-CD3/CD28 beads, IL-2 and VEGF-blocking antibody. On day 11, cells were cultured with overlapping peptides spanning the sequences of four known melanoma antigens. Cells were incubated for 72 hours prior to undergoing FACS analysis to characterize intracellular IFN-$\gamma$, TNF-$\alpha$ and IL-2 expression in $CD4^+$ and $CD8^+$ subpopulations. Stimulation indexes were calculated as stimulated sample /MDLN alone sample expression. **Results:** Coculture of $CD4^+$ (helper T) cells with MAGEA1, NY-ESO1 and Prame/OIP4 resulted in a TNF-$\alpha$ stimulation index of 1.65,1.6 and 3, respectively. Coculture of $CD4^+$ cells with Melan-A/MART-1 and NY-ESO1 resulted in an IL-2 stimulation indexes of 1.66 and 2.73. $CD8^+$ (cytotoxic T) cells cocultured with MAGEA1 and Prame/OIP4 resulted in TNF-$\alpha$ stimulation indexes of 1.85 and 3.85, while coculturing with Melan-A/MART-1 and NY-ESO1 resulted in IL-2 stimulated indexes of 1.56 and 2.22. **Conclusions:** This data demonstrates that activated T cells which recognize defined melanoma peptide antigens can be generated from melanoma draining lymph nodes. Development of a novel assay to identify peptide-specific T cells will have significant applications to monitoring immune responses in patients with melanoma. Our goal will be to incorporate the use of this assay in immune monitoring of peripheral blood T cells in patients enrolled into a Phase I clinical trial of T cell therapy in patients with advanced melanoma.

**3048 General Poster Session (Board #115), Sun, 8:00 AM-11:45 AM**

**Preclinical evaluation of anti-RON antibody-drug maytansinoid conjugates (anti-RON ADC) for targeted colorectal cacner therapy.** *Presenting Author: Liang Feng, School of Pharmacy, Texas Tech University Health Science Center, Amarillo, TX*

**Background:** The receptor tyrosine kinase RON is critical in tumorigenesis and a validated drug target for cancer therapy. Here we report the development and therapeutic efficacy of anti-RON mAb Zt/g4-maytansinoid conjugates (Zt/g4-DM1) with enhanced cytotoxicity against colorectal cancer cells (CRC) in mouse xenograft tumor models. **Methods:** Zt/g4 (IgG1a/κ) was selected as the drug carrier for its ability to induce RON endocytosis in CRC cells. Zt/g4 was conjugated to DM1 via the thioether link to form antibody-drug conjugate Zt/g4-DM1 with an antibody-drug ratio of 1:4 molecules. CRC HCT116, HT29, and SW620 cells were used as the model for in vitro and in vivo studies. **Results:** Zt/g4-DM1 retains the intrinsic activity that causes rapid RON internalization. Targeted payload delivery induced cell cycle arrest at G2/M phase, reduced cell viability with $IC_{50}$ values at ~1.2 μg/ml, which results in massive cell death within a period of 72h. The cytotoxic effect of Zt/g4-DM1 was negligible in cancer cells with minimal RON expression. Studies from the mouse CRC xenograft model revealed that Zt/g4-DM1 is highly effective in delaying HT29 cell-mediated tumor growth in athymic nude mice. In a single cycle of q 4 days x 5 with Zt/g4-DM1 at 1, 3, 7, 10, and 15 mg/kg body weight, we observed significant tumor inhibition (>70% tumor growth delay) when Zt/g4-DM1 was used at 7 mg/kg. Significantly, more than 95% of tumor growth was inhibited at 10 mg/kg or 15 mg/kg of Zt/g4-DM1. Continued observation after last treatment showed that the inhibitory effect of Zt/g4-DM1 is long lasting up to 20 days without signs of tumor regrowth. The prepared Zt/g4-DM1 is stable *in vitro* and has a minimal toxic effect *in vivo*when Zt/g4-DM1 was used below 40 mg/kg. Zt/g4 has been sequenced and a 3D model of antigen-binding domains in variable regions in both heavy and light chains has been created. Zt/g4 is currently under humanization for potential clinical trials. **Conclusions:** Zt/g4-DM1 is a highly effective biotherapeutics for inhibition of CRC growth in mouse xenograft models. The development of humanized Zt/g4-DM1 opens an avenue for potential clincal trials for various types of cancers harboring aberrant RON expression.

**3049 General Poster Session (Board #116), Sun, 8:00 AM-11:45 AM**

**A novel method for identifying downstream signals in tumor-reactive T cells following PD-1 engagement and monitoring endogenous tumor immunity and immunotherapy.** *Presenting Author: Haidong Dong, College of Medicine, Mayo Clinic, Rochester, MN*

**Background:** Therapies targeting programmed cell death 1 (PD-1) or its ligand B7-H1 (aka PD-L1) have yielded promising therapeutic effects in various solid and hematologic malignancies. A reliable method to determine whether PD-1 on T cells has engaged its ligand B7-H1 on tumor cells is highly desirable as it may have significance as a predictive marker for PD-1 targeted therapy. **Methods:** Endogenous tumor-reactive CD8+ T cells were identified by their high expression of PD-1 and CD11a CD8+ T cells and their expression of Bim, a pro-apoptotic molecule, in the peripheral blood of 26 patients with metastatic melanoma and 11 patients with metastatic prostate cancer or healthy donors using flow cytometry. Soluble PD-L1 in patients' sera was quantified using ELISA. **Results:** The target-cell engaged CD8+ T cell population was significantly higher in patients with melanoma and prostate cancer compared to healthy donors, as assessed by CD11a and PD-1 expression. Bim expression was higher in CD8+ T cells in both cancer patients than healthy controls ($p<0.01$). In patients with advanced melanoma, Bim was significantly higher in the PD-1(+) target cell-engaged CD8+ T cells than the PD-1(-) CD-8+ T cells ($P<0.01$). Bim levels above the base line levels of healthy donors in the CD8+ T cells correlated with decreased survival in patients with melanoma (8.9 months v. 13.8 months, $p<0.05$). Our data suggest that the Bim level is dependent on PD-1 expression, and that higher Bim expression may be indicative of PD-1(+) CD8+ T cells which have engaged B7-H1 (PD-L1), either soluble (peripheral blood) or membrane bound (tumor cells), and are susceptible to apoptotic death. **Conclusions:** PD-1+ CD11a high CD8+ T cells identify a unique population of effector cells responsive to target tumor cells in cancer patients. Elevated Bim expression in CD8+ T cells may indicate the active immune inhibiting effects of PD-1/B7-H1 signaling on endogenous antitumor T cell responses. Bim expression can serve as a signaling biomarker for PD-1 function and may be useful in selecting patients who may benefit from checkpoint blockade therapy.

**3050 General Poster Session (Board #117), Sun, 8:00 AM-11:45 AM**

**Antibody-mediated modulation of the IgM B-cell receptor (BCR) expression and signaling.** *Presenting Author: Sydney Welt, Welt Bio-Molecular Pharmaceutical, LLC, Armonk, NY*

**Background:** Targeting the BCR signaling pathway in B-cell malignancies has been shown to be therapeutic, but inhibition of the BCR itself has remained elusive due to serum IgM (sIgM) sequence homology. A unique sequence in the extracellular domain of membrane IgM (ECD-mIgM), designated proximal domain (PD), is not expressed in sIgM. Anti-PD monoclonal antibodies (mAbs) can be used to purify ECD-mIgM for mAb generation. Here we identify an ECD-mIgM conformational epitope not detected in sIgM. **Methods:** High affinity anti-PD monoclonal antibodies (mAbs) were generated by proprietary immunization techniques. These mAbs are shown by ELIZA, Western blots and Scanning Immuno-Electron Microscopy (SEM) to bind to mIgM protein and mIgM+ expressing cell lines (CA 46, SU-DHL-5, CRL-1596, CRL-1432, CRL-1642). Using these high affinity anti-PD mAbs, mIgM was immune-affinity purified. Second generation mAbs detecting mIgM conformational epitopes and not reacting with sIgM in ELIZA/Western/SEM assays were collected. Clonogenic assays were done by limiting dilution/MTT. **Results:** Cell surface binding assays demonstrated the specificity of these mAbs by testing against a panel of mIgM + vs mIgM- (mIgG+) cells. Normal sera failed to block or reduce mAb binding to mIgM+ cells. MAb1-1, mAb2-2b and mAb3-2b internalize mIgM but do not modulate cell growth inhibition. Second generation mAb4-2b mediates BCR internalization and in low density cultures, cell growth inhibition, anti-clonogenic activity and apoptosis are observed. Apoptosis is seen in a variety of malignant B-cell lines including high and low mIgM/Igα/β expressers. **Conclusions:** These data support the contention that BCR internalization is insufficient to interrupt the BCR signaling cascade despite the lack of detectable residual mIgM. Upon mAb4-2b binding to a non-ligand binding site on mIgM, it induces both BCR internalization and in another distinct event, apoptosis. These mAbs are candidates for development as drug/radioisotope targeting agents and/or as a mediator of inhibition of the BCR signaling pathway (mAb 4-2b). These mAbs have a high level of specificity as they do not bind to non-mIgM B-cells, normal lymphocytes and non-lymphatic tissue, thus reducing toxicity.

**3051 General Poster Session (Board #118), Sun, 8:00 AM-11:45 AM**

**Potentiation of immune checkpoint blockade cancer immunotherapy with oncolytic virus.** *Presenting Author: Dmitriy Zamarin, Memorial Sloan Kettering Cancer Center, New York, NY*

**Background:** Therapeutic efficacy of agents targeting immune checkpoints has been limited to a subset of patients and cancer types. Preexisting lymphocytic infiltration of tumors has emerged as an important biomarker predictive of clinical benefit, suggesting that therapeutic effect could be enhanced through strategies that induce tumor inflammation. Here we explored whether the inflammatory responses generated by oncolytic viruses could be harnessed to improve systemic therapeutic efficacy of agents targeting immunologic checkpoints. **Methods:** For our studies we utilized Newcastle Disease Virus (NDV), an avian virus with robust type I IFN-inducing properties. Metastatic disease was modeled by using bilateral flank B16 mouse melanoma model, with NDV administered unilaterally, allowing us to characterize the immune responses in both virus-injected and distant tumors. Therapeutic efficacy and immune responses utilizing intratumoral NDV with systemic immune checkpoint blocking antibodies were further characterized in several mouse models. **Results:** Localized intratumoral therapy of B16 melanoma with NDV induced CD4+ and CD8+ lymphocytic infiltrates and anti-tumor effect in distant (non-virally infected) tumors without viral spread to these sites. Combination therapy with localized NDV and systemic immune checkpoint blockade led to distant tumor rejection in both NDV-susceptible and resistant tumor models and protected the animals from tumor re-challenge. This effect was associated with marked tumor infiltration with activated effector, but not regulatory T cells, and was dependent on CD8 and NK cells, and type I and II interferons. To further enhance the T cell effector function in tumors, we genetically-engineered NDVs expressing co-stimulatory ligands and demonstrated further increase in therapeutic efficacy of the combination therapy in several tumor models. **Conclusions:** In summary, in mouse tumor models, localized therapy with NDV induces inflammatory infiltrates in distant tumors, making them susceptible to systemic therapy with immunomodulatory antibodies. This provides a strong rationale for investigation of combination therapies utilizing NDV and immune checkpoint blockade in clinic.

**3052^ General Poster Session (Board #119), Sun, 8:00 AM-11:45 AM**

**Phase 1 study of VX15/2503, a humanized IgG4 anti-SEMA4D antibody, in advanced cancer patients (pts).** *Presenting Author: Amita Patnaik, START Center for Cancer Care, San Antonio, TX*

**Background:** Semaphorin 4D (SEMA4D) regulates cellular adhesion, motility and activation of cells of the nervous, vascular and immune systems; it also promotes tumor progression and metastasis. SEMA4D and its receptor plexin B1 are widely expressed in human tumors; the interaction of plexin B1 with MET and ERBB2 leads to SEMA4D-mediated transactivation of these membrane receptor kinases promoting tumor cell migration and invasive growth. The murine progenitor of VX15/2503 suppressed tumor growth in syngeneic and transgenic tumors. No toxicologic effects were noted in studies of VX15/2503 using rats and primates and PK/PD profiles were generally predictive of data from clinical trial subjects. **Methods:** A multiple ascending dose trial was initiated in adult pts with advanced refractory solid tumors; pts were administered weekly IV doses of VX15/2503 until progression. Dose levels were 0.3 to 20 mg/kg. Tumors were assessed by RECIST 1.1 after each 8 dose cycle. Biomarkers assessed were SEMA4D, VEGF, HGF, PLGF, and MET. **Results:** Enrollment has been concluded (n=42 Pts); sex 40.5%M/59.5%F. Mean age (yrs) 64.8; ECOG 0/1/2 are 28.6% /69%/4%. No MTD was found. One DLT (grade 3 GGT elevation; 15 mg/kg) was reported in a pancreatic cancer pt with disease progression. As of 12/16/2013 the most frequent treatment-related AE's (n=42 pts) included grade 1/2 nausea (11.7%), arthralgia (7.3%), decreased appetite (7.3%), and fatigue (7.3%); 15 drug unrelated SAE's were reported in 11 pts. No CR/PR were observed. Thirteen of 42 pts at all dose levels exhibited stable disease for at least 8 weeks. Pts with the longest duration of treatment included: 48-55 weeks (colorectal; 9 mg/kg) (breast; 15 mg/kg) (papillary thyroid; 20 mg/kg); these pts had relatively high T or B cell levels. VX15/2503 serum concentrations of $\geq$ 0.3 $\mu$g/mL produced complete T cell SEMA4D saturation. HAHA responses (titer $>$ 100) with possible effects on PK were observed in 4 of 41 pts (10%); in only 1 pt (2%) was an effect of HAHA on PD observed. VX15/2503 half-life was roughly 4-5 days at doses $\geq$1.0 mg/kg. **Conclusions:** VX15/2503 was well tolerated at dose levels up to 20 mg/kg, with 450 doses administered to 42 pts. Future studies will be combination trials in selected tumor types. Clinical trial information: NCT01313065.

**3053 General Poster Session (Board #120), Sun, 8:00 AM-11:45 AM**

**Association between immune-checkpoint inhibitor induced tumor shrinkage and overall survival in advanced melanoma and NSCLC.** *Presenting Author: Yan Feng, Bristol-Myers Squibb, Princeton, NJ*

**Background:** Immune checkpoint inhibitors enhance immunologic antitumor activity and ongoing studies are exploring the potential of such inhibitors to provide long term (OS) benefits across several cancer types. We describe an exploratory analysis of the association between tumor shrinkage (TS) and OS in patients (pts) with melanoma or NSCLC receiving ipilimumab or nivolumab, immune checkpoint inhibitors that augment T-cell activity by blocking CTLA-4 and programmed death-1 receptors, respectively. **Methods:** TS and OS associations for ipilimumab in pts with advanced melanoma were assessed using data from 4 phase II studies (CA184-004/007/008/022, n=351). TS and OS associations for nivolumab were assessed in pts with advanced melanoma (n=97) or NSCLC (n=112) using data from cohorts of a phase I study (CA209-003). A nonlinear mixed-effects model was used to describe longitudinal tumor burden data; TS was determined from the model as % decrease from baseline. The relationship between TS and OS was determined by a multivariate Cox proportional-hazards model. **Results:** Across the pt populations tested, the risk of death decreased with increasing % TS (hazard ratio [HR] coefficients in all 3 models and associated 95% confidence intervals [CIs] $<$1.0). At 30% TS (corresponding to magnitude of RECIST partial response), the association between TS and OS for pts with melanoma was comparable for ipilimumab or nivolumab treatment (HR [95% CI] of 0.602 [0.543–0.668] and 0.502 [0.381–0.662], respectively, relative to no change in % TS). At 30% TS, the association between TS and OS for NSCLC pts treated with nivolumab was comparable with that seen for melanoma pts (HR [95% CI] of 0.361 [0.252–0.517]). **Conclusions:** An association was found between the extent of TS and OS across melanoma pts receiving ipilimumab or nivolumab and NSCLC pts receiving nivolumab in this exploratory retrospective analysis. Measuring the extent and timing of TS may have use in predicting potential OS benefits of immune checkpoint inhibitors; however, this observation would need to be prospectively evaluated in data from a well-controlled study. Additional exploratory analyses are ongoing to assess correlates to OS benefit.

**3054 General Poster Session (Board #121), Sun, 8:00 AM-11:45 AM**

**Immune escape mechanisms associated with tumor recurrence after adoptive cell transfer immunotherapy.** *Presenting Author: Marco Donia, Center for Cancer Immune Therapy, Copenhagen University Hospital Herlev, Herlev, Denmark*

**Background:** Adoptive cell transfer immunotherapy (ACT) with tumor infiltrating lymphocytes (TILs) results in unprecedented rates of durable clinical responses but some patients initially responding achieve only a temporary disease remission before tumor recurrence. **Methods:** Disease relapse in a case of metastatic melanoma experiencing tumor recurrence after complete response to treatment with TILs was characterized at the cellular and molecular level using primary tumor cell lines and tumor infiltrating lymphocytes derived from metastatic lesions resected at different time points. **Results:** Multiple mechanisms linked to tumor-intrinsic evolutional phenomena associated with tumor re-growth despite durable persistence of peripheral antitumor responses were identified. Tumor-cell intrinsic alterations led to both impaired immune sensitivity and universally reduced immune recognition associated with multiple defects in antigen processing machinery, but not to antigen loss or increased expression of immune suppressive molecules such as PD-L1. In addition, cell lines from tumor recurrence were characterized by increased in vivo malignancy independent of immune response sensitivity, in the absence of new known melanoma driver mutations. **Conclusions:** Data from this study brings direct evidence that tumor cell evolutionary mechanisms responsible for immune escape, and associated with disease recurrence in human metastatic tumors after effective immunotherapies targeting multiple antigens, are extraordinarily complex and multifactorial. Future strategies to extend duration of responses to immunotherapy should consider targeting this complexity

**3055 General Poster Session (Board #122), Sun, 8:00 AM-11:45 AM**

**Interim analysis of a phase I/II open label, dose-escalating study to investigate safety, tolerability, and preliminary efficacy of the trifunctional anti-HER2/neu x anti-CD3 antibody ertumaxomab in patients with HER2/neu expressing solid tumors progressing after standard therapy.** *Presenting Author: Nicole Haense, Krankenhaus Nordwest, University Cancer Center, Frankfurt, Germany*

**Background:** Ertumaxomab (ertu) is a bispecific, trifunctional antibody (ab) targeting HER2/neu, CD3 and the Fc$\gamma$-receptors I, IIa, and III forming a tri-cell complex between tumor cell, T cell and accessory cells. Patients (pts) with HER2/neu (1+/SISH positive, 2+ and 3+) expressing tumors progressing after standard therapy are treated to investigate safety, tolerability and preliminary efficacy. **Methods:** In this ongoing investigator driven, non-randomized study, ertu is applied i.v. in 2 cycles following a predefined dose escalating scheme. Each cycle consists of 5 ascending doses (10-500$\mu$g) applied weekly within 28 days with a 21 day treatment-free interval. If 2 pts experience a dose limiting toxicity at a given dose level, the maximum tolerated dose (MTD) will have been exceeded. **Results:** So far, 11 heavily pretreated pts (e.g. breast, rectal, gastric cancer) have been enrolled in the first 4 main cohorts. 1 (9%) pt had a partial remission at end of study (EoS), 2 (18%) pts had a stable disease after the first cycle and PD (progressive disease) at EoS. 7 (63%) pts had a PD after the first cycle and were not further treated. 1 (9%) pt had to be replaced. To date, no therapy related serious adverse event was detected and consequently the MTD is not yet reached. All adverse events (AE) were transient and completely reversible. Most frequent AEs were fatigue (11/11), gastrointestinal disorders (10/11), pyrexia (8/11) and cephalgia (8/11). Single doses up to 300$\mu$g were well tolerated in this dose scheme (total dose up to 800 $\mu$g per cycle). All pts showed a transient decrease of the CD3+lymphocyte count 24h after infusion. 3/4 analyzed pts developed an anti-tumor immune response demonstrated by the induction of either anti-HER2/neu-abs (3/3) or anti-EpCAM-abs (1/3). **Conclusions:** Doses up to 300$\mu$g were safely administered in an escalating dose scheme. First signs of efficacy with mild and reversible AEs warrant further increasing of dosing. The development of anti-HER2/neu and anti-EpCAM abs suggests the promotion of an immunologic memory. Clinical trial information: NCT01569412.

**3056 General Poster Session (Board #123), Sun, 8:00 AM-11:45 AM**

**Effect of interferon-$\alpha$ on redirected T-cell killing of pancreatic and gastric cancers.** *Presenting Author: David M. Goldenberg, Center for Molecular Medicine and Immunology, Morris Plains, NJ*

**Background:** Trop-2 is highly expressed in diverse epithelial cancers with limited presence on normal tissues. (E1)-3s is a T-cell redirecting trivalent bsAb, which comprises an anti-CD3 scFv covalently linked to a stabilized dimer of a Trop-2-targeting Fab (Rossi et al., *mAbs*, 2014; 6(2), in press). IFN$\alpha$ has demonstrated clinical efficacy in multiple solid cancers, and is approved for melanoma, Kaposi sarcoma and various hematologic cancers. We studied the effects of IFN$\alpha$ on (E1)-3s-mediated T-cell killing of gastric and pancreatic cancer cell lines. **Methods:** DOCK-AND-LOCK was used to link an anti-CD3 scFv to a stabilized Fab dimer of the humanized anti-Trop-2 mAb, hRS7. T-cell activation, cytokine induction and cytotoxicity were evaluated ex vivo using PBMCs or purified T cells with NCI-N87 gastric cancer as target cells. In vivo activity was assayed with NCI-N87 and Capan-1 (pancreatic) xenografts. **Results:** In presence of target cells and PBMCs, (E1)-3s did not cause excess cytokine production. When combined with (E1)-3s, peginterferonalfa-2a, which alone did not increase T-cell activation or raise cytokine levels over baseline, enhanced T-cell activation, but did not significantly increase cytokine induction. In vitro, (E1)-3s mediated a highly potent ($IC_{50}$=0.37 pM) T-cell lysis of NCI-N87 target cells. Inclusion of peginterferonalfa-2a potentiated the activity of (E1)-3s, improving the $IC_{50}$ (0.14 pM) by more than 2.5-fold ($P$=.0001). A more potent form of IFN$\alpha$, 20*-2b, enhanced the potency of (E1)-3s by more than 7-fold ($IC_{50}$=0.05 pM; $P$<.0001). In vivo, combining peginterferonalfa-2a with (E1)-3s delayed Capan-1 tumor out-growth longer than each single agent ($P$<0.0007, log-rank), with all animals cured in the combination group (MST>57 d), versus 18% and 14% in the (E1)-3s (MST=50 d) and peginterferonalfa-2a (MST=53 d) groups, respectively. Combination therapy delayed tumor out-growth of NCI-N87 compared to (E1)-3s or peginterferonalfa-2a single-treatment groups (MST>66 vs. 49 or 35 days, respectively; $P$<0.0094). **Conclusions:** T-cell-mediated killing of Trop-2-expressing pancreatic and gastric cancer was effectively induced by (E1)-3s and enhanced significantly with IFN$\alpha$.

**3057 General Poster Session (Board #124), Sun, 8:00 AM-11:45 AM**

**A systematic review of immune-related adverse event (irAE) reporting in clinical trials of immune checkpoint inhibitors (ICIs).** *Presenting Author: Wei-Wu Chen, Drug Development Program, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

**Background:** ICIs are active in various solid tumors. irAEs are associated with ICI therapy that can affect multiple organ systems. Limited data exist regarding the quality of irAE reporting in ICI clinical trial publications. **Methods:** A systematic search of citations from MEDLINE, EMBASE and Cochrane databases identified prospective clinical trials involving ICIs in advanced solid tumors from 2003-2013. A 21-point (pt) (title, abstract, introduction 3 pts; methods 6 pts; results 9 pts and discussion 3 pts) quality score (QS) was adapted from the CONSORT harms extension statement. Items included in the 21-pt QS addressed: methods of irAE assessment; duration of irAE evaluation; time of onset, management, and resolution of irAEs; and consistency of safety reporting with authors' conclusion. Two reviewers independently scored all trials and differences were resolved by consensus. Linear regression was used to identify factors associated with quality reporting. **Results:** After review of 2628 articles, 50 trial reports were included (50% phase I, 38% phase II, 6% phase III, and 6% not specified) with ICIs as monotherapy (52%) or combination treatments (48%). The median QS was 11.25 pts (range 3.5-17.5 pts). The median grade 3/4 toxicity rate reported was 20.5% (range 0-66%) and 29/50 (58%) of trials concluded that irAEs were tolerable. Of these 29 studies, 5 had grade 3/4 toxicity rates that exceeded 33%. Thirteen (26%) studies did not report any details on the outcome of irAEs and 22% did not provide information on how irAEs were managed. Six trials concluded that the ICI tested had reversible or manageable irAEs without presenting any data on irAE treatment or resolution. Multivariate regression analysis revealed that year of publication (within last 5 years) and journal impact factor >15 were significantly associated with a higher QS (p=0.002 for both). **Conclusions:** The reporting of irAEs due to ICIs is often incomplete. A standardized reporting method of irAEs that accounts for tolerability, management and reversibility is needed to ensure completeness and transparency of published trial data. This would enable a more precise evaluation of the therapeutic risk benefit ratio of ICIs.

**3058 General Poster Session (Board #125), Sun, 8:00 AM-11:45 AM**

**Antitumor efficacy of poxvirus-based active immunotherapy alone and in combination with subtherapeutic dosing with immune checkpoint inhibitors.** *Presenting Author: Susan P Foy, Bavarian Nordic Inc., Mountain View, CA*

**Background**: PROSTVAC PSA-targeted immunotherapy for metastatic castration-resistant prostate cancer is being tested in the PROSPECT phase 3 trial. Another poxvirus-based immunotherapy product, MVA-BN-HER2, was tested in early phase clinical trials for breast cancer. We hypothesized that active immunotherapy in combination with immune checkpoint inhibitors (ICI) CTLA-4, PD-1, PDL-1, or LAG-3 would yield significant synergistic benefit for anti-tumor efficacy in non-clinical models compared to any approach alone. Due to toxicities that are associated with some high dose ICI regimens that provide clinical benefit, we tested poxvirus-based immunotherapy combined with lower dose ICI regimens for anti-tumor efficacy. **Methods**: In therapeutic CT26-HER2 solid and metastatic tumor models, mice were administered MVA-BN-HER2 immunotherapy alone or in combination with single and double CTLA-4, PD-1, PD-L1, or LAG-3 ICI regimens. Dose regimens (10, 3, and 1 mg/kg) of ICIs alone and in combination with targeted active immunotherapy were also evaluated. **Results:** Synergistic benefit for anti-tumor efficacy in therapeutic mouse models was observed with various regimens combining poxvirus-based active immunotherapy with single and double ICI dosing. Complete tumor regression resulted from combining MVA-BN-HER2 immunotherapy with anti-PD-1 plus anti-LAG-3. In addition, ICI dose reduction retained significant improvement in survival in combination with MVA-BN-HER2 poxvirus active immunotherapy, even at 1 mg/kg dose. When given without MVA-BN-HER2, ICIs were ineffective at improving survival in lower dose regimens. **Conclusions**: Overall survival following poxvirus-based active immunotherapy shows synergy with single and dual combinations of ICIs in solid and metastatic tumor models. Lowering ICI doses to sub-therapeutic benefit levels still yields survival benefit when combined with poxvirus-based immunotherapy. Therefore, combination therapy of reduced-dose ICIs with poxvirus-based active immunotherapy is predicted to support improved clinical benefit, safety and tolerability over ICI therapy alone.

**3059 General Poster Session (Board #126), Sun, 8:00 AM-11:45 AM**

**Pretreatment serum levels of circulating myeloid-derived suppressor cells (MDSC) as a prognostic indicator in patients with gastrointestinal cancer.** *Presenting Author: Masahiko Shibata, Saitama Medical University, Saitama, Japan*

**Background:** A suppression of cell mediated immunity and malnutrition are commonly seen in patients with advanced cancer and it has been reported that chronic inflammation plays a key role in induction of these conditions. We have reported that MDSC: myeloid-derived suppressor cells, found as a new type of immune suppressor cells that is closely related to chronic inflammation, is increased in patients with various types of cancer including gastrointestinal, hepatopancreatic, breast, thyroid and ovarian cancers, and the levels of MDSC were closely related to systemic inflammation, immunosuppression and nutritional impairment. **Methods:** Peripheral blood mononuclear cells (PBMC) were collected from 123 preoperative patients with gastrointestinal cancer including 18 patients with esophageal, 43 with gastric, 62 with colorectal cancers, and these cells were used for the detection of MDSC (CD11b+CD14-CD33+) by flow cytometry. The circulating levels of MDSC were divided with 1.02% of PBMC which is the median level in healthy volunteer, and the prognosis of these patients was analysed with Kaplan-Meier method. **Results:** In patients with stage IV disease, the overall survival (OS) was significantly shorter (p<0.05) in patients with high MDSC levels than in those with low MDSC levels. Although in patients with high MDSC levels, both of OS and DFS (disease free survival) of the patients with stage IV diseases were shorter (both p<0.001) than those with stages I, II, and III diseases, there were no significant difference in those with low MDSC levels. Furthermore, in patients with colorectal cancer, the OS was shorter in stage IV patients with high MDSC levels than in stage IV patients with low MDSC levels. However, OS was not significantly different with MDSC levels in patients with Stages I, II, and III diseases. **Conclusions:** Therefore, the pretreatment levels of MDSC is effective as a good prognostic indicator especially in patients with advanced gastrointestinal cancers.

**3060 General Poster Session (Board #127), Sun, 8:00 AM-11:45 AM**

**Long-term survival benefit from ipilimumab treatment in metastatic uveal melanoma patients.** *Presenting Author: Mugdha Anand Deo, Universite Catholique de Louvain, Brussels, Belgium*

**Background:** Uveal melanoma is the most common intraocular malignant tumor with an incidence of approximately 5 cases per million per year. Around 50% of the patients relapse after a curative-intended local treatment. Liver metastasis is the most common site of recurrence. The standard treatment is a systemic chemotherapy with an alkylating agent but does not show an overall survival benefit. In this study, we assessed the overall survival benefit from ipilimumab treatment in metastatic uveal melanoma (MUM) patients based on its success in improving overall survival in cutaneous melanoma patients. **Methods:** A retrospective analysis was performed at the Cliniques Universitaires Saint-Luc to assess the long term survival benefit from ipilimumab treatment in previously treated MUM patients. The patients progressing after a first-line chemotherapy were sequentially included if their ECOG score was $\leq 2$. They received 3mg/kg of ipilimumab every 3 weeks with the median cycle number of 3.92. Tumor response was assessed every 3 months using CT scan according to RECIST. Progression free survival (PFS), overall survival (OS) and objective response (OR) were calculated using Kaplan-Meier and median duration of follow-up was calculated by univariate analysis. **Results:** Twenty-four previously treated MUM patients were included in this analysis. No OR was observed in 23 (96%) patients, while 1(4%) patient showed a late partial response after 9 months. Four (17%) patients showed a stable disease lasting $\geq 3$ months. With a median follow-up of 7.3 months, the median PFS was 2.8 months. The median OS was 9.7 months and OS rates at 12 and 24 months were 45.6% and 11.4%, respectively. **Conclusions:** Our findings confirm the very low response rate of ipilimumab in MUM patients. However, this drug has a clear benefit in increasing the overall survival for some patients than that obtained with standard chemotherapy. Most of the published data assessing the efficacy of ipilimumab in ocular melanoma are focused on response rate and median overall survival. We do think that looking at the survival rate at 1-2 years is more relevant to assess the efficacy of ipilimumab. How to select patients benefiting from ipilimumab remains a challenge.

**3061 General Poster Session (Board #128), Sun, 8:00 AM-11:45 AM**

**Phase I trial of ImmunoBody in melanoma patients.** *Presenting Author: Poulam M. Patel, University of Nottingham, Nottingham, United Kingdom*

**Background:** ImmunoBody is a DNA vaccine encoding a human IgG1 antibody with T cell epitopes grafted into its CDR regions. SCIB1 has 3 epitopes grafted from gp100 and one from TRP-2 antigens. The vaccine targets dendritic cells in vivo and stimulates high avidity T cells which result in elimination of established tumors in pre-clinical models. A clinical trial was conducted to determine safety and its ability to induce cellular immune responses. **Methods:** The vaccine was administered via Intramuscular injection with electroporation at 3 weekly intervals for 3 vaccinations, then at 3 and 6 months. In part 1 of the study,one patient with Stage III and 8 with stage IV melanoma were given escalating doses of SCIB1. The 4mg dose was selected for an expansion cohort (part 2) in fully resected patients, 8 with stage III and 6 with stage IV melanoma. Due to lack of toxicity a five further patients with stage IV M1b disease were given 8mg doses. **Results:** No dose-limiting toxicities were observed. The most common adverse event was injection site pain. 4/6 patients in the 2mg/4mg cohorts who received $>3$ doses of SCIB1, are still alive with a median survival time of 26 months. One patient had multiple tumor lesions which all decreased in size or disappeared following treatment except for one lesion which was resected. Immunohistochemistry demonstrated strong expression of PD.L1 on the tumor cells. All patients in part 2 remain alive and only three have progressed. The median survival time in Part 2 is 17 months from study entry and 22 months from diagnosis of metastatic disease. In part 1, one patient in the 0.4mg cohort, all three patients in the 2mg dose cohort and two patients in the 4mg dose cohort mounted an immune response to the vaccine-encoded antigens. 4/5 patients in the 8mg cohort made a $\gamma$IFN elispot response after T cell expansion in-vitro with frequencies exceeding 2% of blood lymphocytes. In part 2, all 14 patients responded immunologically. Six patients responded to all 4 epitopes, five patients responded to 3 epitopes and 3 patients responded to 2 epitopes. **Conclusions:** We demonstrate that SCIB1 is safe. Of 25 evaluable patients, 23 have shown immune responses following repeat dosing with 2 -8 mg of SCIB1. Detection of an objective clinical response and overall survival times are encouraging. Clinical trial information: NCT01138410.

**3062 General Poster Session (Board #129), Sun, 8:00 AM-11:45 AM**

**$\gamma\delta$ T cells in combination with Newcastle disease virus and dendritic cell therapy as a novel immunotherapeutic approach in treating of advanced lung cancer.** *Presenting Author: Jan Nesselhut, Praxisgemeinschaft fuer Zelltherapie, Duderstadt, Germany*

**Background:** $\gamma\delta$ T cells represent a minority white cell in blood, which expand dramatically in acute infections. $\gamma\delta$ T cells recognize antigens usually in a non-MHC-restricted fashion. A number of trials have shown that epithelial tumors were susceptible to $\gamma\delta$ T cell lysis. A combination of $\gamma\delta$ T cells with other cell based immune therapies such as Newcastle disease virus (NDV) or dendritic cell therapy (DC) may enhance their therapeutic efficacy. **Methods:** Peripheral blood mononuclear cells (PBMC) were isolated from 200 ml whole blood for treatment of n=6 patients with advanced metastatic lung cancer. $\gamma\delta$ T cells were expanded ex vivo with an amino –bisphosphonate (5 mM Zometa) and IL-2 (100 U/ml). After 10 to 12 days,$\gamma\delta$ T cells were harvested by MACS techniques. Purity and activity were analyzed by flow cytometry. $\gamma\delta$ T cells was administered to patients intravenously at monthly intervals. Additionally, patients receive a treatment with NDV and DC one day prior to the $\gamma\delta$ T cell application. **Results:** The mean percentage of $\gamma\delta$ T cells within the isolated PBMC was 2.3%. After in-vitro expansion the mean percentage increased to 70% with expansion rates up to 268 fold. Further purification by MACS leads to a mean percentage of 92% (highest 99.6%). The mean number of infused $\gamma\delta$ T cells was $3.82 \times 10^8$ for each treatment. Patients are 2-12 months under treatment to date. 2 patients had disease stabilization and are still alive (8 and 11 months). Another patient with bilateral SCLC and liver metastases showed a complete remission of the lung lesions and a remission of the liver metastases after two treatment cycles and is still alive (12 months). **Conclusions:** $\gamma\delta$ T cells can be efficiently expanded and purified. A combination of DC based therapy, NDV and treatment with $\gamma\delta$ T cells may improve the clinical outcome for advanced lung cancer patients .

**3063 General Poster Session (Board #130), Sun, 8:00 AM-11:45 AM**

**Specific increase in T-cell potency via structure-based design of a T-cell receptor for adoptive immunotherapy.** *Presenting Author: Karolina Malecek, NYU Medical School, New York, NY*

**Background:** Adoptive immunotherapy with antigen-specific T lymphocytes is a powerful strategy for cancer treatment. However, most tumor antigens are non-reactive "self" proteins, which presents an immunotherapy design challenge. Studies have shown that tumor-specific T cell receptors (TCRs) can be transduced into normal peripheral blood lymphocytes, which persist after transfer in about 30% of patients and effectively destroy tumor cells. Still, recent clinical trial with affinity-enhanced TCRs has resulted in severe effects due to cross reactivity to an unrelated peptide. Thus, the challenge for targeted T cell therapy remains to increase T-cell potency in order to improve clinical responses and ensure on-target specificity by avoiding unwanted cross reactivity. **Methods:** We used structure based design to predict point mutations of a TCR (DMF5) that enhance its binding affinity for an agonist tumor differentiation antigen-major histocompatibility complex (pMHC), Mart-1(27L) HLA-A2, which elicits full T cell activation to trigger immune responses. Structural based approaches have been used to increase TCR affinity, however their potential cross-reactivity has not been reported. Here, we analyzed the effects of selected TCR point mutations alone and in combination on T cell activation potency. Further, we analyzed their specificity and cross-reactivity with related antigens presented by different melanoma cell lines and donor-derived antigen presenting cells. **Results:** Our structure-based approach allowed us to rationally design sequence substitutions that improve binding in contact areas between the TCR and pMHC without increasing cross-reactivity with a wide variety of self-antigens. We identified and evaluated point mutations in critical TCR positions resulting in more potent T cell activation but maintaining overall specificity. When double and triple combination mutations were introduced, they exhibited an additive enhancement that further improved T cell activation while retaining a high degree of specificity. **Conclusions:** Such affinity-optimized TCRs could potentially be used in adoptive immunotherapy to treat melanoma while avoiding adverse autoimmunity effects.

**3064 General Poster Session (Board #131), Sun, 8:00 AM-11:45 AM**

**Phase I open-label, multiple ascending dose trial of MSB0010718C, an anti-PD-L1 monoclonal antibody, in advanced solid malignancies.** *Presenting Author: Christopher Ryan Heery, Laboratory of Tumor Immunology and Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD*

**Background:** MSB0010718C is a fully human IgG1 monoclonal antibody targeting the coregulatory protein Programmed Death (PD)-Ligand 1 (PD-L1). PD-1/PD-L1 interactions induce T-cell anergy, protecting tumor cells from elimination by the immune system. MSB0010718C is expected to have antitumor activity by restoring immune system activity and through ADCC. **Objectives:** Assess the safety of MSB0010718C and determine its maximum tolerated dose, and analyze its pharmacokinetic (PK) profile and target receptor occupancy (RO). **Methods:** Twenty-seven patients (pts) with refractory malignancies have been enrolled and treated to date. Dose escalation (3+3 design) has been performed for 4 dose levels (1, 3, 10, and 20 mg/kg, q2w). After dose-level safety was determined, accrual of additional pts was allowed in order to generate additional safety, PK, and RO data. **Results:** Four, 11, 6, and 6 pts have been accrued to dose levels 1–4, respectively. Median pt age is 64 years (range 34–77), ECOG 0–1, with a median of 2 prior lines of therapy for metastatic disease (range 0–5). Eleven pts received prior immunotherapy (range 1–2 lines). Twenty-three pts have been followed for at least 4 weeks by Jan 7, 2014. To date, 12 pts (52.2%) have come off study: 9 (39.1%) for progression, 2 (8.7%) for adverse events (AEs), and 1 (4.3%) for death. Grade ≥3 AEs attributable to drug comprised laboratory abnormalities in 3 pts (2 pts with grade 3 AEs; 1 pt with a grade 4 AE). One DLT was observed in 1 pt at dose level 4: an immune-related AE with creatine kinase increase, myositis and myocarditis. Data from 25 pts were evaluable for PK and RO analysis. Median time to maximum concentration for all doses was approximately 1.5 to 2 h after infusion, with a linear PK. Half-life was 63.4, 80.7, 93.9, and 115.1 h for dose levels 1, 2, 3, and 4, respectively, as measured by ELISA. Target RO data were available for 13 pts, as measured by PD-L1 binding on peripheral leukocytes via flow cytometry. Mean RO prior to second infusion was 75.7, 93.8, and 93.2% for dose levels 1, 2, and 3, respectively. **Conclusions:** MSB0010718C can be safely administered in doses up to 20 mg/kg IV every 2 weeks. Clinical trial information: NCT01772004.

**3065 General Poster Session (Board #132), Sun, 8:00 AM-11:45 AM**

**A phase II, single arm clinical trial involving an alternative cancer treatment psorinum therapy in patients with metastatic renal cell carcinoma.** *Presenting Author: Aradeep Chatterjee, Critical Cancer Management Research Centre and Clinic, Kolkata, India*

**Background:** We prospectively studied the clinical efficacy of an alternative cancer treatment "psorinum therapy" in treating metastatic renal cell carcinoma (mRCC). **Methods:** Our study was phase II, open level, single arm and single stage. Participants' eligibility criteria included (1) pathological confirmation of the malignancy (2) metastatic disease status (3) no prior conventional cancer treatments (4) Karnofsky performance status between 40- 70%. The primary outcome measures of the study were (1) to assess the radiological tumor response rate (using CT scanning procedure and following the RECIST criteria; (2) to assess how many participants survived at least 1 yr, 2yrs, 3yrs, 4yrs and finally, after 5 years. The secondary outcome measure was to assess the side effects of the investigational anti-cancer drug (psorinum) if any. Psorinum (an alcoholic extract of scabies slough and pus cells) was administered orally at a dose of 0.04ml/ Kg body weight/ day as a single dose on an empty stomach for a complete course duration of 2 yrs to all the participants along with allopathic and homeopathic supportive cares. **Results:** 78 participants included in the final analysis at the end of the study. According to the RECIST criteria complete response occurred in 11 (14.10%) cases and partial response occurred in 29 (37.18%) cases. 64 (82.05%) of them survived at least 1yr, 48 (61.54%) survived at least for 2yrs, 41 (52.56%) survived at least 3yrs, 29 (37.18%) survived at least 4yrs, 24 (30.77%) survived at least for 5yrs. These participants didn't receive conventional or any other investigational cancer treatments. **Conclusions:** The results of the study show clinical efficacy of psorinum therapy in treating patients with mRCC. The investigational drug psorinum is non- toxic. Randomized controlled clinical trial should be conducted for further investigation of this alternative cancer treatment in treating metastatic renal cell carcinoma to integrate it into the mainstream oncology.

**3066 General Poster Session (Board #133), Sun, 8:00 AM-11:45 AM**

**Fynomer-antibody fusions targeting HER2 and CD3 for selective killing of HER2 overexpressing tumor cells.** *Presenting Author: Richard Woods, Covagen AG, Zurich-Schlieren, Switzerland*

**Background:** A promising approach in the immunotherapy of cancer is to recruit T cells to attack tumor cells using bispecific therapeutics targeting a tumor-associated surface antigen and CD3 on T cells. Such therapeutics elicit T cell mediated lysis of tumor cells independent of T cell specificity. Fynomers are small 7 kDa globular proteins derived from the SH3 domain of the human Fyn kinase (Fyn SH3) that can be engineered to bind with antibody-like affinity and specificity to virtually any target of choice. Fynomers can be fused to N-terminal and/or C-terminal ends of antibodies to generate bispecific therapeutics (FynomAbs) with tailored architectures. Here, we describe the generation and characterization of anti-CD3/HER2 FynomAbs. **Methods:** Using phage display technology we have isolated Fynomers binding to HER2. After genetic fusion of these Fynomers to anti-CD3 antibodies the resulting bispecific fusion proteins were evaluated for their anti-tumoral activity. **Results:** We have generated novel bispecific FynomAbs which can simultaneously bind HER2 on tumor cells and CD3 on T cells. The bispecific HER2/CD3 targeting FynomAbs potently redirect T cells to HER2 expressing tumor cells showing picomolar tumor cell lysis activity on multiple cell lines. The activity was found to be highly specific, as no lysis of cells was observed in the absence of HER2 expression. In addition, the FynomAbs demonstrate an antibody-like pharmacokinetic profile in mice, which may translate into a convenient administration route without the need for continuous infusion. **Conclusions:** FynomAbs represent an attractive platform to generate bispecific molecules and can be produced using standard antibody technology (GMP production yield of 3.3 g/L at 1000 L scale achieved). We show here the successful generation of bispecific T cell recruiting FynomAbs with antibody-like biophysical and pharmacokinetic properties that allow the redirection of T cells specifically to tumor cells.

**3067 General Poster Session (Board #134), Sun, 8:00 AM-11:45 AM**

**A phase I study with LTX-315, an immunogenic cell death inducer, in patients with transdermally accessible tumors.** *Presenting Author: Paal Brunsvig, Oslo University Hospital, Oslo, Norway*

**Background:** LTX-315, a chemically modified 9-mer peptide derived from naturally occurring membrane-active host defence peptides, induces the release of potent danger signals (i.e. HMGB1) and tumor-associated antigens from treated tumor cells. Preclinical animal studies have demonstrated that treatment of a single tumor with LTX-315 generated a systemic anti-tumor immune response that eradicated distant lesions and prevented reoccurrence following tumor rechallenge. A phase I dose escalating open label, single centre study was designed to evaluate safety profile and determine recommended dose as measured by assessment of adverse events, laboratory values and tumor necrosis. Immunological responses to the injections were exploratory endpoints. **Methods:** Patients received weekly ultrasound guided injections of LTX-315 into a single tumor for a maximum of six injections. Cohorts 1 and 2 received 10% of the tumor volume until DLT or ≥ 50% necrosis of target tumor was observed. In cohort 3, a fixed dose of 4 mg was injected. **Results:** Fourteen patients with lymphomas, malignant melanomas or breast cancer were enrolled. The main safety issue was primarily flushing and transient hypotension related to the dose of study drug and independent of tumor type. Two patients experienced a DLT (hypotension grade 3 and 4). Tumor necrosis was seen in 5 patients. Two of the patients had a reduction in tumor volume ≥ 50%. Tissue necrosis and presence of tumor infiltrating lymphocytes (TILs) was observed in a breast cancer tumor. **Conclusions:** Based on the safety information it seems as LTX-315 is causing reactions that can be controlled by limiting the dose injected into the tumor; dosages ≤ 4.0 mg are well tolerated. The signs of tumor necrosis, presence of TILs and tumor regression without accompanying severe reactions confirms the rationale and the potential benefit of intratumoral injections with LTX-315. A new intratumoral study with LTX-315 at four European sites is ongoing with detailed characterization of immune response. Clinical trial information: NCT01058616.

**3068^ General Poster Session (Board #135), Sun, 8:00 AM-11:45 AM**

**First-in-human study of MM-141: A novel tetravalent monoclonal antibody targeting IGF-1R and ErbB3.** *Presenting Author: Steven J. Isakoff, Massachusetts General Hospital Cancer Center, Boston, MA*

**Background:** MM-141 is a novel tetravalent bi-specific monoclonal antibody that binds IGF-1R and ErbB3, and blocks both ligand dependent and independent IGF-1R/ErbB3/PI3K/AKT/mTOR signaling. In preclinical xenograft models, MM-141 was more active than a combination of anti-ErbB3 and anti-IGF-1R monoclonal antibodies. MM-141 potentiated the activity of gemcitabine, paclitaxel, docetaxel, tamoxifen, and everolimus. These results support the clinical development of MM-141 and a multi-arm Phase 1 study is underway. The completed monotherapy arm of this trial will be reported **Methods:** This is a Phase 1 dose-escalation study evaluating safety, tolerability, pharmacokinetic (PK), and pharmacodynamic (PD) properties of MM-141 as monotherapy (Arm A, n=15) and in combination with everolimus (Arm B) or with nab-paclitaxel and gemcitabine (Arm C). Patients in Arm A were dosed in a "3+3" design at weekly doses of 6 mg/kg (n=3), 12 mg/kg (n=4), or 20 mg/kg (n=4), or at biweekly doses of 40 mg/kg (n=4). Doses were escalated until the maximum tolerated dose (MTD) was identified, or until MM-141 was shown to be tolerable at the highest planned dose. **Results:** Arm A enrolled 15 patients with advanced solid tumors into the dose escalation portion of the study. No dose-limiting toxicities were observed at weekly dose levels of 6mg/kg, 12mg/kg, and 20mg/kg, or at the biweekly dose of 40mg/kg. Adverse events, regardless of relationship, that were reported with a frequency >15% included: vomiting (7/15), nausea (6/15), fatigue (4/15), abdominal pain (4/15), increased AP (4/15), dyspnea (4/15), diarrhea (3/15), anemia (3/15), increased AST (3/15), and rash (3/15). The safety, tolerability, PK and PD profile support weekly and biweekly MM-141 dosing. Detailed PK and PD data will be presented for all cohorts. Disease stabilization was observed in patients with Ewing's Sarcoma (1) and parotid gland carcinoma (1). An expansion cohort at a weekly dose of 20mg/kg (Arm D) is ongoing in patients with hepatocellular carcinoma. Data summarized here are from a data lock at 01/15/2014. **Conclusions:** A recommended dose level for MM-141 on each of weekly and bi-weekly schedules was established. Clinical trial information: NCT01733004.

**3069 General Poster Session (Board #136), Sun, 8:00 AM-11:45 AM**

**Regulatory T-cell inhibition plus antitumor immunotherapy targeted against cytomegalovirus (CMV) in patients with newly diagnosed glioblastoma multiforme (GBM).** *Presenting Author: Gordana Vlahovic, Duke University Medical Center, Durham, NC*

**Background:** Despite aggressive surgery, high-dose focused radiation, and toxic, multimechanistic chemotherapy, malignant gliomas (MG) remain almost universally fatal. The inherent biologic specificity of immunotherapy offers the prospect of targeting neoplastic cells more precisely. Dendritic cells (DCs) are endowed with an extraordinary ability to activate CD4+ and CD8+ T-cells, and DCs loaded with antigens derived from tumor cells (CMV pp65-LAMP mRNA) have the potential to induce potent antitumor immunity. Furthermore, regulatory T-cells (TRegs) which induce a state of reversible immunosuppression in MG and can be functionally inactivated with anti-CD25 antibody (Ab), while dramatically enhancing vaccine-induced immune responses. **Methods:** Eligible were gross totally resected patients (pts) with newly diagnosed GBM. Pts underwent leukapheresis followed by standard of care radiation/temozolomide (XRT/TMZ) therapy. After completion of XRT/TMZ, up to 12 cycles of TMZ 200 mg/m2/x5d were administered. Around Day 21 of the 1st cycle pts also received: anti-CD25 Ab treatment, vaccine #1, and non-specific autologous lymphocyte transfer (ALT). Vaccines #2 and #3 were given biweekly following vaccine#1. A 2nd leukapheresis was conducted prior to the 2nd cycle of TMZ. On Day 21 of the 2$^{nd}$TMZ cycle Vaccine #4 was administered. Pts were followed with serial MRIs until disease progression. **Results:** 7 patients (5 males) were treated. No adverse events attributable to vaccine treatment were observed. Median progression free survival was 23.5 months (95% CI:1.7 to 54.1). Median overall survival was 30.3 months (95% CI:11.8 to 60.8). Overall survival was calculated from the start of vaccine therapy to time of death or last contact if alive. **Conclusions:** Treatment with XRT/TMZ, DC vaccine and anti- CD25 Ab was well tolerated and results are promising. Due to the lack of adverse events, the protocol has been amended for future patients in this ongoing study. The number of vaccines had been increased to 8 (vs. 4) and anti-CD25 antibody is being given with the first two cycles (vs. with 1$^{st}$ cycle only) of adjuvant TMZ. Clinical trial information: 00626483.

**3070 General Poster Session (Board #137), Sun, 8:00 AM-11:45 AM**

**Development of a personalized cellular ex vivo CBL-b silencing cancer immune therapy.** *Presenting Author: Marc Oliver Salzberg, Apeiron Biologics AG, Vienna, Austria*

**Background:** The E3 ubiquitin ligase cbl-b has been identified as an important gatekeeper limiting T cell activation. Concordantly, the immune system of cbl-b deficient mice can effectively fight tumors, thereby validating cbl-b as an excellent target to enhance anti-tumor immune activity. We have recently shown in proof-of-concept experiments that transfer of transiently cbl-b silenced murine T cells had efficacy to enhance the anti-tumor immune response in mouse models. **Methods:** A design algorithm was used to screen for siRNAs that are highly effective to silence cbl-b, and the optimized siRNA was produced at a GMP manufacturer. PBMCs were isolated from healthy donors or cancer patients, transfected with siRNA by electroporation and immune cell phenotype and activation was determined by FACS and ELISA. For enhancement of DC vaccination responses, PBMCs were ex vivo silenced, and co-administrated with the DC preparations intranodally to the cancer patient. **Results:** We have established a highly efficient transfection protocol using a commercial electroporation device enabling us to simultaneously transfect T, B, NK cells and monocytes with minimal cell damage. Using this protocol, we have identified a siRNA that was able to shut down cbl-b expression for more than 7 days in stimulated human T cells, resulting in strong enhancement of T cell activation, cytokine production and proliferation. Moreover, simultaneous silencing of cbl-b in all immune cells of the PBMCs yielded additional advantages, most notably enhancing NK cell reactivity against tumor cell and IL-2 stimulation. Silencing of cancer patient PBMCs yielded similar results ex vivo and intranodal transfer of autologous cbl-b silenced cells together with activated DCs to patients with advanced cancers was feasible and well tolerated. **Conclusions:** To enable the clinical implementation of a cbl-b ex vivo silencing treatment, we have established and tested a protocol that can be easily performed on any clinical unit that applies adoptive cell therapies to patients. Based on these results, a Phase I trial for the systemic administration of cbl-b silenced PBMCs to patients with advanced cancers will be initiated.

**3071 General Poster Session (Board #138), Sun, 8:00 AM-11:45 AM**

**NY-ESO-1 specific CD4$^+$ $T_{helper}1$ cells for immunotherapy of cancer.** *Presenting Author: Simone Kayser, University Children's Hospital, Tübingen, Germany*

**Background:** NY-ESO-1 is an attractive target for adoptive T cell transfer (ACT) as it is expressed on a variety of tumors, but not in normal tissue except germline cells. Immune attack against cancer is mediated by cell lysis or induction of growth arrest through paralysis directly in tumor cells. The latter can be achieved by CD4$^+$, IFN-$\gamma$-producing $T_{helper}1$ (Th1) cells. Translation of this immune mediated mechanisms into clinical application has been limited by complex in vitro protocols and regulatory hurdles. **Methods:** We established a short protocol according to good manufacturing practice (GMP) to generate NY-ESO-1 specific T cells with focus on Th1 cells. After presensitization with overlapping NY-ESO-1-peptides, IL-2 and IL-7, T cells were enriched based on IFN-$\gamma$ capture technique. Cells were expanded using autologous feeder cells and IL-2, IL-7 and IL-15 and T-cell specificity and function was analyzed. **Results:** Large numbers of specific NY-ESO-1 CD4$^+$ T cells with a Th1 cytokine profile and lower numbers of cytokine secreting CD8$^+$ T cells could be generated with a sustained expansion potential. Manufactured CD4$^+$ T cells show strong specific responses with IFN-$\gamma^+$, TNF-$\alpha^+$ and IL-2$^+$ and induce growth arrest and apoptosis in tumor cells. The T-cell products did not include alloreactive or regulatory T cells. Specificity was confirmed with a new identified MHC class II matched NY-ESO-1 derived peptide and recognition of processed NY-ESO-1 Protein was demonstrated. **Conclusions:** Adoptive T-cell transfer by a novel cancer treatment-approach with tumor-antigen specific CD4$^+$ Th1 lymphocytes can be performed to boost anti-cancer immunity and is feasible with T cells from healthy allogeneic donors as well as with autologous T cells from cancer patients. The T-cell generation process was approved by the regulatory authorities. Due to the frequent expression of NY-ESO-1 in tumors the therapy is applicable to a large patient collective in different cancer entities.

**3072 General Poster Session (Board #139), Sun, 8:00 AM-11:45 AM**

**A phase Ib/IIa study of NEO-102: A therapeutic antibody for the treatment of advanced pancreatic and colorectal cancer.** *Presenting Author: Sandip Pravin Patel, Duke University Medical Center, Durham, NC*

**Background:** We have developed a chimeric monoclonal antibody (mAb) that targets a variant of MUC5AC that is expressed specifically by human pancreatic (P) and colorectal (C) tumors with minimal reactivity to normal GI mucosa. In the phase (ph) I trial of the initial formulation NEO-101, 5/19 patients (pts) had stable disease (SD) after completing their 1st course of treatment (tx) (4 doses) and overall survival (OS) of >12 months (mos) observed in 3 C and 2 P pts despite disease progression on standard (std) of care tx regimens. The current study utilizes NEO-102, a glycoengineered form of NEO-101 with improved stability and decreased RBC agglutination. **Methods:** A Ph Ib/IIa open label, multi-center dose-escalation clinical trial with NEO-102 is enrolling pts with advanced P and C cancer refractory to std therapy. NEO-102 is administered every 2 weeks with initial restaging at 8 weeks (after 4 doses) and every 8 weeks after if no progression. Primary objectives: measure efficacy by analysis of CT scans using RECIST criteria, OS, laboratory tests, and physical examination. Secondary objectives: determine safety and tolerability of escalating doses of NEO-102; assess pharmacokinetics (PK) and select immune responses to the mAb. Analyses of pt PBMCs for ADCC and immune cytokine profiling are underway to assess for immunologic outcome and for correlation with clinical benefit. **Results:** 12 pts are evaluable for toxicity (10 C, 2 P) and no DLT has been encountered. Grade 3 adverse events possibly related to NEO-102 are diarrhea and anemia. 8 pts are evaluable for efficacy at day 57, with 5 patients with SD (4/6 C, 1/2 P) and 3 with PD. The maximum number of doses administered is 9+ and the median duration of treatment has been 56+ days (Range 29-131+). **Conclusions:** Preliminary results with NEO-102 mAb have demonstrated signs of clinical activity based on stabilization of disease in heavily pretreated pts with P and C cancer. Safety has been established at the 3 mg/kg dose level and patients are currently being accrued to the 4 mg/kg dose level. If no DLT is observed at the current dose level, we will proceed with 4mg/kg as the dose utilized for expansion cohorts in P (30 pts) and C (40 pts). Clinical trial information: NCT01040000.

**3073 General Poster Session (Board #140), Sun, 8:00 AM-11:45 AM**

**Phase II trial evaluating HER2 targeted activated T cells in advanced HER2 low expressing breast cancer patients.** *Presenting Author: Deepa Bai Jagtap, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

**Background: :** Despite improvements in the treatment of metastatic breast cancer (MBC), there are no curative treatment options. Anti-CD3 monoclonal antibody (mAb) activated T cells (ATC) armed with anti-CD3 x anti-HER2 bispecific antibody (HER2Bi) exhibit anti-HER2 cytotoxicity, proliferate, and secrete immunokines upon tumor engagement. Here we report preliminary results of a phase II immunotherapy trial in which 29 HER2 low expressing(0- 2+) patients (pts) with advanced breast cancer who received infusions of HER2Bi armed ATC (aATC) . Pts were evaluated for time to progression (TTP), overall survival (OS), and immune responses as end points. **Methods:** Peripheral blood mononuclear cells (PBMC) obtained by leukapheresis were activated with anti-CD3 mAb and expanded with IL-2. aATC were harvested, armed with HER2Bi and cryopreserved in aliquots with a target dose of ≥ 48 billion cells. Pts received oncologist's choice of chemotherapy (4 cycles or 4 months) followed by 3-4 infusions of aATC. A subset of 5 pts received 250 mg/m$^2$cyclophosphamide to create immunologic space prior to aATC infusions. The median age was 53.5 yrs (range 29-75yrs) with 59% of pts over the age of 50yrs. **Results:** Nineteen pts were ER positive and had received ≥ 2 lines of endocrine therapy and 16 out of 19 ER positive pts had also received at least 2 lines of chemotherapy for MBC . The overall response rate was 31% defined as stable disease . Anti-tumor immune responses were detected in these pts. The K-M curve for all of the pts who received armed ATC reveals a median OS of 16.7 months (from enrollment). In pts who were evaluable (received ≥ 48 billion aATC), 5 of 16 (31%) were stable at 4 months after all aATC infusions. In pts who received < 48 billion aATC, 2 of 8 (25%) pts were stable at 4 months after aATC infusions. Six severe adverse events (grade ≥3), were documented as probably or definitely related to infusions, in 5 different patients. **Conclusions:** These clinical results suggest that targeting the high risk HER2 low expressing tumors by this approach may provide survival benefit without excessive toxicity. Clinical trial information: NCT01022138.

**3074 General Poster Session (Board #141), Sun, 8:00 AM-11:45 AM**

**An adoptive immunotherapy approach for colorectal cancer (CRC) patients.** *Presenting Author: Marco Bregni, Ospedale di Circolo, Busto Arsizio, Italy*

**Background:** Adoptive T-cell transfer (ACT) refers to an immunotherapeutic approach in which anti-tumor T lymphocytes are identified, grown *ex vivo* and re-infused into the cancer patients. This strategy was successfully applied in metastatic melanoma and renal cell carcinoma. However, adoptive immunotherapy do not play an important role in the treatment of advanced CRC. We developed an ACT protocol for CRC using as source of tumor antigens the irradiated primary CRC cell lines, captured by dendritic cells (DC) to stimulate *in vitro* a specific autologus activation of patient's T cytotoxic lymphocytes (CTL) against tumor. **Methods:** 78 CRC patients were enrolled. Tumor tissues were obtained at surgery, together with 100 ml of heparinized peripheral blood. Tumors were mechanically dissociated to a single-cell suspension and cultured to obtain a primary cell line from each patient. DCs were generated from monocytes, cultured with recombinant human Interleukin-4 and recombinant human Granulocyte- Macrophage Colony-Stimulating Factor for 6-7 days. Anti-tumor CTLs were elicited in co/micro-cultures using DCs, autologous apoptotic tumor cells and T CD8+ lymphocytes enriched effectors, in presence of weakly irradiated T CD4+ lymphocytes, Interleukin 7 and Interleukin 12, with weekly stimulation. CTLs Interferon-$\gamma$ (IFN-$\gamma$) secretion was assessed by ELISpot assay. **Results:** Primary tumor cell lines were obtained from 20 out of 78 patients, with a success rate of 25,6%. DCs were generated from 26 patients, and 6 had the corresponding primary tumor cell line. Co/micro-cultures were set up for 6 patients. ELISpot results showed a strong and significant IFN-$\gamma$ secretion at the third, fourth and fifth stimulations for one patient and at the second for another patient, whereas for three patients a weak secretion was detected during the second and third stimulations. **Conclusions:** The percentage of success in the establishment of primary colon cell lines was higher than those reported in literature, although the intestinal flora adversely affected their obtainment. The generation of tumor-specific CTLs could be useful for supporting an ACT approach in CRC.

**3075 General Poster Session (Board #142), Sun, 8:00 AM-11:45 AM**

**Long-term follow up for a phase I trial HER2/neu-targeted T cells in women with advanced breast cancer.** *Presenting Author: Lawrence G. Lum, Karmanos Cancer Institute, Wayne State University, Detroit, MI*

**Background:** Anti-CD3 x anti-Her2 bispecific antibody (Her2Bi) retargeting transforms activated T cells (ATC) into non-restricted MHC specific cytotoxic T cells. This study reports a phase I immunotherapy trial beginning in 2001 (NCT00027807) in 23 women with Her2 0-3+ metastatic breast cancer consisting of 8 infusions of HER2Bi armed ATC (aATC) in combination with interleukin 2 (IL-2) and granulocyte-macrophage-colony stimulating factor to evaluate safety, feasibility, time to progression, median overall survival (OS), T cell trafficking and immune responses. **Methods:** ATC were expanded in IL-2 after anti-CD3 stimulation of mononuclear cells obtained from leukapheresis. Groups of 3 patients (pts) received 5, 10, 20, or 40 x 10e9 aATC per infusion. **Results:** Total episodes of Grade III-IV side effects for 23pts in decreasing order were chills, headache, nausea/vomiting, back pain, hypertension, and death of 1 pt from congestive heart failure due to digoxin toxicity. aATC persisted in the blood for a week or more and trafficked to tumors. Twelve out of 22 (54.5%) had stable disease (SD) or better. OS was 36.2 months (m) for all pts, 57.4 m for Her2 3+ pts (n=7), and 27.4 m for Her2 0-2+ pts (n=16) with a median follow-up of 36.2 m. For pts with SD, the OS was 57.9 m in the HER2 3+ pts (n=4) and 40 m in the HER2 0-2+ pts (n=7). For pts with progressive disease (PD), OS was 36.6 m in the Her2 3+ pts (n=3) and 21.3 m in the Her2 0-2+ pts (n=9). There was 1 partial response. aATC infusions induced anti-tumor cytotoxicity that persisted >4 m, Th1 cytokines, and increases in IL-12 after 2 weeks. Phenotyping, imaging of In labeled aATC, and tumor biopsies show that aATC circulate > 96 hrs, localize and persist in tumors. **Conclusions:** aATC infusions are safe with manageable side effects. The OS of 36.2 m is encouraging in heavily pretreated pts. Targeting HER2 positive and negative tumors with aATC induced anti-tumor responses, increased Th1 cytokines, and IL-12 serum levels. The clinical responses suggest that aATC infusions may provide a survival benefit in pts with both stable and progressive disease. These results provide the rationale for conducting phase II trials. Clinical trial information: NCT00027807.

**3076 General Poster Session (Board #143), Sun, 8:00 AM-11:45 AM**

**A phase 1 study of MM-121 (a fully human monoclonal antibody targeting the epidermal growth factor receptor family member ErbB3) in combination with cetuximab and irinotecan in patients with advanced cancers.** *Presenting Author: James M. Cleary, Dana-Farber Cancer Institute, Boston, MA*

**Background:** ErbB3-EGFR heterodimers have been implicated in resistance to targeted and conventional therapies across multiple malignancies. **Methods:** This phase 1 trial assessed the safety, tolerability, and pharmacokinetic (PK) properties of MM-121 in combination with cetuximab (Part 1) or with cetuximab and irinotecan (Part 2) in patients (pts) with advanced solid cancers. Pts were dosed in a "3+3" design with escalating doses of MM-121 and cetuximab without (Pat 1) or with (Part 2) biweekly irinotecan. **Results:** Part 1 enrolled 34 pts with a median age of 60. Common (>25%) adverse events (AE) of any grade were: fatigue (64.7%), dermatitis acneiform (47.1%), hypomagnesemia (47.1%), diarrhea (44.1%), decreased appetite (32.4%) and hypokalemia (26.5%). One DLT was observed in the first cohort of Part 1 (G3 lung infection) and dose escalation was able to continue to the highest recommended doses of MM121 and cetuximab. One pts (CRC) had a complete response (CR), and three pts (NCSLC (2), cholangiocarcinoma) had a partial response (PR). Twelve pts had a best response of stable disease (SD). Part 2 enrolled 14 pts with a median age of 58. Common (>25%) AEs of any grade were: diarrhea (92.9%), hypokalemia (57.1%), nausea (50%), fatigue (42.9%), hypomagnesemia (37.5%), decreased appetite (35.7%), dermatitis acneiform (28.6%), mucosal inflammation (28.6%), dehydration (28.6%), and weight decrease (28.6%). Three DLTs were observed in Part 2: one at the first dose level (G3 diarrhea), and two at the second dose level (G3 mucositis with G4 neutropenia and G3 UTI, dehydration, and diarrhea with G4 neutropenia and cardiac arrest and G5 respiratory failure) and an MTD was reached. One CRC pts who previously had developed acquired resistance to cetuximab had a PR, and one pts had a best response of SD in Part 2 of the study. Mandatory pre- and post-treatment biopsies are analyzed to assess the PD correlates of response and resistance to this combination. **Conclusions:** The HER3 antibody, MM121, can be combined with cetuximab +/- irinotecan and had modest activity in a population of refractory solid tumor pts. Clinical trial information: NCT01451632.

**3077 General Poster Session (Board #144), Sun, 8:00 AM-11:45 AM**

**Survival effect of bi-shRNA$^{furin}$/GMCSF DNA-based immunotherapy (FANG) in 123 advanced cancer patients to $\alpha$-interferon-ELISPTOT response.** *Presenting Author: John J. Nemunaitis, Mary Crowley Cancer Research Centers, Dallas, TX*

**Background:** Over the last 3 years, follow up in a series of Phase I (study # CL-PTL-101) and phase II studies (study # CL-PTL-105, -107, -114, -110, -112) involving FANG (BB-IND 14205) have been performed involving 123 advanced cancer patients, most of whom previously failed prior systemic therapy. ELISPOT assay which quantitatively measures responding mononuclear cell $\gamma$IFN release to patient personal tumor was utilized to track immunotherapy activity. **Methods:** Sequential ELISPOT assessment utilizing patient blood mononuclear cells and autologous tumor tissue as antigen source (harvested prior to immune therapy) were measured at baseline and sequentially afterward. **Results:** Sixty-four advanced cancer patients received monthly intradermal injections of FANG and 53 had FANG constructed but elected other therapy (No FANG group). Median survival of FANG treated patients was 729 days vs. No FANG patients 260 days, p=0.001. Patients (4%) who were ELISPOT positive at baseline or before receiving FANG or who crossed over (1%) from No FANG to FANG as part of Phase II trial were excluded. Forty-seven patients received FANG and had sequential ELISPOT analysis. Thirty-five were ELISPOT positive, and 12 were ELISPOT negative. Median survival of the FANG ELISPOT positive patients was 995 days vs. 554 days of the ELISPOT negative patients (p=0.011). No significant toxic effect was demonstrated to FANG over the three year follow up period. Seventy-one percent of the ELISPOT positive FANG treated patients were alive at 2 years and 44% were alive at 3 years. By comparison, only 25% of the FANG treated patients who were ELISPOT negative were alive at 2 years and none have reached 3 year survival. **Conclusions:** Treatment with FANG demonstrates safety and suggests survival benefit in coordination with $\gamma$-interferon ELISPOT assessment. Randomized phase II assessment is ongoing. Updated results will be presented. Clinical trial information: NCT01061840, NCT01309230, NCT01505166, NCT01453361, NCT01867086, NCT01551745.

**3078^ General Poster Session (Board #145), Sun, 8:00 AM-11:45 AM**

**Ascending dose trials of a retroviral replicating vector (Toca 511) in patients with recurrent high-grade glioma.** *Presenting Author: Joan M. Robbins, Tocagen Inc., San Diego, CA*

**Background:** We are conducting ascending dose trials in subjects with High Grade Glioma (HGG, NCT01156584 and NCT01470794), using an investigational retroviral replicating vector (Toca 511, vocimagene amiretrorepvec). Toca 511 encodes an optimized yeast cytosine deaminase that converts 5-fluorocytosine (5-FC) to the anticancer drug 5-FU in infected tumors. Preclinical models provide support for a dual mechanism of action of Toca 511+5-FC that includes both direct killing of tumor by locally produced 5-FU, and induction of a local and systemic immunotherapeutic response resulting in: 1) long term survival after cessation of 5-FC treatment and 2) resistance to tumor re-challenge. **Methods:** Toca 511 is administered once, followed by repeat courses of oral Toca FC (an extended-release formulation of 5-FC). One trial employs direct intratumoral injection of Toca 511 and the other administration into the cavity wall after resection of a recurrent tumor. **Results:** Over 30 patients have been treated in each of these dose escalation trials with 6 and 5 viral dose levels respectively studied to date. Treatment at all dose levels has been well tolerated. Post-treatment resection in some patients showed viral protein and DNA and RNA sequences including the CD protein and gene, suggesting viral spread and persistence. MRI changes consistent with tumor regression and clinical improvements were observed in some patients post-Toca FC dosing. Pooled survival data in these ongoing studies show 82% (28/34) and 46% (13/28) survival at 6 months and 12 months, respectively. **Conclusions:** Completion of these studies is planned, including further dose escalation of Toca 511 and of Toca FC. A third ascending dose study, NCT01985256, in patients with HGG, will evaluate the safety and tolerability of Toca 511 injected intravenously followed by injections into the cavity wall after resection and repeated courses of Toca FC. The current studies provide evidence for the same dual mechanism of action noted in preclinical studies and survival data warrant investigation in a larger clinical trial. Clinical trial information: NCT01156584, NCT01470794, NCT01985256.

**3079 General Poster Session (Board #146), Sun, 8:00 AM-11:45 AM**

**Rapid cell expansion (RACE) technology for production of engineered autologous T-cell therapy: Path toward manageable multicenter clinical trials in aggressive NHL with anti-CD19 CAR.** *Presenting Author: Marc Better, Kite Pharma, Santa Monica, CA*

**Background:** Engineered autologous T cell therapy is proving to be a promising method to treat a variety of tumor types. An ongoing National Cancer Institute (NCI) Phase 1/2a study in patients with refractory B cell malignancies has been particularly encouraging, with data presented most recently at the ASH 2013 annual meeting. To prepare for Kite-sponsored multicenter trials, a rapid and compliant manufacturing process has been developed. Because refractory B cell malignancies can progress quickly, it is important to reduce the time between apheresis of patient PBMCs and administration of the engineered T cells. **Methods:** PBMCs from normal donors and patients with B cell malignancies were stimulated in vitro with anti-CD3 antibody in the presence of IL-2 to initiate T cell growth. The cells were then transduced with a gamma-retroviral vector containing an anti-CD19 CAR gene and propagated in culture to generate sufficient engineered T cells for administration. **Results:** We have developed a 6-day manufacturing process in serum-free media without the use of CD3/CD28 beads. Development studies have demonstrated in vitro analytical comparability to cells produced using an open system at the NCI. **Conclusions:** Kite in conjunction with the NCI Surgery Branch has developed a rapid and efficient proprietary process for the generation of anti-CD19 CAR cells. A Kite-sponsored multicenter clinical trial in patients with aggressive non-Hodgkin lymphoma using T cells generated by this new manufacturing process is expected to begin in early 2015.

**3080 General Poster Session (Board #147), Sun, 8:00 AM-11:45 AM**

**PROSTVAC, PSA-targeted immunotherapy: New evidence for mechanism of action.** *Presenting Author: Stefanie J Mandl, Bavarian Nordic Inc., Mountain View, CA*

**Background:** PROSTVAC is being tested for treatment of metastatic castration-resistant prostate cancer in the PROSPECT phase 3 trial. PROSTVAC immunotherapy comprises subcutaneous dosing in a heterologous prime-boost regimen with recombinant vaccinia virus (PROSTVAC-V) for priming plus recombinant fowlpox virus (PROSTVAC-F) for boosting doses. Both products encode transgenes for PSA as the target tumor antigen plus TRICOM (B7-1, ICAM-1 and LFA-3) to enhance immune activation. Data from clinical and nonclinical studies provide evidence for mechanism of action potentially leading to improved overall survival following PROSTVAC immunotherapy. **Methods:** Subjects from a randomized double-blind placebo controlled Phase 2 study (NCT00078585) received PROSTVAC or empty vector. IFN-$\gamma$ ELISPOT was performed on archived samples meeting viability requirements. Immune responses in therapeutic prostate cancer mouse studies were evaluated by immunoassays. **Results:** Subjects demonstrated significant enhancement of PSA-specific T cell responses following PROSTVAC immunotherapy compared to control subjects. T cells against endogenous, non-PSA tumor antigens (antigen spread) were also elevated following PROSTVAC immunotherapy. Treatment with PROSTVAC-V/F in mice amplified the magnitude and quality of activated PSA-specific T cells following heterologous vs. homologous prime-boost dosing regimen. Tumor-infiltrating CD4 and CD8 T cells were highly functional as evidenced by expression of activation markers, production of multiple cytokines and amplified cytotoxic T cell activity. In vivo CD4 and CD8 T cell depletion revealed that both subsets contributed to anti-tumor efficacy. PROSTVAC immunotherapy also resulted in reduced Treg suppressor cells among total tumor-infiltrating T cells. **Conclusions:** PROSTVAC immunotherapy activates broad, highly functional T cell immunity to PSA directly elicited by active immunotherapy and to endogenous tumor antigens via immune-mediated antigen spreading. These results from clinical and nonclinical studies are predicted to explain improved overall survival following PROSTVAC immunotherapy in a phase 2 trial in advance of evidence from the ongoing phase 3 PROSPECT trial. Clinical trial information: NCT00078585.

**3081 General Poster Session (Board #148), Sun, 8:00 AM-11:45 AM**

**NCI experience using yeast-brachyury vaccine (GI-6301) in patients (pts) with advanced chordoma.** *Presenting Author: Christopher Ryan Heery, Laboratory of Tumor Immunology and Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD*

**Background:** Saccharomyces cerevisiae has been genetically modified to express Brachyury (Br) protein and developed under a CRADA with GlobeImmune/NCI as a heat-killed immune-stimulating therapeutic cancer vaccine (GI-6301). Br is a member of the T-box family of transcription factors and is a key factor in embryonic (mesoderm) development. Chordoma, a rare tumor of the notochord (derived from mesoderm) is known to overexpress Br while expression in normal adult tissue is minimal or not present. Preclinical work has demonstrated Br specific T cells can lyse human Chordoma cells expressing Br in an MHC restricted fashion. **Methods:** We enrolled a cohort of 7 pts with advanced Chordoma on an expansion cohort of a phase I study (NCT01519817) and evaluated their clinical and immunologic outcomes. All pts had undergone previous radiation (median 470 days since radiation: range 111-1883). All received 40 yeast units of vaccine every 2 weeks x 7 with first restaging at day 85. If stable, pts went on to monthly dosing with restaging scans every 2 months. The primary endpoint was safety, but clinical outcomes were followed as well. Br-specific T cell responses were also analyzed by flow-cytometry intracellular staining (ICS) of CD4 and CD8 T lymphocytes for the cytokines IFN-g, TNF, and IL-2. **Results:** All 7 pts had undergone extensive previous treatment. Median age was 59 (41-66). Two pts had relatively stable disease for 6 and 12 months, respectively, coming on the study, and both remain stable at day 141 and 197 restaging, respectively. The remaining 5 had progressive disease at enrollment. Of those 5, 1 had a decrease in index lesions $>$30% at day 141 with a confirmed PR on repeat scan 4 weeks later. 1 has stable disease through day 141 restaging. The other 3 progressed at day 141 restaging. Adverse events were minimal with injection site reaction being the most common (13 events in 63 doses (21%), 6 of 7 pts (86%)). Two of 7 pts had a Br-specific T cell response by ICS. **Conclusions:** This cohort of pts with advanced Chordoma in the phase I study with GI-6301 vaccine demonstrated safety and enhanced immune response with a confirmed PR. These findings are encouraging and warrant further study using this vaccine in pts with Chordoma. Clinical trial information: NCT01519817.

**3082 General Poster Session (Board #149), Sun, 8:00 AM-11:45 AM**

**Combination between a long-acting engineered cytokine (NKTR-214) and checkpoint inhibitors anti-CTLA-4 or anti-PD1 in murine tumor models.** *Presenting Author: Seema S. Kantak, Nektar Therapeutics, San Francisco, CA*

**Background:** Durability of response is the hallmark of immunotherapy but only a fraction of patients experience this prolonged benefit. Recent studies suggest more patients may benefit from combining agents with complementary immunological mechanisms. NKTR-214 is an engineered form of IL-2 that directly activates cytotoxic T cells by targeting the IL-2 receptor beta subunit and exhibits a pharmacokinetic profile that is more like an antibody than a cytokine. Anti-CTLA-4 and anti-PD1 are antibodies that block negative regulation of T cells. Here we show that combining either antibody with NKTR-214, provides significant tumor growth inhibition in resistant mouse models. **Methods:** For combination studies, BALB/c mice bearing established CT-26 (Colon Carcinoma) or EMT6 (Mammary Carcinoma) tumors were treated with single agent NKTR-214, murine anti-CTLA-4 antibody, murine anti-PD-1 or the two agents in combination. **Results:** NKTR-214 exhibits a plasma and tumor exposure that is 600-fold and 500-fold greater respectively, than an equivalent dose of the original IL-2 cytokine. The optimized PK profile allows q9d dosing schedule instead of bid; the latter being typical for cytokines. In both the EMT-6 and the CT-26 models, the combination of NKTR-214 with anti-CTLA-4 provided 10/12 and 8/12 tumor-free animals respectively, up to 40 days after the last dose and showed clear synergy compared to either agent alone. The combination with anti-PD1 was also synergistic and showed tumor regression in 5/10 animals. Single agent administration did not show any significant tumor growth inhibition in these models. The combinations were well tolerated with no body weight loss or other clinical signs. **Conclusions:** NKTR-214 directly stimulates cytotoxic T cells and is therefore complementary to the mechanism of checkpoint inhibition using antibodies. The favorable pharmacokinetics of NKTR-214 enables dosing schedules that are more like an antibody allowing convenient combination with other antibodies. Combining NKTR-214 mediated T cell activation with CTLA-4 or PD1 blockade is synergistic in murine models of cancer and holds the promise for durable responses in humans.

**3083 General Poster Session (Board #150), Sun, 8:00 AM-11:45 AM**

**Immunomodulatory effects of 5-azacytidine in acute myeloid leukemia.** *Presenting Author: Anne Letsch, Hematology,Oncology and Tumorimmunology, Charité CBF, Berlin, Germany*

**Background:** Specific immunotherapeutic approaches in acute myeloid leukemia have recently attracted interest. Several leukemia associated antigens have been identified and early vaccine trials demonstrated promising efficacy. However vaccination strategies might be improved by combination with current standard treatment or other reagents with immunomodulatory activity in order to enhance leukemia directed immune responses. An attractive combination partner is 5-Azacytidine (5-AZA). In preparation of combination studies of specific immunostimulation in concert with 5-AZA, the immunomodulatory effects of 5-AZA on leukemic cells have been analyzed. **Methods:** The leukemic cell lines ML-2, HL-60, TF-1, Oci-AML5, UT-7, THP-1, NB4, SigM5, and HEL as well as blasts from 3 leukemic patients have been incubated with 2$\mu$M 5-AZA for 9 days. Before and during stimulation (day 5, 7 and 9) the following markers have been analyzed by flow cytometry: CD80, CD86, HLA-DR, HLA-ABC, CXCR4, PD-L1, PI-9 and INDO. Mean fluorescence intensity (MFI) of the single markers were compared at different time points. **Results:** The data obtained on the 9 cell lines and blasts from 3 leukemic patients stimulated by 5-AZA have been heterogenous, but some phenomena were observed in a majority of cell lines and patients. Generally in favour of immune control of leukemic cells are the following mechanism: a) Upregulation of CD86 in 8 of 9 cell lines (8/9) and 0 of 3 patients (0/3), b) downregulation of INDO (7/9 and 1/3), and c) downregulation of PI-9 (3/9 and 2/3). On the other hand we observed mechanisms, which would theoretically enhance immune evasion of leukemic cells: a) downregulation of MHC-class-I molecules (7/9 and 2/3), b) upregulation of PD-L1 (4/9 and 2/3) and c) increase of CXCR4 (8/9 and 2/3) by incubation with 5-AZA. The other markers remained generally unchanged. **Conclusions:** Results should be confirmed on mRNA-level and by functional analyses. Nevertheless our current data already points to interesting immunomodulatory effects of 5-AZA, being an attractive candidate as adjuvant in combination therapies with other immune interventions in leukemia and other malignancies. Potential leukemic and tumor promoting effects of 5-AZA have to be further evaluated.

**3084 General Poster Session (Board #151), Sun, 8:00 AM-11:45 AM**

**18F-fluorodeoxyglucose PET/CT imaging for predicting treatment response in patients with advanced melanoma treated with anti-PD1 immunotherapy.** *Presenting Author: Miguel Hernandez Pampaloni, University of California San Francisco, San Francisco, CA*

**Background:** Immune checkpoint inhibitors have dramatically altered the landscape of melanoma therapeutics over the past few years. Anti-PD1 therapy has been reported to produce durable tumor regression in phase 1 trials. Development of biomarkers to evaluate treatment response are pivotal for optimizing individual therapy. We aim to evaluate whether pretreatment 18F-fluorodeoxyglucose (FDG) PET/CT imaging can be a predictor of tumor response or disease progression in patients on anti-PD1 therapy as a marker of tumoral increased glucose utilization rate. **Methods:** Twenty-three patients (15 males) with BRAF wild type mutation advanced melanoma who failed prior treatment with antineoplastic regimens and started therapy with MK-3475 alone were included in the study. Standard of care whole-body FDG PET/CT imaging was performed at baseline before the anti-PD1 therapy was initiated (10 $\pm$ 5 days interval time between FDG PET/CT imaging and therapy start date). FDG uptake was semi-quantitatively measured by maximum standardized uptake value (SUV). Treatment response was evaluated with computed tomography imaging by central radiologic review according to the Response Evaluation Criteria in Solid Tumors (RECIST), version 1.1. **Results:** Sixteen patients showed significant and stable tumor regression to date while seven patients demonstrated tumor progression by conventional imaging wtihin 6 months of the therapy starting date. All patients with treatment response remain currently on MK-3475 monotherapy. Of the seven patients who showed disease progression, all had at least 2 or more abnormal hypermetabolic foci by FDG PET/CT imaging (SUV max 9.44). Interestingly, of the 16 patients with maintained tumor regression, 8 patients did not showed any hypermetabolic finding, while the remaining 8 patients showed hypermetabolic lesions. (SUV max 6.0). **Conclusions:** Absence of abnormally increased FDG uptake by PET/CT imaging may be a useful tool to predict durable anti-PD1 immunotherapy response, while pre-therapy, single time point increased glucose utilization rate could represent a necessary but insufficient step for the assessment of disease progression.

**3085 General Poster Session (Board #152), Sun, 8:00 AM-11:45 AM**

**Intratumoral vaccination with activated allogeneic dendritic cells in patients with newly diganosed metastatic renal cell carcinoma (mRCC).** *Presenting Author: Anders Magnusson, Department of Radiology, Uppsala University, Uppsala, Sweden*

**Background:** Accumulating data indicate that the efficient induction of antigen-specific CTLs characterizing viral infections is caused by cross-priming where infected DCs produce an unique set of inflammatory factors that recruit and activate non-infected "bystander" DCs. Accordingly, we have developed a cellular adjuvant consisting of activated DCs producing high levels of DC-recruiting and DC-maturating factors in a sustained fashion. This concept doesn´t require MHC-compatibility between injected cells and the patient and therefore introduces the possibility of using pre-produced and freeze-stored DCs from healthy blood donors as an "off-the-shelf" anti-tumor vaccine when injected intratumorally. **Methods:** 12 patients with newly diagnosed mRCC (5 with poor prognosis according to Heng criteria) where included in a clinical phase I/II study. Vaccine cells (50 doses) were produced from a leukapheresis-product from one healthy blood donor and subsequently deep-frozen. 5-20 x 10(6) vaccine cells were injected intratumorally twice with 2 weeks interval before nephrectomy. **Results:** No vaccine-related severe adverse events were observed. 9 out of 11 evaluated patients exhibited an increase in circulating tumor-specific lymphocytes (IFN-gamma ELISPOT) after vaccination. A strong infiltration of CD8+ T cells was found in 7 out of 12 removed kidney tumors, of which 5 tumors, to the best of our knowledge, exhibit the most intensive and general infiltration of CD8+ T cells ever reported in any human solid tumor. Median overall survival (mOS) in the poor prognosis (PP) group is still not reached but has already passed (without addition of targeted therapy) the expected mOS in poor prognosis patients on targeted therapy (9.8 vs 7.8 months). 40% of the patients in the PP-group have to date (Jan 2014) survived for more than 17 months (without addition of targeted therapy) compared to an expected 17 months-survival of 20% in PP patient groups on targeted therapy. **Conclusions:** Our findings indicate that intratumoral injections of pre-activated allogeneic DCs is safe and induce a systemic CTL-mediated anti-tumor response that may prolong survival in mRCC patients. Clinical trial information: NCT01525017.

**3087 General Poster Session (Board #154), Sun, 8:00 AM-11:45 AM**

**Randomized phase II study of personalized peptide vaccination with cyclophosphamide pretreatment in refractory advanced biliary tract cancer patients.** *Presenting Author: Tetsuro Sasada, Department of Immunology and Immunotherapy, Kurume University School of Medicine, Kurume, Japan*

**Background:** We previously demonstrated the feasibility of personalized peptide vaccination (PPV), in which appropriate vaccine peptides are individually selected for each patient to boost anti-cancer immunity, in advanced biliary tract cancer (BTC) patients. This study was conducted to assess whether cyclophosphamide (CYP) pretreatment could improve the clinical efficacy of PPV in refractory advanced BTC patients. **Methods:** We conducted a randomized phase II study to examine the effect of CYP pretreatment (100 mg, daily for 7 days before each cycle of 6 vaccinations) on PPV for advanced BTC patients, who failed or progressed after standard chemotherapy regimens. For PPV treatment, a maximum of 4 peptides were selected from 31 candidate peptides based on the HLA class I types and antigen-specific humoral immune responses before vaccination, and subcutaneously administered (6 vaccinations, weekly; thereafter, by-weekly). The primary and secondary endpoints were to examine the immunological responses to vaccine antigens and overall survival (OS), respectively, after PPV with and without CYP pretreatment (PPV plus CYP and PPV alone, respectively). **Results:** Thirty-four BTC patients were randomly assigned; 16 and 18 patients were assigned to the PPV plus CYP and PPV alone groups, respectively. No severe adverse events were observed in the treated patients. There were no statistically significant differences between the two groups with regard to the numbers of patients, who showed increased peptide-specific CTL or IgG responses. However, CTL frequencies in the patients with positive CTL responses were significantly higher in the PPV plus CYP group, compared to those in the PPV alone group. OS in the PPV plus CYP group was significantly longer than that in the PPV alone group ($P = 0.03$ by Fleming-Harrington test). The median OS was 397 and 190 days in the PPV plus CYP and PPV alone groups, respectively. **Conclusions:** Pretreatment with CYP did not enhance antigen-specific immune responses, but might improve the prognosis after PPV in refractory advanced BTC patients. Further larger scale, randomized trials would be needed to confirm this encouraging result. Clinical trial information: 000006249.

**3088 General Poster Session (Board #155), Sun, 8:00 AM-11:45 AM**

**Phase I study to evaluate toxicity and feasibility of intratumoral injection of alpha-gal glycolipids in patients with advanced melanoma.** *Presenting Author: Mark R. Albertini, University of Wisconsin, Madison, WI*

**Background:** Effective uptake of tumor cells by antigen-presenting cells is achieved pre-clinically by labeling them with $\alpha$-gal glycolipids ($\alpha$-gal) that bind the natural anti-Gal antibody. We aimed to evaluate toxicity and feasibility of intratumoral injections of $\alpha$-gal as an autologous tumor vaccine in advanced melanoma patients (pts). **Methods:** Pts with unresectable metastatic melanoma, at least one readily resectable cutaneous, subcutaneous, or palpable lymph node metastasis, and serum anti-Gal titer $\geq$ 1:50 were eligible for treatment with 2 intratumoral injections of $\alpha$-gal given 4 weeks apart on a 3x3 dose escalation schedule (Level I: 0.1 mg/injection; Level II: 1.0 mg/injection; Level III: 10 mg/injection). Monitoring included blood for clinical, autoimmune, and immunological analyses and core tumor biopsies. Overall treatment response was determined 8 weeks after the first $\alpha$-gal injection. **Results:** Nine pts received 2 intratumoral injections of $\alpha$-gal (3 pts/dose level). Vaccine site toxicity was mild, and no systemic toxicity could be attributed to the vaccine. Dose-limiting toxicity was not seen. There was no clinical autoimmunity and no induction of pathologic autoantibodies. Two pts (Level I (1 pt) and Level II (1 pt)) had stable disease by RECIST lasting 8 and 7 months, respectively. All other pts had progressive disease. Tumor nodule biopsies revealed minimal to no change in inflammatory infiltrate between pre and post-treatment biopsies with the exception of 1 pt in dose level III with a post-treatment inflammatory infiltrate. Pretreatment biopsies showed focal tumor cell necrosis in 2 of 9 pts. Two and 4 weeks post injection, target nodules (5 of 9 pts) exhibited tumor cell necrosis without neutrophilic or lymphocytic inflammatory response. Non-target tumor nodules (2 of 4 pts) showed necrosis, which was diffuse in 1 pt. **Conclusions:** Repeated intratumoral injections of $\alpha$-gal are well tolerated, and tumor necrosis was seen in some melanoma pts after tumor injection with $\alpha$-gal. If intratumoral injections of $\alpha$-gal glycolipids can induce anti-melanoma immunity, subsequent investigation in combination with immune checkpoint inhibitors could be informative. Clinical trial information: nct00668382.

**3089 General Poster Session (Board #156), Sun, 8:00 AM-11:45 AM**

**Pilot trial of a WT-1 analog peptide vaccine in patients with high-risk myeloid neoplasms.** *Presenting Author: Jason B. Brayer, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

**Background:** Tumor vaccines targeting known tumor-associated antigens (TAA) represent an exciting concept and, more importantly, a reasonable approach to engaging the immune system. WT-1 is once such TAA well-documented to provoke immune sensitization in myeloid tumors, and thus may serve as an ideal vaccine target. The purpose of this pilot study was to demonstrate the safety and tolerability as well as to assess for immunogenicity of a polyvalent WT-1 peptide vaccine. **Methods:** Patient enrollment included individuals with high-risk MDS or AML after at least 2 prior lines of therapy. The vaccine combined native and synthetic analog peptides derived from the WT-1 protein and emulsified in Montanide ISA 51 VG adjuvant, and coupled with GM-CSF injections to amplify immunogenicity. Six vaccinations were delivered over 12 weeks, then continued monthly until 12 vaccinations were delivered or until evidence of disease relapse or progression. Therapeutic efficacy was evaluated in terms of progression-free and overall survival. Interval quantitative PCR measurements of WT1 transcript levels acted as a surrogate marker of disease burden. Immune responses were evaluated by delayed-type hypersensitivity testing, T cell proliferation, and $CD8^+$T cell IFN$\gamma$ ELISPOT at specified intervals. **Results:** In total, 13 patients received at least 1 vaccination and 4 completed the full course of vaccinations. Vaccinations were well tolerated with no discontinuations due to adverse reaction or vaccine-induced toxicity. One of 2 patients with high-risk MDS experienced a transient decrease in transfusion dependence. Two of 11 AML patients experienced prolonged relapse-free survival greater than a year. Both patients were in CR#2 at time of vaccination and the duration of their remission exceeded the duration of their first remission, suggesting a potential benefit. **Conclusions:** Vaccination against WT-1 using a polyvalent peptide-based approach can be safely administered at well-tolerated doses. The subjective evidence in several patients suggests elicitation of an immune response. Although encouraging, the limited response rate and durability indicate a need for further optimization in future trials. Clinical trial information: NCT00665002.

**3090 General Poster Session (Board #157), Sun, 8:00 AM-11:45 AM**

**Long-term survival for patients with detectable metastatic melanoma at time of treatment with patient-specific tumor stem cell vaccines.** *Presenting Author: Robert Owen Dillman, Hoag Institute for Research and Education, Newport Beach, CA*

**Background:** Autologous, proliferating, self-renewing cancer cells (tumor stem cells) express numerous tumor-associated antigens including unique neoantigens. They are an excellent antigen-source for patient-specific polyvalent vaccines. Data from two single-arm phase II trials, (*Cancer Biother Radiopharm 2007, 2009*) and a 42-patient randomized trial, [*J Immunother 2012]* showed that metastatic melanoma patients treated with autologous dendritic cells loaded with antigens from autologous proliferating tumor cells (DC/TC) had better overall survival (OS) than patients injected with irradiated, proliferating, autologous tumor cells (TC). A survival benefit for DC/TC was seen in patients who had no evidence of disease (NED) at the time of treatment. [*AACR 2014*] In this study we addressed whether better survival was associated with DC/TC in NED-patients. **Methods:** To increase numbers for subset analyses, data for all 170 patients from the 3 trials were pooled. 27 TC-patients were excluded to decrease inter-patient differences associated with poor survival. Remaining patients were classified as NED or non-NED; this report focuses on the non-NED (n=73). Survival curves were generated for 39 treated with DC/TC and 34 treated with TC, and compared by log-rank test. **Results:** 5-year OS for all 73 non-NED patients was 27% (median 25.5 months). No patients were lost to follow up; 15/23 survivors had been followed for at least 5 years. Median ages were 54 and 53 years in the DC/TC and TC cohorts respectively; male gender accounted for 69% and 65%. M1c disease constituted a higher proportion of patients in the DC/TC cohort (44% vs 35%, p=0.071). OS was better in the DC/TC cohort (HR=0.65) with median survival 38.8 vs 14.7 months and 5-year OS 33% vs 20% (p=0.025). In patients with measurable disease by RECIST criteria, survival was better for DC/TC (p=0.035). **Conclusions:** This subset analysis suggests that active specific immunotherapy with DC/TC is associated with longer survivor than TC in patients who have detectable metastatic melanoma at the time of treatment. (*NCI-V01-1646,* NCT00436930) Supported by the Hoag Hospital Foundation and the Cancer Biotherapy Research Group.

**3091 General Poster Session (Board #158), Sun, 8:00 AM-11:45 AM**

**Tolerability, humoral immune response, and disease control in phase 1 patients receiving ONT-10, a MUC1 liposomal vaccine.** *Presenting Author: John J. Nemunaitis, Mary Crowley Cancer Research Centers, Dallas, TX*

**Background:** MUC1 is a high molecular weight glycoprotein overexpressed and aberrantly glycosylated in many cancers. ONT-10, a liposomal vaccine incorporating a synthetic glycolipopeptide MUC1 antigen and the novel synthetic toll-like receptor 4 agonist PET Lipid A, induces strong anti-MUC1 humoral and cellular responses in preclinical models. **Methods:** This phase 1 study is evaluating ONT-10 safety, immune response, and antitumor activity. Pts with end-stage solid tumors associated with MUC1 expression are eligible. Cyclophosphamide 250 mg/m$^2$IV is given on day -3 followed by ONT-10 (250, 500, 1000, or 2000 $\mu$g) SC day 1 and then Q2W for 4 doses or QW for 8 doses using a 3+3 design. Humoral immune response is assessed by ELISA for MUC1 specific antibodies (Ab) and cellular by ELISPOT for MUC1 specific IFN-$\gamma$. Tumor response is per RECIST 1.1 and irRC. Pts without progressive disease at week 12 can receive maintenance ONT-10 every 6 weeks **Results:** 42 pts have been treated: ovarian (n=13), breast (n=6), colorectal (n=6), pancreatic (n=5), endometrial (n=4), lung (n=4), other (n=4), all ECOG 0/1. Median age 62 (35-77); median prior therapies 4 (1-11). There have been no DLTs. All treatment-related AEs have been Grade 1-2, the most common, fatigue (26%) and injection site reactions (16%). MUC1 specific Ab have been seen in the majority of pts at titers up to $>$ 51,200, with the highest IgG responses seen at the higher-dose QW schedules. Cellular analysis is ongoing. Best tumor response has been SD in 23/34 evaluable pts (68%); 12 pts to date have been progression free for $>$ 6 mo (6.4 – 21+ mo). 2 pts with ovarian cancer have had reduced tumor volume (16% at week 9 and 44% at week 34, respectively). 22/36 (61%) eligible pts have gone to maintenance ONT-10. **Conclusions:** ONT-10 has been well tolerated at all doses with no DLTs. Humoral responses have been seen in most pts, with an apparent dose response for IgG on the QW schedule. Encouraging disease control has been seen with SD in 68% of pts, of whom over half have been progression free for $>$ 6 mo. Clinical trial information: NCT01556789.

**3092 General Poster Session (Board #159), Sun, 8:00 AM-11:45 AM**

**Randomized phase II study of personalized peptide vaccination in patients with advanced bladder cancer progressing after chemotherapy.** *Presenting Author: Masanori Noguchi, Division of Clinical Research, Research Center for Cancer Treatment, Kurume University School of Medicine, Kurume, Japan*

**Background:** A personalized selection of the right peptides for each patient could be a novel approach for a cancer vaccine to boost anti-cancer immunity in the majority of patients along with the potential of survival benefits. The purpose of this study was to assess the efficacy and toxicity of personalized peptide vaccination (PPV) as second-line therapy in patients with advanced metastatic bladder cancer. **Methods:** We conducted a multicenter, randomized phase II study to compare PPV plus best supportive care (BSC) with BSC alone in patients with advanced metastatic bladder cancer who failed or progressed after first-line platinum-containing regimens. PPV treatment was using maximum of four peptides chosen from 31 candidate peptides according to human leukocyte antigen (HLA) types and peptide-reactive immunoglobulin (IgG) titers, for 12 times of subcutaneously injections (8 injections, weekly; 4 injections, by-weekly). Primary outcome was progression free survival (PFS). Secondary outcomes were overall survival (OS), immune response and toxicity. **Results:** From 2010 to 2013, 80 patients were randomly assigned; 38 patients were assigned to PPV plus BSC, and 42 patients were assigned to BSC alone. After median follow-up of 4.5 months, the median OS was 8.3 months on PPV plus BSC versus 4.2 months on BSC alone (hazard ratio [HR], 0.533; log-rank p = 0.0423). PFS was not significantly longer on PPV plus BSC (HR, 0.622; log-rank p = 0.0621). Both treatments were well tolerated, without serious adverse drug reactions. Peptide-specific IgG or cytotoxic T-lymphocyte responses were observed in 20 of 26 patients (77%), or 8 of 19 patients (42%) on PPV plus BSC, respectively. **Conclusions:** PPV as second-line therapy in patients with advanced bladder cancer is active and well tolerated improving survival with immune responses. Further large scale, randomized trials are needed to confirm our preliminary results. Clinical trial information: UMIN000003157.

**3093 General Poster Session (Board #160), Sun, 8:00 AM-11:45 AM**

**Immunotherapeutic treatment of metastatic colorectal cancer using ETBX-011.** *Presenting Author: Elizabeth Susan Gabitzsch, Etubics Corporation, Seattle, WA*

**Background:** Cell mediated immune (CMI) induction has become a prominent component of potential immunotherapy of cancer. We have reported on a Phase 1/2 single agent clinical trial of the immunotherapeutic ETBX-011 for the treatment of mCRC. We now report on long-tem immunity to CEA and survival data to provide further insight into the responses following treatment with ETBX-011. **Methods:** Cohorts of patients with advanced colorectal cancer, refractory to prior therapies, received escalating doses from $10^9$ to $5x10^{11}$VP of ETBX-011 (Ad5 [E1-, E2B-]-CEA(6D)) subcutaneously every 3 weeks for 3 immunizations. The induction of CEA-specific cell mediated immunity was measured by ELISPOT and overall survival was determined. Also, in a subset of the ETBX-011 treated mCRC patients the number of T-regs as the percent of CD4 cells and the ratio of T-effector cells to Tregs was determined. **Results:** ETBX-011 was found to be well-tolerated at all doses and there were no drop outs due to treatment. Specific anti-CEA immune responses were observed in the majority of patients and median overall-survival was 11 months. We now report on long term follow-up of the patients. Forty-four percent (48%) of patients still survived at 12 month follow-up and 28% at 18 months following treatments. One patients who developed significant CEA specific cellular immune response also showed a decrease in the Treg:T-effector ratio on follow-up and still survived at 2 years post treatment. **Conclusions:** These results demonstrate that mCRC patients treated with ETBX-011 immunotherapeutic is safe and can be easily administered to patients. ETBX-011 treatment generated significant CMI induction to the tolerated tumor associated antigen CEA and may experience increased overall survival. A single agent randomized, multicenter Phase 2b trial is being initiated to further evaluate the clinical effectiveness. Clinical trial information: NCT01147965.

**3094 General Poster Session (Board #161), Sun, 8:00 AM-11:45 AM**

**Phase II clinical trial of multiple peptide vaccination for advanced head and neck cancer patients with induced immune responses and a prolonged OS.** *Presenting Author: Yoshihiro Yoshitake, Department of Oral & Maxillofacial Surgery, Graduate School of Medical Sciences, Kumamoto University, Kumamoto City, Japan*

**Background:** The peptides derived from ideal cancer-testis antigens, including LY6K, CDCA1 and IMP3 (identified using genome-wide cDNA microarray analyses), were utilized in immunotherapy for head and neck squamous cell cancer (HNSCC). In this trial, we analyzed the immune response to and safety and efficacy of vaccine therapy. **Methods:** A total of 37 patients with advanced HNSCC were enrolled in this trial of peptide vaccine therapy, and the OS, PFS and immunological response were evaluated using enzyme-linked ImmunoSpot (ELISPOT) and pentamer assays. The peptides were subcutaneously administered weekly with IFA. The primary endpoints were evaluated based on differences between *HLA-A*2402*-positive (A24(+)) patients treated with peptide vaccine therapy and –negative (A24(-)) patients treated without peptide vaccine therapy among those with advanced HNSCC. **Results:** Our cancer vaccine therapy was well tolerated. The OS of the A24(+)vaccinated group (n = 37) was statistically significantly longer than that of the A24(-) group (n=18) (MST 4.9 vs. 3.5 month, respectively, $p<0.05$). One of the patients exhibited a complete response. In the A24(+) vaccinated group, the ELISPOT assay identified LY6K-, CDCA1- and IMP3-specific CTL responses in 85.7%, 64.3% and 42.9% of the patients, respectively. The patients showing LY6K- and CDCA1-specific CTL responses demonstrated a longer OS than those without CTL induction. Moreover, the patients exhibiting CTL induction for multiple peptides demonstrated better clinical responses. **Conclusions:** The immune response induced by this vaccine may improve the prognosis of patients with advanced HNSCC. Clinical trial information: 000008379.

**3095 General Poster Session (Board #162), Sun, 8:00 AM-11:45 AM**

**Combined chemoimmunotherapy of castrate-resistant prostate cancer with dendritic-cell based vaccine DCVAC/Pca.** *Presenting Author: Michal Podrazil, 2nd Medical School Charles University, Prague, Czech Republic*

**Background:** Appropriate combination of tumor mass reduction and neutralization of tumor-induced immunosuppression might potentiate the induction of anti-tumor immunity. We performed an open label, single arm Phase I/II clinical trial in patients with metastatic castrate resistant prostate cancer (mCRPC) eligible for docetaxel using autologous mature dendritic cells pulsed with killed LNCap prostate cancer cell line, DCVAC/PCa. **Methods:** Eligible patients had progressive mCRPC despite androgen deprivation. None of the patients received abiraterone or enzalutamide. DCVAC/PCa treatment consisted of, on average ten doses of $1x10^7$ dendritic cells injected s.c. Treatment comprised of initial 7d administration of metronomic cyclophosphamide, and subsequent 2 doses of DCVAC/PCa. Patients then started docetaxel (75 mg/m$^2$) and prednisone (5 mg twice daily) treatment administered every 3-weeks and DCVAC/PCa was given every 6 weeks up to a maximum number of doses manufactured from one leukapheresis. The primary end point was safety, the secondary end-point immune response. Overall survival (OS) was compared to the predicted OS according to Halabi and MSKCC nomograms. **Results:** Data from twenty-five patients were evaluated. The mean age at the start of immunotherapy was 67 years, median PSA 109 ng/ml and Hb 11,9 g/dl. 48% patients had GS $\geq$8. No serious DCVAC/PCa-related adverse events have been reported. There were no clinical or laboratory signs of autoimmunity. Median OS was 19 months (95% CI: 14.69-23.31) while the predicted median OS was 12 months (95% CI: 11.19-12.81). We observed no significant changes of the peripheral blood Tregs and MDSCs during the course of the trial. Long-term administration of DCVAC/PCa led to the induction and maintenance of the stable levels of T cells specific against multiple tumor antigens including PSA, NY-ESO1, MAGE-A1 and MAGE-A3. **Conclusions:** In patients with mCRPC, the alternate administration of DCVAC/PCa cancer immunotherapy and docetaxel results in the stabilization of the disease progression and longer than expected survival. Chemotherapy does not preclude the induction of tumor specific T cells. Clinical trial information: 2009-017259-24.

**3096 General Poster Session (Board #163), Sun, 8:00 AM-11:45 AM**

**Long-term survival of patients suffering from solid extra-cranial neoplasias after dendritic cell-based cancer immune therapy.** *Presenting Author: Friedrich Erhart, St. Anna Children's Cancer Research Institute, Vienna, Austria*
